

BOARD MEETING DATE: December 7, 2012

AGENDA NO. 30

PROPOSAL: Adopt Draft Final 2012 Air Quality Management Plan

SYNOPSIS: The Draft Final 2012 Air Quality Management Plan (AQMP) has been developed in partnership with CARB, U.S. EPA, SCAG and stakeholders throughout the region, including input from local government, health and environmental organizations, and the business community. The AQMP is the legally enforceable blueprint for how to meet and maintain state and federal air quality standards. The 2012 AQMP identifies control measures needed to demonstrate attainment with the federal 24-hour standard for PM2.5 by 2014 in the South Coast Air Basin. In addition, the 2012 AQMP provides updates on progress towards meeting the 8-hour ozone standard for 2023, an attainment demonstration for the revoked 1-hour ozone standard, a VMT offset demonstration for ozone standards, and a report on the health effects of PM2.5.

COMMITTEE: Mobile Source, Reviewed (January 20, February 17, March 16, April 20, May 18, June 15, July 27, September 21, and October 19, 2012)

RECOMMENDED ACTIONS:

1. Append to Appendix I (Health Effects) any additional material or information submitted at the Public Adoption Hearing and then accept Appendix I, which includes a report on the health effects from particulate matter in the South Coast Air Basin, as in conformance with Health and Safety Code Section 40471(b).
2. Certify the Final Program Environmental Impact Report for the 2012 AQMP, in accordance with the attached Resolution (Attachment A);

3. Adopt the 2012 AQMP in accordance with the attached Resolution;
4. Authorize the Executive Officer to make appropriate changes to the adopted 2012 AQMP and its appendices (if necessary) to reflect amendments adopted at the Public Hearing; and then
5. Direct the Executive Officer to forward the adopted 2012 AQMP (as changed) including its appendices to the California Air Resources for its approval and subsequent submittal to the U.S. Environmental Protection Agency.

Barry R. Wallerstein, D.Env.
Executive Officer

EC:PF:vm

Background

The U.S. Environmental Protection Agency (EPA) promulgated the National Ambient Air Quality Standards (NAAQS) for Fine Particles (PM_{2.5}) and 8-hour ozone (O₃) in July 1997 which became effective in June 2004 and April 2005, respectively. The federal 1-hour ozone standard of 1979 was revoked by the U.S. EPA and replaced by the 8-hour average ozone standard, effective June 15, 2005. However, the South Coast Air Basin (Basin) and the former Southeast Desert Modified Air Quality Management Area (which included the Coachella Valley) did not attain the 1-hour federal ozone NAAQS by the attainment date and have some continuing obligations under the former standard. Ozone and PM_{2.5} are the main regional pollutants for which the U.S. EPA has designated the Basin as nonattainment. The Coachella Valley is also a nonattainment area for ozone, but PM_{2.5} concentrations remain below the federal standards.

Several changes to the NAAQS have occurred since the last Air Quality Management Plan (AQMP) update in 2007:

- In 2006, U.S. EPA significantly lowered the level of the 24-hour PM_{2.5} standard, from 65 to 35 µg/m³, while retaining the level of the annual PM_{2.5} standard, 15µg/m³. On December 14, 2009, the U.S. EPA designated the Basin as nonattainment for the 2006 24-hour PM_{2.5} NAAQS. A SIP revision is due to U.S. EPA no later than three years from the effective date of designation, December 14, 2012, demonstrating attainment with the standard by 2014.
- Effective May 27, 2008, the 8-hour ozone NAAQS was subsequently lowered from 80 to 75 ppb. The SIP submittal for this standard is not due until 2015. However, nonattainment areas for the 1997 8-hour ozone standard have continuing obligations to implement their plan and demonstrate attainment of that standard by the applicable attainment date.

- In 2008, the California Air Resources Board (CARB) withdrew key components of its emission reduction commitments in the 2003 South Coast 1-hour ozone SIP. In 2009, U.S EPA approved certain elements of the 2003 South Coast 1-Hour Ozone SIP but disapproved the attainment demonstration, largely because CARB's 2008 withdrawal of emission reduction commitments rendered the plan insufficient to demonstrate attainment. Based on the court decision in *Ass'n of Irrigated Residents v. EPA*, 686 F.3d 668 (9th Cir. 2012), on September 19, 2012, U.S EPA published a proposed SIP call under Section 110(k)(5) of the CAA, finding the existing approved 1-hour ozone SIP substantially inadequate to provide for attainment of the revoked 1-hour ozone standard by the applicable attainment date of November 15, 2010. U.S EPA's proposed SIP call would give the State up to one year after the effective date of the final SIP call to submit the revised attainment demonstration. The District's submittal of the updated 1-hour ozone attainment demonstration as part of this Final 2012 AQMP is in response to this recent U.S. EPA proposed action. Pursuant to the AIR case, U.S EPA also disapproved the SIP revisions submitted by the State of California to meet the vehicle miles traveled (VMT) emissions offset requirement under the Clean Air Act for the Los Angeles-South Coast Air Basin 1-hour and 8-hour ozone nonattainment areas.

The purposes of the 2012 AQMP for the Basin are to set forth a comprehensive and integrated program that will lead the Basin into compliance with the federal 24-hour PM_{2.5} air quality standard, to satisfy the planning requirements of the federal Clean Air Act, and to provide an update to the Basin's commitments towards meeting the federal 8-hour ozone standards. It will also serve to satisfy the recent U.S. EPA proposed requirement for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a VMT emissions offset demonstration. Specifically, the Plan will serve as the official SIP submittal for the federal 2006 24-hour PM_{2.5} standard, for which U.S. EPA has established a due date of December 14, 2012. In addition, the 2012 AQMP will update specific new control measures and commitments for emissions reductions to implement the attainment strategy for the 8-hour ozone SIP, and thus help to reduce reliance on CAA Section 182(e)(5) long-term measures. Once approved by the District Governing Board and CARB, the 2012 AQMP will be submitted to U.S. EPA as the 24-hour PM_{2.5} SIP addressing the 2006 PM_{2.5} NAAQS and as a limited update to the approved 8-hour ozone SIP. The 1-hour ozone attainment demonstration and VMT emissions offset demonstration will also be submitted through CARB to EPA.

The 2012 AQMP also includes an update on the air quality status of the Salton Sea Air Basin (SSAB) in the Coachella Valley, a discussion of the emerging issues of ultrafine particle and near-roadway exposures, a report on the health effects of PM_{2.5}, and an analysis of the energy supply and demand issues that face the Basin and their relationship to air quality. Pursuant to statute, the public hearing will also discuss the report on health effects of PM_{2.5} (Health & Safety Code §40471).

Public Process

The development of the 2012 AQMP has been a regional, multi-agency effort including the District Governing Board, CARB, Southern California Association of Governments (SCAG), and U.S. EPA. A 2012 AQMP Advisory Group was formed to provide feedback and recommendations on the development of the plan, including policy issues and control strategies. The Advisory Group represents a diverse cross section of stakeholders such as large and small businesses, government agencies, environmental and community groups, and academia. In addition, a Scientific, Technical, and Modeling Peer Review (STMPR) Advisory Group convened to make recommendations on air quality modeling, emissions inventory and socioeconomic modeling and analysis. Both Advisory Groups met monthly throughout the AQMP development process and those meetings have been open to the public.

The AQMD conducted a Technology Symposium in September 2011 with the participation of over 150 attendees, including representatives from federal, state, and local governments, academia, industry experts and the public. The goal of the symposium was to solicit new and innovative control concepts to assist in designing a plan for attaining the ambient air quality standards. Based on input received, District staff developed 38 control measures for the 2012 AQMP.

In conjunction with the development of the 2012 AQMP, staff prepared an enhanced 2012 AQMP Outreach Program to inform and engage a wide range of stakeholders on the requirements, approach, goals, and impacts of the 2012 AQMP. In addition to on-going AQMP Advisory Group and Scientific, Technical, Modeling & Peer Review Advisory Group meetings, and the mandatory regional workshops/hearings, staff engaged in enhanced outreach to all stakeholders in the region through numerous presentations, workshops, focus groups throughout the Basin. In all, over 100 meetings were conducted in which the 2012 AQMP was presented or discussed.

A Draft 2012 AQMP was released in July 2012 in order to provide the public and other stakeholders an early opportunity for review. Subsequent to the release of the Draft 2012 AQMP, four regional hearings were held throughout the four counties in September 2012 to discuss the Draft 2012 AQMP and solicit public input.

Based on comments received, revisions to the Draft 2012 AQMP were made publicly available in a Revised Draft 2012 AQMP released in September 2012. An additional four regional public hearings were held in November 2012 in each of the four counties, where additional public input and comments were solicited. These hearings also discussed Appendix I, which reports on the health effects of PM_{2.5}. As a result of this extensive public process, the Final Draft 2012 AQMP is being submitted to the Board for its consideration.

Proposal

The 2012 AQMP incorporates the most recent planning assumptions and the best available information including: revised stationary point and area source emissions inventories; on-road and off-road mobile source emissions inventories based on CARB's latest EMFAC2011 and Off-Road Models; the use of new meteorological episodes for ozone and expanded air quality modeling analysis; and the latest demographic growth forecasts based on the approved 2012 Regional Transportation Plan (2012 RTP) developed by SCAG. The Plan also includes control strategies for demonstrating attainment with the federal 24-hour PM_{2.5} air quality standard, and provides an update to the Basin's commitments towards meeting the federal 8-hour ozone standards. It will also serve to satisfy recent U.S. EPA proposed requirements for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a VMT emissions offset demonstration.

Draft 2012 AQMP

The Draft 2012 AQMP was released on July 2012 and provided the initial strategy for meeting and maintaining the federal 24-hour PM_{2.5} air quality standard by attainment date of 2014, for satisfying the planning requirements of the federal Clean Air Act, and for providing an update to the Basin's commitments towards meeting the federal 8-hour ozone standards. The Draft 2012 AQMP provided base-year and projected emissions inventory updates, Reasonably Available Control Technology (RACT) and Reasonably Available Control Measure (RACM) analysis, control strategies, an attainment demonstration, contingency measures, and transportation conformity budgets.

Revised Draft 2012 AQMP

Based on the comments received and additional analysis, the Revised Draft 2012 AQMP was released in September 2012. The Revised Draft 2012 AQMP included baseline emission inventory refinements, and clarifications to several control measures. Also, in response to public comments, the initial NO_x RECLAIM Phase I measure was shifted from the main strategy to a contingency measure. Based on discussions with SCAG staff, an inter-pollutant flexibility mechanism was developed to allow for emissions below the budget for one pollutant to be used to supplement another pollutant exceeding the budget based on established ratios. During the release of the Revised Draft 2012 AQMP, staff also released two additional appendices to satisfy the recent U.S. EPA proposed requirements for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a VMT emissions offset demonstration; Appendix VII - 1-Hour Ozone Attainment Demonstration; and Appendix VIII - Demonstration of Offset of Growth in Emissions Associated with Growth in Vehicle Miles Traveled Under Section 182(d)(1)(A) of The Federal CAA.

Draft Final 2012 AQMP

The Draft Final 2012 AQMP includes additional revisions to the Revised Draft Plan. Noted revisions include: 1) updated discussions of the 1-hour ozone SIP submittal requirements; 2) finalized emissions inventory data; 3) finalized modeling results; 4) updated precursor equivalency ratios; 5) added clarifications to a few control measures; and 6) added an alternative VMT offset demonstration base year approach. A list of the documents contained in the Draft Final 2012 AQMP is provided as Attachment B to this Board letter. Since the release of the Draft Final AQMP, some minor clarifications were made to several control measures in response to comments received. These changes are included in Attachment F.

Key Findings

Some of the key findings and highlights of the 2012 AQMP include:

- 1) **Air Quality Trends** - Although the long-term trend of air quality in the Basin shows continuous improvement due to existing air quality regulations, the slowing rate of improvement in ozone levels is a cause for concern. Both PM10 and PM2.5 levels have improved dramatically over the past two decades. Annual average PM10 and PM2.5 concentrations have been cut in half since 1990 and 1999, respectively. The Basin has met the PM10 standards at all stations and a request for re-designation to attainment is pending with U.S. EPA. The 2012 AQMP demonstrates attainment of the federal 24-hour PM2.5 standard by 2014 in the Basin through adoption of all feasible measures. However, substantial reductions are still needed to meet the federal 8-hour and 1-hour ozone standards by the applicable attainment dates.
- 2) **Emissions Inventory** - The emission inventory consists of the emissions that occurred in the Basin during the 2008 base year, and the projected emissions in the milestone years of 2014, 2019, 2023, and 2030. The future year emissions are based on growth projections and implementation of adopted air regulations. The emissions inventory is divided into four major classifications: stationary, area, on-road, and off-road sources. Despite projected growth in the population and the economy, baseline emissions decrease over time due to continued implementation of existing regulations. The baseline emission projections provide an estimate of future air quality conditions, including the effects from already adopted rules and regulations, but without the proposed control strategy.
- 3) **Control Strategy** - The overall control strategy proposed in the Final 2012 AQMP will provide for attainment of the 2006 24-hour PM2.5 standard by the 2014 attainment date through implementation of short-term 24-hour PM2.5 control measures. The short term measures primarily consist of enhancements to episodic burning curtailment programs for residential wood burning and open burning. The control strategy also specifies ozone measures to further implement the U.S. EPA approved ozone plan for the 8-hour ozone standard. The control strategy includes

emission reductions from both stationary and mobile sources. The proposed control measures in the 2012 AQMP are based on implementation of all feasible control measures through the application of available cleaner technologies, best management practices, incentive programs, as well as development and implementation of zero- and near-zero technologies and control methods.

Although the Basin is projected to meet the 2006 24-hour PM_{2.5} standards by the applicable attainment deadlines, significant challenges remain in meeting the federal ozone standards. The next AQMP in 2015 will include a more comprehensive strategy to demonstrate attainment of the 1997 and 2008 8-hour ozone standards by 2023 and 2032. The 2007 State Implementation Plan (SIP) for the 8-hour ozone NAAQS contains commitments for emission reductions that rely on advancement of technologies, as authorized under Section 182(e)(5) of the federal Clean Air Act. These innovative strategy (182)(e)(5) measures account for a substantial portion of the NO_x emission reductions needed to attain the federal ozone standards – over 200 tons/day. The deadlines to achieve these reductions in the region is 2023 (to attain the 80 ppb NAAQS) with necessary rulemaking completed by 2020. Therefore, all currently feasible ozone control measures are included in the 2012 AQMP as an update to the previously approved 2007 8-hour ozone SIP.

- 4) **24-Hour PM_{2.5} Attainment Demonstration and RFP-** The CAA requires SIPs for most nonattainment areas to demonstrate reasonable further progress (RFP) towards attainment through emission reductions phased in from the time of the SIP submission until the attainment date time frame. The RFP requirements in the CAA are intended to ensure that there are sufficient PM_{2.5} and precursor emission reductions in each nonattainment area to attain the 2006 24-hour PM_{2.5} NAAQS by the December 14, 2014 deadline. The 2012 AQMP demonstrates attainment with the 24-hour PM_{2.5} standard in 2014, which is five years from the 2009 designation date. In such cases, EPA does not require a separate RFP plan.

With respect to the contingency measure requirements, the 2012 AQMP contains an excess of 1.2 µg/m³ air quality improvement (or 71 tpd of NO_x equivalent reductions) through the proposed measures.

- 5) **SIP Submission -** In order to design the most efficient path to clean air with clear regulatory commitments for the immediate future, the 2012 AQMP is an integrated plan addressing multiple pollutants and multiple deadlines. It serves as the official SIP submittal for the federal 2006 24-hour PM_{2.5} standard, for which U.S. EPA has established a due date of December 14, 2012. The 2012 AQMP also provides a limited update of specific new control measures and commitments for emissions reductions to implement the attainment strategy for the approved 8-hour ozone SIP and to reduce reliance on the Section 182(e)(5) long-term measures;

- 6) **1-Hour Ozone Attainment Demonstration** - The 2012 1-hour attainment demonstration was prepared in response to the U.S. EPA's published "SIP call" proposal on September 19, 2012, finding the existing approved 1-hour ozone SIP substantially inadequate to provide for attainment of the revoked 1-hour ozone standard by the applicable attainment date of November 15, 2010. As a result, the state must submit an attainment demonstration for the South Coast for the 1-hour ozone standard showing attainment "as expeditiously as practicable," but not to exceed 10 years beyond the effective date of the SIP call. EPA's proposed SIP call would give the State up to one year after the effective date of the final SIP call to submit the revised attainment demonstration. The District has demonstrated that a period of the full 10 years allowed by law is needed to attain the 1-hour standard. The 1-hour ozone attainment demonstration is a stand-alone document, but with references to the 2012 AQMP and related documents. The attainment demonstration is based on emissions in the 2008 base year and projected controlled emissions for the 2022 when reductions need to be achieved. Given the approximate alignment of the attainment dates, the control strategy for the 1-hour ozone standard is identical to the control strategy for the 1997 federal 8-hour ozone standard. The form of the 1-hour standard allows for a single exceedance at a station annually. The modeling analysis produces a Basin carrying capacity of 410 tons per day of VOC and 150 tons per day of NOx emissions to bring the Basin into attainment with the 1-hour ozone standard. These emissions translate into 30 TPD (7 percent) reduction in VOC emissions and a 185 TPD (55 percent) reduction in NOx emissions beyond 2022 baseline emissions.
- 7) **VMT Offset Requirement Demonstration** - The VMT emissions offset demonstration for the 1-hour and 8-hour ozone standards is prepared in response to U.S. EPA's proposed action entitled "Disapproval of Implementation Plan Revisions; State of California; South Coast VMT Emissions Offset Demonstrations" published on September 19, 2012 (77 Fed. Reg. 58067). The VMT offset demonstration is performed in accordance with EPA's new guidance for both the 8-hour and 1-hour ozone requirements. To address U.S. EPA's guidance on the selection of a base year, two analyses are provided: One using 1990 as base year for both ozone air quality standards, and a second alternative using 2002 as the base year in conjunction with the 8-hour ozone attainment demonstration provided in the 2007 SIP. Based on the 2007 SIP for the 8-hour ozone attainment demonstration, it is projected that the 8-hour ozone ambient air quality standard will be achieved by 2023. The 1-hour ozone attainment demonstration shows that the revoked 1-hour ozone standard will be achieved by 2022. Although District staff believes that 1990 is the appropriate base year for both the 1-hour and 8-hour demonstration, an alternative analysis using 2002 is provided for the 8-hour ozone. In both analyses, there are sufficient transportation control strategies and TCMs to offset the emissions increase due to growth in VMT.

Public Comments

Numerous comments have been received during the Plan development. The specific responses to 99 written comment letters on the 2012 AQMP are addressed in Attachment C, "Response to Comments to the 2012 AQMP," dated November 2012. Additional responses to comment letters not included in the "Draft Final 2012 AQMP Responses to Comments to the 2012 AQMP" publicly released on November 21, 2012 are included as an Addendum to Attachment C.

Key Policy Issues

There are seven key policy issues related to the adoption of the 2012 AQMP for Board consideration which are briefly presented here:

1. **Inclusion of an Ozone Strategy in the 2012 AQMP** – Comments were received stating that the primary purpose of the 2012 AQMP should be to demonstrate attainment with the 24-hour PM_{2.5} standard, which is the only legal requirement, and the Plan should not include SIP commitments to address the 8-hour ozone standard.

Staff believes that given the short timeframe until 2023, and the fact that a significant fraction of the large amount of emission reductions needed to meet the 8-hour ozone standard by 2023 is still from innovative strategy measures, it is important to identify specific measures to achieve the needed reductions in a timely manner. . Comments and potential litigation on U.S EPA's approval of the 2007 ozone SIP have called into question the relative size and reliance on innovative strategy (182)(e)(5) measures to demonstration ozone attainment. Making SIP commitments for reductions when they are identified as feasible demonstrates AQMD's strong commitment to reduce reliance on (182)(e)(5) measures as attainment deadlines approach and preempts possible litigation. Moreover, federal law requires expeditious progress and state law requires all feasible measures towards meeting clean air standards. Including an 8-hour ozone strategy has been supported by U.S. EPA (comment letter dated August 30, 2012).

2. **Need for VOC Controls in the Ozone Strategy** - Comments received stated that there is no reason for additional VOC controls in the ozone strategy given the need for a NO_x-heavy control approach to meet the 8-hour ozone standards. Industry believes any additional measures aimed at the lowering of VOC content in products, restriction on flexibility provisions, or removal of exemptions will create compliance challenges, and will result in the loss of business activity in the Basin.

Modeling efforts by staff have shown that while a NO_x heavy strategy is needed for 8-hour ozone attainment, continued modest VOC reductions are

also needed to ensure that all areas of the Basin show improvement in ozone levels. This is due to the fact that ozone levels not only depend upon overall VOC and NOx emissions levels, but they also depend on the atmospheric ratio of VOC to NOx. When this ratio increases due to necessarily aggressive NOx reductions, it can lead to increases in ozone levels in some areas, especially in the western portion of the Basin. Reduction in VOC emissions could also lessen the burden of controlling the NOx emissions. The additional VOC reductions are nominal, with some proposed measures ensuring that existing claimed reductions will be realized.

3. **Timing of the Submittal of the 1-hour Ozone Attainment Demonstration -** A requirement for the submittal of an attainment demonstration for the revoked 1-hour ozone standard has been proposed by U.S. EPA, and the submittal will be due by no later than the latter part of 2013 or early 2014. Since the emissions inventory, control strategy, and RACT/RACM analysis has already been developed for the 2012 AQMP, and because attainment of the 1-hour standard relies on the same strategy proposed for the 8-hour ozone standard, staff was able to complete an attainment demonstration for the 1-hour ozone standard as an Appendix to the 2012 AQMP. Some commenters would prefer to delay the submittal of the 1-hour ozone attainment demonstration.

Staff believes that there is no reason to delay submitting the 1-hour ozone attainment demonstration given that the overall control strategy is the same as that for the 8-hour standard. Utilizing the current 2012 AQMP emissions inventory, modeling framework and public process is the most efficient use of resources and time. Furthermore, there is little current or expected guidance from U.S. EPA on the technical approach to the 1-hour ozone attainment demonstration. Staff believes it has developed the most reasonable technical approach, and that the early submittal of the 1-hour ozone attainment demonstration with the 2012 AQMP is the best way to get feedback from and provide input to U.S. EPA on its approach. Finally, because this issue is currently before the Court regarding credit rules, submittal now of the 1-hour attainment demonstration should preempt that issue in the current lawsuit.

4. **Evaluation of the Consumer Products Low Vapor Pressure (LVP) Exemption -** Various affected industries (e.g., cleaning product companies, fragrance manufacturers, etc.) were concerned about their ability to successfully reformulate their products if implementation of control measure CTS-04 results in the removal of exemptions for low vapor pressure components.

The purpose of this measure is to assess the effectiveness of existing rules with an LVP exemption. Recent studies indicate many solvents that currently enjoy the LVP exemption volatilize just as rapidly and exhibit reactivity values

comparable to those of conventional solvents. CTS-04 does not seek an across the board elimination of the LVP exemption but rather the re-evaluation of the criteria for the exemption to ensure that the environmental benefit of the consumer product regulation is fully achieved. The control measure seeks a phased implementation starting with data collection of sales and formulation. Then, it will identify product categories for lab testing of evaporative potential where the exemption may need revision. Finally, alternatives to LVP-VOCs will be identified. CARB has authority over the relevant consumer product regulations, and staff is working in partnership with CARB on proposed technical studies and data collection. Any alteration to the LVP exemption will be developed pursuant to the traditional rulemaking process that includes detailed feasibility and cost benefit evaluations as well as extensive public participation. Potential emission reductions are not being committed into SIP. Proposed clarifications to CTS-04 in the Draft Final Plan are included in Attachment F.

5. **Implementing BCM-01 (Residential Wood Burning)** – Concerns were raised as to whether the burning of wood from residential fireplaces is a major source of PM_{2.5} pollution and if curtailment has any substantial benefits. There have also been comments regarding the need for extensive outreach and education associated with the curtailment measure.

Modeling by staff has clearly shown that the wood burning curtailment substantially reduces PM_{2.5} concentration levels during high pollution episodes, and thus is the primary control measure allowing the Basin to achieve the 24-hour PM_{2.5} standard by 2014. Staff is aware of the challenges in raising public awareness of the curtailment program, in providing sufficient notice on curtailment days, and in communicating the health impacts of wood smoke. Staff believes that education and outreach are the most important components of this measure, and strategic planning for communication programs is already underway. Other air districts in the state of California have successfully implemented a similar program, thus, it is considered a feasible control measure.

6. **Backstop Rule for Indirect Sources at Ports** – The Ports of Los Angeles and Long Beach have provided comments on Control Measure IND-01: Backstop Measure for Indirect Sources of Emissions from Ports and Port Related Sources (Port Backstop Measure). Through the Clean Air Action Plan (CAAP), the Ports have voluntarily implemented programs to reduce emissions from a variety of port-related sources. The Ports have commented that the AQMD “reconsider its approach and allow the continuation of the successful collaborative work by the ports, regulatory agencies and other stakeholders under the voluntary Clean Air Action Plan and the San Pedro Bay Standards.”

As a result, the Ports have requested that the Port Backstop Measure be removed from the 2012 AQMP. The Ports have commented that they “can’t accept any regulatory action by the AQMD that will result in AQMD oversight and approvals of port actions, or enforcement actions by the AQMD on the ports for failure of the port industry to meet the ports’ emission reduction goals.”The AQMD staff agrees that the Ports have made significant progress in reducing emissions. It still remains however, that the Ports of Los Angeles and Long Beach are collectively the single largest fixed source of air pollution in Southern California. Port sources such as marine vessels, locomotives, trucks, harbor craft and cargo handling equipment, continue to be the largest sources of NO_x, PM_{2.5} and PM_{2.5} precursors in the region. These sources play a major role in the Basin’s ability to achieve the national PM_{2.5} ambient air quality standards. The AQMD staff believes that it is appropriate and necessary to include a backstop measure to ensure that the Basin’s largest source of NO_x and PM_{2.5} emissions maintains its course of emission reductions.

In response to comments from the Ports, the AQMD staff has made revisions to the Port Backstop Measure that further clarifies the intent and rule development process (see Attachment F). AQMD staff has clarified that a backstop rule will become effective only if emissions from port-related sources exceed targets for NO_x, SO_x, and PM_{2.5} in 2014. In addition, the measure has been revised to further clarify that if additional emission reductions are needed, the Ports would be required to submit a plan on only the emission reduction shortfall. The backstop rule would not require any strategy to be implemented that lacked legal authority, was not cost-effective, or was found to be infeasible. In addition, staff clarified that the backstop rule would include time extension to achieve the targets, if necessary. Lastly, language has been added to the measure regarding enforcement of the port backstop rule. The AQMD staff is committed to continue to work collaboratively with the Ports, agencies, environmental community groups, industry representatives, and other interested parties through the rule development process

7. **NO_x RECLAIM Reduction** - Comments were made as to the need for the first phase of NO_x emissions reductions from RECLAIM facilities. Commenters have also expressed opinions on the mechanism for the NO_x RECLAIM shave (all RECLAIM sources, larger RECLAIM sources, etc.)

State law requires a periodic review and the last re-evaluation of NO_x RECLAIM occurred 7-8 years ago (2004-2005). Further NO_x reductions are necessary for attainment of the ozone standard. In the Revised Draft 2012 AQMP, the first phase of the NO_x RECLAIM shave has been shifted to a contingency measure, only to be implemented if the Basin fails to attain the 24-

hour PM2.5 standard by 2014. The measure will have a gradual implementation to fully achieve a total of 3-5 tons per day NOx RECLAIM reductions by 2020. Staff will assess mechanisms for the NOx RECLAIM shave during rule development. Proposed clarifications to CMB-01 in the Draft Final Plan are included in Attachment F.

8. **Compressed Schedule** - Concern has been raised that the 2012 AQMP development schedule has been compressed, with limited time for review and public input on all documents.

A total of 17 months for public discussion and review occurred during the 2012 AQMP development process. All data and information has been provided to the public as soon as it became available in an open and transparent process. The review period for most of the documents has been extended, additional workshops and regional public hearings have been added, and the scheduled Governing Board adoption hearing date was postponed from September to December 2012. The Draft Plan was released for 51 days; the Revised Draft for 61 days and the Draft Final for 30 days. The Draft Program EIR and Socioeconomic Report were circulated for public review and comment for 45-days. There have been seven public workshops, eight regional hearings in the four-county region, 13 AQMP Advisory Group meetings and 11 STMPR Advisory Group meetings. Staff participated in 75 outreach meetings and provided 65 formal presentations on the 2012 AQMP. Thus, there has been extensive outreach and sufficient time for public comment was provided.

CEQA

Pursuant to California Environmental Quality Act (CEQA) Guidelines §15168, the AQMD has prepared a Program Environmental Impact Report (PEIR) for the 2012 AQMP. The Draft PEIR was released for a 45-day public review and comment period beginning on September 7, 2012, and ending on October 23, 2012. The Draft PEIR analyzed potential adverse impacts from implementing AQMP control measures in the following environmental areas: aesthetics; air quality; energy; hazards and hazardous materials; hydrology and water quality; land use; noise; solid/hazardous waste; and transportation/traffic. Responses to all comments received have been prepared and incorporated into the Final PEIR for the proposed project. Finally, since significant adverse environmental impacts and mitigation measures were identified for the proposed project, a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan were prepared in accordance with the requirements of CEQA (Attachment 2 to the Board Resolution).

Socioeconomic Analysis

The socioeconomic analysis for the 2012 AQMP includes costs of control measures, benefits of clean air, job impacts, and other socioeconomic impacts. The analysis is presented at the sub-county level (21 regions within the four-county area).

The projected average annual implementation cost of the 2012 AQMP is \$448 million. The PM_{2.5} strategy, including TCMs proposed by the Southern California Association of Governments (SCAG), is projected to cost \$326.6 million. The cost of TCMs alone is \$326.4 million. The projected cost for all the ozone measures is approximately \$122 million annually, of which \$40 million is attributable to stationary source controls.

Compliance with the federal 24-hour PM_{2.5} standard and progress toward the ozone standards are projected to result in an average annual clean air benefit of \$3.5 billion. The \$3.5 billion benefit includes approximately \$519 million for congestion relief from TCMs, \$2.2 billion for reductions in premature deaths and averted illness, \$696 million for visibility improvements, and \$14 million for reduced damage to materials.

The socioeconomic analysis represents a rigorous application of statistical and economic framework, epidemiological studies, and computer modeling to assess the aggregate potential impacts of the overall suite of control measures and their resulting clean air benefits. The analysis has undergone external peer-review to improve information for the 2012 AQMP and seek suggestions for enhancement of future analyses.

Based on the analysis, the 2012 AQMP is not expected to result in dramatic impacts on the region's competitiveness. The estimated \$3.5 billion benefit is greater than the estimated \$448 million cost. There is a net modest job gain as a result of the 2012 AQMP.

Staff utilized all available information and state-of-the-art models for the socioeconomic analysis, and the methodology underwent extensive peer-review. Key comments received from stakeholders on the socioeconomic report include the need for the quantification of cost effectiveness for all control measures, as well as questioning the assumptions used to quantify the job creation benefits of cleaner air.

Cost effectiveness values were determined for all the control measures with committed SIP emissions reductions, except for one measure which requires further technology assessment and selection to estimate the costs. Staff is committed to conducting a review of its socioeconomic methodology during 2013, convening a panel of experts, and updating the underlying technical studies and assumptions, the assessment methods, and the modeling approaches as appropriate.

Particulate Matter Health Effects

Appendix I (Health Effects) in the 2012 AQMP was prepared to discuss the overall health effects from criteria pollutants (e.g., ozone, PM, CO, NO₂, SO₂, sulfates, lead) and toxic air contaminants. The Appendix includes a report on the health effects of particulate matter in the South Coast Air Basin as required by California Health & Safety Code Section 40471(b). The evaluation was prepared in conjunction with public health agencies, CARB and OEHHA, and peer-reviewed by an Advisory Council made up of 16 members chosen by the Governing Board members and Advisory Groups pursuant to California Health & Safety Code Section 40428. Appendix I was modified to reflect any comments received from the Advisory Council, health agencies and general public. Findings include that a large body of scientific evidence shows adverse impacts of air pollution including PM_{2.5} on human and animal health. Population-based and laboratory studies link air pollution including PM_{2.5} and increased morbidity and, in some instances, earlier mortality. Finally, while methods to study air pollution health effects have progressed, there are still no clear thresholds below which no adverse effects are demonstrated for some pollutants.

The 2012 AQMP submitted for the Governing Boards' consideration consists of the documents entitled:

- Resolution (Attachment A)
- Draft Final 2012 AQMP (Attachment B)
 - Appendix I - Health Effects
 - Appendix II - Current Air Quality
 - Appendix III - Base and Future Year Emission Inventory
 - Appendix IV (A) - District's Stationary Source Control Measures
 - Appendix IV (B) - Proposed 8-Hour Ozone Measures
 - Appendix IV (C) - Regional Transportation Strategies & Control Measures
 - Appendix V - Modeling & Attainment Demonstrations
 - Appendix VI - Reasonably Available Control Measures (RACM) Demonstration
 - Appendix VII - 1-Hour Ozone Attainment Demonstration
 - Appendix VIII - VMT Offset Requirement Demonstration
- Responses to Comments on the 2012 AQMP (November 2012) – (Attachment C)
- Final Program Environmental Impact Report for the 2012 AQMP (Attachment D)
 - Findings, Statement of Overriding Considerations, and Mitigation Monitoring and Reporting Plan (*Attachment 2 to the Resolution*)
- Draft Final Socioeconomic Report for the 2012 AQMP (Attachment E)
- Changes to Control Measures IND-01, CMB-01, CTS-01 and CTS-04 (Attachment F)

All of the above documents, as well as previous drafts and marked-up versions, have been made available to the public on the AQMD Website (<http://www.aqmd.gov/aqmp/2012aqmp/DraftFinal/index.html>) and have also been made available through the AQMD Public Information Center.

**ATTACHMENT A
RESOLUTION NO. 12-xx**

A Resolution of the South Coast Air Quality Management District (AQMD or District) Governing Board Certifying the Final Program Environmental Impact Report for the 2012 Air Quality Management Plan (AQMP), adopting the Draft Final 2012 AQMP, to be referred to after adoption as the Final 2012 AQMP, and to be submitted into the California State Implementation Plan.

WHEREAS, the U.S. Environmental Protection Agency (U.S. EPA) promulgated a 24-hour fine particulate matter (PM_{2.5}) national ambient air quality standard (NAAQS or standard) in 2006, and 8-hour ozone NAAQS in 1997, followed up by implementation rules which set forth the classification and planning requirements for State Implementation Plans (SIP); and

WHEREAS, the South Coast Air Basin was classified as nonattainment for the 2006 24-hour PM_{2.5} standard on December 14, 2009, with an attainment date by December 14, 2014; and

WHEREAS, the U.S. EPA revoked the 1-hour ozone standard effective June 15, 2005, but on September 19, 2012 issued a proposed call for a California SIP revision for the South Coast to demonstrate attainment of the 1-hour ozone standard; and

WHEREAS, the 1997 8-hour ozone standard became effective on June 15, 2004, with an attainment date for the South Coast of December 31, 2024; and

WHEREAS, the South Coast Air Basin was classified as “extreme” nonattainment for 8-hour ozone for the 1997 standard with attainment dates by 2024; and

WHEREAS, EPA approved the South Coast SIP for 8-hour ozone on March 1, 2012; and

WHEREAS, the federal Clean Air Act requires SIPs for regions not in attainment with the NAAQS be submitted no later than three years after the nonattainment area was designated, whereby, a SIP for the South Coast Air Basin must be submitted for 24-hour PM_{2.5} by December 14, 2012; and

WHEREAS, the South Coast Air Quality Management District has jurisdiction over the South Coast Air Basin and the desert portion of Riverside County known as the Coachella Valley; and

WHEREAS, 40 Code of Federal Regulations (CFR) Part 93 requires that transportation emission budgets for certain criteria pollutants be specified in the SIP, and

WHEREAS, 40 CFR Part 93.118(e)(4)(iv) requires a demonstration that transportation emission budgets submitted to U.S. EPA are “consistent with applicable requirements for reasonable further progress, attainment, or” maintenance (whichever is relevant to the given implementation plan submission); and

WHEREAS, the South Coast Air Quality Management District is committed to comply with the requirements of the federal Clean Air Act; and

WHEREAS, the Lewis-Presley Air Quality Management Act requires the District’s Governing Board adopt an AQMP to achieve and maintain all state and federal air quality standards; to contain deadlines for compliance with federal primary ambient air quality standards; and to achieve the state standards and federal secondary air quality standards by the application of all reasonably available control measures, by the earliest date achievable (Health and Safety Code Section 40462) and the California Clean Air Act requires the District to endeavor to achieve and maintain state ambient air quality standards for ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide by the earliest practicable date (Health and Safety Code Section 40910); and

WHEREAS, the California Clean Air Act requires a nonattainment area to evaluate and, if necessary, update its AQMP under Health & Safety Code §40910 triennially to incorporate the most recent available technical information; and

WHEREAS, the South Coast Air Quality Management District Governing Board is committed to comply with the requirements of the California Clean Air Act; and

WHEREAS, the South Coast Air Quality Management District is unable to specify an attainment date for state ambient air quality standards for 8-hour ozone, PM2.5, and PM10, however, the 2012 AQMP, in conjunction with earlier AQMPs contains every feasible control strategy and measure to ensure progress toward attainment and the AQMP will be reviewed and revised to ensure that progress toward all standards is maintained; and

WHEREAS, the 2012 AQMP must meet all applicable requirements of state law and the federal Clean Air Act; and

WHEREAS, the South Coast Air Quality Management District Governing Board is committed to achieving healthful air in the South Coast Air Basin and all other parts of the District at the earliest possible date; and

WHEREAS, the 2012 AQMP is the result of 17 months of staff work, public review and debate, and has been revised in response to public comments; and

WHEREAS, the 2012 AQMP incorporates updated emissions inventories, ambient measurements, new meteorological episodes, improved air quality modeling analyses, and updated control strategies by the District, and the Southern California Association of Governments (SCAG) and will be forwarded to the California Air Resources Board (CARB) for any necessary additions and submission to EPA; and

WHEREAS, as part of the preparation of an AQMP, in conjunction or coordination with public health agencies such as CARB and the Office of Environmental Health Hazard Assessment (OEHHA), a report has been prepared and peer-reviewed by the Advisory Council on the health impacts of particulate matter air pollution in the South Coast Air Basin pursuant to California Health and Safety Code § 40471, which has been included as part of Appendix I (Health Effects) of the 2012 AQMP together with any required appendices; and

WHEREAS, the 2012 AQMP establishes transportation conformity budgets for the 24-hour PM_{2.5} standard based on the latest planning assumptions; and

WHEREAS, the AQMP satisfies all the attainment deadlines for federal ambient air quality standards for 24-hour PM_{2.5} and 1-hour ozone NAAQS; and

WHEREAS, the 2012 AQMP satisfies the planning requirements set forth in the federal and California Clean Air Acts; and

WHEREAS, the 2012 AQMP includes the 24-hour PM_{2.5} attainment demonstration plan, reasonably available control measure (RACM) and reasonably available control technology (RACT) determinations, and transportation conformity budgets for the South Coast Air Basin; and

WHEREAS, the 2012 AQMP updates the U.S. EPA approved 8-hour ozone control plan with new measures designed to reduce reliance on the

federal Clean Air Act (CAA) Section 182(e)(5) long-term measures for NOx and VOC reductions; and

WHEREAS, in order to reduce reliance on the CAA Section 182(e)(5) long-term measures, the SCAQMD will need emission reductions from sources outside of its primary regulatory authority and from sources that may lack, in some cases, the financial wherewithal to implement technology with reduced air pollutant emissions; and

WHEREAS, a majority of the measures identified to reduce reliance on the CAA Section 182(e)(5) long-term measures rely on continued and sustained funding to incentivize the deployment of the cleanest on-road vehicles and off-road equipment; and

WHEREAS, the 2012 AQMP includes a new demonstration of 1-hour ozone attainment (Appendix VII) and vehicle miles travelled (VMT) emissions offsets (Appendix VIII), as per recent proposed U.S. EPA requirements; and

WHEREAS, the South Coast Air Quality Management District Governing Board finds and determines with certainty that the 2012 AQMP is considered a “project” pursuant to CEQA; and

WHEREAS, pursuant to the California Environmental Quality Act (CEQA) a Notice of Preparation (NOP) of a Draft Program Environmental Impact Report (PEIR) and Initial Study for the 2012 AQMP was prepared and released for a 30-day public comment period, preliminarily setting forth the potential adverse environmental impacts of adopting and implementing the 2012 AQMP; and

WHEREAS, pursuant to CEQA a Draft PEIR on the 2012 AQMP (State Clearinghouse Number 2012061093), including the NOP and Initial Study and responses to comments on the NOP and Initial Study, was prepared and released for a 45-day public comment period, setting forth the potential adverse environmental impacts of adopting and implementing the 2012 AQMP; and

WHEREAS, the Draft PEIR on the 2012 AQMP included an evaluation of project-specific and cumulative direct and indirect impacts from the proposed project and four project alternatives; and

WHEREAS, the AQMD staff reviewed the 2012 AQMP and determined that it may have the potential to generate significant adverse environmental impacts; and

WHEREAS, the Draft PEIR on the 2012 AQMP has been revised based on comments received and modifications to the draft 2012 AQMP and all

comments received were responded to, such that it is now a Final PEIR on the 2012 AQMP; and

WHEREAS, the Governing Board finds and determines, taking into consideration the factors in §(d)(4)(D) of the Governing Board Procedures, that the modifications that have been made to 2012 AQMP, since the Draft PEIR on the 2012 AQMP was made available for public review would not constitute significant new information within the meaning of the CEQA Guidelines; and

WHEREAS, none of the modifications to the 2012 AQMP alter any of the conclusions reached in the Draft PEIR on the 2012 AQMP, nor provide new information of substantial importance that would require recirculation of the Draft PEIR on the 2012 AQMP pursuant to CEQA Guidelines §15088.5; and

WHEREAS, it is necessary that the adequacy of the Final PEIR on the 2012 AQMP be determined by the AQMD Governing Board prior to its certification; and

WHEREAS, it is necessary that the adequacy of responses to all comments received on the Draft PEIR on the 2012 AQMP be determined prior to its certification; and

WHEREAS, it is necessary that the AQMD prepare Findings and a Statement of Overriding Considerations pursuant to CEQA Guidelines §§15091 and 15093, respectively, regarding adverse environmental impacts that cannot be mitigated to insignificance; and,

WHEREAS, Findings and a Statement of Overriding Considerations have been prepared and are included in Attachment 2 to this Resolution, which is attached and incorporated herein by reference; and

WHEREAS, the provisions of Public Resources Code §21081.6 – Mitigation Monitoring and Reporting - require the preparation and adoption of implementation plans for monitoring and reporting measures to mitigate adverse environmental impacts identified in environmental documents; and

WHEREAS, staff has prepared such a plan which sets forth the adverse environmental impacts, mitigation measures, methods, and procedures for monitoring and reporting mitigation measures, and agencies responsible for monitoring mitigation measure, which is included as Attachment 2 to the Resolution and incorporated herein by reference; and

WHEREAS, the South Coast Air Quality Management District Governing Board voting on this Resolution has reviewed and considered the Final Program Environmental Impact Report on the 2012 AQMP, including responses to

comments on the Draft Program Environmental Impact Report on the 2012 AQMP, the Statement of Findings, Statement of Overriding Considerations, and the Mitigation Monitoring and Reporting Plan; and

WHEREAS, the Draft Socioeconomic Report on the 2012 AQMP was prepared and released for public review and comment; and

WHEREAS, the Draft Socioeconomic Report for the 2012 AQMP is revised based on comments received and modifications to the Draft 2012 AQMP such that it is now a Draft Final Socioeconomic Report for the 2012 AQMP; and

WHEREAS, the 2012 AQMP includes every feasible measure and an expeditious adoption schedule; and

WHEREAS, the CARB and the U.S. EPA have the responsibility to control emissions from motor vehicles, motor vehicle fuels, and non-road engines and consumer products which are primarily under their jurisdiction representing over 80 percent of ozone precursor emissions in 2023; and

WHEREAS, significant emission reductions must be achieved from sources under state and federal jurisdiction for the South Coast Air Basin to attain the federal air quality standards; and

WHEREAS, the formal deadline for submission of the 24-hour PM_{2.5} attainment plan is December 14, 2012, and the formal deadline for submission of the 1-hour ozone SIP revision is expected to be late 2013 or early 2014, but since the emissions inventory and control strategy for ozone has already been developed for the 2012 AQMP, and attaining the 1-hour ozone standard can rely on the same strategy for the 8-hour ozone standard, an attainment demonstration for the 1-hour ozone standard is included as an Appendix to the 2012 AQMP; and

WHEREAS, the 1-hour ozone attainment demonstration (Appendix VII) uses the same base year (2008) and future year inventories as presented in Appendix III of the 2012 AQMP and satisfies the pre-base year offset requirement by including pre-base year emissions in the growth projections, consistent with 40 CFR § 51.165(a)(3)(i)(C)(1), as described on page III-2-54 of Appendix III of the 2012 AQMP.

WHEREAS the South Coast Air Quality Management District Governing Board hereby requests that CARB commit to submitting contingency measures as required by Section 182(e)(5) as necessary to meet the requirements for demonstrating attainment of the 1-hr ozone standard; and

WHEREAS, the South Coast Air Quality Management District Governing Board directs staff to move expeditiously to adopt and implement feasible new control measures to achieve long-term reductions while meeting all applicable public notice and other regulatory development requirements; and

WHEREAS, the South Coast Air Quality Management District has held six public workshops on the Draft 2012 AQMP, one public workshop on the Draft Socioeconomic Report, four public hearings throughout the four-county region in September on the Revised Draft 2012 AQMP, 14 AQMP Advisory Group meetings, 11 Scientific, Technical, and Modeling, Peer Review Advisory Group meetings, four public hearings in November throughout the four-county region on the Draft Final 2012 AQMP, and one adoption hearing pursuant to section 40466 of the Health and Safety Code; and

WHEREAS, pursuant to section 40471(b) of the Health and Safety Code, as part of the six public workshops on the Draft 2012 AQMP, four public hearings on the Revised Draft 2012 AQMP, the four public hearings on the Draft Final 2012 AQMP, and adoption hearing, public testimony and input were taken on Appendix I (Health Effects); and

WHEREAS, the record of the public hearing proceedings is located at South Coast Air Quality Management District, 21865 Copley Drive, Diamond Bar, California 91765, and the custodian of the record is the Clerk of the Board; and

WHEREAS, an extensive outreach program took place that included over 75 meetings with local stakeholders, key government agencies, focus groups, topical workshops, and over 65 presentations on the 2012 AQMP provided; and

WHEREAS, the record of the CEQA proceedings is located at South Coast Air Quality Management District, 21865 Copley Drive, Diamond Bar, California 91765, and the custodian of the record is the Assistant Deputy Executive Officer, Planning, Rule Development, and Area Sources.

NOW, THEREFORE BE IT RESOLVED, that the South Coast Air Quality Management District Governing Board does hereby certify that the Final PEIR for the 2012 AQMP including the responses to comments has been completed in compliance with the requirements of CEQA and finds that the Final PEIR on the 2012 AQMP, including responses to comments, was presented to the AQMD Governing Board, whose members reviewed, considered and approved the information therein prior to acting on the 2012 AQMP; and finds that the Final PEIR for the 2012 AQMP reflects the AQMD's independent judgment and analysis; and

BE IT FURTHER RESOLVED, that the District will develop, adopt, submit, and implement the short-term PM2.5 control measures as identified in Table 4-2 and the 8-hour ozone measures in Table 4-4 of Chapter 4 in the 2012 AQMP (Main Document) as expeditiously as possible in order to meet or exceed the commitments identified in Tables 4-10 and 4-11 of the 2012 AQMP (Main Document), and to substitute any other measures as necessary to make up any emission reduction shortfall.

BE IT FURTHER RESOLVED, the District commits to update AQMP emissions inventories, baseline assumptions and control measures as needed to ensure that the best available data is utilized and attainment needs are met.

BE IT FURTHER RESOLVED, the District commits to conduct a review of its socioeconomic analysis methods during 2013, convene a panel of experts, and update assessment methods and approaches, as appropriate.

BE IT FURTHER RESOLVED, the District commits to continue working with the ports on the implementation of control measure IND-01(Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Sources).

BE IT FURTHER RESOLVED, that the Executive Officer is hereby directed to enhance outreach and education efforts related to the “Check before you Burn” residential wood burning curtailment program, and to expand the current incentive programs for gas log buydown and to include potentially wood stove replacements working closely with U.S. EPA and other stakeholders.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, pursuant to the requirements of Title 14 California Code of Regulations, does hereby adopt the Statement of Findings pursuant to §15091, and adopts the Statement of Overriding Considerations pursuant to §15093, included in Attachment 2 and incorporated by reference; and

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, does hereby adopt the Mitigation Monitoring and Reporting Plan, as required by Public Resources Code, Section 21081.6, attached hereto and incorporated by reference; and

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board finds that the mobile source control measures contained in Appendix IV-B are technically feasible and cost-effective and requests that CARB consider them in any future incentives programs or rulemaking.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board does hereby direct staff to work with state agencies and state legislators, federal agencies and U.S. Congressional and Senate members to identify funding sources and secure funding for the expedited replacement of older existing vehicles and off-road equipment to help reduce the reliance on the CAA Section 182(e)(5) long-term measures.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board finds that transportation emission budgets are “consistent with applicable requirements for reasonable further progress, attainment, or maintenance (whichever is relevant to the given implementation plan submission)” pursuant to 40 CFR 93.118(e)(4)(iv).

BE IT FURTHER RESOLVED, that the Executive Officer is hereby directed to finalize the 2012 AQMP including the main document, appendices, and related documents as adopted at the December 7, 2012 public hearing.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, whose members reviewed, considered and approved the information contained in the documents listed herein, adopts the 2012 AQMP dated December 7, 2012 consisting of the document entitled 2012 AQMP as amended by the final changes set forth by the AQMD Governing Board and the associated documents listed in Attachment 1 to this Resolution, the Draft Final Socioeconomic Report for the 2012 AQMP; the Final Program EIR for the 2012 AQMP, and the Statements of Findings and Overriding Considerations and Mitigation Monitoring Plan (Attachment 2 to this Resolution).

BE IT FURTHER RESOLVED, the Executive Officer is hereby directed to work with CARB and the U.S. EPA to ensure expeditious approval of this 2012 AQMP for PM2.5 and 1-hour ozone attainment.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, requests that the 2012 AQMP serve as the SIP revision submittal for the 24-hour PM2.5 attainment demonstration plan including the RACM/RACT determinations for the PM2.5 standard for the South Coast Air Basin, and the PM2.5 Transportation Conformity Budgets for the South Coast Air Basin.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, requests that the 2012 AQMP (Appendix VII) serve as the SIP revision submittal for the 1-hour ozone NAAQS attainment demonstration.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, requests that the 2012 AQMP (Appendix VIII) serve as the SIP revision submittal for a revised VMT emissions offset demonstration as required under Section 182(d)(1)(A) for both the 1-hour ozone and 8-hour ozone SIPs for the South Coast Air Basin.

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board, requests that the 2012 AQMP serve as an update to the approved 2007 8-hour ozone SIP for the South Coast Air Basin with specific control measures designed to further implement the 8-hour ozone SIP and reduce reliance on Section 182(e)(5) long term measures.

BE IT FURTHER RESOLVED, that the 2012 AQMP does not serve as a revision to the previously approved 8-hour ozone SIP with respect to emissions inventories, attainment demonstration, RFP, and transportation emissions budgets or any other required SIP elements.

BE IT FURTHER RESOLVED, that the Executive Officer is hereby directed to forward a copy of this Resolution, the 2012 AQMP and its appendices as amended by the final changes, to CARB, and to request that these documents be forwarded to the U.S. EPA for approval as part of the California State Implementation Plan. In addition, the Executive Officer is directed to forward a copy of this Resolution, comments on the 2012 AQMP and responses to comments, public notices, and any other information requested by the U.S. EPA for informational purposes.

Dated: _____

Clerk of the District Board

ATTACHMENT 1

The Final 2012 Air Quality Management Plan submitted for the South Coast Air Quality Management District Governing Board's consideration consists of the documents entitled:

- Draft Final 2012 AQMP (Attachment B) including the following appendices:
 - Appendix I - Health Effects
 - Appendix II - Current Air Quality
 - Appendix III - Base and Future Year Emission Inventory
 - Appendix IV (A) - District's Stationary Source Control Measures
 - Appendix IV (B) - Proposed 8-Hour Ozone Measures
 - Appendix IV (C) - Regional Transportation Strategies & Control Measures
 - Appendix V - Modeling & Attainment Demonstrations
 - Appendix VI - Reasonably Available Control Measures (RACM) Demonstration
 - Appendix VII - 1-Hour Ozone Attainment Demonstration
 - Appendix VIII - VMT Offset Requirement Demonstration
- Comments on the 2012 Air Quality Management Plan, and Responses to Comments (November 2012) – (Attachment C)
- Final Program Environmental Impact Report for the 2012 Air Quality Management Plan (Attachment D)
 - Findings, Statement of Overriding Considerations, and Mitigation Monitoring and Reporting Plan (Attachment 2 to the Resolution)
- Draft Final Socioeconomic Report for the 2012 Air Quality Management Plan (Attachment E)
- Changes to Control Measures IND-01, CMB-01, CTS-01 and CTS-04 (Attachment F)

1.0 INTRODUCTION

The California Environmental Quality Act (CEQA), Public Resources Code §21000 et seq., requires that the potential environmental impacts of proposed projects be evaluated and that feasible methods to reduce or avoid identified significant adverse environmental impacts of these projects be identified. To fulfill the purpose and intent of CEQA, the SCAQMD has prepared a Program Environmental Impact Report (EIR) to address the potential environmental impacts associated with the proposed 2012 Air Quality Management Plan (AQMP). The South Coast Air Quality Management District (SCAQMD) is the lead agency for the proposed project and, therefore, has prepared a Final Program EIR pursuant to CEQA. The purpose of the Final Program EIR is to describe the proposed project and to identify, analyze, and evaluate any potentially significant adverse environmental impacts that may result from adopting and implementing the proposed 2012 AQMP. A Draft Program EIR was circulated to the public for a 45-day review and comment period from September 7, 2012 to October 23, 2012. The SCAQMD received 13 comment letters during the 45-day public review and comment period. Responses to all comments were prepared and comments and responses are included in Appendix G of the Final Program EIR.

The California Legislature adopted the Lewis Air Quality Act in 1976, creating the SCAQMD from a voluntary association of air pollution control districts in Los Angeles, Orange, Riverside, and San Bernardino counties. The new agency was charged with developing uniform plans and programs for the South Coast Air Basin (Basin) to attain federal air quality standards by the dates specified in federal law. While the Basin has one of the worst air quality problems in the nation, there have been significant improvements in air quality in the Basin over the last two decades, although some air quality standards are still exceeded relatively frequently, and by a wide margin. The agency was also required to meet state standards by the earliest date achievable through the use of reasonably available control measures.

The Lewis Air Quality Act (now known as the Lewis-Presley Air Quality Management Act) requires that the SCAQMD prepare an Air Quality Management Plan (AQMP) consistent with federal planning requirements. In 1977, amendments to the federal Clean Air Act (CAA) included requirements for submitting State Implementation Plans (SIPs) for non-attainment areas that fail to meet all federal ambient air quality standards (Health and Safety Code §40462). The federal CAA was amended in 1990 to specify attainment dates and SIP requirements for ozone, carbon monoxide (CO), nitrogen dioxide (NO₂) and particulate matter less than 10 microns in diameter (PM₁₀). The California Clean Air Act (CCAA), adopted in 1988, requires the SCAQMD to endeavor to achieve and maintain state ambient air quality standards for ozone, CO, sulfur dioxide (SO₂), and NO₂ by the earliest practicable date (Health and Safety Code §40910), and establishing requirements to update the plan periodically. The first AQMP was prepared and approved by the SCAQMD in 1979 and has been updated and revised a number of times. The CCAA requires a three-year plan review and update to the AQMP.

On November 22, 2010, U.S. EPA issued a notice of proposed partial approval and partial disapproval of the 2007 South Coast SIP for the 1997 Fine Particulate Matter Standards and the corresponding 2007 State Strategy. Specifically, U.S. EPA proposed approving the SIP's inventory and regional modeling analyses, but it also proposed disapproving the attainment demonstration because it relied too extensively on commitments to emission reductions in lieu of

fully adopted, submitted, and SIP-approved rules. The notice also cited deficiencies in the SIP's contingency measures.

- In response the U.S. EPA's proposed partial disapproval of the 2007 SIP, on March 4, 2011, the SCAQMD Governing Board approved Revisions to the 2007 PM_{2.5} and Ozone State Implementation Plan for the South Coast Air Basin and Coachella Valley. The revisions to the 2007 PM_{2.5} and Ozone SIP consist of the following:
 - Updated implementation status of SCAQMD control measures necessary to meet the 2015 PM_{2.5} attainment date;
 - Revisions to the control measure adoption schedule;
 - Changes made to the emission inventory resulting from CARB's December 2010 revisions to the on-road truck and off-road equipment rules; and
 - An SCAQMD commitment to its "fair share" of additional NO_x emission reductions, if needed, in the event U.S. EPA does not voluntarily accept the "federal assignment."
- In response to the July 14, 2011 U.S. EPA notice of proposed partial approval and partial disapproval of the 2007 South Coast IP for the 1997 Fine Particulate Matter Standards, at the October 7, 2011 public hearing, the SCAQMD Governing Board approved Further Revisions to PM_{2.5} and Ozone State Implementation Plan for South Coast Air Basin and Coachella Valley. Revisions to the PM_{2.5} SIP included a three-prong approach for identifying contingency measures needed to address U.S. EPA's partial disapproval:
 - Equivalent emission reductions achieved through improvements in air quality;
 - Relying on committed emission reductions for the 2007 ozone plan;
 - Quantifying excess emission reductions achieved by existing rules and programs that were not originally included in the 2007 PM_{2.5} SIP;
 - U.S. EPA approved the PM_{2.5} SIP except for contingency measures on November 9, 2011. Action is pending on the contingency measures; and
 - U.S. EPA approved the 2007 SIP for the eight-hour ozone standard on March 1, 2012.

The 2012 AQMP outlines a comprehensive control strategy that meets the requirement for expeditious progress towards attainment with the federal 24-hour PM_{2.5} ambient air quality standard with all feasible control measures and demonstrates attainment of the standard by 2014. The 2012 AQMP is also an update to the eight-hour ozone control plan with new emission reduction commitments from a set of new control measures, which implement the 2007 AQMP's §182 (e)(5) commitments. In addition, in response to a U.S. EPA's "SIP call" and in anticipation that it will be finalized, the 2012 AQMP *One-hour Ozone Attainment Demonstration*, which demonstrates attainment of the federal one-hour (revoked) ozone standard by the year 2022. U.S. EPA published in the Federal Register a proposal to withdraw its approval of, and then to disapprove, the transportation control measure (TCM) demonstrations, also referred to as vehicle miles travelled (VMT) emissions offset demonstrations, in the 2003 one-hour ozone plan and the 2007 eight-hour ozone plan. As a result, the 2012 AQMP also includes a *VMT Offset Requirement Demonstration*.

2.0 CERTIFICATION OF THE FINAL PROGRAM EIR

The SCAQMD Governing Board certifies that it has been presented with the Final Program EIR and that it has reviewed and considered the information contained in the Final Program EIR prior to making the following certifications and findings. Pursuant to CEQA Guidelines §15090 (Title 14 of the California Code of Regulations, §15090), the SCAQMD Governing Board certifies that the Final Program EIR, including responses to comments, has been completed in compliance with the CEQA statutes and the CEQA Guidelines. The SCAQMD Governing Board certifies the Final Program EIR for the actions described in these findings and in the Final Program EIR, i.e., the proposed project. The SCAQMD Governing Board further certifies that the Final Program EIR reflects its independent judgment and analysis. The Governing Board Resolution includes the certification of the Final Program EIR.

2.1 ENVIRONMENTAL REVIEW PROCESS

To fulfill the purpose and intent of CEQA, the SCAQMD, as the lead agency for the proposed project, prepared and released a Notice of Preparation and Initial Study (NOP/IS), which is a preliminary evaluation of potentially significant adverse environmental impacts associated with the proposed project to be further analyzed in the Draft Program EIR. The original NOP/IS was distributed to responsible agencies and interested parties for a 30-day review and comment period on June 28, 2012. Subsequent to the release of the June 28, 2012 NOP/IS, minor modifications were made to three control measures in the 2012 AQMP. In response to comments received regarding the modifications to the 2012 AQMP, a revised NOP/IS was circulated from August 2, 2012 to August 31, 2012, in compliance with the requirement for a minimum comment period of 30 days. The NOP/IS formed the basis for, and focus of, the technical analyses in the Draft Program EIR.

The following environmental topics were identified in the June 28, 2012 NOP/IS as potentially significant and were further analyzed in the Draft Program EIR: aesthetics, air quality and greenhouse gas emissions; energy; hazards and hazardous materials; hydrology and water quality; and solid and hazardous waste. The June 28, 2012 NOP/IS concluded that there would be no significant adverse impacts on agricultural and forestry resources, biological resources, cultural resources, geology and soils, land use and planning, mineral resources, noise, population and housing, public services, recreation, and transportation and traffic. Based on comments received during the public comment period for the June 28, 2012 NOP/IS, the topics of land use and planning, noise, and, transportation and traffic were identified as potentially significant impact areas in the August 2, 2012 NOP/IS and were also addressed in the Draft Program EIR. A copy of the August 2, 2012 NOP/IS can be found in Appendix A of the Final Program EIR.

Both the June 28, 2012 NOP/IS and August 2, 2012 NOP/IS were circulated to local jurisdictions and public agencies, 2012 AQMP stakeholders, and interested individuals in order to solicit input on the scope of the environmental analysis to be included in the Draft Program EIR. Eleven comment letters were received relative to the June 28, 2012 NOP/IS. Comments and responses to comments received on the June 28, 2012 NOP/IS are included in Appendix B of the Final Program EIR. No comment letters were received on the August 2, 2012 NOP/IS. Finally, comments were made during the seven scoping meetings for the 2012 AQMP that were held on July 10, 2012 (two meetings), July 11, 2012, July 12, 2012, July 24, 2012, August 9, 2012 and

August 23, 2012, and responses to these comments are provided in Appendix D of the Final Program EIR.

The Draft Program EIR was released for a 45-day public review and comment period from September 7, 2012 through October 23, 2012. As with the June 28, 2012 NOP/IS and August 2, 2012 NOP/IS, the Draft Program EIR was circulated for public review and comment to local jurisdictions and public agencies, 2012 AQMP stakeholders, and interested individuals. The environmental topics that were determined to have potentially significant impacts were further analyzed in the Draft Program EIR, and included the following topics: aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, land use and planning, noise, solid and hazardous waste, and transportation and traffic. The analysis concluded that significant adverse project-specific environmental impacts from the proposed project are expected to occur after implementing mitigation measures for: construction air quality, energy, hazards and hazardous materials, hydrology and water quality, noise, and, transportation and traffic. Similarly, significant adverse cumulative environmental impacts were identified for: air quality impacts during construction, energy impacts, hazards and hazardous materials impacts, hydrology and water quality impacts, noise impacts, and cumulatively considerable transportation and traffic impacts.

Thirteen comment letters were received during the public comment period on the Draft Program EIR. Draft Program EIR comments and responses to the comments have been prepared and are included in Appendix G of the Final Program EIR. Changes to the proposed project, including the *One-hour Ozone Attainment Demonstration* and *VMT Offset Requirement Demonstration*, were evaluated and minor modifications have been made to the Draft Program EIR such that it is now a Final Program EIR. However, none of the modifications alter any of the conclusions reached in the Draft Program EIR or provide new information of substantial importance relative to the draft document that would require recirculation of the Draft Program EIR pursuant to CEQA Guidelines §15088.5. Because the 2012 AQMP has the potential to generate significant adverse environmental impacts that cannot be mitigated to less than significance, Findings and a Statement of Overriding Considerations are required and have been prepared pursuant to CEQA Guidelines §15091 and §15093, respectively.

The Final Program EIR consists of an executive summary, project description, environmental setting, environmental impacts and mitigation measures, cumulative impacts, project alternatives, the August 2, 2012 NOP/IS (Appendix A of the Final Program EIR), comments and responses to comments on the June 28, 2012 NOP/IS (Appendix B of the Final Program EIR), a statement that no comments were received on the August 2, 2012 NOP/IS (Appendix C of the Final Program EIR), scoping meeting comments and responses to comments (Appendix D of the Final Program EIR), SCAG's TCM table (Appendix E of the Final Program EIR), *Examples of Measures That Could Reduce Impacts from Planning, Development and Transportation Projects* from SCAG's 2012–2035 RTP/SCS (Appendix F of the Final Program EIR), and comments and responses to comments on the Draft Program EIR (Appendix G of the Final Program EIR). All documents comprising the Final Program EIR for the proposed project are available at SCAQMD headquarters, 21865 Copley Drive, Diamond Bar, California, 91765. The Final Program EIR was made available to the public on November 20, 2012, and can be obtained by contacting the SCAQMD's Public Information Center at (909) 396-2039 or by accessing the SCAQMD's CEQA webpage at: <http://www.aqmd.gov/ceqa/nonaqmd.html>.

2.2 SUMMARY OF THE PROPOSED PROJECT

The purpose of the 2012 AQMP for the South Coast Air Basin (Basin) is to set forth a comprehensive and integrated program that will lead the Basin into compliance with the federal 24-hour PM_{2.5} air quality standard, and to provide an update of the Basin's projections in meeting the federal eight-hour ozone standard. Specifically, the 2012 AQMP would serve as the official SIP submittal for the federal 2006 24-hour PM_{2.5} standard, for which U.S. EPA has established a due date of December 14, 2012. In addition, the 2012 AQMP would update specific elements of the previously approved eight-hour ozone SIP: 1) an updated emissions inventory; 2) new control measures and commitments for emissions reductions to help fulfill the §182 (e)(5) portion of the eight-hour ozone SIP; 3) include an attainment demonstration for the federal one-hour ozone standard (revoked) by the year 2022; and 4) provide a VMT offset requirement demonstration pursuant to U.S. EPA guidance.

2.3 ABSENCE OF NEW INFORMATION

CEQA Guidelines §15088.5 requires a lead agency to recirculate an EIR for further review and comment when significant new information is added to the EIR after public notice is given of the availability of the draft EIR but before certification of a final EIR. New information added to an EIR is not "significant" unless the EIR is changed in a way that deprives the public of a meaningful opportunity to comment upon a substantial adverse environmental effect of the project or a feasible way to mitigate or avoid such an effect that the project proponent declines to implement. The CEQA Guidelines provide examples of significant new information under this standard. Recirculation is not required where the new information added to the EIR merely clarifies or amplifies or makes insignificant modifications in an adequate EIR.

The SCAQMD Governing Board recognizes that the Final Program EIR incorporates information obtained by SCAQMD since the Draft Program EIR was completed, and contains additions and clarifications. With respect to this information, the SCAQMD Governing Board finds as follows.

Updated Information: As described in the Final Program EIR, since the Draft Program EIR was circulated, a number of environmental topic areas were modified in response to comments on the 2012 AQMP or to further clarify 2012 AQMP and the associated control measures. Examples of modifications between the Draft and Final Program EIR are summarized below, and discussed in more detail throughout the Response to Comments document (included in Appendix G of the Final Program EIR):

- In response to a U.S. EPA's "SIP call" and in anticipation that it will be finalized, the *One-hour Ozone Attainment Demonstration*, which demonstrates attainment of the federal one-hour (revoked) ozone standard by the year 2022, was prepared and is included as Appendix VII of the 2012 AQMP. In anticipation that U.S. EPA would likely request that the SCAQMD prepare a one-hour ozone SIP, the Final Program EIR for the 2012 AQMP includes 11 project objectives, two that specifically address attaining the federal one-hour ozone standard. The *One-hour Ozone Attainment Demonstration* concluded that the same control measures and TCMs already included in the 2012 AQMP can be relied on to address progress in attaining the federal one-hour (revoked) and eight-hour ozone standards by 2022 – 2023. This means that the *One-hour Ozone Attainment Demonstration* includes all of the

same ozone-related control measures currently in the 2012 AQMP that were already analyzed in the Draft Program EIR. Therefore, no further environmental analysis is necessary.

- U.S. EPA published in the Federal Register a proposal to withdraw its approval of, and then to disapprove, VMT emissions offset demonstrations, in the 2003 one-hour ozone plan and the 2007 eight-hour ozone plan. As a result, the 2012 AQMP also includes a *VMT Offset Requirement Demonstration*. The *VMT Offset Requirement Demonstration* concluded that the same TCMs already included in the 2012 AQMP can be relied on to comply with the VMT offset requirement. This means that the *VMT Offset Requirement Demonstration* includes all of the same TCMs currently in the 2012 AQMP that were already analyzed in the Draft Program EIR. Therefore, no further environmental analysis is necessary.
- Minor modifications to improve clarity and to provide additional information were made to several 2012 AQMP control measures. The summary descriptions of these control measure were modified in Chapter 2 – Project Description, to reflect these changes.
- In response to comments, minor corrections were made in Subchapter 3.6 – Land Use and Planning, to the Orange County discussion in subsection 3.6.3.2.
- Based on updated information minor changes to inventory and emission reduction estimates were made in Subchapter 4.2 – Air Quality.
- Based on updated information minor changes to inventory and emission reduction estimates were made to the project alternatives in Chapter 6 – Alternatives.

The SCAQMD Governing Board finds that these changes to 2012 AQMP are in accordance to requests by responsible agencies or other entities to comply with their regulatory requirements and processes, but do not cause any new or more severe environmental impacts. Therefore, in accordance with CEQA and the CEQA Guidelines, no recirculation of the Final Program EIR is necessary based on the changes to 2012 AQMP.

Responses to Comments: In response to comments, a number of environmental topic areas were clarified and described in more detail. The SCAQMD Governing Board finds that this additional information does not constitute significant new information requiring recirculation, but rather that the additional information clarifies or amplifies an adequate Program EIR. Specifically, the SCAQMD Governing Board finds that the additional information including the changes described above, does not show that:

1. A new significant environmental impact would result from the project.
2. A substantial increase in the severity of an environmental impact would result.
3. A feasible project alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the significant environmental impacts of the project, but the project's proponents decline to adopt it.
4. The Draft Program EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded.

Based on the foregoing reasons, and having reviewed the information contained in the Final Program EIR and in the record of SCAQMD's proceedings, including the comments on the Draft Program EIR and the responses thereto, and the above-described information, the SCAQMD

Governing Board hereby finds that no significant new information has been added to the Final Program EIR since public notice was given of the availability of the Draft Program EIR that would require recirculation of the Draft Program EIR.

2.4 DIFFERENCES OF OPINION REGARDING THE IMPACTS OF THE PROJECT

In making its determination to certify the Final Program EIR and to approve the proposed project, the SCAQMD Governing Board recognizes that the proposed project involves a number of controversial environmental issues and that a range of opinion exists with respect to those issues. The SCAQMD Governing Board has acquired an understanding of the range of opinion by its review of the Draft Program EIR, comments received on the Draft Program EIR and the responses to those comments in the Final Program EIR (Appendix G). Additionally, the SCAQMD Governing Board has its own experience and expertise in assessing air quality effects and in administering its regulatory programs. The SCAQMD Governing Board has reviewed and considered, as a whole, the evidence and analysis presented in the Draft Program EIR, the analysis presented in the comments on the Draft Program EIR, the analysis presented in the Final Program EIR, and the expert opinions of SCAQMD staff addressing those comments. The SCAQMD Governing Board has gained a comprehensive and well-rounded understanding of the environmental issues presented by the proposed project. In turn, this understanding has enabled the SCAQMD Governing Board to make its decisions after weighing and considering the various viewpoints on these important issues. The SCAQMD Governing Board accordingly certifies that its findings are based on full appraisal of all of the information contained in the Final Program EIR, as well as the evidence and other information in the record.

2.5 IMPACTS AND MITIGATION MEASURES

This attachment provides the written analysis and conclusions of the SCAQMD Governing Board regarding the environmental impacts of the proposed project and the mitigation measures proposed in the Final Program EIR and adopted by the decision-making body. In making these findings, the SCAQMD Governing Board has considered the opinions of other members of the public, including opinions that disagree with some of the analysis in the Final Program EIR. The SCAQMD Governing Board finds that the appropriate methodology for calculating effects and determining significance is a judgment within the discretion of the decision-making body; the method of analysis used in the Final Program EIR is supported by substantial evidence in the record, including the expert opinions of the SCAQMD staff; and the significance thresholds used in the Final Program EIR provide reasonable and appropriate means of assessing the significance of the adverse environmental effects of the proposed project.

Table 1 below summarizes the environmental determinations of the Final Program EIR regarding the proposed project's impacts. This table does not attempt to describe the full analysis of each environmental impact contained in the Final Program EIR. Instead, Table 1 provides a summary description of each impact and states the decision-making body's findings on the significance of each impact. A full explanation of these environmental findings and conclusions can be found in the Final Program EIR. These findings hereby incorporate by reference the discussion and analysis in the Final Program EIR supporting the Final Program EIR's determinations regarding the proposed project's impacts and mitigation measures designed to address those impacts. In

making these findings, the SCAQMD Governing Board ratifies, adopts, and incorporates the analysis and explanation in the Final Program EIR, and ratifies, adopts, and incorporates in these findings the determinations and conclusions of the Final Program EIR relating to environmental impacts and mitigation measures, except to the extent any such determinations and conclusions are specifically and expressly modified by these findings. Findings need not be made for environmental impacts that are not significant.

**Table 1
Summary of Environmental Impacts**

Impact	Project-Specific Impact	Cumulative Impact
Aesthetics		
Potential visual impacts and impacts to scenic highways due to overhead power lines	Not significant	Not significant
Air Quality		
Construction emissions of CO and PM10	Significant	Significant
Secondary impacts from increased electricity demand	Not significant	Not significant
Secondary impacts from control of stationary sources	Not significant	Not significant
Secondary impacts from change in use of lower VOC materials	Not significant	Not significant
Secondary impacts from mobile sources	Not significant	Not significant
Secondary impacts from miscellaneous sources	Not significant	Not significant
Impacts associated with toxic air contaminants	Not significant	Not significant
GHG impacts from the implementation of control measures	Not significant	Not significant
Energy		
Increase in energy demand associated with control strategies	Significant	Significant
Increase in natural gas demand	Significant	Significant
Increase in petroleum fuel use	Not significant	Not significant
Increase in alternative fuel use	Not significant	Not significant

Table 1 (Continued)
Summary of Environmental Impacts

Impact	Project-Specific Impact	Cumulative Impact
Hazards and Hazardous Materials		
Fire hazards associated with reformulated coatings, solvents, adhesives, mold release, and consumer products	Mitigated to be less than significant	Not significant
Hazards associated with the use of alternative fuels	Not significant	Not significant
Hazards associated with the transportation of LNG	Significant	Significant
Hazards associated with the release of ammonia during transport	Mitigated to less than significant	Not significant
Hazards associated with the onsite spill of ammonia	Mitigated to less than significant	Not significant
Hazards associated with fuel additives	Not significant	Not significant
Hazards associated with safety issues during start-up, shutdown, and turnaround procedures from the increased use of catalysts	Not significant	Not significant
Hydrology and Water Quality		
Increased wastewater treatment impact on water quality	Not significant	Not significant
Increased use of alternative fuels impact on water quality	Not significant	Not significant
Increased use of electric and hybrid vehicles impact on water quality	Not significant	Not significant
Water demand associated with the manufacture and use of waterborne and add-on air pollution control technologies	Significant	Significant
Impacts associated with the use and application of SBS on water quality	Not significant	Not significant
Impacts associated with the onsite spill of ammonia	Not significant	Not significant
Land Use and Planning		
Conflicts with applicable land use plans, policies, or regulations or the physical division of an established community	Not significant	Not significant

Table 1 (Concluded)
Summary of Environmental Impacts

Impact	Project-Specific Impact	Cumulative Impact
Noise		
Noise and vibration impacts due to construction activities	Significant	Significant
Noise and vibration impacts due to operational activities	Not significant	Not significant
Solid and Hazardous Waste		
Increase in the use of batteries associated with more electric and hybrid vehicles	Not significant	Not significant
Impacts associated with air pollution control technologies	Not significant	Not significant
Impacts associated with new equipment from the implementation of new control measures	Not significant	Not significant
Transportation and Traffic		
Construction related traffic associated with the installation of catenary overhead electrical lines and related facilities	Significant	Significant
Operational related traffic associated with dedicated lanes of the overhead catenary electrical lines	Mitigation required on a project-specific basis	Significant

Notes:

CO = carbon monoxide

PM10 = particulate matter less than 10 microns in diameter

VOC = volatile organic compound

3.0 FINDINGS

When considering the approval of a proposed project, CEQA prohibits a public agency from approving or carrying out the project for which a CEQA document has been completed which identifies one or more significant adverse environmental effects of the project unless the public agency makes one or more written findings for each of those significant effects, accompanied by a brief explanation of the rationale for each finding (CEQA Guidelines §15091). The analysis in the Final Program EIR concluded that the 2012 AQMP has the potential to generate significant adverse air quality, noise, and traffic impacts from construction activities associated with the proposed project, while increased demand for electricity and natural gas, increased water demand, hazards associated with transport of LNG, and traffic impacts were identified during operation of various PM2.5 and ozone control measures. These findings provide the written analysis and conclusions of the Governing Board regarding the environmental impacts of the

2012 AQMP and the mitigation measures included in the Final Program EIR and adopted by the Governing Board as part of approving the 2012 AQMP.

In making these findings, the Governing Board has considered the opinions of other members of the public, including opinions that disagree with some of the analysis used in the Final Program EIR. The Governing Board finds that the appropriate methodology for calculating effects and determining significance is a judgment within the discretion of the Governing Board; the method of analysis used in the Final Program EIR is supported by substantial evidence in the record, including the expert opinions of the SCAQMD staff; and the significance thresholds used in the Final Program EIR provide reasonable and appropriate means of assessing the significance of the adverse environmental effects of the Project. Having received, reviewed, and considered the Final Program EIR and other information in the record of proceedings, the SCAQMD Governing Board hereby adopts the findings below in compliance with CEQA and the CEQA Guidelines.

The following sets forth findings for the significant adverse impacts identified in the Final Program EIR that cannot be reduced to insignificance, those that can be mitigated to less than significant, and the rationale for each finding. The findings are supported by substantial evidence in the record as explained in each finding. These findings will be included in the record of project approval and will also be noted in the Notice of Determination.

3.1 POTENTIALLY SIGNIFICANT IMPACTS WHICH CANNOT BE MITIGATED TO A LEVEL OF INSIGNIFICANCE

The Final Program EIR identified potentially significant project-specific adverse environmental impacts that cannot be reduced to a level of insignificance for the following environmental topics: 1) air quality (CO and PM10) impacts from construction activities; 2) energy – increased demand for electricity and natural gas; 3) hazards associated with an accidental release of LNG during transport; 4) increased demand for water; 5) noise impacts from construction activities; and, 6) traffic impacts from construction activities and operations. The Final Program EIR also identified six potentially significant cumulative adverse environmental impacts that cannot be reduced to a level of insignificance: 1) construction air quality; 2) energy – increased electricity and natural gas demand; 3) hazards and hazardous materials; 4) hydrology and water quality; 5) noise; and, 6) transportation and traffic.

3.1.1 Project-specific CO and PM10 Emissions Associated with Construction Activities Exceed SCAQMD Significance Thresholds Following Mitigation

Finding: The SCAQMD's Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse construction air quality impacts, but not to less than significant; 2) such mitigation measures are within the jurisdiction of the SCAQMD; and, 3) no feasible measures were identified that would mitigate significant adverse construction CO and PM10 air quality impacts to less than significant. The air quality analysis showed that no other criteria pollutant emissions during construction would exceed any of the applicable construction air quality significance thresholds.

Explanation: An analysis of potentially significant adverse project-specific construction air quality impacts from implementing the 2012 AQMP control measures was performed and it was

concluded that construction CO and PM10 emissions are expected to exceed the applicable SCAQMD regional significance thresholds (see Final Program EIR, Subchapter 4.2 – Air Quality, section 4.2.4). An analysis of potential mitigation measures was conducted to determine if construction CO and PM10 emissions could be mitigated to less than the applicable regional significance threshold. Seven feasible mitigation measures were identified that could reduce significant CO and PM10 construction emission impacts, but would not reduce the pollutant emissions to less than significant. Although these measures would not reduce construction emissions below the applicable SCAQMD CO and PM10 construction air quality significance thresholds, no other feasible mitigation measures or project alternatives have been identified that would reduce the construction impacts to less than significant. Therefore, construction air quality impact of CO and PM10 emissions are expected to remain significant following mitigation.

3.1.2 Project-specific Energy – Electricity Demand Impacts Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse electricity demand impacts, but not to less than significant; 2) such mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local utilities, project sponsors, or other CEQA lead agencies; and, 3) no feasible measures were identified that would mitigate significant adverse electric energy impacts to insignificance.

Explanation: Project-specific increased electricity demand impacts resulting from implementing the 2012 AQMP control measures, where sufficient data exist, are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.3 – Energy, section 4.3.4). An analysis of potential mitigation measures was conducted to determine if increased electricity demand impacts could be mitigated to less than the applicable significance threshold. Seven feasible mitigation measures were identified that could reduce electricity demand impacts, but would not reduce the level to less than significant. Although these measures would not reduce electricity demand to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the electricity demand impacts to less than significant. The analysis included the worst-case assumption that all emissions sources affected by a control measure that have the potential to increase demand for electricity, would operate using electricity rather than the more likely result of multiple types of energy being used. In addition, any increase in electricity demand would likely result in a concurrent reduction in demand for other types of fuels, particularly petroleum-based fuels. Therefore, electricity demand impacts are expected to remain significant following mitigation.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD's authority to implement mitigation measures for electricity demand impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §15040 (a)). Further, CEQA Guidelines §15040 (b) specifically states, "CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws." Thus, it may not be feasible for

the SCAQMD to implement appropriate project-specific mitigation measures for electricity demand impacts identified in the Final Program EIR.

3.1.3 Project-specific Energy – Natural Gas Demand Impacts Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse natural gas demand impacts, but not to less than significant; 2) such mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local utilities, project sponsors, or other CEQA lead agencies; and, 3) no feasible measures were identified that would mitigate significant adverse natural gas demand impacts to insignificance.

Explanation: Project-specific natural gas demand impacts resulting from implementing the 2012 AQMP control measures, where sufficient data exist, are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.3 – Energy, section 4.3.4). An analysis of potential mitigation measures was conducted to determine if natural gas demand impacts could be mitigated to less than the applicable significance threshold. Five feasible mitigation measures were identified that could reduce natural gas demand impacts, but would not reduce the level to less than significant. Although these measures would not reduce natural gas demand impacts to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the natural gas demand impacts to less than significant. The analysis included the worst-case assumption that all emissions sources affected by a control measure that have the potential to increase demand for natural gas, would operate using natural gas rather than the more likely result of multiple types of energy being used. In addition, any increase in natural gas demand would likely result in a concurrent reduction in demand for other types of fuels, particularly petroleum-based fuels. Therefore, natural gas demand impacts are expected to remain significant following mitigation.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD's authority to implement mitigation measures for natural gas demand impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §15040 (a)). Further, CEQA Guidelines §15040 (b) specifically states, "CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws." Thus, it may not be feasible for the SCAQMD to implement appropriate project-specific mitigation measures for natural gas demand impacts identified in the Final Program EIR.

3.1.4 Project-specific Hazards Associated with Transport of LNG Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse hazard impacts associated with the potential accidental release of LNG during transport, but not to less than significant; 2) such mitigation measures are within the jurisdiction of the SCAQMD; and, 3) no feasible measures

were identified that would mitigate significant adverse hazard impacts associated with the potential accidental release of LNG during transport to less than significant.

Explanation: Project-specific hazard impacts associated with transport of LNG are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.4 – Hazards and Hazardous Materials, section 4.4.4). An analysis of potential mitigation measures was conducted to determine if LNG transport release impacts could be mitigated to less than the applicable significance threshold. Four feasible mitigation measures were identified that could reduce hazard impacts from an accidental release of LNG during transport, but would not reduce the impact to less than significant. Though these measures will not reduce hazard impacts from an accidental release of LNG during transport to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the hazard impacts associated with transport of LNG to less than significant. Therefore, hazard impacts from an accidental release of LNG during transport are expected to remain significant following mitigation.

3.1.5 Project-specific Water Demand Impacts Associated with Control Technologies Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse water demand impacts associated with the manufacture and use of waterborne coatings and add-on air pollution control technologies, but not to less than significant; 2) such mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local water agencies, project sponsors, or other CEQA lead agencies; and, 3) no feasible measures were identified that would mitigate significant adverse water demand impacts associated with the manufacture and use of waterborne coatings and add-on air pollution control technologies to less than significant.

Explanation: Project-specific water demand impacts associated with increased use of waterborne coatings and add-on air pollution control technologies are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.5 – Hydrology and Water Quality, section 4.5.4). An analysis of potential mitigation measures was conducted to determine if increased water demand impacts could be mitigated to less than the applicable significance threshold. Four feasible mitigation measures were identified that could reduce water demand impacts, but would not reduce the impacts to less than significant. Although these measures would not reduce water demand impacts to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the water demand impacts associated with waterborne coatings and add-on air pollution control technologies to less than significant. The analysis included the worst-case assumption that all future compliant coatings would be formulated with water instead of exempt solvents and that, where applicable, operators of emissions sources would only install control equipment that uses water as part of the control process instead of the more likely result of multiple types of control equipment being used. Therefore, water demand impacts are expected to remain significant following mitigation.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD's authority to implement mitigation measures for water demand

impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §15040 (a)). Further, CEQA Guidelines §15040 (b) specifically states, “CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws.” Thus, it may not be feasible for the SCAQMD to implement all appropriate project-specific mitigation measures for water demand impacts identified in the Final Program EIR.

3.1.6 Project-specific Noise Associated with Construction Activities Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse noise impacts associated with construction activities, but not to insignificance; 2) some noise impact mitigation measures may be within the jurisdiction of the SCAQMD, while other mitigation measures are within the jurisdiction of local land use agencies, project sponsors, or other CEQA lead agencies; and, 3) no feasible measures were identified that would mitigate significant adverse noise impacts associated construction activities to less than significant.

Explanation: Project-specific noise impacts associated with construction activities are expected to exceed the applicable SCAQMD significance thresholds (see Final Program EIR, Subchapter 4.7 – Noise, section 4.7.4). An analysis of potential mitigation measures was conducted to determine if noise impacts could be mitigated to less than the applicable significance threshold. Nine feasible mitigation measures were identified that could reduce noise impacts, but would not reduce noise impacts to less than significant. Though these measures would not reduce noise impacts to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the noise impacts associated with construction activities to less than significant. Therefore, noise impacts are expected to remain significant following mitigation. It should be noted that, once construction activities cease, potentially significant adverse noise impacts during construction from implementing 2012 AQMP control measures would also cease.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD’s authority to implement mitigation measures for noise impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §15040 (a)). Further, CEQA Guidelines §15040 (b) specifically states, “CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws.” Thus, it may not be feasible for the SCAQMD to implement all appropriate project-specific mitigation measures for noise impacts identified in the Final Program EIR.

3.1.7 Project-specific Traffic Impacts Associated with Construction Activities and Operations Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse traffic impacts associated with construction activities and operations, but not to less than significant; 2) some traffic impact mitigation measures may be within the jurisdiction of the SCAQMD, while other mitigation

measures are within the jurisdiction of local land use agencies, project sponsors, or other CEQA lead agencies; and, 3) no feasible measures were identified that would mitigate significant adverse traffic impacts associated construction activities and operations to insignificance.

Explanation: The project-specific traffic impacts associated with construction activities and operations are expected to exceed the applicable SCAQMD significance thresholds (see Final Program EIR, Subchapter 4.9 – Transportation and Traffic, section 4.9.4). An analysis of potential mitigation measures was conducted to determine if traffic impacts could be mitigated to less than the applicable significance threshold. One feasible mitigation measure was identified that could reduce traffic impacts, but would not reduce the impacts to less than significant. Although this measure would not reduce traffic impacts to less than the applicable SCAQMD significance threshold, no other feasible mitigation measures or project alternatives have been identified that would reduce the traffic impacts associated with construction activities to less than significant. Therefore, traffic impacts during construction and operation are expected to remain significant following mitigation. It should be noted that, once construction activities cease, potentially significant adverse traffic impacts during construction from implementing 2012 AQMP control measures would also cease.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD's authority to implement mitigation measures for traffic impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §15040 (a)). Further, CEQA Guidelines §15040 (b) specifically states, "CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws." Thus, it may not be feasible for the SCAQMD to implement all appropriate project-specific mitigation measures for traffic and transportation impacts identified in the Final Program EIR.

3.1.8 Cumulative Construction Emissions Were Concluded to Be Significant and Would Remain Significant Following Mitigation

SCAG's TCMs and related strategies, measures and recommendations included in the 2012-2035 RTP/SCS are also included in the 2012 AQMP. Because the TCMs, their associated mitigation measures, and their emissions reductions are included along with the 2012 AQMP and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate related or similar impacts compared to the 2012 AQMP, the 2012-2035 RTP/SCS is considered to be a cumulatively related project.

Finding: The SCAQMD Governing Board finds that: 1) project-specific mitigation measures were incorporated into the project that would also reduce significant adverse cumulative construction air quality impacts, but not to less than significant; 2) such project-specific mitigation measures are within the jurisdiction of the SCAQMD; 3) no additional feasible measures were identified in the Final Program EIR for the 2012 AQMP that would mitigate significant adverse cumulative construction air quality impacts to less than significant; 4) feasible mitigation measures to reduce significant adverse construction air quality impacts were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing construction air quality impacts mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative construction air quality impacts remain significant.

Explanation: Project-specific construction air quality impacts were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). As a result, cumulative construction air quality impacts are concluded to be cumulatively significant (see Final Program EIR, Chapter 5 – Cumulative Impacts, section 5.4.1). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse construction air quality impacts. Eighteen feasible mitigation measures were identified in the Program EIR for the 2012-2035 RTP/SCS that could reduce project-specific construction air quality impacts, but would not reduce the impacts to less than significant. Any concurrent emissions-generating activities from reasonably foreseeable construction activities from both the 2012 AQMP and the 2012-2035 RTP/SCS would add additional construction air quality emissions burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.1.9 Cumulative Energy Impacts Were Concluded to Be Significant and Would Remain Significant Following Mitigation

SCAG's TCMs and related strategies, measures and recommendations included in the 2012-2035 RTP/SCS are also included in the 2012 AQMP. Because the TCMs, their associated mitigation measures, and their emissions reductions are included along with the 2012 AQMP and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate related or similar impacts compared to the 2012 AQMP, the 2012-2035 RTP/SCS is considered to be a cumulatively related project.

Finding: The SCAQMD Governing Board finds that: 1) project-specific mitigation measures were incorporated into the project that would also reduce significant adverse cumulative electricity and natural gas demand impacts, but not to less than significant; 2) some of the mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local utilities, project sponsors, or other CEQA lead agencies; 3) no additional feasible measures were identified in the Final Program EIR for the 2012 AQMP that would mitigate significant adverse cumulative energy demand impacts to less than significant; 4) feasible mitigation measures to reduce significant adverse energy demand impacts were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing energy demand impact mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative energy demand impacts remain significant.

Explanation: Project-specific electricity and natural gas demand impacts were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). As a result, cumulative electricity and natural gas demand impacts are concluded to be cumulatively significant (see Final Program EIR, Chapter 5 – Cumulative Impacts, section 5.4.1). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse electricity and natural gas demand impacts. Over 60 feasible mitigation measures were identified in the Program EIR for the 2012-2035 RTP/SCS that could reduce electricity and natural gas demand impacts, but would not reduce the impacts to less than significant. Concurrent operations from reasonably

foreseeable activities from both the 2012 AQMP and the 2012-2035 RTP/SCS that increase demand for electricity and natural gas would add additional electricity and natural gas demand burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.1.10 Cumulative Hazards and Hazardous Materials Impacts Were Concluded to Be Significant and Would and Remain Significant Following Mitigation

SCAG's TCMs and related strategies, measures and recommendations included in the 2012-2035 RTP/SCS are also included in the 2012 AQMP. Because the TCMs, their associated mitigation measures, and their emissions reductions are included along with the 2012 AQMP and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate related or similar impacts compared to the 2012 AQMP, the 2012-2035 RTP/SCS is considered to be a cumulatively related project.

Finding: The SCAQMD Governing Board finds that: 1) project-specific mitigation measures were incorporated into the project that would reduce the significant adverse hazard impacts associated with an accidental release of LNG during transport, but not to less than significant; 2) such mitigation measures are within the jurisdiction of the SCAQMD; 3) no additional feasible measures were identified that would mitigate these significant adverse hazard impacts to less than significant; 4) feasible mitigation measures to reduce significant adverse hazard impacts were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing hazard impact mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative energy demand impacts remain significant.

Explanation: Project-specific hazard impacts from an accidental release of LNG during transport were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse hazard impacts. Approximately 14 feasible mitigation measures were identified in the Program EIR for the 2012-2035 RTP/SCS that could reduce hazard impacts, but would not reduce the impacts to less than significant. Concurrent operations from reasonably foreseeable activities from both the 2012 AQMP and the 2012-2035 RTP/SCS that increase transport of hazardous materials would add additional hazard burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.1.11 Cumulative Hydrology and Water Quality Impacts Were Concluded to Be Significant and Would Remain Significant Following Mitigation

SCAG's TCMs and related strategies, measures and recommendations included in the 2012-2035 RTP/SCS are also included in the 2012 AQMP. Because the TCMs, their associated mitigation

measures, and their emissions reductions are included along with the 2012 AQMP and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate related or similar impacts compared to the 2012 AQMP, the 2012-2035 RTP/SCS is considered to be a cumulatively related project.

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse water demand impacts, but not to less than significant; 2) some of the mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local water agencies, project sponsors, or other CEQA lead agencies; 3) no additional feasible measures were identified in the Final Program EIR for the 2012 AQMP that would mitigate significant adverse cumulative water demand impacts to less than significant; 4) feasible mitigation measures to reduce significant adverse water demand impacts were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing water demand impact mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative water demand impacts remain significant.

Explanation: Project-specific water demand impacts were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). As a result, cumulative water demand impacts are concluded to be cumulatively significant (see Final Program EIR, Chapter 5 – Cumulative Impacts, section 5.10). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse electricity and natural gas demand impacts. Over 60 feasible mitigation measures were identified in the Program EIR for the 2012-2035 RTP/SCS that could reduce water demand impacts, but would not reduce the impacts to less than significant. Concurrent operations from reasonably foreseeable activities from both the 2012 AQMP and the 2012-2035 RTP/SCS that increase demand for water would add additional water demand burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.1.12 Cumulative Noise Impacts Were Concluded to Be Significant and Would Remain Significant Following Mitigation

SCAG's TCMs and related strategies, measures and recommendations included in the 2012-2035 RTP/SCS are also included in the 2012 AQMP. Because the TCMs, their associated mitigation measures, and their emissions reductions are included along with the 2012 AQMP and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate related or similar impacts compared to the 2012 AQMP, the 2012-2035 RTP/SCS is considered to be a cumulatively related project.

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse noise impacts from construction activities, but not to less than significant; 2) some of the mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local land use agencies, project sponsors, or other CEQA lead agencies; 3) no additional feasible measures were identified in the

Final Program EIR for the 2012 AQMP that would mitigate significant adverse cumulative noise impacts during construction to less than significant; 4) feasible mitigation measures to reduce significant adverse noise impacts during construction were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing construction noise impact mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative construction noise impacts remain significant.

Explanation: Project-specific noise impacts during construction were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). As a result, cumulative construction noise impacts are concluded to be cumulatively significant (see Final Program EIR, Chapter 5 – Cumulative Impacts, section 5.10). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse noise impacts during both construction and operation of future 2012-2035 RTP/SCS projects. Approximately 18 feasible mitigation measures were identified in the Program EIR for the 2012-2035 RTP/SCS that could reduce potential impacts during construction and operation, but would not reduce the impacts to less than significant. Concurrent operations from reasonably foreseeable activities from both the 2012 AQMP and the 2012-2035 RTP/SCS that increase noise impacts during construction would add additional construction noise burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.1.13 Cumulative Transportation and Traffic Impacts Were Concluded to Be Significant and Would Remain Significant Following Mitigation

Finding: The SCAQMD Governing Board finds that: 1) mitigation measures were incorporated into the project that would reduce the significant adverse transportation and traffic impacts from construction activities, but not to less than significant; 2) some of the mitigation measures are not within the jurisdiction of the SCAQMD, but are within the jurisdiction of local utilities, project sponsors, or other CEQA lead agencies; 3) no additional feasible measures were identified in the Final Program EIR for the 2012 AQMP that would mitigate significant adverse cumulative transportation and traffic impacts to less than significant; 4) feasible mitigation measures to reduce significant adverse transportation and traffic impacts were identified in the Program EIR for the 2012-2035 RTP/SCS; and, 5) in spite of implementing transportation and traffic impact mitigation measures from the 2012 AQMP and the 2012-2035 RTP/SCS Program EIRs, cumulative transportation and traffic impacts remain significant.

Explanation: Project-specific transportation and traffic impacts were concluded to be significant and, therefore, cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1). As a result, cumulative transportation and traffic impacts are concluded to be cumulatively significant (see Final Program EIR, Chapter 5 – Cumulative Impacts, section 5.18). The Program EIR for the 2012-2035 RTP/SCS concluded that implementing the 2012-2035 RTP/SCS also has the potential to generate significant adverse transportation and traffic impacts. The Program EIR for the 2012-2035 RTP/SCS evaluated potential transportation and traffic impacts to six different areas. One transportation and traffic impact area was identified that

would produce related or similar types of transportation and traffic impacts compared to the 2012 AQMP. It was concluded in the Program EIR for the 2012-2035 RTP/SCS that implementing roadway improvement projects, the 2012-2035 RTP/SCS would contribute to a cumulatively considerable amount of transportation VMT impacts despite regional planning efforts.

The Program EIR for the 2012-2035 RTP/SCS identified 98 feasible mitigation measures were that could reduce transportation and traffic impacts for all areas analyzed, including increased VMT impacts, but would not reduce the impacts to less than significant. Concurrent operations from reasonably foreseeable activities from both the 2012 AQMP and the 2012-2035 RTP/SCS that increase transportation and traffic impacts would add additional transportation and traffic burdens to these significance determinations. However, implementing the 2012-2035 RTP/SCS would likely include other entities or agencies, acting as the lead agency, which would be responsible for implementing feasible mitigation measures if required. For these impacts, SCAQMD incorporates by reference the mitigation measures and mitigation, monitoring and reporting program for the 2012-2035 RTP/SCS.

3.2 POTENTIALLY SIGNIFICANT IMPACTS WHICH CAN BE MITIGATED TO A LEVEL OF INSIGNIFICANCE

The Final Program EIR for the 2012 AQMP identified significant adverse impacts to the following environmental topics: increased flammability of potential replacement solvents; hazard impacts associated with an accidental release of ammonia during transport; and hazard impacts associated with an accidental release of ammonia stored onsite. As explained in the following paragraphs, feasible mitigation measures were identified that have the potential to reduce the significant adverse environmental impacts identified here.

Potential hazard impacts associated with increased flammability of potential replacement solvents, reformulated coatings, and consumer products are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.4 – Hazards and Hazardous Materials, section 4.4.3). An analysis of potential mitigation measures was conducted to determine if fire hazards could be mitigated to less than the applicable significance threshold. The analysis identified two feasible mitigation measures that could reduce fire hazards to less than significant. Therefore, applying the mitigation measure would reduce the fire hazard impacts to less than significant.

Potential hazard impacts associated with an accidental release of ammonia during transport are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.4 – Hazards and Hazardous Materials, subsection 4.4.4.3). An analysis of potential mitigation measures was conducted to determine if transportation hazards could be mitigated to less than the applicable significance threshold. The analysis identified one feasible mitigation measure that could reduce ammonia transport hazards to less than significant. Therefore, applying the mitigation measure would reduce the ammonia transport hazard impacts to less than significant.

Potential hazard impacts associated with an accidental release of ammonia stored onsite are expected to exceed the applicable SCAQMD significance threshold (see Final Program EIR, Subchapter 4.4 – Hazards and Hazardous Materials, subsection 4.4.4.3). An analysis of potential

mitigation measures was conducted to determine if onsite storage hazards could be mitigated to less than the applicable significance threshold. The analysis identified four feasible mitigation measures that could reduce onsite ammonia storage hazards to less than significant. Therefore, applying the mitigation measure would reduce the onsite ammonia storage hazard impacts to less than significant.

3.3 IMPACTS ASSOCIATED WITH ALTERNATIVES

The Final Program EIR includes an evaluation of four potential alternatives to the 2012 AQMP. The Final Program EIR examines the environmental impacts of each alternative in comparison with the proposed project and the relative ability of each alternative to satisfy the project objectives. The Final Program EIR also summarizes the criteria used to identify a range of reasonable alternatives for review and describes proposals that SCAQMD concluded did not merit additional, more-detailed review either because they did not present viable alternatives to the proposed project or they are variations on the alternatives that are evaluated in detail.

In making these findings, the SCAQMD Governing Board certifies that it has independently reviewed and considered the information on alternatives provided in the Final Program EIR, including the information provided in comments on the Draft Program EIR and the responses to those comments in the Final Program EIR. The Final Program EIR's discussion and analysis of these alternatives is not repeated in these findings, but the discussion and analysis of the alternatives in the Final Program EIR is incorporated in these findings by reference.

3.3.1 Description of Project Objectives

CEQA Guidelines §15124 (b) requires an EIR to include a statement of objectives, which describes the underlying purpose of the proposed project. The purpose of the statement of objectives is to aid the lead agency in identifying alternatives and the decision-makers in preparing findings and a statement of overriding considerations, if necessary. The objectives of the proposed 2012 AQMP are summarized in the following points.

1. Reduce PM_{2.5} nonattainment pollutants and their precursors on an expeditious implementation schedule;
2. Demonstrate attainment of the 24-hour PM_{2.5} national ambient air quality standard at the earliest possible date;
3. Reduce population exposure to PM_{2.5} by achieving the 24-hour PM_{2.5} national ambient air quality standard;
4. Continue making expeditious progress towards attaining the federal eight-hour ozone standard and demonstrate attainment of the federal one-hour ozone standard (revoked) by 2022 – 2023;
5. Reduce population exposure to ozone through continued progress towards attaining the federal one-hour (revoked) and eight-hour ozone standards by 2022 – 2023;
6. Reduce nonattainment pollutants at a rate of five percent per year, or include all feasible measures and an expeditious adoption schedule;

7. Update planning assumptions and the best available information such as SCAG's 2012 RTP, CARB's latest EMFAC2011 for the on-road mobile source emissions inventory, and CARB's OFF-ROAD 2011 model;
8. Update emission inventories using 2008 as the base year and incorporate emission reductions achieved from all applicable rules and regulations and the latest demographic forecasts;
9. Update any remaining control measures from the 2007 AQMP and incorporated into the 2012 AQMP as appropriate;
10. Compliance with federal contingency measure requirements;
11. Continue to work closely with businesses and industry groups to identify the most cost-effective and efficient path to meeting clean air goals while being sensitive to their economic concerns.

3.3.2 Project Alternatives that Would Reduce the Potentially Significant Impacts are Not Available

Finding: The Final Program EIR describes and evaluates four alternatives to the proposed project. The SCAQMD Governing Board finds that the proposed project would satisfy the Project Objectives. The SCAQMD Governing Board finds that the alternatives are unable to satisfy the project objectives to the same degree as the proposed project. The SCAQMD Governing Board further finds that, on balance, none of the alternatives has environmental advantages over the proposed project that are sufficiently great to justify approval of such an alternative instead of the 2012 AQMP, in light of each such alternative's inability to satisfy the proposed project objectives to the same degree as the proposed project. Accordingly, the SCAQMD Governing Board has determined to approve the proposed project instead of approving any of the alternatives.

In making this determination, the SCAQMD Governing Board finds that when compared to the alternatives described and evaluated in the Final Program EIR, the proposed project provides a reasonable balance between fully satisfying the project objectives and reducing potential environmental impacts to an acceptable level. The SCAQMD Governing Board further finds and determines that the proposed project should be approved, rather than one of the other alternatives.

Explanation: Potential adverse environmental impacts from four project alternatives were analyzed and their relative merits were compared to the 2012 AQMP. Alternatives evaluated in the Final Program EIR for the 2012 AQMP include: the No Project Alternative, PM2.5 Attainment Plan Localized PM Control in Mira Loma Area, Greater Reliance on NOx Emissions Reductions, and PM2.5 Emissions Reductions Strategies Only. No feasible alternatives were identified that would attain most of the basic objectives of the 2012 AQMP, described above in subsection 3.3.1, and generate fewer or less severe environmental impacts than those of the proposed project, as shown in Table 2.

Table 2
Environmental Impacts of Alternatives Compared to the 2012 AQMP

Environmental Topic	PROJECT				
	2012 AQMP	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Aesthetics					
PM2.5	NS	NS (=)	NS (=)	NS (=)	NS (=)
Ozone	NS	NS (=)	NS (=)	NS (=)	NS (-)
Cumulative	NS	NS (=)	NS (=)	NS (=)	NS (-)
Direct Air Quality Impacts – PM2.5 Attainment Year					
	2014	2019	2017	2017	2014
Secondary Air Quality Impacts

Notes:

NS = Not Significant

S = Significant

(-) = Potential impacts are less than the proposed project.

(+) = Potential impacts are greater than the proposed project.

(=) = Potential impacts are approximately the same as the proposed project.

Summary of Findings Regarding Alternatives: For all of the foregoing reasons, the SCAQMD Governing Board has determined to approve the proposed project instead of one of the alternatives to the proposed project. The SCAQMD Governing Board finds that the range of alternatives evaluated in the Final Program EIR reflects a reasonable attempt to identify and evaluate various types of alternatives that would potentially be capable of reducing the proposed project's environmental effects, while accomplishing most, but not all of the project objectives. The SCAQMD Governing Board finds that the alternatives analysis is sufficient to inform the SCAQMD Governing Board and the public regarding the tradeoffs between the degree to which alternatives to the proposed project could reduce environmental impacts and the corresponding degree to which the alternatives would hinder the SCAQMD's ability to achieve the project objectives.

3.4 FINDINGS CONCLUSION

Changes or alterations have been incorporated into the proposed project to mitigate or minimize the potentially significant adverse environmental effects associated with the following six potentially significant project-specific adverse environmental impacts that cannot be reduced to a level of insignificance: 1) air quality (CO and PM10) impacts from construction activities; 2) energy – increased electricity and natural gas demand; 3) hazards associated with an accidental release of LNG during transport; 4) increased demand for water; 5) noise impacts from construction activities; and, 6) traffic impacts from construction activities and operations. No additional feasible mitigation measures or alternatives were identified that could further reduce the significant project-specific and cumulative environmental impacts identified here. The 2012 AQMP also achieves the project objectives, as described above in subsection 3.3.1, more effectively than the project alternatives analyzed.

Based on the above information, the SCAQMD Governing Board finds that the proposed project achieves the best balance between minimizing potential adverse environmental impacts and achieving the overall project objectives. The SCAQMD Governing Board further finds that all of the findings presented here are supported by substantial evidence in the record.

4.0 STATEMENT OF OVERRIDING CONSIDERATION

If significant adverse impacts of a proposed project remain after incorporating feasible mitigation measures, or no feasible measures to mitigate the adverse impacts are identified, the lead agency must make a determination that the benefits of the proposed project outweigh the unavoidable, significant, adverse environmental effects if it is to approve the project. In accordance with CEQA Guidelines §15093, the SCAQMD Governing Board has, in determining whether or not to approve the proposed project, balanced the economic, social, technological, and other project benefits against its unavoidable environmental risks, and finds that each of the benefits of the proposed project set forth below outweigh the significant adverse environmental effects that are not mitigated to less than significant levels. This statement of overriding considerations is based on the decision-making body's review of the Final Program EIR, responses to comments, and other information in the administrative record. Each of the benefits identified below provides a separate and independent basis for overriding the significant adverse environmental effects of the 2012 AQMP. Accordingly, this Statement of Overriding Considerations regarding potentially significant adverse environmental impacts resulting from the 2012 AQMP, as set forth below,

has been prepared. Pursuant to CEQA Guidelines §15093 (c), a Statement of Overriding Considerations will be included in the record of the project approval and will also be noted in the Notice of Determination.

Having reduced the potential effects of the proposed project through all feasible mitigation measures as described previously in this attachment, and balancing the benefits of the proposed project against its potential unavoidable adverse impacts on air quality, demand for electricity, demand for natural gas, transportation hazards, demand for water, noises, and traffic, the SCAQMD finds that the following legal requirements and benefits of the proposed project outweigh the potentially significant unavoidable adverse impacts for the following reasons:

1. The analysis of potential adverse environmental impacts incorporates a “worst-case” approach. This means that whenever the analysis requires assumptions to be made, those assumptions that result in the greatest adverse environmental impacts are typically chosen. This method likely overestimates the actual significant adverse environmental impacts from the 2012 AQMP.
2. The proposed project would reduce PM2.5 nonattainment pollutants and their precursors on an expeditious implementation schedule;
3. The proposed project would demonstrate attainment of the 24-hour PM2.5 national ambient air quality standard by the year 2014, as required by the federal CAA;
4. The proposed project would reduce population exposure to PM2.5 by achieving the 24-hour PM2.5 national ambient air quality standard by 2014, as required by the federal CAA;
5. The proposed project would continue making expeditious progress towards attaining the federal eight-hour ozone standard and demonstrate attainment of the federal one-hour ozone standard (revoked) by the years 2022 and 2023, respectively;
6. The proposed project would reduce population exposure to ozone through continued progress towards attaining the federal one-hour (revoked) and eight-hour ozone standards by 2022 – 2023;
7. The proposed project would include all feasible measures and an expeditious adoption schedule;
8. The proposed project would update planning assumptions and the best available information such as SCAG’s 2012 RTP, CARB’s latest EMFAC2011 for the on-road mobile source emissions inventory, and CARB’s OFF-ROAD 2011 model;
9. The proposed project would update emission inventories using 2008 as the base year and incorporate emission reductions achieved from all applicable rules and regulations and the latest demographic forecasts;
10. The proposed project would update any remaining control measures from the 2007 AQMP and incorporated into the 2012 AQMP as appropriate;
11. The proposed project would demonstrate compliance with federal contingency measure requirements;
12. Implementing Mitigation Measures AQ-1 through AQ-2 would reduce significant adverse construction air quality impacts to the maximum extent feasible, but not to less than significant, while also providing construction emission reduction co-benefits because using

Tier 3 construction engines would additionally provide PM and hydrocarbon emission reduction benefits.

13. Implementing Mitigation Measures E-1 through E-12 would reduce significant adverse energy impacts to the maximum extent feasible, but not to less than significant.
14. Implementing Mitigation Measures HZ-1 through HZ-10 would reduce significant adverse hazards and hazardous materials impacts to the maximum extent feasible, but not to less than significant.
15. Implementing Mitigation Measures HWQ-1 through HWQ-4 would reduce significant adverse hydrology and water quality impacts to the maximum extent feasible, but not to less than significant.
16. Implementing Mitigation Measures NO-1 through NO-9 would reduce significant adverse noise impacts to the maximum extent feasible, but not to less than significant.
17. Implementing Mitigation Measure TT-1 would reduce significant adverse transportation and traffic impacts to the maximum extent feasible, but not to less than significant.

In balancing the benefits of the overall project described above with the proposed project's unavoidable and significant adverse environmental impacts, SCAQMD Governing Board finds that the proposed project's benefits individually and collectively outweigh the unavoidable adverse impacts, such that these impacts are acceptable. The SCAQMD Governing Board further finds that substantial evidence presented in the Final Program EIR supports adopting the Final Program EIR despite the proposed project's potential adverse impacts.

5.0 RECORD OF PROCEEDINGS

Upon certification, the record of approval for this proposed project, i.e., the Notice of Determination, will be posted and recorded by the county clerks of Los Angeles, Orange, Riverside, and San Bernardino counties. The record of approval for the proposed project and all documents and other materials related to this proposed project may be found at SCAQMD Headquarters, 21865 Copley Drive, Diamond Bar, California, 91765. The Custodian of the Record is the Deputy Executive Officer of Planning, Rules and Area Sources.

6.0 MITIGATION, MONITORING, AND REPORTING PLAN

Pursuant to CEQA Guidelines §15097 and PRC §21081.6, when a public agency conducts an environmental review of a proposed project in conjunction with approving it, the lead agency shall adopt a program for monitoring or reporting on the measures it has imposed to mitigate or avoid significant adverse environmental effects. PRC §21081.6 states in part that when making the findings required by PRC §21081 (a):

“...the public agency shall adopt a reporting or monitoring program for the changes made to the project or conditions of project approval, adopted in order to mitigate or avoid significant effects on the environment. The reporting or monitoring program shall be designed to ensure compliance during project implementation. For those changes

which have been required or incorporated into the project at the request of a responsible agency or a public agency having jurisdiction by law over natural resources affected by the project, that agency shall, if so requested by the lead or responsible agency, prepare and submit a proposed reporting or monitoring program.”

No responsible agencies or public agencies having jurisdiction by law over natural resources affected by the 2012 AQMP requested changes or mitigation measures relative to potentially significant adverse environmental impacts be incorporated into the 2012 AQMP. Further, it should be noted that the SCAQMD does not construct or operate projects that may result from implementing 2012 AQMP control measures as rules or regulations. As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, where applicable and within the jurisdiction of the SCAQMD, enforcement of implementing mitigation measures, monitoring, and reporting requirements described in this mitigation, monitoring, and reporting plan (MMRP) is the responsibility of the SCAQMD as the lead agency under CEQA. However, as noted in discussions under Section 3.0 Findings, some of the mitigation measures identified in the Final Program EIR for the 2012 AQMP may not be within the jurisdiction of the SCAQMD, but are within the jurisdiction of local land use agencies, project sponsors, public agencies having jurisdiction by law over natural resources affected by the project, or other CEQA lead agencies.

A public agency may delegate reporting or monitoring responsibilities to another public agency or to a private entity which accepts the delegation; however, until mitigation measures have been completed the lead agency remains responsible for ensuring that implementation of the mitigation measures occurs in accordance with the program (CEQA Guidelines §15097 (a)). As a result, this MMRP will identify other public agencies that “can and should” comply with CEQA in assessing and mitigating project-specific impacts.

Finally, the responsibility for mitigation monitoring and reporting described in this MMRP will vary depending on the location and jurisdiction of individual projects because the individual projects resulting from implementing 2012 AQMP control measures as rules or regulations may affect a wide variety of commercial, institutional, industrial, and even residential emission sources located throughout the district. It is expected that additional and more specific mitigation measures and monitoring requirements may be developed as specific rules are promulgated. Similarly, additional and more specific mitigation measures and monitoring requirements may be required for individual projects required to comply with any future rules or regulations that must also undergo an environmental analysis pursuant to CEQA.

6.1 AIR QUALITY IMPACTS AND MITIGATION MEASURES

The analysis of secondary air quality impacts in the Final Program EIR for the 2012 AQMP concluded that construction-related CO and PM10 emissions have the potential to exceed the applicable SCAQMD regional significance thresholds for daily construction emissions. Emission sources contributing to significant CO and PM10 air quality impacts include worker vehicles, heavy construction equipment, and grading/construction activities. The construction air quality mitigation measures identified in the following paragraphs are intended reduce potential construction emissions associated with construction-related emission sources to the maximum extent feasible. Mitigation measure AQ-1 would serve to reduce impacts from on-road mobile

sources and mitigation measures AQ-2 through AQ-7 would serve to reduce impacts from off-road mobile sources. The timing of implementing the construction air quality mitigation measures would be ongoing over the life of the 2012 AQMP and includes the following mitigation measures:

- AQ-1** Develop a Construction Emission Management Plan for the proposed project. The Construction Emission Management Plan shall be submitted to SCAQMD CEQA for approval prior to the start of construction. The Plan shall include measures to minimize emissions from vehicles including, but not limited to consolidating truck deliveries, description of truck routing, description of deliveries including hours of delivery, description of entry/exit points, locations of parking, and construction schedule. At a minimum the Construction Emission Management Plan would include the following types of mitigation measures.
- AQ-2** Maintain construction equipment tuned up and with two to four degree retard diesel engine timing or tuned to manufacturer's recommended specifications that optimize emissions without nullifying engine warranties.
- AQ-3** The project proponent shall survey and document the proposed project's construction areas and identify all construction areas that are served by electricity. This documentation shall be provided as part of the Construction Emissions Management Plan. Electric welders shall be used in all construction areas that are demonstrated to be served by electricity.
- AQ-4** The project proponent shall survey and document the proposed Project's construction areas and identify all construction areas that are served by electricity. This documentation shall be provided as part of the Construction Emissions Management Plan. Onsite electricity rather than temporary power generators shall be used in all construction areas that are demonstrated to be served by electricity.
- AQ-5** The project proponent shall use cranes rated 200 hp or greater equipped with Tier 3 or equivalent engines. Engines equivalent to Tier 3 may consist of Tier 2 engines retrofitted with diesel particulate filters and oxidation catalysts, selective catalytic reduction, or other equivalent NOx control equipment. Retrofitting cranes rated 200 hp or greater with PM and NOx control devices must occur before the start of construction. If cranes rated 200 hp or greater equipped with Tier 3 engines are not available or cannot be retrofitted with PM and NOx control devices, the project proponent shall use cranes rated 200 hp or greater equipped with Tier 2 or equivalent engines. The project proponent shall provide documentation that cranes rated 200 hp or greater equipped with Tier 3 or equivalent engines are not available in the Construction Emissions Management Plan.
- AQ-6** For off-road construction equipment rated 50 to 200 hp that will be operating for eight hours or more, the project proponent shall use equipment rated 50 to 200 hp equipped with Tier 3 or equivalent engines. Engines equivalent to Tier 3 may consist of Tier 2 engines retrofitted with diesel particulate filters and oxidation catalysts, selective catalytic reduction, or other equivalent NOx control equipment. Retrofitting equipment rated 50 to 200 hp with PM and NOx control devices must occur before the start of construction. If equipment rated 50 to 200 hp equipped with Tier 3 engines are not available or cannot be retrofitted with PM and NOx control devices, the project proponent shall use equipment rated 50 to 200 hp equipped with Tier 2 or equivalent engines. The project proponent shall provide documentation that equipment rated 50 to

200 hp equipped with Tier 3 or equivalent engines are not available in the Construction Emissions Management Plan or associated subsequent status reports as information becomes available.

AQ-7 Suspend use of all construction activities that generate air pollutant emissions during first stage smog alerts.

6.2 AIR QUALITY MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, some of the 2012 AQMP construction air quality mitigation measures in this MMRP may be described as general policies, although some refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing construction air quality mitigation measures from the Final Program EIR for the 2012 AQMP for future projects that have the potential to generate construction air quality impacts from complying with 2012 AQMP control measures promulgated as rules or regulations would be project applicants, project sponsors, or public agencies within the district.

To the extent that the SCAQMD is the lead agency for future projects that must comply with 2012 AQMP control measures promulgated as rules or regulations, it can enforce implementation of 2012 AQMP air quality mitigation measures through its authority to impose binding permit conditions on permit applicants at the time permit applications are processed and approved. Similarly, if the SCAQMD is a responsible agency for such future projects, it would still have the ability to enforce 2012 AQMP mitigations through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD has no approval authority over future projects that have the potential to generate construction air quality impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose 2012 AQMP mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken project applicants, project sponsors, or public agencies throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring would be accomplished as follows:

MMAQ-1 A project applicant, project sponsor, or public agency shall develop and submit a Construction Emission Management Plan to the lead agency for approval. Alternatively, the lead agency can develop a monitoring plan applicable to projects within its jurisdiction. The Construction Emission Management Plan shall include the following: description of construction traffic control methods such as flag persons, contractor entry/exit gates, etc.; construction schedule including hours of operation; description of truck routing; and description of deliveries, including hours of delivery.

The plan shall be submitted to the lead agency for approval prior to beginning construction activities. The lead agency can and should conduct routine inspections of the construction site to verify compliance.

- MMAQ-2** The project applicant, project sponsor, or public agency shall maintain or cause to be maintained maintenance records for the construction equipment. All construction vehicles must be maintained in compliance with the manufacturer's recommended maintenance schedule. Equipment maintenance records would be kept for the duration of the construction phase and at least two years following completion of construction. Equipment maintenance records must be available upon the request of the appropriate agency inspector.
- MMAQ-3** The use of gas or diesel welders shall be prohibited in areas that have access to electricity. Construction areas where electricity is not available will be identified on a site plan as part of the Construction Emission Management Plan submitted to the lead agency for approval. The use of gas or diesel welders within these identified areas will be allowed. The use of gas or diesel welders outside of these identified areas shall be prohibited. The project applicant, project sponsor, or public agency shall include in all construction contracts the requirement that gas and diesel welders are prohibited in certain portions of the site as identified on the site plan. The applicant shall maintain records on where the gas or diesel welders are actually used and their duration of use.
- MMAQ-4** The use of temporary power generators shall be prohibited in areas that have access to electricity. Construction areas where electricity is not available will be identified on a site plan as part of the Construction Emission Management Plan. The use of temporary power generators within these identified areas will be allowed. The use of temporary power generators outside of these identified areas shall be prohibited. The project applicant, project sponsor, or public agency shall include in all construction contracts the requirement that the use of temporary power generators is prohibited in certain portions of the site as identified on the site plan. The applicant shall maintain records on where the generators are actually used and the duration of use.
- MMAQ-5** The use of cranes rated 200 hp or greater shall be limited to cranes equipped with Tier 3 or equivalent engines. Engines equivalent to Tier 3 may consist of Tier 2 engines retrofitted with diesel particulate filters and oxidation catalysts, selective catalytic reduction, or other equivalent NOx control equipment. Retrofitting cranes rated 200 hp or greater with PM and NOx control devices must occur before the start of construction. If cranes rated 200 hp or greater equipped with Tier 3 engines are not available or cannot be retrofitted with PM and NOx control devices, the project proponent shall use cranes rated 200 hp or greater equipped with Tier 2 or equivalent engines. The project applicant, project sponsor, or public agency shall provide documentation that cranes rated 200 hp or greater equipped with Tier 3 or equivalent engines are not available in the Construction Emission Management Plan.
- MMAQ-6** The project applicant, project sponsor, or public agency must ensure that all off-road construction equipment meets the exhaust emission standards and test procedures for heavy-duty off-road diesel cycle engines as presented in the California Code of Regulations, Title 13, §2423 (b)(1). The exhaust emissions from new off-road compression-ignition engines, sold in California, must not exceed the exhaust emission standards set forth for each Tier and corresponding

model year. The project applicant, project sponsor, or public agency will supply the local/lead agency with a report prior to commencement of construction activities that documents the availability of retrofit technologies for large construction equipment, such as diesel particulate filters/traps, oxidation catalysts, and air enhancement technologies. In the event a Tier 3 engine is not available for any off-road engine larger than 100 horsepower, the project applicant, project sponsor, or public agency will ensure that the engine be equipped with a diesel particulate filter, unless certified by engine manufacturers that the use of such devices is not practical for specific engine types. A copy of this report shall be maintained on-site along with other recordkeeping required by this Mitigation Monitoring Plan.

MMAQ-7 The project applicant, project sponsor, or public agency shall maintain a log that contains the days when first stage smog alerts occur and the time that construction activities were suspended or the reasons (emergency conditions) that the activities were not suspended. A copy of this log shall be maintained on-site along with other recordkeeping required by this Mitigation Monitoring Plan.

6.3 ENERGY IMPACTS AND MITIGATION MEASURES

The analysis of secondary air quality impacts in the Final Program EIR for the 2012 AQMP concluded that the 2012 AQMP has the potential to generate significant adverse electricity and natural gas demand impacts associated with converting conventionally-fueled stationary and mobile sources to electricity or natural gas fueled sources. The mitigation measures identified in the following paragraphs are intended to reduce impacts associated with these sources to the maximum extent feasible. Mitigation measures E-1 through E-7 would serve to reduce impacts from increased electricity demand and mitigation measures E-8 through E-12 would reduce impacts from increased demand for natural gas. The timing of implementing electricity and natural gas demand mitigation measures would be ongoing over the life of the 2012 AQMP and includes the following types of control measures:

- E-1** Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.
- E-2** Utilities should increase capacity of existing transmission lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- E-3** Project sponsors should submit projected electricity calculations to the local electricity provider for any project anticipated to require substantial electricity consumption. Any infrastructure improvements necessary should be completed according to the specifications of the electricity provider.
- E-4** Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.
- E-5** Project sponsors should evaluate the potential for reducing peak energy demand by encouraging charging of electrical vehicles and other mobile sources during off-peak hours.

- E-6** Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.
- E-7** Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of electrified stationary sources during off-peak hours (e.g., cargo handling equipment).
- E-8** Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.
- E-9** Utilities should increase capacity of existing natural gas lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- E-10** Project sponsors should submit projected natural gas calculations to the local natural gas provider for any project anticipated to require substantial natural gas consumption. Any infrastructure improvements necessary should be completed according to the specifications of the natural gas provider.
- E-11** Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.
- E-12** Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of natural gas stationary sources during off-peak hours.

6.4 ENERGY MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, some of the electricity or natural gas demand mitigation measures in this MMRP may be described as general policies, although some refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing electricity or natural gas demand mitigation measures from the Final Program EIR for the 2012 AQMP for future projects that have the potential to generate electricity or natural gas demand impacts from complying with 2012 AQMP control measures promulgated as rules or regulations would be project applicants, project sponsors, and public agencies, including cities or counties, within the district.

To the extent that the SCAQMD is the lead agency for future projects that must comply with 2012 AQMP control measures promulgated as rules or regulations, it may be able to enforce implementation of some 2012 AQMP electricity or natural gas demand mitigation measures through its authority to impose binding permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD is a responsible agency or has no approval authority over future projects that have the potential to generate electricity or natural gas demand impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose 2012 AQMP Final Program EIR mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments. Similarly, to the extent allowed by state and federal regulations, electricity generating utilities or natural gas provider utilities within the district as the entities that provide electricity and natural to users may be

responsible for implementing some of the 2012 AQMP mitigation measures, specifically those mitigation measures that call for increased energy generating and supply capacities.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken by project applicants, project sponsors, public agencies, public electricity generating utilities, or public natural gas provider utilities throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring would be accomplished as follows:

- MME-1** A project applicant, project sponsor, or public agency shall provide to the lead agency documentation for approval of incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation prior to the beginning of project operation. The lead agency can and should conduct routine inspections of the project to verify compliance.
- MME-2** To the extent allowed by state and federal law, electricity generating utilities within the district can and should increase capacity of existing transmission lines to meet forecast electricity demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- MME-3** The project applicant, project sponsor, or public agency should submit projected electricity calculations to the local electricity provider for any project anticipated to require substantial electricity consumption. Such electricity calculations can and should be used by the local electricity provider when forecasting future electricity demand. Any infrastructure improvements necessary should be completed according to the specifications of the electricity provider.
- MME-4** The project applicant, project sponsor, or public agency should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy. The lead agency can and should conduct routine inspections of the project to verify compliance with any energy conservation mitigation measures.
- MME-5** The project applicant, project sponsor, or public agency should evaluate the potential for reducing peak energy demand by encouraging charging of electrical vehicles and other mobile sources during off-peak hours. The lead agency can and should conduct routine inspections of the project to verify compliance with any mitigation measures encouraging charging of electrical vehicles and other mobile sources during off-peak hours.
- MME-6** The project applicant, project sponsor, or public agency should evaluate the potential for reducing peak energy demand by encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours. The lead agency can and should conduct routine inspections of the project to verify compliance with any mitigation measures encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.
- MME-7** The project applicant, project sponsor, or public agency should evaluate the potential for reducing peak energy demand by encouraging the use of electrified stationary sources during off-peak hours (e.g., cargo handling equipment). The lead

agency can and should conduct routine inspections of the project to verify compliance with any energy conservation mitigation measures encouraging the use of electrified stationary sources during off-peak hours.

- MME-8** The project applicant, project sponsor, or public agency should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation. The lead agency can and should conduct routine inspections of the project to verify compliance with any mitigation measures that encourage the use of energy efficient equipment and vehicles and promote energy conservation.
- MME-9** To the extent allowed by state and federal law, natural gas provider utilities should increase capacity of existing natural gas lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- MME-10** Project sponsors should submit projected natural gas calculations to the local natural gas provider for any project anticipated to require substantial natural gas consumption. Any infrastructure improvements necessary should be completed according to the specifications of the natural gas provider.
- MME-11** Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.
- MME-12** Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of natural gas stationary sources during off-peak hours.

6.5 HAZARDS AND HAZARDOUS MATERIALS IMPACTS AND MITIGATION MEASURES

The analysis of secondary hazards and hazardous materials impacts in the Final Program EIR for the 2012 AQMP concluded that 2012 AQMP has the potential to generate significant adverse hazards and hazardous materials impacts as follows: from reformulating coating and solvent products with flammable or more flammable products, impacts related to an accidental release of either ammonia or LNG during transport, or impacts related to an accidental release of ammonia stored onsite. The mitigation measures identified in the following discussion are intended to reduce hazardous and hazardous materials impacts associated with these sources to the maximum extent feasible. Mitigation measures HZ-1 and HZ-2 would serve to reduce impacts from reformulating coatings or solvents with flammable or more flammable products, mitigation measures HZ-3 through HZ-6 would reduce impacts related to an accidental release of either ammonia or LNG during transport, and mitigation measures HZ-7 through HZ-10 would reduce impacts from an accidental release of ammonia stored onsite. The timing of implementing the hazards and hazardous materials mitigation measures would be ongoing over the life of the 2012 AQMP and includes the following mitigation measures:

- HZ-1** Add consumer warning requirements for all flammable and extremely flammable products; and,
- HZ-2** Add requirements to conduct a public education and outreach program in joint cooperation with local fire departments regarding flammable and extremely flammable products that may be included in consumer paint thinners and multipurpose solvents.

- HZ-3** Install secondary containment (e.g., berms).
- HZ-4** Install valves that fail shut.
- HZ-5** Install emergency release valves and barriers around LNG storage tanks to prevent the physical damage to storage tanks or limit the release of LNG from storage tanks.
- HZ-6** Perform integrity testing of LNG storage tanks to assist in preventing failure from structural problems. Construct a containment system to be used for deliveries during off-loading operations.
- HZ-7** Install safety devices, including but not limited to: continuous tank level monitors (e.g., high and low level), temperature and pressure monitors, leak monitoring and detection system, alarms, check valves, and emergency block valves.
- HZ-8** Install secondary containment to capture 110 percent of the storage tank volume in the event of a spill:
- HZ-9** Install a grating-covered trench around the perimeter of the delivery bay to passively contain potential spills from the tanker truck during the transfer of aqueous ammonia from the delivery truck to the storage facility.
- HZ-10** The truck loading/unloading area was designed to be equipped with an underground gravity drain that flows to a large on-site retention basin to provide sufficient ammonia dilution to the extent that no hazards impact is possible in the event of an accidental release during transfer of aqueous ammonia.

6.6 HAZARDS AND HAZARDOUS MATERIALS MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, some of the hazards and hazardous materials mitigation measures in this MMRP may be described as general policies, although some refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing 2012 AQMP control measures for future projects that have the potential to generate hazards and hazardous materials impacts would be project applicants, project sponsors and public agencies, including cities or counties within the district.

To the extent that hazards and hazardous materials use results from complying with SCAQMD rules that have been promulgated from 2012 AQMP control measures, the SCAQMD can impose permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD is a responsible agency or has no approval authority over future projects that have the potential to generate significant adverse hazards and hazardous materials impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose 2012 AQMP mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments. Similarly, to the extent allowed by state and federal regulations, cities or counties within the district as the entities that may have primary approval authority over projects implementing 2012 AQMP control measures may also be responsible for implementing some of the 2012 AQMP mitigation measures.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken by project applicants, project sponsors, or public agencies, throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring would be accomplished as follows:

- MMHZ-1** Add consumer warning requirements for all flammable and extremely flammable products; and,
- MMHZ-2** Add requirements to conduct a public education and outreach program in joint cooperation with local fire departments regarding flammable and extremely flammable products that may be included in consumer paint thinners and multipurpose solvents.
- MMHZ-3** Install secondary containment (e.g., berms).
- MMHZ-4** Install valves that fail shut.
- MMHZ-5** Install emergency release valves and barriers around LNG storage tanks to prevent the physical damage to storage tanks or limit the release of LNG from storage tanks.
- MMHZ-6** Perform integrity testing of LNG storage tanks to assist in preventing failure from structural problems. Construct a containment system to be used for deliveries during off-loading operations.
- MMHZ-7** Install safety devices, including but not limited to: continuous tank level monitors (e.g., high and low level), temperature and pressure monitors, leak monitoring and detection system, alarms, check valves, and emergency block valves.
- MMHZ-8** Install secondary containment to capture 110 percent of the storage tank volume in the event of a spill:
- MMHZ-9** Install a grating-covered trench around the perimeter of the delivery bay to passively contain potential spills from the tanker truck during the transfer of aqueous ammonia from the delivery truck to the storage facility.
- MMHZ-10** The truck loading/unloading area was designed to be equipped with an underground gravity drain that flows to a large on-site retention basin to provide sufficient ammonia dilution to the extent that no hazards impact is possible in the event of an accidental release during transfer of aqueous ammonia.

6.7 HYDROLOGY AND WATER QUALITY IMPACTS AND MITIGATION MEASURES

The analysis of secondary air quality impacts in the Final Program EIR for the 2012 AQMP concluded that the 2012 AQMP has the potential to generate significant adverse hydrology and water quality impacts, specifically water demand impacts. Certain air pollution control technologies and the use of waterborne coatings may significantly increase the demand for water. The mitigation measures that would be implemented for water demand impacts would depend on the characteristics of individual projects, the volume of water expected to be used, and could vary among jurisdictions. The timing of implementing the hydrology and water quality

mitigation measures would be ongoing over the life of the 2012 AQMP and includes the following types of control measures:

- HWQ-1** Local water agencies should continue to evaluate future water demand and establish the necessary supply and infrastructure to meet that demand, as documented in their Urban Water Management Plans.
- HWQ-2** Project sponsors should coordinate with the local water provider to ensure that existing or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements. In accordance with State Law, a Water Supply Assessment should be required for projects that meet the size requirements specified in the regulations. In coordination with the local water provider, each project sponsor will identify specific on- and off-site improvements needed to ensure that impacts related to water supply and conveyance demand/pressure requirements are addressed prior to issuance of a certificate of occupancy. Water supply and conveyance demand/pressure clearance from the local water provider will be required at the time that a water connection permit application is submitted.
- HWQ-3** Project sponsors should implement water conservation measures and use recycled water for appropriate end uses.
- HWQ-4** Project sponsors should consult with the local water provider to identify feasible and reasonable measures to reduce water consumptions.

6.8 HYDROLOGY AND WATER QUALITY MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, some of the water demand mitigation measures in this MMRP may be described as general policies, although some refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing mitigation measures for future projects that have the potential to generate hydrology and water quality impacts from complying with 2012 AQMP control measures promulgated as rules or regulations would be project applicants, project sponsors, public agencies, and water provider utilities within the district.

To the extent that water demand results from complying with SCAQMD rules that have been promulgated from AQMP control measures, the SCAQMD can impose permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD is a responsible agency or has no approval authority over future projects that have the potential to generate water demand impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose 2012 AQMP mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments. Similarly, to the extent allowed by state and federal regulations, water provider utilities within the district as the entities that provide water to users may be responsible for implementing some of the 2012 AQMP mitigation measures.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken by project applicants, project sponsors, public agencies, water provider utilities throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring would be accomplished as follows:

MMHWQ-1 Local water agencies should continue to evaluate future water demand and establish the necessary supply and infrastructure to meet that demand, as documented in their Urban Water Management Plans.

MMHWQ-2 Project sponsors should coordinate with the local water provider to ensure that existing or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements. In accordance with State Law, a Water Supply Assessment should be required for projects that meet the size requirements specified in the regulations. In coordination with the local water provider, each project sponsor will identify specific on- and off-site improvements needed to ensure that impacts related to water supply and conveyance demand/pressure requirements are addressed prior to issuance of a certificate of occupancy. Water supply and conveyance demand/pressure clearance from the local water provider will be required at the time that a water connection permit application is submitted.

MMHWQ-3 Project sponsors should implement water conservation measures and use recycled water for appropriate end uses.

MMHWQ-4 Project sponsors should consult with the local water provider to identify feasible and reasonable measures to reduce water consumptions.

6.9 NOISE IMPACTS AND MITIGATION MEASURES

The analysis of secondary air quality impacts in the Final Program EIR for the 2012 AQMP concluded that the 2012 AQMP has the potential to generate significant adverse construction-related noise impacts associated with construction activities that have the potential to generate noise from heavy construction equipment and construction-related traffic. The mitigation measures in the 2012 AQMP Final Program EIR as identified in the following discussion are intended to minimize the impacts associated with these sources. The timing of implementing the construction-related noise mitigation measures would be ongoing over the life of the 2012 AQMP and includes the following types of control measures:

NO-1 To reduce noise impacts due to construction, project sponsors may require construction contractors to implement a site-specific noise reduction program, subject to the Lead Agency (or other appropriate government agency) review and approval, which includes the following measures:

- Equipment and trucks used for project construction may utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).

- Except as may be exempted by the Lead Agency (or other appropriate government agency), impact tools (e.g., jack hammers, pavement breakers, and rock drills) used for project construction may be hydraulically or electrically powered to avoid noise associated with compressed air exhaust from pneumatically powered tools. However, where use of pneumatic tools is unavoidable, an exhaust muffler on the compressed air exhaust may be used; this muffler can lower noise levels from the exhaust by up to about 10 dBA. External jackets on the tools themselves may be used, if such jackets are commercially available and this could achieve a reduction of five dBA. Quieter procedures may be used, such as drills rather than impact equipment, whenever such procedures are available and consistent with construction procedures.
- Stationary noise sources may be located as far from adjacent sensitive receptors as possible and they may be muffled and enclosed within temporary sheds, incorporate insulation barriers, or use other measures as determined by the Lead Agency (or other appropriate government agency) to provide equivalent noise reduction.

NO-2 Prior to the issuance of a building permit, along with the submission of construction documents, each project sponsor may submit to the Lead Agency (or other government agency as appropriate) a list of measures to respond to and track complaints pertaining to construction noise. These measures may include:

- A procedure and phone numbers for notifying the Lead Agency staff and local Police Department (during regular construction hours and off-hours);
- A sign posted on-site pertaining with permitted construction days and hours and complaint procedures and who to notify in the event of a problem. The sign may also include a listing of both the Lead Agency and construction contractor's telephone numbers (during regular construction hours and off hours);
- The designation of an on-site construction complaint and enforcement manager for the project;
- Notification of neighbors and occupants within 300 feet of the project construction area at least 30 days in advance of extreme noise generating activities about the estimated duration of the activity; and
- A preconstruction meeting may be held with the job inspectors and the general contractor/on-site project manager to confirm that noise measures and practices (including construction hours, neighborhood notification, posted signs, etc.) are completed.

NO-3 Project sponsor may implement use of portable barriers in the vicinity of sensitive receptors during construction including construction of subsurface barriers, debris basins, and storm water drainage facilities.

NO-4 For projects that require pile driving or other construction noise above 90 dBA in proximity to sensitive receptors, to further reduce potential pier drilling, pile driving and/or other extreme noise generating construction impacts greater than 90dBA, a set of site-specific noise attenuation measures may be completed under the supervision of a qualified acoustical consultant. Prior to commencing construction, a plan for such measures may be submitted for review and approval by the Lead Agency (or other appropriate government agency) to ensure that maximum feasible noise attenuation

would be achieved. This plan may be based on the final design of the project. A third-party peer review, paid for by the project sponsor, may be required to assist the Lead Agency in evaluating the feasibility and effectiveness of the noise reduction plan submitted by the project sponsor. The criterion for approving the plan may be a determination that maximum feasible noise attenuation would be achieved. The noise reduction plan may include, but not be limited to, an evaluation of implementing the following measures. These attenuation measures may include as many of the following control strategies as applicable to the site and construction activity:

- Erect temporary plywood noise barriers around the construction site, particularly along on sites adjacent to residential buildings;
- Implement “quiet” pile driving technology (such as pre-drilling of piles, the use of more than one pile driver to shorten the total pile driving duration), where feasible, in consideration of geotechnical and structural requirements and conditions;
- Utilize noise control blankets on the building structure as the structures are erected to reduce noise emission from the site;
- Evaluate the feasibility of noise control at the receivers by temporarily improving the noise reduction capability of adjacent buildings by the use of sound blankets for example and implement such measure if such measures are feasible and would noticeably reduce noise impacts; and
- Monitor the effectiveness of noise attenuation measures by taking noise measurements.

NO-5 Noise generated from any rock-crushing or screening operations performed within 3,000 feet of any occupied residence may be mitigated by the project sponsor by strategic placement of material stockpiles between the operation and the affected dwelling or by other means approved by the local jurisdiction.

NO-6 Where feasible, pile holes may be pre-drilled to reduce potential noise and vibration impacts.

NO-7 As necessary, each project sponsor may retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent historic or other structure subject to damage, and design means and construction methods to not exceed the thresholds.

NO-8 Project sponsors may comply with all local sound control and noise level rules, regulations, and ordinances.

NO-9 As part of the appropriate environmental review of each project, a project-specific noise evaluation may be conducted and appropriate mitigation identified and implemented.

6.10 NOISE MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, some of the construction-related noise mitigation measures in this MMRP may be described as general policies, although some refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing construction-related noise

mitigation measures from the Final Program EIR for the 2012 AQMP for future projects that have the potential to generate construction-related noise impacts from complying with 2012 AQMP control measures promulgated as rules or regulations would be project applicants, project sponsors, public agencies, electricity generating utilities, or natural gas provider utilities within the district.

To the extent that noise impacts result from complying with SCAQMD rules that have been promulgated from AQMP control measures, the SCAQMD may be able to impose permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD is a responsible agency or has no approval authority over future projects that have the potential to generate construction-related noise impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments. Similarly, to the extent allowed by state and federal regulations, cities or counties within the district as the entities that regulate noise sources through ordinances or general plan noise elements, may be responsible for implementing some of the 2012 AQMP mitigation measures.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken by project applicants, project sponsors, or public agencies, throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring would be accomplished as follows:

MMNO-1 To reduce noise impacts due to construction, project sponsors should require construction contractors to implement a site-specific noise reduction program, subject to the Lead Agency (or other appropriate government agency) review and approval, which includes the following measures:

- Equipment and trucks used for project construction should utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).
- Except as exempted by the Lead Agency (or other appropriate government agency), impact tools (e.g., jack hammers, pavement breakers, and rock drills) used for project construction should be hydraulically or electrically powered, where feasible, to avoid noise associated with compressed air exhaust from pneumatically powered tools. However, where use of pneumatic tools is unavoidable, an exhaust muffler on the compressed air exhaust should be used; this muffler can lower noise levels from the exhaust by up to about 10 dBA. External jackets on the tools themselves should also be used, if such jackets are commercially available and a reduction of five dBA can be achieved. Quieter procedures should also be used such as drills rather than impact equipment, whenever such procedures are available and consistent with construction procedures.
- Stationary noise sources should be located as far from adjacent sensitive receptors as possible and they should be muffled and enclosed within

temporary sheds, incorporate insulation barriers, or use other measures as determined by the Lead Agency (or other appropriate government agency) to provide equivalent noise reduction, where feasible.

MMNO-2 Prior to the issuance of a building permit, along with the submission of construction documents, each project sponsor should submit to the Lead Agency (or other government agency as appropriate) a list of measures to respond to and track complaints pertaining to construction noise. These measures should include:

- A procedure and phone numbers for notifying the Lead Agency staff and local Police Department (during regular construction hours and off-hours);
- A sign posted on-site pertaining with permitted construction days and hours and complaint procedures and who to notify in the event of a problem. The sign should also include a listing of both the Lead Agency and construction contractor's telephone numbers (during regular construction hours and off hours);
- The designation of an on-site construction complaint and enforcement manager for the project;
- Notification of neighbors and occupants within 300 feet of the project construction area at least 30 days in advance of extreme noise generating activities about the estimated duration of the activity; and
- A preconstruction meeting should be held with the job inspectors and the general contractor/on-site project manager to confirm that noise measures and practices (including construction hours, neighborhood notification, posted signs, etc.) are completed.

MMNO-3 Project sponsor should implement use of portable barriers in the vicinity of sensitive receptors during construction including construction of subsurface barriers, debris basins, and storm water drainage facilities.

MMNO-4 For projects that require pile driving or other construction noise above 90 dBA in proximity to sensitive receptors, to further reduce potential pier drilling, pile driving and/or other extreme noise generating construction impacts greater than 90dBA, a set of site-specific noise attenuation measures should be completed under the supervision of a qualified acoustical consultant. Prior to commencing construction, a plan for such measures should be submitted for review and approval by the Lead Agency (or other appropriate government agency) to ensure that maximum feasible noise attenuation would be achieved. This plan should be based on the final design of the project. A third-party peer review, paid for by the project sponsor, should be required to assist the Lead Agency in evaluating the feasibility and effectiveness of the noise reduction plan submitted by the project sponsor. The criterion for approving the plan should be based on a determination that maximum feasible noise attenuation would be achieved. The noise reduction plan should include, but not be limited to, an evaluation of implementing the following measures. These attenuation measures should also include as many of the following control strategies as applicable to the site and construction activity:

- Erect temporary plywood noise barriers around the construction site, particularly along on sites adjacent to residential buildings;
- Implement “quiet” pile driving technology (such as pre-drilling of piles, the use of more than one pile driver to shorten the total pile driving duration), where feasible, in consideration of geotechnical and structural requirements and conditions;
- Utilize noise control blankets on the building structure as the structures are erected to reduce noise emission from the site;
- Evaluate the feasibility of noise control at the receivers by temporarily improving the noise reduction capability of adjacent buildings by the use of sound blankets for example and implement such measure if such measures are feasible and would noticeably reduce noise impacts; and
- Monitor the effectiveness of noise attenuation measures by taking noise measurements.

MMNO-5 Noise generated from any rock-crushing or screening operations performed within 3,000 feet of any occupied residence should be mitigated, where feasible, by the project sponsor by strategic placement of material stockpiles between the operation and the affected dwelling or by other means approved by the local jurisdiction.

MMNO-6 Where feasible, pile holes should be pre-drilled to reduce potential noise and vibration impacts.

MMNO-7 As necessary, each project sponsor should retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent historic or other structure subject to damage, and design means and construction methods to not exceed the thresholds.

MMNO-8 Project sponsors should comply with all local sound control and noise level rules, regulations, and ordinances.

MMNO-9 As part of the appropriate environmental review of each project, a project-specific noise evaluation should be conducted and appropriate mitigation identified and implemented, where feasible.

6.11 TRANSPORTATION AND TRAFFIC IMPACTS AND MITIGATION MEASURES

The analysis of secondary air quality impacts in the Final Program EIR for the 2012 AQMP concluded that the 2012 AQMP has the potential to generate significant adverse traffic impacts during construction activities and during operation. Construction activities could generate construction-related traffic and adversely affect traffic flow through lane closures or other traffic restrictions. To the extent that catenary lines are constructed over roadways and the roadways are restricted to heavy-duty trucks equipped to use the lines, more vehicles could be required to use existing roadways. Mitigation measure TT-1 would serve to reduce potential traffic impacts during construction. No mitigation measures were identified for traffic impacts during operation. The timing of implementing the construction traffic impact mitigation measure would be

ongoing over the life of the 2012 AQMP and include the following types of mitigation measure activities:

TT-1: Project sponsors and construction contractors can and should meet with the appropriate Lead Agency (or other government agency) to determine traffic management strategies to reduce, to the maximum extent feasible, traffic congestion and the effects of parking demand by construction workers during construction of this project and other nearby projects that could be simultaneously under construction. The project sponsor should develop a construction management plan for review and approval by the Lead Agency (or other government agency as appropriate). The plan should include at least the following items and requirements:

- A set of comprehensive traffic control measures, including scheduling of major truck trips and deliveries to avoid peak traffic hours, detour signs if required, lane closure procedures, signs, cones for drivers, and designated construction access routes.
- Notification procedures for adjacent property owners and public safety personnel regarding when major deliveries, detours, and lane closures will occur.
- Location of construction staging areas for materials, equipment, and vehicles at an approved location.
- A process for responding to, and tracking, complaints pertaining to construction activity, including identification of an onsite complaint manager. The manager should determine the cause of the complaints and should take prompt action to correct the problem. The Lead Agency should be informed who the Manager is prior to the issuance of the first permit.
- Provision for accommodation of pedestrian flow.
- As necessary, provision for parking management and spaces for all construction workers to ensure that construction workers do not park in on street spaces.
- Any damage to the street caused by heavy equipment, or as a result of this construction, should be repaired, at the project sponsor's expense, within one week of the occurrence of the damage (or excessive wear), unless further damage/excessive wear may continue; in such case, repair should occur prior to issuance of a final inspection of the building permit. All damage that is a threat to public health or safety should be repaired immediately. The street should be restored to its condition prior to the new construction as established by the Lead Agency (or other appropriate government agency) and/or photo documentation, at the sponsor's expense, before the issuance of a Certificate of Occupancy.
- Any heavy equipment brought to the construction site should be transported by truck, where feasible.
- No materials or equipment should be stored on the traveled roadway at any time.
- Prior to construction, a portable toilet facility and a debris box should be installed on the site, and properly maintained through project completion.
- All equipment should be equipped with mufflers.

- Prior to the end of each work-day during construction, the contractor or contractors should pick up and properly dispose of all litter resulting from or related to the project, whether located on the property, within the public rights-of-way, or properties of adjacent or nearby neighbors.

6.12 TRANSPORTATION AND TRAFFIC MITIGATION MONITORING AND REPORTING

Implementing Party: Because the 2012 AQMP is a regional plan that can be characterized as an ongoing regulatory program, the construction traffic impact mitigation measure in this MMRP may be described as a general policy even though some of the activities refer to specific actions. The SCAQMD finds that the party or parties responsible for implementing the construction traffic mitigation measure on future projects that have the potential to generate construction traffic impacts from complying with the 2012 AQMP control measures promulgated as rules or regulations would be project applicants, project sponsors, public agencies, electricity generating utilities, or natural gas provider utilities within the district.

To the extent that traffic impacts during construction and/or operation result from complying with SCAQMD rules that have been promulgated from 2012 AQMP control measures, the SCAQMD can impose permit conditions on permit applicants at the time permit applications are processed and approved. If the SCAQMD is a responsible agency or has no approval authority over future projects that have the potential to generate significant adverse construction and/or operation traffic impacts from complying with 2012 AQMP control measures promulgated as rules or regulations, then the public agency with primary approval authority over these future projects can and should impose 2012 AQMP mitigation measures through its authority to impose permit conditions on permit applicants at the time permit applications are processed and approved or through other legally binding instruments. Similarly, to the extent allowed by state and federal regulations, CalTrans or local transportation agencies within the district as the entities that may have approval authority over roadway projects and also responsible for implementing the 2012 AQMP Final Program EIR construction traffic mitigation measure.

Monitoring Agency: Because future projects to implement 2012 AQMP control measures promulgated as rules or regulations could be undertaken by project applicants, project sponsors, or public agencies, throughout the district, the monitoring agency is expected to vary and may include a variety of public agencies performing the role of lead agency. Monitoring will be accomplished as follows:

MMTT-1 Project sponsors and construction contractors can and should meet with the appropriate lead agency (or other public agency with approval authority over the project) to determine traffic management strategies to reduce, to the maximum extent feasible, traffic congestion and the effects of parking demand by construction workers during construction of this project and other nearby projects that could be simultaneously under construction. The project sponsor should develop a construction management plan for review and approval by the Lead Agency (or other government agency as appropriate).

7.0 CONCLUSION

To the extent that the SCAQMD is the lead agency with primary approval authority over projects implementing 2012 AQMP control measures, project applicants, project sponsors, or public agencies will maintain records onsite of applicable compliance activities to demonstrate the steps taken to assure compliance with imposed mitigation measures as specified in Table 3. All construction logs and other records shall be made available to SCAQMD inspectors upon request by the project proponent. The project proponent may be required to submit quarterly (or some other specified time duration) reports to the SCAQMD during the construction phase that summarize the construction progress, including all required logs, inspection reports, and monitoring reports, as well as identify any problems and corrective actions, as necessary. SCAQMD staff and the project proponent will evaluate the effectiveness of this monitoring program during the construction period. It is expected that, as part of the CEQA document for any future projects implementing 2012 AQMP control measures, mitigation measures identified in this MMRP would be required as necessary, along with any additional mitigation measures identified at that time by the SCAQMD or other responsible agencies.

THIS PAGE INTENTIONALLY LEFT BLANK

Table 3
Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
Air Quality			
AQ-1 / Develop a Construction Emission Management Plan for the proposed project.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve the Construction Emission Management Plan submitted to them for approval if adequate.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction
AQ-2 / Maintain construction equipment tuned up and with two to four degree retard diesel engine timing or tuned to manufacturer's recommended specifications that optimize emissions without nullifying engine warranties.	Project Applicant/Project Sponsor/Public Agency	Maintain any required records onsite for two years and make available upon request to the appropriate agency inspector/monitor.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Daily during construction and at least 2 years after construction ends.
AQ-3 / The project proponent shall survey and document the proposed project's construction areas and identify all construction areas that are served by electricity. Electric welders shall be used in all construction areas that are demonstrated to be served by electricity.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve documentation in the Construction Emission Management Plan, if adequate, those construction areas without electricity and maintain records of gas or diesel welder use and duration of use. Maintain any required records onsite and make available upon request to the appropriate agency inspector/monitor.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Prior to start of construction
AQ-4 / The project proponent shall survey and document the proposed Project's construction areas and identify all construction areas that are served by electricity. Onsite electricity rather than temporary power generators shall be used in all construction areas that are demonstrated to be served by electricity.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve documentation in the Construction Emission Management Plan, if adequate, construction areas without electricity and maintain records of temporary power generator use and duration of use. Maintain any required records onsite and make available upon request to the appropriate agency inspector/monitor.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Prior to start of construction

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
Energy			
E-1 / Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary documentation of incentives to encourage energy efficiency and conservation.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and throughout implementation of the 2012 AQMP
E-2 / Utilities should increase capacity of existing transmission lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.	Electric Utilities	Electricity generating utilities within the district can and should coordinate with local public agencies, to the extent allowed by state and federal law, with regard to increasing capacity of existing transmission lines to meet forecast demand.	1. Electricity Utilities 2. Electricity Utilities 3. During the environmental review process and before the start of construction
E-3 / Project sponsors should submit projected electricity calculations to the local electricity provider for any project anticipated to require substantial electricity consumption. Any infrastructure improvements necessary should be completed according to the specifications of the electricity provider.	Project Applicant/Project Sponsor/Public Agency	When forecasting future electricity demand and/or infrastructure improvements, electricity utilities can and should consider the effects of local projects on future energy demand.	1. Electricity Utilities 2. Electricity Utilities 3. During the environmental review process and before the start of construction
E-4 / Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses and make a determination that all feasible energy conservation goals are identified.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
E-5 / Project sponsors should evaluate the potential for reducing peak energy demand by encouraging charging electrical vehicles and other mobile sources during off-peak hours.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses that encourage charging electric vehicles and other mobile sources during off-peak hours.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process

Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
E-6 / Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses that encourage using catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
E-7 / Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of electrified stationary sources during off-peak hours (e.g., cargo handling equipment).	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses that encourage using electrified stationary sources during off-peak hours.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
E-8 / Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses that encourage the use of energy efficient equipment and vehicles and promote energy conservation.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
E-9 / Utilities should increase capacity of existing natural gas lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.	Natural Gas Utilities	Natural gas utilities within the district can and should coordinate with local public agencies, to the extent allowed by state and federal law, with regard to increasing capacity of existing natural gas lines to meet forecast demand.	<ol style="list-style-type: none"> 1. Natural Gas Utilities/Other Lead Agencies 2. Natural Gas Utilities/Other Lead Agencies 3. During the environmental review process and throughout implementation of the 2012 AQMP
E-10 / Project sponsors should submit projected natural gas calculations to the local natural gas provider for any project anticipated to require substantial natural gas consumption. Any infrastructure improvements necessary should be completed according to the specifications of the natural gas provider.	Project Applicant/Project Sponsor/Public Agency	When forecasting future natural gas demand and/or infrastructure improvements, natural gas utilities can and should consider the effects of local projects on future energy demand.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction

Table 3 (Continued)
Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
E-11 / Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses and make a determination that all feasible energy conservation goals are identified.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
E-12 / Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of natural gas stationary sources during off-peak hours.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully evaluate the adequacy of any required energy analyses that encourage the use of natural gas stationary sources during off-peak hours.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process
Hazards and Hazardous Materials			
HZ-1 / Add consumer warning requirements for all flammable and extremely flammable products.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments or hazmat departments, as appropriate, to develop appropriate warnings and locations of warning labels.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before operation
HZ-2 / Add requirements to conduct a public education and outreach program in joint cooperation with local fire departments regarding flammable and extremely flammable products that may be included in consumer paint thinners and multipurpose solvents.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments or school districts, as appropriate, to develop appropriate education campaigns and outreach programs regarding the flammability of consumer paint thinners and solvents.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before operation begins
HZ-3 / Install secondary containment (e.g., berms).	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that secondary containment has been installed before giving final approval of the project.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
HZ-4 / Install valves that fail shut.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that fail shut valves have been installed before giving final approval of the project..	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins

Table 3 (Continued)

Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
HZ-5 / Install emergency release valves and barriers around LNG storage tanks to prevent the physical damage to storage tanks or limit the release of LNG from storage tanks.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that emergency release valves and barriers around LNG storage tanks have been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
HZ-6 / Perform integrity testing of LNG storage tanks to assist in preventing failure from structural problems. Construct a containment system to be used for deliveries during off-loading operations.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that integrity testing of LNG storage tanks has been performed and containment systems to be used for deliveries during off-loading operations have been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
HZ-7 / Install safety devices, including but not limited to: continuous tank level monitors (e.g., high and low level), temperature and pressure monitors, leak monitoring and detection system, alarms, check valves, and emergency block valves.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that safety devices, including but not limited to: continuous tank level monitors (e.g., high and low level), temperature and pressure monitors, leak monitoring and detection system, alarms, check valves, and emergency block valves have been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
HZ-8 / Install secondary containment to capture 110 percent of the storage tank volume in the event of a spill:	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that secondary containment that can capture 110 % of the storage tank volume has been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins

Table 3 (Continued)

Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
HZ-9 / Install a grating-covered trench around the perimeter of the delivery bay to passively contain potential spills from the tanker truck during the transfer of aqueous ammonia from the delivery truck to the storage facility.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure a grating-covered trench around the perimeter of the delivery bay to passively contain potential spills from the tanker truck during the transfer of aqueous ammonia from the delivery truck to the storage facility has been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
HZ-10 / The truck loading/unloading area should be designed to be equipped with an underground gravity drain that flows to a large on-site retention basin to provide sufficient ammonia dilution to the extent that no hazards impact is possible in the event of an accidental release during transfer of aqueous ammonia.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local fire departments to ensure that the truck loading/unloading area is designed and equipped with an underground gravity drain that flows to a large on-site retention basin, which has been installed before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before operation begins
Hydrology and Water Quality (Water Demand)			
HWQ-1 / Local water agencies should continue to evaluate future water demand and establish the necessary supply and infrastructure to meet that demand, as documented in their Urban Water Management Plans.	Local Water Agencies	Local water agencies within the district can and should coordinate with local public agencies, to the extent allowed by state and federal law, with regard to forecasting future water demand and providing the necessary water supply infrastructure to meet forecast demand.	<ol style="list-style-type: none"> 1. Local Water Agencies 2. Local Water Agencies 3. During the environmental review process and throughout implementation of the 2012 AQMP
HWQ-2 / Project sponsors should coordinate with the local water provider to ensure that existing or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with local water providers to ensure that existing or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements before giving final approval of the project.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction

Table 3 (Continued)

Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
HWQ-3 / Project sponsors should implement water conservation measures and use recycled water for appropriate end uses.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary documentation of incentives to encourage water conservation measures and recycled water use.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction
HWQ-4 / Project sponsors should consult with the local water provider to identify feasible and reasonable measures to reduce water consumptions.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should carefully coordinate with local water providers to evaluate the adequacy of any required measures to reduce water consumption.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction
Noise			
NO-1 /To reduce noise impacts due to construction, project sponsors may require construction contractors to implement a site-specific noise reduction program, subject to the Lead Agency (or other appropriate government agency) review and approval.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve any required noise reduction program submitted to them for approval if adequate. Maintain any required records onsite and make available upon request to the appropriate agency inspector/monitor.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction
NO-2 / Prior to the issuance of a building permit, along with the submission of construction documents, each project sponsor may submit to the Lead Agency (or other government agency as appropriate) a list of measures to respond to and track complaints pertaining to construction noise.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve any required list of measures for responding to and tracking construction noise complaints submitted to them for approval if adequate. Maintain any required records onsite and make available upon request to the appropriate agency inspector/monitor.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction

Table 3 (Continued)**Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan**

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
NO-3 / Project sponsor may implement use of portable barriers in the vicinity of sensitive receptors during construction including construction of subsurface barriers, debris basins, and storm water drainage facilities.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should coordinate with the project applicant, project sponsor, or public agency to ensure that portable barriers are installed, if required.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before the start of construction
NO-4 / For projects that require pile driving or other construction noise above 90 dBA in proximity to sensitive receptors, to further reduce potential pier drilling, pile driving and/or other extreme noise generating construction impacts greater than 90dBA, a set of site-specific noise attenuation measures may be completed under the supervision of a qualified acoustical consultant.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve any required noise attenuation measures submitted to them for approval if adequate.	<ol style="list-style-type: none"> 1. SCAQMD 2. SCAQMD 3. During the environmental review process and before the start of construction
NO-5 / Noise generated from any rock-crushing or screening operations performed within 3,000 feet of any occupied residence may be mitigated by the project sponsor by strategic placement of material stockpiles between the operation and the affected dwelling or by other means approved by the local jurisdiction.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary documentation of the need to place material stockpiles between any rock crushing operation and residences within 3,000 feet.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and during construction
NO-6 / Where feasible, pile holes may be pre-drilled to reduce potential noise and vibration impacts.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary documentation of the need to pre-drill pile holes.	<ol style="list-style-type: none"> 1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before the start of construction

Table 3 (Continued)

Mitigation, Monitoring and Reporting Plan for 2012 Air Quality Management Plan

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
NO-7 / As necessary, each project sponsor may retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent historic or other structure subject to damage, and design means and construction methods to not exceed the thresholds.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary documentation of the need to retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent structures.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Before construction starts and daily during construction activities
NO-8 / Project sponsors may comply with all local sound control and noise level rules, regulations, and ordinances.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should send inspectors or other enforcement personnel to construction sites to ensure that project sponsors comply with all local sound control and noise level rules, regulations, and ordinances.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. Daily during construction
NO-9 / As part of the appropriate environmental review of each project, a project-specific noise evaluation may be conducted and appropriate mitigation identified and implemented.	Project Applicant/Project Sponsor/Public Agency	The lead agency can and should approve, as appropriate and adequate, any necessary environmental review containing a noise evaluation requirement and noise mitigation measures.	1. SCAQMD/Other Lead Agencies 2. SCAQMD/Other Lead Agencies 3. During the environmental review process and before start of construction

Mitigation Measure/Implementation Requirement	Party Responsible for Implementing Mitigation	Monitoring Action	<ol style="list-style-type: none"> 1. Enforcement Agency 2. Monitoring Agency 3. Monitoring Phase
Transportation and Traffic			
TT-1 / Project sponsors and construction contractors can and should meet with the appropriate Lead Agency (or other government agency) to determine traffic management strategies to reduce, to the maximum extent feasible, traffic congestion and the effects of parking demand by construction workers during construction of this project and other nearby projects that could be simultaneously under construction. The project sponsor should develop a construction management plan for review and approval by the Lead Agency (or other government agency as appropriate).	Project Applicant/Project Sponsor/Public Agency	Obtain approval of the constuction management plan from the appropriate agency(ies).	<ol style="list-style-type: none"> 1. SCAQMD/ Other Lead Agencies 2. SCAQMD/ Other Lead Agencies 3. Before the start of construction

DRAFT FINAL 2012 Air Quality Management Plan

November 2012

South Coast Air Quality Management District

Cleaning the air that we breathe...

**DRAFT FINAL 2012 AIR QUALITY
MANAGEMENT PLAN**

NOVEMBER 2012

**SOUTH COAST AIR QUALITY MANAGEMENT DISTRICT
GOVERNING BOARD**

CHAIRMAN: WILLIAM A. BURKE, Ed.D.
Speaker of the Assembly Appointee

VICE CHAIR: DENNIS YATES
Mayor, Chino
Cities of San Bernardino

MEMBERS:

MICHAEL D. ANTONOVICH
Supervisor, Fifth District
County of Los Angeles

JOHN J. BENOIT
Supervisor, Fourth District
County of Riverside

MICHAEL A. CACCIOTTI
Mayor, South Pasadena
Cities of Los Angeles County/Eastern Region

JOSIE GONZALES
Supervisor, Fifth District
San Bernardino County Representative

RONALD O. LOVERIDGE
Mayor, City of Riverside
Cities Representative, Riverside County

JOSEPH K. LYOU, Ph.D.
Governor's Appointee

JUDITH MITCHELL
Councilmember, Rolling Hills Estates
Cities of Los Angeles County/Western Region

SHAWN NELSON
Supervisor, Fourth District
County of Orange

CLARK E. PARKER, Ph.D.
Senate Rules Appointee

JAN PERRY
Councilmember, Ninth District
City of Los Angeles

MIGUEL A. PULIDO
Mayor, Santa Ana
Cities of Orange County

TABLE OF CONTENTS

EXECUTIVE SUMMARY

Introduction	ES-1
Why Is This Draft Final Plan Being Prepared?	ES-2
Is Air Quality Improving?	ES-2
How Did the Recent Recession Affecting Air Quality?	ES-8
What Are the Major Sources Contributing to Air Quality Problems?	ES-8
What is the Overall Control Strategy in the 2012 AQMP?	ES-9
Why Not Request the Full 5-year Extension to Meet the 24-Hour PM2.5 Standard?	ES-11
Why and How is the 8-Hour Ozone Plan Being Updated?	ES-11
Given the Current Difficult & Uncertain Economic Condition, Should the District Wait Before Adding Refined Control Commitments Into the SIP?	ES-12
Is the 2012 AQMP Being Coordinated with the State & Greenhouse Gas Reduction Efforts?	ES-12

1. INTRODUCTION

Purpose	1-1
Constraints in Achieving Standards	1-2
Setting	1-2
Emission Sources	1-4
Population	1-5
The Recent Recession	1-7
Control Efforts	1-8
History	1-8
Air Quality Impact of Control Efforts	1-9
Progress in Implementing the 2007 AQMP	1-10
District's Actions	1-10
CARB Actions	1-14
U.S. EPA Actions	1-17
Draft Final 2012 AQMP	1-18
Scope	1-18
Approach	1-18
Need for Integrated and Coordinated Planning	1-19
Economic Considerations	1-20
Federal CAA Planning Requirements Addressed by the 2012 AQMP	1-21
State Law Requirements Addressed by the Draft Final 2012 AQMP	1-24
Format of This Document	1-24

2. AIR QUALITY AND HEALTH EFFECTS

Introduction	2-1
Ambient Air Quality Standards	2-2
Federal and State Standards	2-2
NAAQS Attainment Status	2-6

Current Air Quality _____	2-10
Particulate Matter (PM2.5 and PM10) Specific Information _____	2-13
Health Effects, Particulate Matter _____	2-13
Air Quality, PM2.5 _____	2-14
Air Quality, PM10 _____	2-16
Ozone (O ₃) Specific Information _____	2-18
Health Effects, O ₃ _____	2-18
Air Quality, O ₃ _____	2-18
Other Criteria Pollutants _____	2-21
Carbon Monoxide (CO) Specific Information _____	2-21
Health Effects, CO _____	2-22
Air Quality, CO _____	2-22
Nitrogen Dioxide (NO ₂) Specific Information _____	2-23
Health Effects, NO ₂ _____	2-23
Air Quality, NO ₂ _____	2-24
Sulfur Dioxide (SO ₂) Specific Information _____	2-25
Health Effects, SO ₂ _____	2-25
Air Quality, SO ₂ _____	2-26
Sulfates (SO ₄ ²⁻) Specific Information _____	2-27
Health Effects, SO ₄ ²⁻ _____	2-27
Air Quality, SO ₄ ²⁻ _____	2-28
Lead (Pb) Specific Information _____	2-29
Health Effects, Pb _____	2-29
Air Quality, Pb _____	2-29
Comparison to Other U.S. Areas _____	2-30
Summary _____	2-33

3. BASE YEAR & FUTURE EMISSIONS

Introduction _____	3-1
Emission Inventories _____	3-2
Stationary Sources _____	3-2
Mobile Sources _____	3-4
On-Road _____	3-4
Off-Road _____	3-7
Uncertainty in the Inventory _____	3-11
Gridded Emissions _____	3-11
Base Year Emissions _____	3-12
2008 Emission Inventory _____	3-12
Future Emissions _____	3-20
Data Development _____	3-20
Summary of Baseline Emissions _____	3-21
Impact of Growth _____	3-31
Pre-Base-Year Offsets _____	3-31
Top Ten Source Categories (2008, 2014, 2023) _____	3-33

4. CONTROL STRATEGY AND IMPLEMENTATION

Introduction _____	4-1
Overall Attainment Strategy _____	4-1

24-Hour PM2.5 Strategy _____	4-4
Modeling Results _____	4-4
Sensitivity Analysis _____	4-5
Basin-wide Short Term PM2.5 Measures _____	4-5
8-hour Ozone Strategy _____	4-6
Proposed PM2.5 Short-term Control Measures _____	4-7
Combustion Sources _____	4-9
PM Sources _____	4-10
Multiple Component Sources _____	4-12
Indirect Sources _____	4-12
Educational Programs _____	4-13
Proposed PM2.5 Contingency Measures _____	4-13
SCAG's Regional Transportation Strategy and Transportation Control Measures _____	4-14
Linking Regional Transportation Planning to Air Quality Planning _____	4-15
Regional Transportation Strategy and Transportation Control Measures _____	4-15
Reasonably Available Control Measures (RACM) Analysis _____	4-16
Proposed 8-hour Measures _____	4-17
Proposed Stationary Source 8-hour Measures _____	4-21
Coatings and Solvents _____	4-25
Combustion Sources _____	4-26
Petroleum Operations and Fugitive VOC Emissions _____	4-27
Multiple Components Sources _____	4-28
Incentive Programs _____	4-29
Educational Programs _____	4-29
Proposed Mobile Source 8-hour Measures _____	4-31
On-Road Mobile Source Measures _____	4-34
Off-Road Mobile Sources Measures _____	4-35
Actions to Deploy Advanced Control Technologies _____	4-36
District's SIP Emission Reduction Commitment _____	4-41
SIP Emission Reduction Tracking _____	4-41
Reductions from Adopted Rules _____	4-42
Reductions from District's Stationary Source Control Measures _____	4-42
Adoption and Implementation of District's Stationary Control Measures _____	4-43
Adoption and Implementation of Alternative/Substitute Measures _____	4-44
Overall Emission Reductions _____	4-46
Implementation _____	4-47
Responsible Agencies _____	4-48

5. FUTURE AIR QUALITY

Introduction _____	5-1
Background _____	5-1
Modeling Approach _____	5-2
Design Values and Relative Response Factors (RRF) _____	5-2
Design Value Selection _____	5-2
RRF and Future Year Design Values _____	5-4
PM2.5 Modeling _____	5-5
24-Hour PM2.5 Modeling Approach _____	5-7
Weight of Evidence _____	5-7

Future Air Quality _____	5-8
24-Hour PM2.5 _____	5-8
Spatial Projections of PM2.5 Design values _____	5-9
Weight of Evidence Discussion _____	5-12
Control Strategy Choices _____	5-14
Additional Modeling Analyses _____	5-16
Annual PM2.5 _____	5-16
Annual PM2.5 Modeling Approach _____	5-16
Future Annual PM2.5 Air Quality _____	5-17
Ozone Modeling _____	5-18
Ozone Representativeness _____	5-19
Ozone Modeling Approach _____	5-21
Future Ozone Air Quality _____	5-22
Spatial Projections of 8-Hour Ozone Design Values _____	5-24
A First Look at Attaining the 2006 8-Hour Ozone Standard _____	5-26
Summary and Conclusions _____	5-27

6. FEDERAL & STATE CLEAN AIR ACT REQUIREMENTS

Introduction _____	6-1
Specific 24-Hour PM2.5 Planning Requirements _____	6-1
Federal Air Quality Standards for Fine Particulates _____	6-1
Federal Clean Air Act Requirements _____	6-3
Attainment Demonstration and Modeling _____	6-4
Reasonable Further Progress (RFP) _____	6-4
Reasonably Available Control Measures (RACM) and Reasonably Available Control Technology (RACT) Requirements _____	6-5
New Source Review _____	6-7
Contingency Measures _____	6-7
Contingency Measure Requirements _____	6-7
Air Quality Improvement Scenario _____	6-8
Magnitude of Contingency Measure Air Quality Improvements _____	6-11
Satisfying the Contingency Measure Requirements _____	6-12
Transportation Control Measures _____	6-13
California Clean Air Act Requirements _____	6-14
Plan Effectiveness _____	6-15
Emission Reductions _____	6-16
Population Exposure _____	6-17
Cost-Effectiveness Ranking _____	6-17
Transportation Conformity Budgets _____	6-20

7. CURRENT & FUTURE AIR QUALITY – DESERT NONATTAINMENT AREAS

Introduction _____	7-1
Air Quality Setting _____	7-3
Air Quality Summary _____	7-3
Attainment Status _____	7-4
PM10 _____	7-7
PM2.5 _____	7-9
Ozone (O ₃) _____	7-9

Other Criteria Pollutants _____	7-12
Pollutant Transport _____	7-12
Emissions Inventories _____	7-15
Future Air Quality _____	7-19
Conclusions _____	7-20

8. LOOKING BEYOND CURRENT REQUIREMENTS

Introduction _____	8-1
Potential Changes in the Federal Ozone Standard _____	8-1
Implications of a New Ozone Standard for the Basin _____	8-1
1-Hour Ozone Requirements _____	8-3
Proposed Changes to the Federal Particulate Matter Standards _____	8-4
Implications of the Proposed New PM _{2.5} Standards for the Basin _____	8-6

9. NEAR ROADWAY EXPOSURE AND ULTRAFINE PARTICLES

Introduction _____	9-1
Ultrafine Particles _____	9-4
Formation and Transport _____	9-4
Ambient Diurnal and Seasonal Variations _____	9-6
Concentration Levels in Different Environments _____	9-7
Chemical Composition _____	9-8
Measurement Methods _____	9-9
Other Near-roadway Pollutants _____	9-10
Ambient Measurements _____	9-12
Near Roadway Studies _____	9-12
On-road Studies and In-Vehicle Exposure _____	9-15
Important Factors Affecting Near-Roadway Measurements _____	9-17
Health Effects _____	9-18
Ultrafine Particles _____	9-18
Near-Roadway Health Impacts _____	9-21
Future Research and Assessment Needs _____	9-22
Chemical Composition _____	9-22
Processes Leading to Formation _____	9-22
Standardized Measurement Methods and Procedures _____	9-22
Increased Measurements at “Hot Spot” Locations _____	9-22
Emission Inventories _____	9-23
Air Quality Modeling _____	9-23
Health Effects _____	9-23
Other Types of Sources _____	9-23
Planning and Regulatory Issues _____	9-24
Jurisdiction over Near-Roadway Exposures _____	9-24
Sustainable Community Strategies _____	9-25
Enhanced Environmental Analysis _____	9-25
Mitigation Measures _____	9-27
Emission Control Technologies _____	9-28

PREFACE

The 2012 AQMP represents a regional blueprint for achieving healthful air on behalf of the 16 million residents of the South Coast Basin.

The air quality challenges are great, the stakes are high...and the legal deadlines loom sooner than most people realize.

STEADY PROGRESS AND MOMENTUM

The primary task of the 2012 AQMP is to bring our Basin into attainment with federal health-based standards for unhealthy fine particulate matter (PM_{2.5}) by 2014. Yet to have any reasonable expectation of meeting the 2023 ozone deadline, the scope and pace of continued air quality improvement must greatly intensify.

- Regulatory frameworks to reduce unhealthy emissions are mostly pollutant-specific, focusing on one pollutant at a time to meet clean air standards. However, outdoors, people inhale pollutants as a mixture, and the chemical interactions of multiple pollutants are complex. For this reason, each AQMP is also a comprehensive plan that examines multiple pollutants and the most up-to-date scientific knowledge, in order to achieve the greatest air quality and health benefits for Southland residents while also balancing factors of cost and available funding.
- The 2012 AQMP is a critical opportunity to re-sharpen our approach to achieve both breathable air and a healthier, revitalized economic future. Fuel combustion for goods movement, transportation, and energy is the major cause of our worst-in-the-nation ozone problem, while strategies for climate protection that reduce fuel use & energy consumption also have corresponding air quality benefits for everyone in the Southland region.

ECONOMIC SENSITIVITY

The District remains sensitive to our region's slow recovery from recession, while retaining the precept that healthful air is not a luxury, but a right. Therefore the 2012 AQMP seeks to maintain steady momentum along a dollar-wise path - - one that will reduce near-term public health expenses and lay a long-term foundation for more livable, energy-efficient communities and open additional economic opportunities.

- Wherever possible, the plan seeks to identify solutions that can solve multiple problems from focused investments and clean-technology incentives. Also, a number of the proposed measures are voluntary incentives and/or education programs that encourage innovation and early adoption. In addition, the District, the California Air Resources Board (CARB), and fellow non-attainment district San Joaquin Valley have engaged in a major effort to collaborate on concepts for combined clean air gains and more efficient energy production & usage, especially in transportation - - in a coordinated manner.

COLLABORATIVE, SYNERGISTIC EFFORTS

Key to timely implementation of the 2012 AQMP will be coordinated, integrated planning efforts among local, regional, state, and federal entities, together with effective public-private partnerships; and continuing active participation by stakeholders including community health groups, academic, research, & training institutions, and experts in advanced near-zero and zero-emission technologies, especially as related to advanced goods movement technologies.

- Recent years have seen co-funded projects among entities including SCAQMD, U.S. EPA, U.S. DOE, CARB, CEC, metropolitan planning organizations (such as SCAG), Clean Cities affiliates, Councils of Government, major OEMS, utility providers, goods movement authorities, and even international environmental consortiums. These efforts have been an important first step - - but the time for redoubled commitment by all parties is **now**.

Cleaning the air that we breathe...

EXECUTIVE SUMMARY

Introduction

Why Is This Draft Final Plan Being Prepared?

Is Air Quality Improving?

How Did the Recent Recession Affect Air Quality?

What Are the Major Sources Contributing to Air Quality Problems?

What Is the Overall Control Strategy in the 2012 AQMP?

**Why Not Request The Full 5-Year Extension to Meet the 24-Hour
PM2.5 Standard?**

Why and How Is the 8-Hour Ozone Plan Being Revised?

**Given the Current Difficult and Uncertain Economic Conditions,
Shouldn't the District Wait Before Adding Additional Regulatory
Refined Control Commitments into the SIP?**

**Is the 2012 AQMP Being Coordinated with the State's Greenhouse Gas
Reduction Efforts?**

INTRODUCTION

The long-term trend of the quality of air we Southern Californians breathe shows continuous improvement, although the slowing rate of improvement in ozone levels causes concern. The remarkable historical improvement in air quality since the 1970's is the direct result of Southern California's comprehensive, multiyear strategy of reducing air pollution from all sources as outlined in its Air Quality Management Plans (AQMP). Yet the air in Southern California is far from meeting all federal and state air quality standards and, in fact, is among the worst in the nation. Stemming from the preponderance of latest health evidence, new federal fine particulate (PM_{2.5}) and 8-hour surface-level ozone standards are more stringent than the previous standards. To reach federal Clean Air Act (CAA) deadlines over the next two decades, Southern California must significantly accelerate its pollution reduction efforts.

Continuing the Basin's progress toward clean air is a challenging task, not only to recognize and understand complex interactions between emissions and resulting air quality, but also to pursue the most effective possible set of strategies to improve air quality, maintain a healthy economy, and coordinate efforts with other key public and private partners to meet a larger set of transportation, energy and climate objectives. To ensure continued progress toward clean air and comply with state and federal requirements, the South Coast Air Quality Management District (AQMD or District) in conjunction with the California Air Resources Board (CARB), the Southern California Association of Governments (SCAG) and the U.S. Environmental Protection Agency (U.S. EPA) have prepared the Draft Final 2012 AQMP (Plan). The Plan employs the most up-to-date science and analytical tools and incorporates a comprehensive strategy aimed at controlling pollution from all sources, including stationary sources, on-road and off-road mobile sources and area sources.

The Draft Final Plan demonstrates attainment of the federal 24-hour PM_{2.5} standard by 2014 in the South Coast Air Basin (Basin) through adoption of all feasible measures. The Draft Final Plan also updates the U.S. EPA approved 8-hour ozone control plan with new measures designed to reduce reliance on the CAA Section 182 (e)(5) long-term measures for NO_x and VOC reductions.

The Draft Final 2012 AQMP also addresses several state and federal planning requirements, incorporating new scientific information, primarily in the form of updated emissions inventories, ambient measurements, and new meteorological air quality models. This Plan builds upon the approaches taken in the 2007 AQMP for the South Coast Air Basin for the attainment of federal PM and ozone standards, and highlights the

significant amount of reductions needed and the urgent need to engage in interagency coordinated planning to identify additional strategies, especially in the area of mobile sources, to meet all federal criteria pollutant standards within the timeframes allowed under federal Clean Air Act.

The Draft Final 2012 AQMP also includes an update on the air quality status of the Salton Sea Air Basin (SSAB) in the Coachella Valley, a discussion of the emerging issues of ultrafine particle and near-roadway exposures, an analysis of the energy supply and demand issues that face the Basin and their relationship to air quality. The Plan also includes a new demonstration of 1-hour ozone attainment and vehicle miles travelled (VMT) emissions offsets, as per recent U.S. EPA requirements.

This Draft Final Plan as well as other key supporting information are available electronically and can be downloaded from the District's home page on the Internet (<http://www.aqmd.gov/aqmp/2012aqmp/index.htm>).

WHY IS THIS DRAFT FINAL PLAN BEING PREPARED?

The federal Clean Air Act requires a 24-hour PM_{2.5} non-attainment area to prepare a State Implementation Plan (SIP) which must be submitted to U.S. EPA by December 14, 2012. The SIP must demonstrate attainment with the 24-hour PM_{2.5} standard by 2014, with the possibility of up to a five-year extension to 2019, if needed. U.S. EPA approval of any extension request is based on the lack of feasible control measures to move forward the attainment date by one year. The District's attainment demonstration shows that, with implementation of all feasible controls, the earliest possible attainment date is 2014, and thus no extension of the attainment date is needed.

In addition, the U.S. EPA requires that transportation conformity budgets be established based on the most recent planning assumptions (i.e., within the last five years) and approved motor vehicle emission models. The Draft Final Plan is based on the most recent assumptions provided by both CARB and SCAG for motor vehicle emissions and demographic updates and includes updated transportation conformity budgets.

IS AIR QUALITY IMPROVING?

Yes. Over the years, the air quality in the Basin has improved significantly, thanks to the comprehensive control strategies implemented to reduce pollution from mobile and stationary sources. For instance, the total number of days on which the Basin

experiences high ozone levels has decreased dramatically over the last two decades. As shown in Figure ES-1, the majority of exceedances occur in the mountains and valleys of Southwestern San Bernardino County. The maximum 8-hour ozone levels measured in the Basin were well above 200 ppb in the early 1990s, and are now less than 140 ppb. Figure ES-2 shows the long-term trend in ambient 8-hour average and 1-hour average ozone levels since 1990. However, the Basin still exceeds the federal 8-hour standard more frequently than any other location in the U.S. Under federal law, the Basin is designated as an "extreme" nonattainment area for the 8-hour ozone standard.

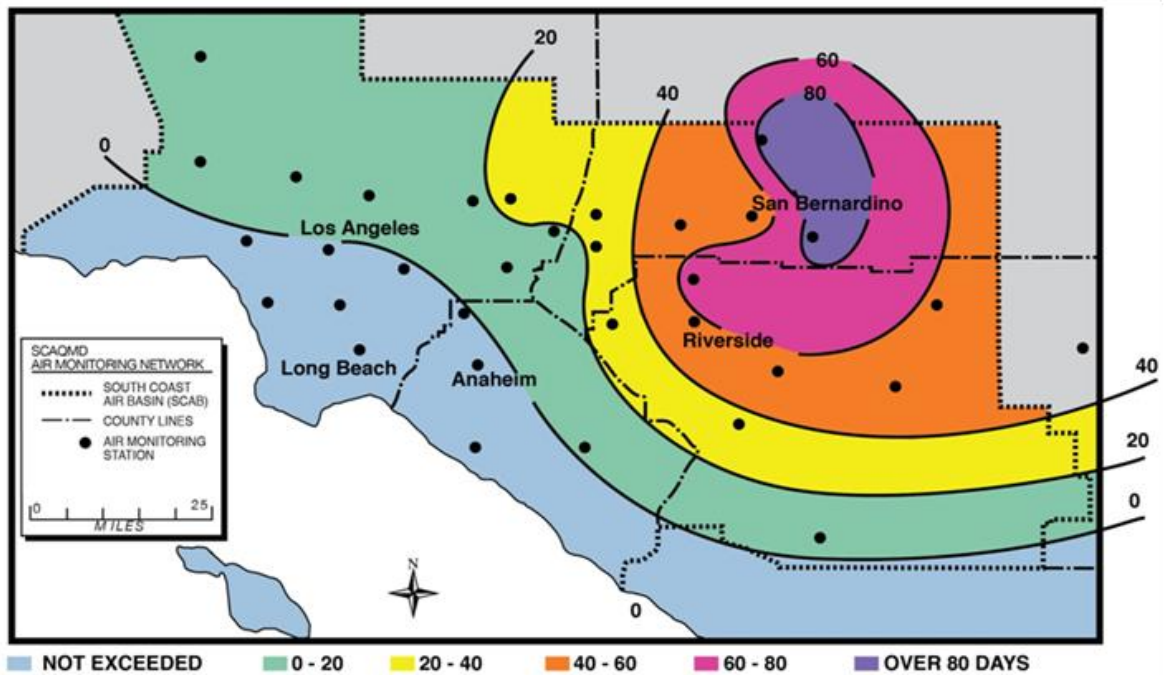

FIGURE ES-1

2011 8-Hour Ozone: Number of Days Exceeding the Current Federal Standard (8-hour average ozone > 0.075 ppm)

FIGURE ES-2

Maximum 1-Hour and 8-Hour Average Ozone Trends in the Basin

The rate of progress in improving ozone air quality has slowed for the last several years. The District has conducted extensive analysis, held technical forums, and reviewed all available scientific literature examining the issue of why progress has slowed, including the accuracy of emissions inventories, the effectiveness of control strategies, and the knowledge of photochemical processes. The overall result is that a strategy focusing primarily on NO_x reductions has been deemed the best way to achieve long-term ozone attainment objectives. However, a recurring policy question is whether another approach, such as significant VOC reductions, would be as effective at reducing ozone levels. But given that NO_x reductions are needed not only to achieve the ozone standards but also to achieve the PM_{2.5} standards, and given that a heavy VOC reduction strategy alone could not achieve the ozone standards, a NO_x-heavy control strategy is considered best. VOC reductions are, however, still needed to provide additional ozone benefits, especially in the western areas of the Basin.

Relative to the 1-hour ozone standard, which was revoked by the U.S. EPA in favor of the new 8-hour ozone standard, the past air pollution control programs have had an overall positive impact. The number of days in which the Basin exceeds the federal 1-hour ozone standard has continually declined over the years. But as seen in Figure ES-2, the rate of progress has slowed since 2000. The Basin currently still experiences ozone levels over the revoked 1-hour federal standard on approximately 5% of the days. U.S. EPA guidance has indicated that while certain planning requirements remained in effect, a new SIP would not be required if an area failed to attain the standard by the attainment date. However, recent litigation and court decisions have suggested that there is likely a need for the District to prepare a new 1-hour ozone SIP in the near future. If a 1-hour ozone SIP is requested by U.S. EPA, the SIP would be due within 12 months of such a SIP call. The attainment demonstration in the SIP would have to show attainment within 5 years with a potential 5-year extension, which would be a similar time frame as the 1997 8-hr ozone standard deadline of 2023. Based on previous modeling estimates, the control strategies that are needed to attain the 8-hour ozone standard are nearly identical to those that would be needed to attain the 1-hour ozone standard.

Both PM₁₀ and PM_{2.5} levels have improved dramatically over the past two decades. Annual average PM₁₀ concentrations have been cut in half since 1990, and likewise, annual average PM_{2.5} concentrations have been cut in half since measurements began in 1999 (Figure ES-3). The Basin has met the PM₁₀ standards at all stations and a request for re-designation to attainment is pending with U.S. EPA. In 2011, both the annual PM_{2.5} standard (15 µg/m³) and the 24-hour PM_{2.5} standard (98th percentile greater than 35 µg/m³) were exceeded at only one air monitoring station, Mira Loma, in Northwestern Riverside County (Figure ES-4). The primary focus of this Draft Final 2012 AQMP is to bring the Basin into attainment with the 24-hour PM_{2.5} standard.

FIGURE ES-3

Maximum-Site Annual Average PM10, PM2.5 Trends in the Basin

FIGURE ES-4

2011 PM_{2.5}: Annual Average Concentration Compared to the Federal Standard
(Federal standard = 15 µg/m³, annual arithmetic mean)

In 2011, the Basin did not exceed the standards for carbon monoxide, nitrogen dioxide, or sulfur dioxide¹.

Although exposure to pollution has decreased substantially in the Basin through several decades of implementing pollution controls, increases in the population over that time have made further emissions reductions more difficult. Many sources, such as automobiles and stationary sources, have been significantly controlled. However, increases in the number of sources, particularly those growing proportionately to population, can offset the potential air quality benefits of past and existing regulations. The net result is that unless additional steps are taken to further control air pollution, growth itself may begin to reverse the gains of the past decades.

¹ U.S. EPA recently revised the NO₂ and SO₂ air quality, but analysis to date shows continued compliance with these newly mandated levels.

HOW DID THE RECENT RECESSION AFFECT AIR QUALITY?

As shown above, air quality has improved over the last five years. Many factors affect air quality, including meteorological conditions, emissions, and control programs designed to reduce those emissions. The recession that began in late 2007, and continued reduced economic activity in the Basin, has also impacted pollutant emission levels. For example, goods movement activity declined by more than 20%, construction activity dropped by approximately 40%, and high fuel prices led to less vehicle miles travelled. It is difficult to determine exactly which portion of the air quality gains seen over the last five years are related to the economic downturn, but a rough estimate suggests that 15 - 20% of the recent improvements in air quality are attributable to economic factors. As the economy recovers, commercial activity will increase, and there is the potential for some emissions increases. The Draft Final 2012 AQMP utilizes the most recent economic data and projections, including data from SCAG, which include some levels of economic growth. Using these assumptions, the analysis demonstrates that air quality will continue to improve in the future, but not to the degree necessary to achieve air quality standards without additional control programs.

WHAT ARE THE MAJOR SOURCES CONTRIBUTING TO AIR QUALITY PROBLEMS?

Figure ES-5 shows the sources of NO_x, VOC, SO_x, and direct PM_{2.5} emissions for 2008. PM_{2.5} levels benefit from reductions in all four pollutants. On a per ton basis, the greatest PM_{2.5} benefit results from SO_x and direct PM_{2.5} emissions reductions. In the Basin, ozone levels benefit from both NO_x and VOC reductions.

FIGURE ES-5

Relative Contribution by Source Category to 2008 Emission Inventory
(VOC & NOx – Summer Planning; SOx, & PM2.5 – Annual Average Inventory)

WHAT IS THE OVERALL CONTROL STRATEGY IN THE 2012 AQMP?

The Draft Final 2012 AQMP outlines a comprehensive control strategy that meets the requirement for expeditious progress towards attainment with the 24-hour PM2.5 NAAQS in 2014 with all feasible control measures. The Plan also includes specific measures to further implement the ozone strategy in the 2007 AQMP to assist attaining the 8-hour ozone standard by 2023. The 2007 AQMP demonstrated attainment with the

2023 8-hour ozone standard using a provision of the federal CAA, Section 182(e)(5), that allows credit for emissions reductions from future improvements in control techniques and technologies. These “black box” emissions reductions are still needed to show attainment with the 2023 8-hour ozone NAAQS. Accordingly, these Section 182(e)(5) reductions still account for about 65% of the remaining NOx emissions reductions needed in 2023. Given the magnitude of these needed emission reductions, it is critical that the Basin maintain its continuing progress and work actively towards achieving as many specific emissions reductions as possible, and not wait until subsequent AQMPs to begin to address this looming shortfall.

As stated above, the only air monitoring station that is currently exceeding or projected to exceed the 24-hour PM2.5 standard by 2014 is Mira Loma in Western Riverside County. Consistent with U.S. EPA guidance, seasonal or episodic controls that focus on bringing the Mira Loma station into compliance can be considered as a method to bring the Basin into attainment.

The control measures contained in the Draft Final 2012 AQMP can be categorized as follows:

Basin-wide Short-term PM2.5 Measures. Measures that apply Basin-wide, have been determined to be feasible, will be implemented by the 2014 attainment date, and are required to be implemented under state and federal law. The main short-term measures are episodic, in that they only apply during high PM2.5 days and will only be implemented as needed to achieve the necessary air quality improvements.

Contingency Measures. Measures to be automatically implemented if the Basin fails to achieve the 24-hour PM2.5 standard by 2014.

8-hour Ozone Measures. Measures that provide for necessary actions to maintain progress towards meeting the 2023 8-hour ozone NAAQS, including regulatory measures, technology assessments, key investments, and incentives.

Transportation Control Measures. Measures generally designed to reduce vehicle miles travelled (VMT) as included in SCAG’s 2012 Regional Transportation Plan.

Many of the control measures proposed are not regulatory in form, but instead focus on incentives, outreach, and education to bring about emissions reductions through voluntary participation and behavioral changes needed to complement regulations.

WHY NOT REQUEST THE FULL 5-YEAR EXTENSION TO MEET THE 24-HOUR PM_{2.5} STANDARD?

The U.S. EPA deadline for meeting the 24-hour PM_{2.5} NAAQS is 2014, with a possible extension of up to five years. The extension is not automatic, and approval of an extension request will be based on a demonstration that there are no additional feasible control measures available to move up the attainment date by one year. As demonstrated in Chapter 5 of this Draft Final 2012 AQMP, with the existing control program the Basin can attain the 24-hour PM_{2.5} standard by 2019, the latest possible attainment date with a full five-year extension granted by U.S. EPA. Under the federal CAA, the Basin must achieve the federal NAAQS “as expeditiously as practicable.” Therefore, if feasible measures to advance attainment are available, they must be adopted and implemented in the SIP. With all feasible measures implemented, including the episodic controls proposed, the Basin can achieve attainment by 2014 without requesting an extension.

WHY AND HOW IS THE 8-HOUR OZONE PLAN BEING UPDATED?

Given the continuing challenge of achieving the magnitude of emissions reductions needed to meet the federal 2023 8-hour ozone deadline, this Plan updates the previous 8-hour ozone plan with new emission reduction commitments from a set of new control measures, which further implement the 2007 AQMP commitments. The 2023 deadline is fast approaching and the magnitude of needed emission reductions remains about the same as it was in the 2007 AQMP. It is not a prudent or efficient strategy to wait for future plans and controls to achieve all of these reductions when they are possible today. Thus, these Draft Final 2012 AQMP measures serve as a down payment for the much larger reductions that will be needed in future years.

Furthermore, these additional emissions reductions are needed to demonstrate attainment with the revoked 1-hour ozone standard. Due to a recent court decision, U.S. EPA has proposed to require a new 1-hour ozone attainment demonstration. The 1-hour ozone attainment strategy is essentially identical to the 8-hour ozone attainment strategy, including the updates in the Draft Final 2012 AQMP. The 1-hour ozone attainment demonstration is included as an appendix to this Plan.

The U.S. EPA approved the 8-hour ozone SIP portion of the 2007 AQMP in 2011. The submittal of the Draft Final 2012 AQMP will update certain portions of that SIP submittal. Namely, the new 8-hour ozone control measures will be submitted into the SIP with commitments for corresponding emissions reductions.

GIVEN THE CURRENT DIFFICULT AND UNCERTAIN ECONOMIC CONDITIONS, SHOULD THE DISTRICT WAIT BEFORE ADDING REFINED CONTROL COMMITMENTS INTO THE SIP?

No. The PM_{2.5} measures are required to be submitted by December 14, 2012. As for ozone, the challenges are too great, the stakes too high, and the deadlines too soon. Waiting until the last few years to try and achieve the necessary emission reductions will make the efforts more difficult, disruptive, and probably more expensive. However, the district remains sensitive to the current economic climate and the struggles that many local businesses are experiencing. That is why this Draft Final 2012 AQMP strives to identify the most cost-effective and efficient path to achieve federal clean air standards. A number of the measures proposed in the Plan are voluntary incentive and/or education programs that aim to achieve emission reductions without imposing new regulatory requirements. The episodic control approach seeks to minimize overall cost and economic impacts by focusing on the limited numbers of days and locations still experiencing the exceedances of the federal standards.

Furthermore, the effort to achieve multiple clean air goals will require significant public investments in the region over a long period of time. These investments need to be accomplished in an optimum fashion starting now. This also has the potential to create new Southern California jobs in clean technology sectors such as renewable power, energy efficiency, clean products, and advanced emissions controls. Fulfilling this unique opportunity to concentrate these clean air investments and jobs in the region where the air quality problems exist will require strong partnerships among all levels of government and business interests.

IS THE 2012 AQMP BEING COORDINATED WITH THE STATE'S GREENHOUSE GAS REDUCTION EFFORTS?

The Basin faces several ozone and PM attainment challenges, as strategies for significant emission reductions become harder to identify and the federal standards continue to become more stringent. California's Greenhouse Gas reductions targets under AB32 add new challenges and timelines that affect many of the same sources that emit criteria pollutants. In finding the most cost-effective and efficient path to meet multiple deadlines for multiple air quality and climate objectives, it is essential that an integrated planning approach is developed. Responsibilities for achieving these goals span all levels of government, and coordinated and consistent planning efforts among multiple government agencies are a key component of an integrated approach.

To this end, and concurrent with the development of the 2012 AQMP, the District, the Air Resources Board, and San Joaquin Valley Air Pollution Control District engaged in a joint effort to take a coordinated and integrated look at strategies needed to meet California's multiple air quality and climate goals, as well as its energy policies. California's success in reducing smog has largely relied on technology and fuel advances, and as health-based air quality standards are tightened, the introduction of cleaner technologies must keep pace. More broadly, a transition to zero- and near-zero emission technologies is necessary to meet 2023 and 2032 air quality standards and 2050 climate goals. Many of the same technologies will address air quality, climate and energy goals. As such, strategies developed for air quality and climate change planning should be coordinated to make the most efficient use of limited resources and the time needed to develop cleaner technologies. The product of this collaborative effort, the draft *Vision for Clean Air: A Framework for Air Quality and Climate Planning*, examines how those technologies can meet both air quality and climate goals over time. A public review draft of this document is now available at <http://www.aqmd.gov/aqmp/2012aqmp> and serves as context and a resource for the 2012 AQMP.

Cleaning the air that we breathe...

CHAPTER 1

INTRODUCTION

Purpose

Constraints in Achieving Standards

Control Efforts

Progress in Implementing the 2007 AQMP

Draft Final 2012 AQMP

Format of This Document

PURPOSE

The purpose of the 2012 Air Quality Management Plan (AQMP or Plan) for the South Coast Air Basin (Basin) is to set forth a comprehensive and integrated program that will lead the Basin into compliance with the federal 24-hour PM_{2.5} air quality standard, and to provide an update to the Basin's commitments towards meeting the federal 8-hour ozone standards. It will also serve to satisfy recent U.S. EPA requirements for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a vehicle miles travelled (VMT) emissions offset demonstration. The Plan will be submitted to the U.S. Environmental Protection Agency (U.S. EPA) as the State Implementation Plan (SIP) once it is approved by the South Coast Air Quality Management District's (AQMD or District) Governing Board and the California Air Resources Board (CARB). Specifically, the Plan will serve as the official SIP submittal for the federal 2006 24-hour PM_{2.5} standard, for which U.S. EPA has established a due date of December 14, 2012. In addition, the Plan will update specific new control measures and commitments for emissions reductions to implement the attainment strategy for the 8-hour ozone SIP and help reduce reliance on the Section 182(e)(5) long-term measures. The key federal and state planning requirements are summarized briefly later in this chapter. Given the challenges and complexities in demonstrating attainment with air quality standards, District staff believes it is important to initiate broad public dialogue on a broad range of air quality issues, to inform the public regarding the challenges ahead, and to solicit public input in an open and transparent process. This Draft Final 2012 AQMP sets forth programs which require integrated planning efforts and the cooperation of all levels of government: local, regional, state, and federal.

At the federal level, U.S. EPA is charged with establishing emission standards for on-road motor vehicles; train, airplane, and ship pollutant exhaust and fuel standards; and establishing emissions standards for non-road engines less than 175 horsepower. CARB, at the state level, also establishes on-road vehicle emission standards, fuel specifications, some off-road source requirements, and most consumer product standards. CARB is also primarily responsible for the implementation of California's greenhouse gas emission reduction program as mandated by AB 32. The strategies to achieve air quality and climate goals have significant overlap in terms of sources and control measures. When also considering other regional needs and constraints, such as energy supply, mobility, goods movement, and jobs, it is clear that an integrated and coordinated planning approach is needed to efficiently achieve multiple objectives.

Since air pollution is not constrained within city and county boundaries, it is largely a regional issue. As the regional air quality agency for Orange County and portions of Los Angeles, Riverside, and San Bernardino Counties, including the Coachella Valley, the District is responsible for stationary sources with some limited mobile source and consumer product authority. The District also has the primary responsibility for the development and adoption of the AQMP. Lastly, at the local level, the cities, counties and their various departments (e.g., harbors and airports) have a dual role related to transportation and land use. Their efforts are coordinated through the regional metropolitan planning organization (MPO) for the Basin, the Southern California Association of Governments (SCAG). Along with CARB, SCAG is the District's partner in the preparation of the AQMP, providing the latest economic forecasts and developing transportation control measures. Interagency commitment and cooperation are keys to the success of the AQMP. No one agency can design or implement the Plan alone and the strategies in the Plan reflect this fact.

CONSTRAINTS IN ACHIEVING STANDARDS

The District is faced with a number of constraints and that make achieving clean air standards a difficult challenge. These include the physical and meteorological setting, the large pollutant emissions burden of the Basin (including pollution from international goods movement), and the continued population growth of the area.

Setting

The District has jurisdiction over an area of approximately 10,743 square miles, consisting of the South Coast Air Basin, and the Riverside County portions of the Salton Sea Air Basin (SSAB) and Mojave Desert Air Basin (MDAB). The Basin, which is a subregion of the District's jurisdiction, is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. It includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley. The federal nonattainment area (known as the Coachella Valley Planning Area) is a sub-region of Riverside County and the SSAB that is bounded by the San Jacinto Mountains to the west and the eastern boundary of the Coachella Valley to the east. The Los Angeles County portion of the MDAB (known as North County or Antelope Valley) is bounded by the San Gabriel Mountains to the south and west, the Los Angeles/Kern County border to the north,

and the Los Angeles/San Bernardino County border to the east. The SSAB and MDAB were previously included in a single large basin called the Southeast Desert Air Basin (SEDAB). On May 30, 1996, CARB replaced the SEDAB with the SSAB and MDAB. In July 1997, the Antelope Valley area of MDAB was separated from the District and incorporated into a new air district under the jurisdiction of the newly formed Antelope Valley Air Pollution Control District (AVAPCD). The entire region is shown in Figure 1-1.

The Coachella Valley Planning Area is impacted by pollutant transport from the South Coast Air Basin. In addition, pollutant transport also impacts the Antelope Valley, Mojave Desert, Ventura County, and San Diego County. As part of this AQMP, an update on the status of the Coachella Valley ozone non-attainment area is also provided.

FIGURE 1-1

Boundaries of the South Coast Air Quality Management District
and Federal Planning Areas

The topography and climate of Southern California combine to make the Basin an area of high air pollution potential. During the summer months, a warm air mass frequently descends over the cool, moist marine layer produced by the interaction

between the ocean's surface and the lowest layer of the atmosphere. The warm upper layer forms a cap over the cooler surface layer which inhibits the pollutants from dispersing upward. Light winds during the summer further limit ventilation. Additionally, abundant sunlight triggers the photochemical reactions which produce ozone and the majority of particulate matter. The region experiences more days of sunlight than any other major urban area in the nation except Phoenix.

The Basin's economic base is diverse. Historically, the four counties of the Basin have collectively comprised one of the fastest-growing local economies in the United States. Significant changes have occurred in the composition of the industrial base of the region in the past twenty years. As in many areas of the country, a large segment of heavy manufacturing, including steel and tire manufacturing as well as automobile assembly, has been phased down. Due to growth in shipping and trade, small service industries and businesses have replaced much of the heavy industry.

Emission Sources

The pollution burden of the Basin is substantial. In spite of substantial reductions already achieved through effective control strategies, additional significant reductions of volatile organic compounds (VOCs), oxides of nitrogen (NO_x), sulfur oxides (SO_x), and particulate matter (PM) in the Basin are needed to attain the federal and state air quality standards.

Air pollution forms either directly or indirectly from pollutants emitted from a variety of sources. These sources can be natural, such as oil seeps, vegetation, or windblown dust, but the majority of emissions are related to human activity. Emissions result from fuel combustion sources, such as cars and trucks; from the evaporation of organic liquids, such as those used in coating and cleaning processes; and through abrasion processes, such as tires on roadways. The air pollution control strategy in the Draft Final 2012 AQMP is directed entirely at controlling man-made sources. The emission sources in the Basin are described in Chapter 3. Natural emissions are included in the air quality modeling analysis in Chapter 5.

Population

Since the end of World War II, the Basin has experienced faster population growth than the rest of the nation. Although growth has slowed somewhat, the region's population is expected to increase significantly through 2023 and beyond. Table 1-1 shows the projected growth based on SCAG's regional growth forecast.

TABLE 1-1
Population Growth

YEAR	POPULATION	AVERAGE PERCENT INCREASE PER YEAR OVER THE PERIOD
1990	13.0 million	--
2000	14.8 million	1.4
2008	15.6 million	0.7
2023 ^a	17.3 million	0.7
2030 ^a	18.1 million	0.7

^a Based on SCAG forecasts in the 2012 Regional Transportation Plan

Despite this growth, air quality has improved significantly over the years, primarily due to the impacts of the region’s air quality control program. Figure 1-2 shows the trends since 1990 in the annual average PM10 and PM2.5 concentrations. PM10 levels have declined almost 50% since 1990, and PM2.5 levels have also declined 50% since measurements began in 1999. As shown in Chapters 2 and 5, the only air monitoring station that is currently exceeding or projected to exceed the 24-hour PM2.5 standard from 2011 forward is the Mira Loma station in Western Riverside County. Figure 1-3 shows the improvements in the 1-hour ozone and 8-hour ozone levels over the same time period. Similar improvements are observed with ozone, although the rate of ozone decline has slowed in recent years.

Although exposure to pollution has decreased substantially in the Basin through several decades of implementing pollution controls, increases in the population over that time have made further emission reductions more difficult. Many sources, such as automobiles and stationary sources, have been significantly controlled. However, increases in the number of sources, particularly those growing proportionately to population, can offset the potential air quality benefits of past and existing regulations. The net result is that unless additional steps are taken to further control air pollution, growth itself may reverse the gains of the past decades.

FIGURE 1-2

Maximum Annual Average PM10, PM2.5 Trends in the Basin

FIGURE 1-3

Maximum 1-hour and 8-hour Average Ozone Trends in the Basin

The Recent Recession

The collapse in the housing and financial markets precipitated the economic recession that began in the fourth quarter of 2007. By technical economic definitions, the recession ended in the second quarter of 2009, but the economy is still being affected and recovery has been slow. Certain industries, such as housing and construction, were disproportionately affected and continue to struggle to return to pre-recessionary growth levels. While unemployment has improved since the height of the recession, it still remains above historical levels. As many businesses continue to struggle under difficult and uncertain economic conditions, the District will continue to work closely with businesses and industry groups to identify the most cost-effective and efficient path to meeting clean air goals while being sensitive to their economic concerns.

CONTROL EFFORTS

History

The seriousness of the local air pollution problem in the Basin was recognized in the early 1940s. In 1946, the Los Angeles County Board of Supervisors established the first air pollution control district in the nation to address the problems of industrial air pollution. In the mid-1950s, California established the first state agency to control motor vehicle emissions. County or regional air pollution districts were formed in California by the 1970s. Many of the control strategies originating in California became the basis for the federal control programs which began in the 1960s.

Nearly all control programs developed to date have relied on the development and application of cleaner technologies and add-on emission control devices. Emissions from industrial and vehicular sources have been significantly cut by the use of these technologies. Only recently have preventive efforts come to the forefront of the air pollution control program, including alternative materials, waste minimization, and maintenance procedures for industrial sources.

In the 1970s, it became apparent at both the state and federal levels that local programs were not enough to solve a problem that was regional in nature and was not contained within city and county jurisdictional boundaries. Instead, air basins, defined by logical geographical boundaries, became the basis for regulatory programs.

In 1976, the California Legislature adopted the Lewis Air Quality Management Act which created the South Coast Air Quality Management District from a voluntary association of air pollution control districts in Los Angeles, Orange, Riverside, and San Bernardino Counties. The new agency was charged with developing uniform plans and programs for the region to attain federal standards by the dates specified in federal law. The agency was also mandated to meet state standards by the earliest date achievable, using reasonably available control measures.

Rule development in the 1970s through 1990s resulted in dramatic improvement in Basin air quality (see Chapter 2 and Appendix II). However, the effort to impose incremental rule changes on the thousands of stationary sources through the command-and-control regulatory process began to be challenged as less economically efficient than programs taking advantage of market incentives. The 1991 AQMP introduced the concept of a Marketable Permits Program and outlined

the framework of an idea that was the forerunner to what is now known as the Regional Clean Air Incentives Market (RECLAIM). RECLAIM, a NO_x and SO_x cap-and-trade program, calls for declining mass emission limits on the total emissions from all facilities within the program and achieves cost-effective emission reductions. In addition to the implementation of RECLAIM, other statewide incentive programs such as the Carl Moyer Memorial Air Quality Standards Attainment Program (Carl Moyer Program) and the Highway Safety, Traffic reduction, Air Quality, and Port Security Bond Act of 2006 (Proposition 1B) were implemented and provide expedited reductions through accelerated fleet turnover that would otherwise have been difficult to obtain through regulatory mandates and their associated lead time for implementation.

In summary, while the region's effort to attain applicable ambient air quality standards continues to rely on the successful command-and-control regulatory structure, the strategy is supplemented, where appropriate, with market incentive and compliance flexibility strategies.

Air Quality Impact of Control Efforts

Air pollution controls have had a positive impact on the Basin's air quality relative to the now revoked 1979 federal 1-hour ozone standard. The number of days where the Basin exceeded the federal 1-hour ozone standard has continually declined over the years. However, while the number of days exceeding the federal 1-hour ozone standard has dropped since the 1990s, the rate of progress has slowed since 2000. The Basin experienced ozone levels over the revoked federal 1-hour ozone standard on 7 days in 2010, the original attainment year for the revoked 1-hour ozone standard, and the maximum recorded value exceeded the standard by nearly 20 percent.

Although past controls were primarily designed to address the federal 1-hour ozone and the PM₁₀ standards, they also benefited the more recent efforts to attain the 8-hour ozone and the PM_{2.5} standards. The 8-hour ozone levels have been reduced by half over the past 20 years, nitrogen dioxide and sulfur dioxide standards have been met, and other criteria pollutant concentrations have significantly declined. The federal and state CO standards were also met as of the end of 2002. The Basin has met the PM₁₀ standards at all stations and has requested a redesignation to attainment status. However, the Basin still experiences substantial exceedances of the 8-hour ozone standards and nominal exceedances of the PM_{2.5} standards. Air quality summaries and health effects in the Basin are discussed in Chapter 2;

Appendix II provides an in-depth analysis of air quality as measured within the District's jurisdiction.

PROGRESS IN IMPLEMENTING THE 2007 AQMP

District's Actions

The ozone portion of the 2007 AQMP has been approved by U.S. EPA into the SIP. The majority of the PM_{2.5} portion of the 2007 AQMP has also been approved by U.S. EPA, with the only exception being the failure to meet contingency measure requirements. These approvals include SIP revisions submitted in response to U.S. EPA's initial findings. The District has also submitted a SIP revision designed to meet the contingency measure requirement for the annual PM_{2.5} plan.

The District continues to implement the 2007 AQMP. Progress in implementing the 2007 AQMP can be measured by the number of control measures that have been adopted as rules and the resulting tons of pollutants targeted for reduction. Emission reduction commitments and reductions which will be achieved in 2014 and 2023 through already adopted measures are based on the emissions inventories from the 2007 AQMP. Between 2008 and 2011, twelve control measures or rules have been adopted or amended by the District. Table 1-2 lists the District's 2007 AQMP commitments and the control measures or rules that were adopted through 2011. The table is largely derived from the PM_{2.5} SIP revisions submitted to U.S. EPA in 2011, and thus emissions substitutions and other factors are included in the footnotes. As shown in Table 1-2, for the control measures adopted by the District over this period, 22.5 tons per day of VOC reductions, 7.6 tons per day of NO_x reductions, 4.0 tons per day of SO_x reductions, and 1.0 tons per day of PM_{2.5} reductions will be achieved by 2014. Additional reductions from these adopted rules will be achieved by 2023.

^(a) 2014 reductions estimated in average annual day, 2023 in planning inventory.

^(b) SIP commitment for VOC reductions in the PM2.5 Plan was met via excess reductions achieved from CTS-04 (R1143).

^(c) No SIP emission reduction commitment for the PM2.5 Plan. Rulemaking is delayed due to potential co-benefits of SB375 reduction targets.

^(d) Reduction commitment for NOx and PM2.5 reductions in the PM2.5 SIP was met via excess reductions achieved from the 2010 SOx RECLAIM amendments. The PM2.5 forming potential established in the 2007 AQMP is NOx: PM2.5:SOx=1:10:15.

NA: Not applicable, no SIP Reductions quantified in the 2007 AQMP

CARB Actions

Table 1-3 lists the 2007 AQMP's control measure commitments that have been adopted (either entirely or partially) by CARB since the 2007 AQMP was adopted. The emissions are presented in terms of remaining emissions, rather than reductions, due to some significant changes to the inventory that preclude a direct comparison of committed emissions to those achieved. The table is based on SIP revisions submitted to U.S. EPA in 2011, and thus reflect adopted measures through specific dates in 2011 as described in the footnotes. To date, CARB has achieved more than the committed 2014 emissions reductions for all pollutants for these source categories. The same is true for VOC and NO_x emissions in 2023.

- a. The 2014 emissions data reflect the 2014 Emissions Inventory that was included in the March 2011 *Progress Report on Implementation of PM2.5 State Implementation Plans*. The inventory is in the process of being updated, and may change slightly in the final AQMP draft.
- b. The 2023 emissions data tables reflect the 2023 Emissions Inventory that was current as of August 2011. The inventory is in the process of being updated, and may change slightly in the final AQMP draft.
- c. These are remaining emissions. If achieved emissions are lower than the committed emissions, it means the SIP targets are met.
- d. Remaining emissions are included in "other local, state, and federal emissions"
- e. Includes benefits of local emission reductions that were not reflected in the revised RFP estimates.

The actual emissions inventory in 2008, the base year of the Draft Final 2012 AQMP, can be compared to the previous projections for 2008 in the 2007 AQMP. As shown in Figure 1-4, actual 2008 emissions were lower than 2007 AQMP projections for VOC, NO_x, and direct PM_{2.5}. The only exception, SO_x, was due to a court ordered stay of a CARB marine vessel regulation that resulted in higher emissions of SO_x in 2008 than what was projected. However, the regulation was reinstated in 2009 and beyond, and thus SO_x emissions have been lower than projections since 2008.

FIGURE 1-4

Actual 2008 Emissions Compared with 2008 Projections in the 2007 AQMP (tpd)

U.S. EPA Actions

The U.S. EPA did not commit to SIP-creditable emissions reductions in their approval of the 2007 AQMP. However, their actions will facilitate future emissions reductions, although some with implementation timelines too late for the Basin's mandated deadlines. U.S. EPA actions taken since the 2007 AQMP include the 2008 Locomotive Rule which promulgated more stringent Tier 3 and Tier 4 emission standards; the 2009 Category 3 Marine Diesel Engine regulation for U.S. flagged ocean-going ships which established more stringent emission standards and marine fuel sulfur limits; and, along with the Canadian Government, the successful proposal to the International Maritime Organization (IMO), which will amend MARPOL Annex VI to designate most North American coastal waters as an emissions control area (ECA) for the control of SO_x, NO_x, and PM.

DRAFT FINAL 2012 AQMP

Scope

As mentioned earlier in this chapter, this 2012 AQMP is designed to address the federal 24-hour PM_{2.5} air quality standards in the Basin, to satisfy the planning requirements of the federal Clean Air Act, and to provide an update on the strategy to meet the 8-hour ozone standard. Once approved by the District Governing Board and CARB, the Draft Final 2012 AQMP will be submitted to U.S. EPA as the 24-hour PM_{2.5} SIP addressing the 2006 PM_{2.5} National Ambient Air Quality Standards (NAAQS) and as limited updates to the current 8-hour ozone SIP.

In addition, the 2012 AQMP includes a chapter on the emerging issues surrounding ultrafine particles and near-roadway exposures (Chapter 9). It also includes a chapter on energy issues within the Basin and their relationship to the region's climate and air quality challenges. A separate chapter reporting on the air quality status of the Salton Sea Air Basin (Coachella Valley) is also included. Two separate appendices serve to satisfy recent U.S. EPA requirements for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a vehicle miles travelled (VMT) emissions offset demonstration.

Approach

The U.S. EPA deadline for meeting the 24-hour PM_{2.5} NAAQS is 2014, with a possible extension of up to five years. The extension is not automatic, and approval of an extension request is based on a demonstration that there are no additional feasible control measures available to move up the attainment date by one year. However, as demonstrated in Chapter 5, with the existing control program and the new control strategy in the Draft Final 2012 AQMP, the Basin can attain the 24-hour PM_{2.5} standard by 2014. Under the federal CAA, the Basin must achieve the federal NAAQS "as expeditiously as practicable." Therefore, if feasible measures are available, they must be adopted and implemented in the SIP. Chapter 4 of the Draft Final 2012 AQMP outlines a comprehensive control strategy that meets the requirement for expeditious progress towards a 2014 attainment date for the 24-hour PM_{2.5} NAAQS. The strategy also includes specific measures and commitments to continue implementing measures that assist in attaining the 1997 8-hour ozone (80 ppb) standard by 2023. The 2007 AQMP demonstrated attainment with the 80 ppb standard using a provision of the federal CAA Section 182(e)(5) that allows credit for emissions reductions from future improvements in control techniques and

technologies. As shown in the ozone discussion in Chapter 5, these “black box” emissions reductions are still needed to show attainment with the 1997 8-hour ozone NAAQS. Accordingly, these Section 182(e)(5) reductions still account for about 65% of the remaining NOx emissions in 2023. Given the magnitude of these needed emission reductions, it is critical that the District maintain its continuing progress and work actively towards achieving as many emissions reductions as possible, and not wait until subsequent AQMPs to begin to address this looming shortfall.

The control measures contained in the Draft Final 2012 AQMP, described in Chapter 4, can be categorized as follows:

Basin-wide and Episodic Short-term PM2.5 Measures. Measures that apply Basin-wide and in some cases only episodically, have been determined to be feasible, will be implemented prior to the 2014 attainment date, and are required to be implemented under state and federal law. *Contingency Measures.* Measures to be automatically implemented if the Basin fails to achieve the 24-hour PM2.5 standard by 2014.

8-hour Ozone Implementation Measures. Measures that provide for necessary actions to meet the 1997 8-hour ozone NAAQS, including technology assessments, key investments, incentives, and rules.

Transportation Control Measures. Measures generally designed to reduce vehicle miles travelled (VMT) as included in SCAG’s 2012 Regional Transportation Plan or otherwise.

Many of the control measures proposed are not based on command and control regulations, but instead focus on incentives, outreach, and education to bring about emissions reductions through voluntary participation and behavioral changes.

Need for Integrated and Coordinated Planning

The Basin faces several ozone and PM2.5 attainment challenges as strategies for significant emission reductions become harder to identify and the federal standards continue to become more stringent. California’s greenhouse gas reductions targets under AB 32 add new challenges and timelines that affect many of the same sources that emit criteria pollutants. In finding the most cost-effective and efficient path to meet multiple deadlines for multiple air quality and climate objectives, it is best that an integrated planning approach is developed. Responsibilities for achieving these goals span all levels of government, and coordinated and consistent planning efforts among multiple government agencies are a key component of an integrated approach.

To this end and concurrent with the development of the Draft Final 2012 AQMP, the District, CARB, and San Joaquin Valley Air Pollution Control District engaged in a joint effort to take a coordinated and integrated look at strategies needed to meet California's multiple air quality and climate goals. California's success in reducing smog has largely relied on technology and fuel advances, and as health-based air quality standards are tightened, the introduction of cleaner technologies must keep pace. More broadly, a transition to zero- and near-zero emission technologies is necessary to meet 2023 and 2032 air quality standards and 2050 climate goals. Many of the same technologies will address both air quality and climate needs. As such, strategies developed for air quality and climate change planning should be coordinated to make the most efficient use of limited resources and the time needed to develop cleaner technologies. The product of this collaborative effort, the draft *Vision for Clean Air: A Framework for Air Quality and Climate Planning*, examines how those technologies can meet both air quality and climate goals over time. A public review draft of this document is now available (<http://www.aqmd.gov/aqmp/2012aqmp/VisionDocument>), and serves as context and a resource for the Draft Final 2012 AQMP.

Economic Considerations

As the Basin slowly emerges from the recession, it remains important to be cognizant of the economic impacts of control strategies in the 2012 AQMP. However, history has shown that large improvements to air quality can be achieved concurrent with periods of healthy economic growth. As shown in Figure 1-5, approximately 50% air quality improvements were realized over a time period where the Basin's population and Gross Domestic Product (GDP, inflation adjusted) increased by approximately 22% and 42%, respectively. But as many businesses continue to struggle under difficult and uncertain economic conditions, it is imperative for the District to work closely with businesses and industry groups to identify the most cost-effective and efficient path to meeting clean air goals.

Furthermore, the effort to achieve multiple clean air goals will require significant public investments in the region. This has the potential to create new Southern California jobs in clean technology sectors such as renewable power, energy efficiency, clean products, and advanced emissions controls. Fulfilling this unique opportunity to concentrate these clean air investments and jobs in the region where the air quality problems exist will require strong partnerships between all levels of government and business interests.

FIGURE 1-5

Percent Change in Air Quality Along with Demographic Data of the 4-County Region (1990-2011)

Federal CAA Planning Requirements Addressed by the Draft Final 2012 AQMP

In November 1990, Congress enacted a series of amendments to the Clean Air Act intended to intensify air pollution control efforts across the nation. One of the primary goals of the 1990 CAA Amendments was an overhaul of the planning provisions for those areas not currently meeting National Ambient Air Quality Standards. The CAA identifies specific emission reduction goals, requires both a demonstration of reasonable further progress and an attainment demonstration, and incorporates more stringent sanctions for failure to attain or to meet interim milestones.

There are several sets of general planning requirements in the federal CAA, both for nonattainment areas (Section 172(c)) and for implementation plans in general (Section 110(a) (2)). These requirements are listed and briefly described in Tables 1-4 and 1-5, respectively. The general provisions apply to all applicable pollutants unless superseded by pollutant-specific requirements. Chapter 6 of the AQMP describes how the Draft Final 2012 AQMP satisfies these CAA requirements.

TABLE 1-4

Nonattainment Plan Provisions
[CAA Section 172(c)]

REQUIREMENT	DESCRIPTION
Reasonably available control measures	Implementation of all reasonably available control measures as expeditiously as practicable.
Reasonable further progress	Provision for reasonable further progress which is defined as “such annual incremental reductions in emissions of the relevant air pollutant as are required for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date.”
Inventory	Development and periodic revision of a comprehensive, accurate, current inventory of actual emissions from all sources.
Allowable emission levels	Identification and quantification of allowable emission levels for major new or modified stationary sources.
Permits for new and modified stationary sources	Permit requirements for the construction and operation of new or modified major stationary sources.
Other measures	Inclusion of all enforceable emission limitations and control measures as may be necessary to attain the standard by the applicable attainment deadline.
Contingency measures	Implementation of contingency measures to be undertaken in the event of failure to make reasonable further progress or to attain the NAAQS.

TABLE 1-5
 General CAA Requirements for Implementation Plans
 [CAA Section 110(a)]

REQUIREMENT	DESCRIPTION
Ambient monitoring	An ambient air quality monitoring program. [Section 110(a)(2)(B)]
Enforceable emission limitations	Enforceable emission limitations or other control measures as needed to meet the requirements of the CAA. [Section 110(a)(2)(A)]
Enforcement and regulation	A program for the enforcement of adopted control measures and emission limitations and regulation of the modification and construction of any stationary source to assure that the NAAQS are achieved. [Section 110(a)(2)(C)]
Interstate transport	Adequate provisions to inhibit emissions that will contribute to nonattainment or interfere with maintenance of NAAQS or interfere with measures required to prevent significant deterioration of air quality or to protect visibility in any other state. [Section 110(a)(2)(D)]
Adequate resources	Assurances that adequate personnel, funding, and authority are available to carry out the plan. [Section 110(a)(2)(E)]
Source testing and monitoring	Requirements for emission monitoring and reporting by the source operators. [Section 110(a)(2)(F)]
Emergency authority	Ability to bring suit to enforce against source presenting imminent and substantial endangerment to public health or environment. [Section 110(a)(2)(G)]
Plan revisions	Provisions for revising the air quality plan to incorporate changes in the standards or in the availability of improved control methods. [Section 110(a)(2)(H)]
Other CAA requirements	Adequate provisions to meet applicable requirements relating to new source review, consultation, notification, and prevention of significant deterioration and visibility protection contained in other sections of the CAA. [Section 110(a)(2)(I),(J)]
Impact assessment	Appropriate air quality modeling to predict the effect of new source emissions on ambient air quality. [Section 110(a)(2)(K)]
Permit fees	Provisions requiring major stationary sources to pay fees to cover reasonable costs for reviewing and acting on permit applications and for implementing and enforcing the permit conditions. [Section 110(a)(2)(L)]
Local government participation	Provisions for consultation and participation by local political subdivisions affected by the plan. [Sections 110(a)(2)(M) & 121]

The CAA requires that most submitted plans include information on tracking plan implementation and milestone compliance. Requirements for these elements are described in Section 182(g). Chapter 4 addresses these issues.

The U.S. EPA also requires a public hearing on many of the required elements in SIP submittals before considering them officially submitted. The District's AQMP public process includes multiple public workshops and public hearings on all of the required elements prior to submittal. Chapter 11 describes the comprehensive outreach program for the Draft Final 2012 AQMP.

State Law Requirements addressed by the Draft Final 2012 AQMP

The California Clean Air Act (CCAA) was signed into law on September 30, 1988, became effective on January 1, 1989, and was amended in 1992. Also known as the Sher Bill (AB 2595), the CCAA established a legal mandate to achieve health-based state air quality standards at the earliest practicable date. The Lewis Presley Act provides that the District's plan must also contain deadlines for compliance with all state ambient air quality standards and the federally mandated primary ambient air quality standards (Health and Safety Code (H&SC) 40462(a)). In September 1996, AB 3048 (Olberg) amended Sections 40716, 40717.5, 40914, 40916, 40918, 40919, 40920, 40920.5, and 44241, and repealed Sections 40457, 40717.1, 40925, and 44246 of the Health and Safety Code relating to air pollution. The amendments to the Health and Safety Code became effective January 1, 1997. Chapter 6 describes how the Draft Final 2012 AQMP meets the state planning requirements under the CCAA, including plan effectiveness, emissions reductions of 5% per year or adoption of all feasible measures, reducing population exposure, and control measure ranking by cost-effectiveness. While these requirements do not specifically apply to PM_{2.5}, they provide useful benchmarks.

FORMAT OF THIS DOCUMENT

This document is organized into eleven chapters, each addressing a specific topic. Each of the remaining chapters is summarized below.

Chapter 2, "Air Quality and Health Effects," discusses the Basin's current air quality in comparison with federal and state air pollution standards.

Chapter 3, "Base Year and Future Emissions," summarizes recent updates to the emissions inventories, estimates current emissions by source and pollutant, and projects future emissions with and without growth.

Chapter 4, "Control Strategy and Implementation," presents the control strategy, specific measures, and implementation schedules to attain the air quality standards by the specified attainment dates.

Chapter 5, “Future Air Quality,” describes the modeling approach used in the AQMP and summarizes the Basin’s future air quality projections with and without controls.

Chapter 6, “Federal and State Clean Air Act Requirements,” discusses specific federal and state requirements as they pertain to the Draft Final 2012 AQMP.

Chapter 7, “Current and Future Air Quality – Desert Nonattainment Areas,” describes the air quality status of the Coachella Valley, including emissions inventories, designations, and current and future air quality.

Chapter 8, “Looking Beyond Current Requirements,” assesses the Basin’s status with respect to the recently proposed lowering of the annual PM_{2.5} standard from 15 ug/m³ to 12-13 ug/m³, as well as potential new ozone standards under consideration.

Chapter 9, “Near-Roadway Exposure and Ultrafine Particles,” examines the emerging issue of near-roadway exposure and health impacts, including a focus on ultrafine particles, research needs and potential future actions.

Chapter 10, “Energy and Climate” provides a description of current and projected energy demand and supply issues in the Basin and their relationship to air quality improvement and greenhouse gas mitigation goals.

Chapter 11, “Public Process and Participation” describes the District’s public outreach effort associated with the development of the Draft Final 2012 AQMP.

A “Glossary” is provided at the end of the document, presenting definitions of commonly used terms found in the Draft Final 2012 AQMP.

Air Quality and Health Effects

South Coast Air Quality Management District
Cleaning the air that we breathe...

CHAPTER 2

AIR QUALITY AND HEALTH EFFECTS

Introduction

Ambient Air Quality Standards

Current Air Quality

Comparison to Other U.S. Areas

Summary

INTRODUCTION

In this chapter, air quality is summarized for the year 2011, along with prior year trends, in both the South Coast Air Basin (Basin) and the Riverside County portion of the Salton Sea Air Basin (SSAB), primarily the Coachella Valley, as monitored by the South Coast Air Quality Management District (District). The District's 2011 air quality is compared to national ambient air quality standards (NAAQS). Nationwide air quality data for 2011 is also briefly summarized in this chapter, comparing air quality in the Basin to that of other U.S. and California urban areas. Health effects of the criteria air pollutants, that is, those that have NAAQS, are also discussed. More detailed information on the health effects of air pollution can be found in Appendix I: Health Effects.

Statistics presented in this chapter indicate the current attainment or non-attainment status of the various NAAQS for the criteria pollutants to assist the District in planning for future attainment. For ozone (O₃) and fine particulate matter (PM_{2.5}, particles less than 2.5 microns in diameter), the main pollutants for which the U.S. EPA has declared the Basin to be a nonattainment area, maps are included to spatially compare the air quality throughout the Basin in 2011. The Los Angeles County portion of the Basin is also currently a nonattainment area for the federal lead (Pb) standard due to source-specific monitoring, but Pb air quality data and attainment has been addressed separately in greater detail in the 2012 Lead SIP for Los Angeles County. The Basin is a nonattainment area for the federal PM₁₀ (particulates less than 10 microns in diameter) standard, although a request to U.S. EPA to redesignate to attainment is pending. The Coachella Valley is currently declared a nonattainment area for both ozone and PM₁₀ by U.S. EPA, although a request to redesignate to attainment for PM₁₀ is pending. Appendix II: Current Air Quality provides additional information on current air quality and air quality trends, changes in the NAAQS, the impact on the District's attainment status for different pollutants, and air quality compared to state standards, as well as more information on specific monitoring station data.

There were some minor changes to the AQMD monitoring network since the 2007 AQMP, which included air quality data through 2005. New stations were added at South Long Beach, close to the Ports of Los Angeles and Long Beach, and at Temecula in southern Riverside County. In addition, the extent and frequency of PM_{2.5} monitoring has been increased throughout the District.

AMBIENT AIR QUALITY STANDARDS

Federal and State Standards

Ambient air quality standards for ozone (O₃), carbon monoxide (CO), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), particulate matter (PM₁₀ and PM_{2.5}), and lead (Pb) have been set by both the State of California and the federal government. The state has also set standards for sulfates (SO₄²⁻) and visibility. The state and federal ambient air quality standards for each of the criteria pollutants and their effects on health are summarized in Table 2-1.

Several changes to the NAAQS have occurred since the last AQMP update in 2007. The federal 1-hour ozone standard was revoked by the U.S. EPA and replaced by the 8-hour average ozone standard, effective June 15, 2005. However, the Basin and the former Southeast Desert Modified Air Quality Management Area (which included the Coachella Valley) had not attained the 1-hour federal ozone NAAQS by the attainment date and have some continuing obligations under the former standard. The 8-hour ozone NAAQS was subsequently lowered from 0.08 to 0.075 ppm, effective May 27, 2008. However, the SIP submittal for this standard is not due until 2015. In 2010, U.S. EPA proposed to lower the 8-hour ozone NAAQS again and solicited comments on a proposed standard between 0.060 and 0.070 ppm. To date, U.S. EPA has not taken final action on a lower ozone standard and the NAAQS currently remains at 0.075 ppm, as established in 2008. Statistics presented in this chapter refer to the most current 2008 8-hour ozone standard (0.075 ppm) and the former 1979 1-hour ozone standard for purposes of historical comparison.

U.S. EPA revoked the annual PM₁₀ NAAQS (50 µg/m³) and lowered the 24-hour PM_{2.5} NAAQS from 65 µg/m³ to 35 µg/m³, effective December 17, 2006. On June 14, 2012, U.S. EPA proposed to strengthen the annual PM_{2.5} federal standard from 15 µg/m³ to a proposed range between 12 and 13 µg/m³. U.S. EPA also proposed to require near-roadway PM_{2.5} monitoring. Final action on the proposed PM_{2.5} standards is expected by December 14, 2012.

The national standard for Pb was revised on October 15, 2008 to a rolling 3-month average of 0.15 µg/m³, from a quarterly average of 1.5 µg/m³. Most recently, U.S. EPA established a new 1-hour NO₂ federal standard of 0.100 ppm, effective April 7, 2010, and revised the SO₂ federal standard by establishing a new 1-hour standard of 0.075 ppm and revoking the annual (0.03 ppm) and 24-hour (0.14 ppm) standards, effective August 2, 2010.

TABLE 2-1
Current Ambient Air Quality Standards and Health Effects

AIR POLLUTANT	STATE STANDARD	FEDERAL STANDARD (NAAQS)	RELEVANT HEALTH EFFECTS [#]
	Concentration, Averaging Time	Concentration, Averaging Time	
Ozone (O₃)	0.09 ppm, 1-Hour 0.070 ppm, 8-Hour	0.075 ppm, 8-Hour (2008) 0.08 ppm, 8-Hour (1997)	(a) Pulmonary function decrements and localized lung edema in humans and animals; (b) Risk to public health implied by alterations in pulmonary morphology and host defense in animals; (c) Increased mortality risk; (d) Risk to public health implied by altered connective tissue metabolism and altered pulmonary morphology in animals after long-term exposures and pulmonary function decrements in chronically exposed humans; (e) Vegetation damage; (f) Property damage
Carbon Monoxide (CO)	20 ppm, 1-Hour 9.0 ppm, 8-Hour	35 ppm, 1-Hour 9 ppm, 8-Hour	(a) Aggravation of angina pectoris and other aspects of coronary heart disease; (b) Decreased exercise tolerance in persons with peripheral vascular disease and lung disease; (c) Impairment of central nervous system functions; (d) Possible increased risk to fetuses
Nitrogen Dioxide (NO₂)	0.18 ppm, 1-Hour 0.030 ppm, Annual	100 ppb, 1-Hour 0.053 ppm, Annual	(a) Potential to aggravate chronic respiratory disease and respiratory symptoms in sensitive groups; (b) Risk to public health implied by pulmonary and extra-pulmonary biochemical and cellular changes and pulmonary structural changes; (c) Contribution to atmospheric discoloration
Sulfur Dioxide (SO₂)	0.25 ppm, 1-Hour 0.04 ppm, 24-Hour	75 ppb, 1-Hour	Bronchoconstriction accompanied by symptoms which may include wheezing, shortness of breath, and chest tightness during exercise or physical activity in persons with asthma
Suspended Particulate Matter (PM₁₀)	50 µg/m ³ , 24-Hour 20 µg/m ³ , Annual	150 µg/m ³ , 24-Hour	(a) Exacerbation of symptoms in sensitive patients with respiratory or cardiovascular disease; (b) Decline in pulmonary function or growth in children; (c) Increased risk of premature death
Suspended Particulate Matter (PM_{2.5})	12.0 µg/m ³ , Annual	35 µg/m ³ , 24-Hour 15.0 µg/m ³ , Annual	
Sulfates-PM₁₀ (SO₄²⁻)	25 µg/m ³ , 24-Hour	N/A	(a) Decrease in lung function; (b) Aggravation of asthmatic symptoms; (c) Aggravation of cardio-pulmonary disease; (d) Vegetation damage; (e) Degradation of visibility; (f) Property damage
Lead (Pb)	1.5 µg/m ³ , 30-day	0.15 µg/m ³ , 3-month rolling	(a) Learning disabilities; (b) Impairment of blood formation and nerve conduction
Visibility-Reducing Particles	In sufficient amount such that the extinction coefficient is greater than 0.23 inverse kilometers at relative humidity less than 70 percent, 8-hour average (10am - 6pm)	N/A	Visibility impairment on days when relative humidity is less than 70 percent

ppm – parts per million by volume ppb – parts per billion by volume
 State standards are “not-to-exceed” values; Federal standards follow the design value form of the NAAQS
[#] More detailed health effect information can be found in the 2012 AQMP Appendix I or the U.S. EPA NAAQS documentation at <http://www.epa.gov/ttn/naaqs/>

U.S. EPA allows certain air quality data to be flagged in the U.S. EPA Air Quality System (AQS) database and not considered for NAAQS attainment status when that data is influenced by exceptional events, such as high winds, wildfires, volcanoes, or some cultural events (Independence Day fireworks) that meet strict requirements. For a few PM measurements in the Basin in 2007 and 2008, the District applied the U.S. EPA Exceptional Events Rule to flag PM₁₀ and PM_{2.5} data due to high wind natural events, wildfires and Independence Day fireworks (the District has submitted the required documentation and U.S. EPA concurrence with these flags is pending). In the Coachella Valley, PM₁₀ data has been flagged for high wind natural events, under the current Exceptional Events Rule and the previous U.S. EPA Natural Events Policy¹. All of the exceptional event flags through 2011 have been submitted by the District to U.S. EPA's AQS along with the data. The most recent of these are pending submittal of the District's final documentation for each event and all are pending U.S. EPA concurrence. The pending PM₁₀ redesignation request for the Coachella Valley may hinge on U.S. EPA's concurrence with the exceptional event flags and the appropriate treatment of these uncontrollable natural events.

In this chapter and in Appendix II, air quality statistics are presented for the maximum concentrations measured at stations or in air basins, as well as for the number of days exceeding state or federal standards. These statistics are instructive in regards to trends and control effectiveness. However, it should be noted that an exceedance of the concentration level of a federal standard does not necessarily mean that the NAAQS was violated or that it would cause a nonattainment designation. The form of the standard must also be considered. For example, for 24-hour PM_{2.5}, the form of the standard is the 98th percentile measurement of all of the 24-hour PM_{2.5} samples at each station. For 8-hour ozone, the form of the standard is the 4th highest measured 8-hour average concentration at each station. For NAAQS attainment/nonattainment decisions, the most recent 3 years of data are considered (1 year for CO and 24-hour SO₂), along with the form of the standard, and are typically averaged to calculate a *design value*² for each station. The overall design value for an air basin is the highest

¹ The U.S. EPA Exceptional Events Rule, *Treatment of Data Influence by Exceptional Events*, became effective May 21, 2007. The previous U.S. EPA *Natural Events Policy* for Particulate Matter was issued May 30, 1996. On July 6, 2012, U.S. EPA released the *Draft Guidance To Implement Requirements for the Treatment of Air Quality Monitoring Data Influenced by Exceptional Events* for public comment.

² A design value is a statistic that describes the air quality status of a given area relative to the level and form of the National Ambient Air Quality Standards (NAAQS). For most criteria pollutants, the design value is a 3-year average and takes into account the form of the short-term standard (e.g., 98th percentile, fourth high value, etc.) Design values are especially helpful when the standard is exceedance-based (e.g. 1-hour ozone, 24-hour PM₁₀, etc.) because they are expressed as a concentration instead of an exceedance count, thereby allowing a direct comparison to the level of the standard.

design value of all the stations in that basin. Table 2-2 shows the NAAQS, along with the design value and form of each federal standard.

TABLE 2-2

National Ambient Air Quality Standards (NAAQS) and Design Value Requirements

POLLUTANT	AVERAGING TIME	STANDARD LEVEL	DESIGN VALUES AND FORM OF STANDARDS*
Ozone (O₃)	1-Hour** (1979)	0.12 ppm	Not to be exceeded more than once per year averaged over 3 years
	8-Hour** (1997)	0.08 ppm	Annual fourth highest 8-hour average concentration, averaged over 3 years
	8-Hour (2008)	0.075 ppm	Annual fourth highest 8-hour average concentration, averaged over 3 years
Carbon Monoxide (CO)	1-Hour	35 ppm	Not to be exceeded more than once a year
	8-Hour	9 ppm	
Nitrogen Dioxide (NO₂)	1-Hour	100 ppb	3-year avg. of the annual 98 th percentile of the daily maximum 1-hour average concentrations (rounded)
	Annual	0.053 ppm	Annual avg. concentration, averaged over 3 years
Sulfur Dioxide (SO₂)	1-Hour	75 ppb	99 th percentile of 1-hour daily maximum concentrations, averaged over 3 years
	24-Hour [#]	0.14 ppm	Not to be exceeded more than once per year
	Annual [#]	0.03 ppm	Annual arithmetic average
Particulate Matter (PM₁₀)	24-Hour	150 µg/m ³	Not to be exceeded more than once per year averaged over 3 years
	Annual**	50 µg/m ³	Annual average concentration, averaged over 3 years
Particulate Matter (PM_{2.5})	24-Hour	35 µg/m ³	3-year average of the annual 98 th percentile of daily 24-hour concentration
	Annual	15.0 µg/m ³	Annual avg. concentration, averaged over 3 years
Lead (Pb)	3-Month Rolling ^{###}	0.15 µg/m ³	Highest rolling 3-month average of the 3 years

* Standard is attained when the design value (form of concentration listed) is equal to or less than the NAAQS; for pollutants with the design values based on “exceedances” (1-hour O₃, 24-hour PM₁₀, CO, and 24-hour SO₂), the NAAQS is attained when the concentration associated with the design value is less than or equal to the standard:

- For 1-hour O₃ and 24-hour PM₁₀, the standard is attained when the 4th highest daily concentrations of the 3-year period is less than or equal to the standard
- For CO and 24-hour SO₂, the standard is attained when the 2nd highest daily concentration of the most recent year is equal to or less than the standard

** Standard is revoked or revised. For 1-hour O₃, nonattainment areas have some continuing obligations under the former 1979 standard. For 8-hour O₃, standard is lowered from (0.08 ppm to 0.075 ppm), but the 1997 O₃ standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA

Annual and 24-hour SO₂ NAAQS will be revoked one year from attainment designations for the new (2010) 1-hour SO₂ standard

3-month rolling averages of the first year (of the three year period) include November and December monthly averages of the prior year. The 3-month average is based on the average of “monthly” averages

NAAQS Attainment Status

Figure 2-1 shows the South Coast and Coachella Valley 3-year design values (2009-2011) for ozone and PM2.5, as a percentage of the corresponding federal standards. The current status of NAAQS attainment for the criteria pollutants is presented in Table 2-3 for the Basin and in Table 2-4 for the Riverside County portion of the SSAB (Coachella Valley).

FIGURE 2-1

South Coast Air Basin and Coachella Valley 3-Year (2009-2011) Design Values
(Percentage of Federal Standards, by Criteria Pollutant)

TABLE 2-3National Ambient Air Quality Standards (NAAQS) Attainment Status
South Coast Air Basin

CRITERIA POLLUTANT	AVERAGING TIME	DESIGNATION ^{a)}	ATTAINMENT DATE ^{b)}
1979 1-Hour Ozone^{c)}	1-Hour (0.12 ppm)	Nonattainment (Extreme)	11/15/2010 (not attained) ^{c)}
1997 8-Hour Ozone^{d)}	8-Hour (0.08 ppm)	Nonattainment (Extreme)	6/15/2024
2008 8-Hour Ozone	8-Hour (0.075 ppm)	Nonattainment (Extreme)	12/31/2032
CO	1-Hour (35 ppm) 8-Hour (9 ppm)	Attainment (Maintenance)	6/11/2007 (attained)
NO₂^{e)}	1-Hour (100 ppb)	Unclassifiable/Attainment	Attained
	Annual (0.053 ppm)	Attainment (Maintenance)	9/22/1998
SO₂^{f)}	1-Hour (75 ppb)	Designations Pending	Pending
	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	3/19/1979 (attained)
PM10	24-hour (150 µg/m ³)	Nonattainment (Serious) ^{g)}	12/31/2006 (redesignation request submitted) ^{g)}
PM2.5	24-Hour (35 µg/m ³)	Nonattainment	12/14/2014 ^{h)}
	Annual (15.0 µg/m ³)	Nonattainment	4/5/2015
Lead	3-Months Rolling (0.15 µg/m ³)	Nonattainment (Partial) ⁱ⁾	12/31/2015

a) U.S. EPA often only declares Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable

b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration

c) 1-hour O₃ standard (0.12 ppm) was revoked, effective June 15, 2005; however, the Basin has not attained this standard based on 2008-2010 data and has some continuing obligations under the former standard

d) 1997 8-hour O₃ standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the 1997 O₃ standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA

e) New NO₂ 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO₂ standard retained

f) The 1971 annual and 24-hour SO₂ standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO₂ 1-hour standard. Area designations are expected in 2012, with Basin designated Unclassifiable /Attainment

g) Annual PM10 standard was revoked, effective December 18, 2006; redesignation request to Attainment of the 24-hour PM10 standard is pending with U.S. EPA

h) Attainment deadline for the 2006 24-Hour PM2.5 NAAQS is December 14, 2014

i) Partial Nonattainment designation – Los Angeles County portion of Basin only

TABLE 2-4

National Ambient Air Quality Standards (NAAQS) Attainment Status
Coachella Valley Portion of the Salton Sea Air Basin

CRITERIA POLLUTANT	AVERAGING TIME	DESIGNATION ^{a)}	ATTAINMENT DATE ^{b)}
1979 1-Hour Ozone ^{c)}	1-Hour (0.12 ppm)	Nonattainment (Severe-17)	11/15/2007 (not timely attained ^{e)})
1997 8-Hour Ozone ^{d)}	8-Hour (0.08 ppm)	Nonattainment (Severe-15)	6/15/2019
2008 8-Hour Ozone	8-Hour (0.075 ppm)	Nonattainment (Severe-15)	12/31/2027
CO	1-Hour (35 ppm) 8-Hour (9 ppm)	Unclassifiable/Attainment	Attained
NO₂ ^{e)}	1-Hour (100 ppb)	Unclassifiable/Attainment	Attained
	Annual (0.053 ppm)	Unclassifiable/Attainment	Attained
SO₂ ^{f)}	1-Hour (75 ppb)	Designations Pending	Pending
	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	Attained
PM10	24-hour (150 µg/m ³)	Nonattainment (Serious) ^{g)}	12/31/2006 (redesignation request submitted) ^{g)}
PM2.5	24-Hour (35 µg/m ³) Annual (15.0 µg/m ³)	Unclassifiable/Attainment	Attained
Lead	3-Months Rolling (0.15 µg/m ³)	Unclassifiable/Attainment	Attained

- a) U.S. EPA often only declares Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable
- b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration
- c) 1-hour O₃ standard (0.13 ppm) was revoked, effective June 15, 2005; the Southeast Desert Modified Air Quality Management Area, including the Coachella Valley, has not attained this standard based on 2005-2007 data and has some continuing obligations under the former standard (latest 2009-2011 data shows attainment)
- d) 1997 8-hour O₃ standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the 1997 O₃ standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA
- e) New NO₂ 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO₂ standard retained
- f) The 1971 Annual and 24-hour SO₂ standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO₂ 1-hour standard. Area designations expected in 2012 with SSAB designated Unclassifiable /Attainment
- g) Annual PM10 standard was revoked, effective December 18, 2006; redesignation request to Attainment of the 24-hour PM10 standard is pending with U.S. EPA

In 2011, the Basin exceeded federal standards for either ozone or PM_{2.5} at one or more locations on a total of 124 days, based on the current federal standards for 8-hour ozone and 24-hour PM_{2.5}. Despite substantial improvement in air quality over the past few decades, some air monitoring stations in the Basin still exceed the NAAQS for ozone more frequently than any other stations in the U.S. In 2011, three of the top five stations in the nation most frequently exceeding the 8-hour federal ozone NAAQS were located within the Basin (i.e., Central San Bernardino Mountains, East San Bernardino Valley and Metropolitan Riverside County). In the year 2011, the former 1-hour³ and current 8-hour average federal standard levels for ozone were exceeded at one or more Basin locations on 16 and 106 days, respectively.

PM_{2.5} in the Basin has improved significantly in recent years, with 2010 and 2011 being the cleanest years on record. In 2011, only one station in the Basin (Metropolitan Riverside County at Mira Loma) exceeded the annual PM_{2.5} NAAQS and the 98th percentile form of the 24-hour PM_{2.5} NAAQS, as well as the 3-year design values for these standards. (Although other stations had 24-hour averages exceeding the federal 24-hour PM_{2.5} standard concentration level in 2011, the 98th percentile concentration did not exceed.) Basin-wide, the federal PM_{2.5} 24-hour standard level was exceeded in 2011 on 17 sampling days⁴.

The Basin and the Coachella Valley have technically met the PM₁₀ NAAQS and redesignation for attainment for the federal PM₁₀ standard has been requested for both. These requests are still pending with U.S. EPA at this time⁵.

The District is currently in attainment for the federal standards for SO₂, CO, and NO₂. While the concentration level of the new 1-hour NO₂ federal standard (100 ppb) was exceeded in the Basin at two stations (Central Los Angeles and Long Beach, on the same day) in 2011, the NAAQS NO₂ design value has not been exceeded (the 3-year average of the annual 98th percentile of the daily 1-hour maximums). Therefore, the Basin remains in attainment of the NO₂ NAAQS. U.S. EPA requirements for future

³ The federal 1-hour O₃ NAAQS has been revoked by U.S. EPA, although certain nonattainment areas, including the Basin, may be still required to demonstrate attainment of that standard based on recent court decisions.

⁴ The number of PM exceedances may have been higher at some locations, since PM_{2.5} samples are collected every 3 days at most sites. However, seven sites sample every day, including the Basin maximum concentration stations. PM₁₀ filter samples are collected every 6 days, except at the design value maximum sites in the Basin and the Coachella Valley at which samples are collected every 3 days. Daily PM₁₀ data for the Basin maximum stations is provided by supplementing the filter measurements with Federal Equivalent Method (FEM) continuous monitors. The gaseous pollutants, including O₃, NO₂, SO₂, and CO, are sampled continuously.

⁵ U.S. EPA has requested additional PM₁₀ monitoring in the southeastern Coachella Valley for a 1-year period to further assess windblown dust in that area. This project is currently ongoing.

near-road NO₂ measurements are not a part of the current ambient NO₂ NAAQS determinations.

U.S. EPA designated the Los Angeles County portion of the Basin (excluding the high desert areas, and San Clemente and Santa Catalina Islands) as nonattainment for the recently revised (2008) federal lead standard (0.15 µg/m³, rolling 3-month average), due to the addition of source-specific monitoring under the new federal regulation. This designation was based on two source-specific monitors in Vernon and in the City of Industry exceeding the new standard in the 2007-2009 period of data used. For the most recent 2009-2011 data period, only one of these stations (Vernon) still exceeded the lead standard, with a maximum 3-month rolling average of 0.67 µg/m³ occurring in 2009. In 2011, the rolling 3-month average at that site was 0.46 µg/m³.

The remainder of the Basin, outside the Los Angeles County nonattainment area, and the Coachella Valley remain in attainment of the new standard and no ambient monitors that are not source-oriented exceed. For areas in attainment of the old 1978 standard (1.5 µg/m³, as a quarterly average), the 1978 lead standard remained in effect until one year after an area was designated for the 2008 standard. While the entire Basin and the Coachella Valley have remained in attainment of the 1978 lead standard, U.S. EPA's current lead designations for the new standard became effective on December 31, 2010; thus, the old standard is now superseded by the 2008 revised NAAQS. A separate SIP revision addressing the 2008 lead standard has been submitted to U.S. EPA.

CURRENT AIR QUALITY

In 2011, O₃, PM_{2.5}, NO₂ and Pb exceeded federal standard concentration levels at one or more of the routine monitoring stations in the Basin. An exceedance of the concentration level does not necessarily mean a violation of the NAAQS, given that the form of the standard must be considered. For example, the Basin did not violate the federal NO₂ standard, based on the form of the standard. Ozone and PM₁₀ concentrations exceeded the federal standard concentration levels in the Coachella Valley.

The PM_{2.5} 2011 maximum 24-hour average (94.6 µg/m³, measured in the East San Gabriel Valley area) and annual average (15.3 µg/m³, measured in the Metropolitan Riverside County area) concentrations were 266 and 101 percent of the federal 24-hour and annual average standard concentration levels, respectively. The highest 24-

hour PM_{2.5} concentration in the Basin, mentioned above, was recorded on July 5, 2011, associated with Independence Day firework activities and has been flagged in the U.S. EPA Air Quality System (AQS) database for exclusion for NAAQS compliance consideration according to the U.S. EPA Exceptional Event Rule. The next highest 24-hour average PM_{2.5} concentration was 65 µg/m³ recorded in Central San Bernardino Valley. The PM_{2.5} federal standard was nearly exceeded on one day in the Coachella Valley, during an exceptional event in which dust was entrained by outflow from a large summertime thunderstorm complex over Arizona and Mexico, transporting high concentrations of PM₁₀ and PM_{2.5} into the Coachella Valley. None of these three stations with the highest 24-hour average PM_{2.5} concentrations had 98th percentile concentrations exceeding the standard. Only the Metropolitan Riverside County (Mira Loma) station had a 98th percentile concentration over the 24-hour federal standard.

The 2011 maximum PM₁₀ 24-hour average concentration measured in the South Coast Air Basin was 152 µg/m³ in the Metropolitan Riverside County area, nearly 100% of the federal standard (but not exceeding it, since a concentration of 155 µg/m³ is needed to exceed the PM₁₀ standard). This maximum 24-hour average concentration was measured with a Federal Equivalent Method (FEM) continuous monitor. The highest 24-hour PM₁₀ concentration in the Basin measured with the Federal Reference Method (FRM) filter sampler was 84 µg/m³ recorded in Central San Bernardino Valley, 56 percent of the standard. The maximum annual average PM₁₀ concentration (42.3 µg/m³ in the Metropolitan Riverside County area) is 85 percent of the former (now revoked) federal annual average standard level. The two routine AQMD monitoring stations in the Coachella Valley exceeded the 24-hour PM₁₀ federal standard on two days, both related to windblown dust generated by thunderstorm activity. These two days have been flagged by the District in the U.S. EPA AQS database for consideration under the Exceptional Event Rule.

The 2011 maximum ozone concentrations continued to exceed federal standards by wide margins. Maximum 1-hour and 8-hour average ozone concentrations (0.160 ppm and 0.136 ppm, both recorded in the Central San Bernardino Mountains area) were 128 and 181 percent of the former 1-hour and current 8-hour federal standards, respectively. The Coachella Valley did not exceed the former 1-hour federal standard in 2011, but the maximum 8-hour concentration (0.098 ppm) was 130 percent of the current federal standard.

The maximum 1-hour average NO₂ concentration in 2011 (110 ppb, measured in Central Los Angeles) was 109 percent of the federal standard, exceeding the

concentration level, but not the 98th percentile form of the NAAQS. Lead concentrations in 2011 were well below the recently (2008) revised federal standard at all ambient monitoring sites not located near lead sources. However, the source-specific monitoring site immediately downwind of a stationary lead source in the City of Vernon recorded a maximum 3-month rolling average of 0.46 $\mu\text{g}/\text{m}^3$, or 297 percent of the standard. Concentrations of other criteria pollutants (SO_2 and CO) remained well below the federal standards.

Figure 2-2 shows the trend of maximum pollutant concentrations in the Basin for the past two decades, as percentages of the corresponding federal standards. Most pollutants show significant improvement over the years, with PM2.5 showing the most dramatic decrease. Again, these are maximum concentrations and actual attainment of the standards is based on the design value.

FIGURE 2-2

Trends of South Coast Air Basin Maximum Pollutant Concentrations (Percentages of Federal Standards)

Particulate Matter (PM_{2.5} and PM₁₀) Specific Information

Health Effects, Particulate Matter

A significant body of peer-reviewed scientific research, including studies conducted in Southern California, points to adverse impacts of particulate matter air pollution on both increased illness (morbidity) and increased death rates (mortality). The 2009 U.S. EPA *Integrated Science Assessment for Particulate Matter*⁶ describes these health effects and discusses the state of the scientific knowledge. A summary of health effects information and additional references can also be found in the 2012 AQMP, Appendix I.

There was considerable controversy and debate surrounding the review of particulate matter health effects and the consideration of ambient air quality standards when U.S. EPA promulgated the initial PM_{2.5} standards in 1997⁷. Since that time, numerous additional studies have been published⁸. In addition, some of the key studies supporting the 1997 standards were closely scrutinized and the analyses repeated and extended. These reanalyses confirmed the initial findings associating adverse health effects with PM exposures.

Several studies have found correlations between elevated ambient particulate matter levels and an increase in mortality rates, respiratory infections, number and severity of asthma attacks, and the number of hospital admissions in different parts of the United States and in various areas around the world. In recent years, studies have reported an association between long-term exposure to PM_{2.5} and increased mortality, reduction in life-span, and an increased mortality from lung cancer.

Daily fluctuations in PM_{2.5} concentration levels have also been related to increased mortality due to cardiovascular or respiratory diseases, hospital admissions for acute respiratory conditions, school and kindergarten absences, a decrease in respiratory function in normal children, and increased medication use in children and adults with asthma. Long-term exposure to PM has been found to be associated with reduced lung function growth in children. The elderly, people with pre-existing respiratory

and/or cardiovascular disease, and children appear to be more susceptible to the effects of PM10 and PM2.5.

The U.S. EPA, in its most recent review, has concluded that long term exposure to PM2.5 is causally related to increases in mortality rates. Despite this, skepticism remains among some quarters whether exposures to PM2.5 in California are responsible for increases in mortality.⁹ An expanded discussion of studies relating to PM exposures and mortality is contained in Appendix I of this document.

Air Quality, PM2.5

The District began regular monitoring of PM2.5 in 1999 following the U.S. EPA's adoption of the national PM2.5 standards in 1997. In 2011, PM2.5 concentrations were monitored at 21 locations throughout the District, 20 of which had filter-based FRM monitoring sites while one had only continuous monitoring. Six sites had collocated, continuous monitoring in addition to the FRM samplers. The maximum 24-hour and annual average PM2.5 concentrations in 2011 are shown in Tables 2-5 and 2-6.

Figure 2-3 maps the distribution of annual average PM2.5 concentrations in different areas of the Basin. Similar to PM10 concentrations, PM2.5 concentrations were higher in the inland valley areas of metropolitan Riverside County (highest at the Mira Loma Station). PM2.5 concentrations were also elevated in the metropolitan area of Los Angeles County, but did not exceed the level of the annual federal standard in 2011. Although maximum 24-hour concentrations exceed the standard, the 98th percentile form of the 2009-2011 design value only exceeded the standard at one station in Metropolitan Riverside County (Mira Loma).

The higher PM2.5 concentrations in the Basin are mainly due to the secondary formation of smaller particulates resulting from mobile, stationary and area source emissions of precursor gases (i.e., NO_x, SO_x, NH₄, and VOC) that are converted to PM in the atmosphere. In contrast to PM10, PM2.5 concentrations were low in the Coachella Valley area of SSAB. PM10 concentrations are normally higher in the desert areas due to windblown and fugitive dust emissions; PM2.5 is relatively low in the desert area due to fewer combustion-related emissions sources.

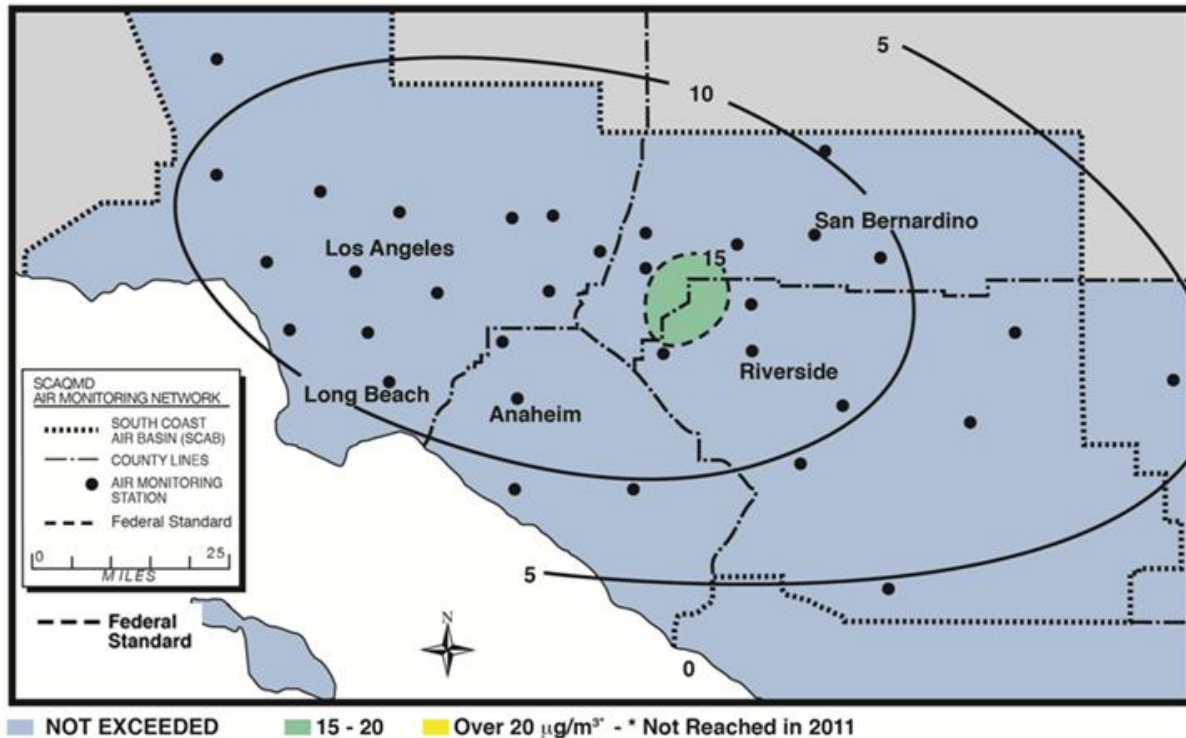

FIGURE 2-3

2011 PM_{2.5}: Annual Average Concentration Compared to the Federal Standard
(Federal standard = 15 µg/m³, annual arithmetic mean)

Air Quality, PM₁₀

In 2011, the District monitored PM₁₀ concentrations at 25 routine sampling locations, 22 with Federal Reference Method (FRM) filter samplers and 3 with Federal Equivalent Method (FEM) continuous monitors. Five sites had collocated FRM and FEM samplers. Maximum 24-hour and annual average PM₁₀ concentrations in 2011 are shown in Tables 2-7 and 2-8.

The highest annual PM₁₀ concentrations were recorded in Riverside and San Bernardino Counties, in and around the metropolitan Riverside County area and further inland in the San Bernardino valley areas. The federal 24-hour standard was not exceeded at any of the locations monitored in 2011, although Riverside County came close with a 24-hour average concentration of 152 µg/m³ (155 µg/m³ is needed to exceed). The revoked annual average PM₁₀ federal standard (50 µg/m³) was not exceeded in either the Basin or the Coachella Valley in 2011. The much more stringent state standards were exceeded in most areas of the Basin and in the Coachella Valley.

Ozone (O₃) Specific Information

Health Effects, O₃

The adverse effects of ozone air pollution exposure on health have been studied for many years, as is documented by a significant body of peer-reviewed scientific research, including studies conducted in southern California. The 2006 U.S. EPA document, *Air Quality Criteria for Ozone and Related Photochemical Oxidants*¹⁰, describes these health effects and discusses the state of the scientific knowledge and research. A summary of health effects information and additional references can also be found in the 2012 AQMP, Appendix I.

Individuals exercising outdoors, children, and people with preexisting lung disease, such as asthma and chronic pulmonary lung disease, are considered to be the most susceptible sub-groups to ozone effects. Short-term exposures (lasting for a few hours) to ozone at levels typically observed in Southern California can result in breathing pattern changes, reduction of breathing capacity, increased susceptibility to infections, inflammation of the lung tissue, and some immunological changes. Elevated ozone levels are associated with increased school absences and daily hospital admission rates. An increased risk for asthma has been found in children who participate in multiple sports and live in high ozone communities.

Ozone exposure under exercising conditions is known to increase the severity of the above-mentioned observed responses. Animal studies suggest that exposures to a combination of pollutants which include ozone may be more toxic than exposure to ozone alone. Although lung volume and resistance changes observed after a single exposure diminish with repeated exposures, biochemical and cellular changes appear to persist, which can lead to subsequent lung structural changes.

Air Quality, O₃

In 2011, the District regularly monitored ozone concentrations at 29 locations in the Basin and the Coachella Valley portion of the SSAB. All areas monitored measured 1-hour average ozone levels well below the Stage 1 episode level (0.20 ppm), but the maximum concentrations measured in the Basin exceeded the health advisory level (0.15 ppm, 1-hour) in San Bernardino County. The maximum ozone concentrations in Los Angeles, Riverside and San Bernardino Counties all exceeded the former 1-

¹⁰ U.S. EPA. (2006). *Air Quality Criteria for Ozone and Related Photochemical Oxidants* (2006 Final). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-05/004aF-cF.

hour federal standard in 2011; Orange County and the Coachella Valley did not exceed that standard. Maximum ozone concentrations in the SSAB areas monitored by the District were lower than in the Basin and were below the health advisory level. All counties of the Basin and the Coachella Valley exceeded the current 8-hour ozone standard in 2011. Tables 2-9 and 2-10 show maximum 1-hour and 8-hour ozone concentrations by air basin and county.

TABLE 2-9

2011 Maximum 1-Hour Average Ozone Concentrations by Basin and County

San Bernardino	0.136	180	Central San Bernardino Mountains
Salton Sea Air Basin			
Riverside	0.098	130	Coachella Valley

The number of days exceeding federal standards for ozone in the Basin varies widely by area. Figures 2-4 and 2-5 map the number of days in 2011 exceeding the current 8-hour and former 1-hour ozone federal standards in different areas of the Basin in 2011. The former 1-hour federal standard was not exceeded in areas along or near the coast in the Counties of Los Angeles and Orange, due in large part to the prevailing sea breeze which transports emissions inland before high ozone concentrations are reached. The standard was exceeded most frequently in the Central San Bernardino Mountains. Ozone exceedances also extended through San Bernardino and Riverside County valleys in the eastern Basin, as well as the northeast and northwest portions of Los Angeles County in the foothill and valley areas. The number of exceedances of the 8-hour federal ozone standard was also lowest at the coastal areas, increasing towards the Riverside and San Bernardino valleys and the adjacent mountain areas. The Central San Bernardino Mountains area recorded the greatest number of exceedances of the 1-hour and 8-hour federal standards (8 days and 84 days, respectively) and 8-hour state standard (103 days). While the Coachella Valley did not exceed the former 1-hour ozone standard in 2011, the 2008 8-hour federal standard was exceeded on 54 days.

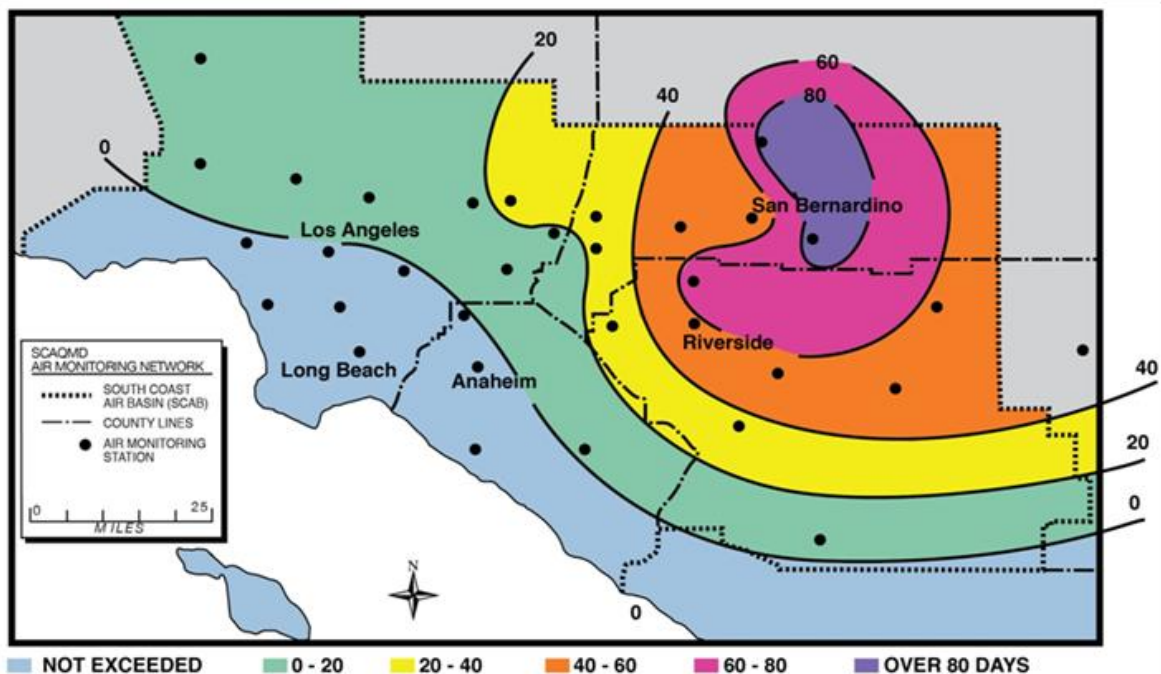

FIGURE 2-4

(1-hour average O₃ > 0.12 ppm)

Other Criteria Air Pollutants

Carbon Monoxide (CO) Specific Information

Health Effects, CO

The adverse effects of ambient carbon monoxide air pollution exposure on health have been recently reviewed in the 2006 U.S. EPA *Integrated Science Assessment for Carbon Monoxide*.¹¹ This document presents a detailed review of the available scientific studies and conclusions on the causal determination of the health effects of CO. A summary of health effects information and additional references can also be found in the 2012 AQMP, Appendix I.

Individuals with a deficient blood supply to the heart are the most susceptible to the adverse effects of CO exposure. The effects observed include earlier onset of chest

¹¹ U.S. EPA. (2010). *Integrated Science Assessment for Carbon Monoxide (Final Report)*. U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-09/019F.

pain with exercise, and electrocardiograph changes indicative of worsening oxygen supply delivery to the heart.

Inhaled CO has no known direct toxic effect on the lungs, but exerts its effect on tissues by interfering with oxygen transport, by competing with oxygen to combine with hemoglobin present in the blood to form carboxyhemoglobin (COHb). Hence, people with conditions requiring an increased oxygen supply can be adversely affected by exposure to CO. Individuals most at risk include patients with diseases involving heart and blood vessels, fetuses, and patients with chronic hypoxemia (oxygen deficiency) as seen at high altitudes.

Reductions in birth weight and impaired neurobehavioral development have been observed in animals chronically exposed to CO resulting in COHb levels similar to those observed in smokers. Recent studies have found increased risks for adverse birth outcomes with exposure to elevated CO levels. These include pre-term births and heart abnormalities.

Air Quality, CO

Carbon monoxide concentrations were measured at 25 locations in the Basin and neighboring SSAB areas in 2011. Table 2-11 shows the 2011 maximum 8-hour and 1-hour average concentrations of CO by air basin and county.

In 2011, no areas exceeded the CO air quality standards. The highest concentrations of CO continued to be recorded in the areas of Los Angeles County where vehicular traffic is most dense, with the maximum 8-hour and 1-hour concentration (4.7 ppm and 6.0 ppm, respectively) recorded in the South Central Los Angeles County area. All areas of the Basin have continued to remain below the federal standard level since 2003.

TABLE 2-11

Nitrogen Dioxide (NO₂) Specific Information

Health Effects, NO₂

The adverse effects of ambient nitrogen dioxide air pollution exposure on health have been recently reviewed in the 2008 U.S. EPA *Integrated Science Assessment for Oxides of Nitrogen – Health Criteria*¹². This document presents a detailed review of the available scientific studies and conclusions on the causal determination of the health effects of NO₂, including evidence supporting the recently adopted short-term NO₂ standard (1-hour, 100 ppb). A summary of health effects information and additional references can also be found in the 2012 AQMP, Appendix I.

Population-based studies suggest that an increase in acute respiratory illness, including infections and respiratory symptoms in children (not infants), is associated with long-term exposures to NO₂ at levels found in homes with gas stoves, which are higher than ambient concentrations found in Southern California. Increase in resistance to air flow and airway contraction is observed after short-term exposure to NO₂ in healthy subjects. Larger decreases in lung functions are observed in

¹² U.S. EPA. (2008). *Integrated Science Assessment for Oxides of Nitrogen – Health Criteria (Final Report)*. U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/071.

individuals with asthma and/or chronic obstructive pulmonary disease (e.g., chronic bronchitis, emphysema) than in healthy individuals, indicating a greater susceptibility of these sub-groups. More recent studies have found associations between NO₂ exposures and cardiopulmonary mortality, decreased lung function, respiratory symptoms, and emergency room asthma visits.

In animals, exposure to levels of NO₂ that are considerably higher than ambient concentrations results in increased susceptibility to infections, possibly due to the observed changes in cells involved in maintaining immune functions. The severity of lung tissue damage associated with high levels of ozone exposure increases when animals are exposed to a combination of ozone and NO₂.

Based on the review of the NO₂ standards, U.S. EPA has established the 1-hour NO₂ standard to protect the public health against short-term exposure. The standard is set at 100 ppb 1-hour average, effective April 7, 2010.

Air Quality, NO₂

In 2011, NO₂ concentrations were monitored at 25 locations, including one in the Coachella Valley. The Basin has not exceeded the federal annual standard for NO₂ (0.0534 ppm) since 1991, when the Los Angeles County portion of the Basin recorded the last exceedance of the standard in any U.S. county. The recently established 1-hour average NO₂ standard (100 ppb), however, was exceeded on one day in 2011 (but the 98th percentile form of the standard was not exceeded). The higher relative concentrations in the Los Angeles area are indicative of the concentrated emission sources, especially motor vehicles. The maximum 1-hour and annual average concentrations for 2011 are shown in Table 2-12, by basin and county.

TABLE 2-12

2011 Maximum 1-Hour and Annual Average NO₂ Concentrations by Basin and County

Riverside	44.7	44	8.0	15	Coachella Valley

* Although the maximum 1-hour concentrations exceeded the standard, the 98th percentile form of the design value did not exceed the NAAQS

Sulfur Dioxide (SO₂) Specific Information

Health Effects, SO₂

The adverse effects of SO₂ air pollution exposure on health have been recently reviewed in the 2008 U.S. EPA *Integrated Science Assessment (ISA) for Sulfur Oxides – Health Criteria*.¹³ This document presents a detailed review of the available scientific studies and conclusions on the causal determination of the health effects of SO₂, including the justification to rescind the 24-hour standard and replace it with the new (2010) 1-hour standard (75 ppb). A summary of health effects information and additional references can also be found in the 2012 AQMP, Appendix I.

Individuals affected by asthma are especially sensitive to the effects of SO₂. Exposure to low levels (0.2 to 0.6 ppm) of SO₂ for a few (5-10) minutes can result in airway constriction in some exercising asthmatics. In asthmatics, increase in

¹³ U.S. EPA. (2008). *Integrated Science Assessment (ISA) for Sulfur Oxides – Health Criteria (Final Report)*. U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-08/047F.

resistance to air flow, as well as reduction in breathing capacity leading to severe breathing difficulties, are observed after acute high exposure to SO₂. In contrast, healthy individuals do not exhibit similar acute responses even after exposure to higher concentrations of SO₂.

Animal studies suggest that even though SO₂ is a respiratory irritant, it does not cause substantial lung injury at ambient concentrations. However, very high levels of exposure can cause lung edema (fluid accumulation), lung tissue damage, and sloughing off of cells lining the respiratory tract.

Some population-based studies indicate that the mortality and morbidity effects associated with fine particles show a similar association with ambient SO₂ levels. In these studies, efforts to separate the effects of SO₂ from those of fine particles have not been successful. It is not clear whether the two pollutants act synergistically or one pollutant alone is the predominant factor.

Based on the review of the SO₂ standards, U.S. EPA has established the 1-hour SO₂ standard to protect the public health against short term exposure. The 1-hour average standard is set at 75 ppb, revoking the existing annual (0.03 ppm) and 24-hour (0.14 ppm) standards, effective August 2, 2010.

Air Quality, SO₂

No exceedances of federal or state standards for sulfur dioxide occurred in 2011 at any of the seven District locations monitored. Though sulfur dioxide concentrations remain well below the standards, sulfur dioxide is a precursor to sulfate, which is a component of fine particulate matter. Maximum concentrations of sulfur dioxide for 2011 are shown in Table 2-13. Sulfur dioxide was not measured at the Coachella Valley sites in 2011. Historical measurements showed concentrations in the Coachella Valley to be well below state and federal standards and monitoring has been discontinued.

TABLE 2-13

2011 Maximum 1-Hour Average SO₂ Concentrations by Basin and County

Salton Sea Air Basin			
Riverside	N.D.		Coachella Valley

N.D. = No Data. Historical measurements and lack of emissions sources indicate concentrations are well below standards

Sulfates (SO₄²⁻) Specific Information

Health Effects, SO₄²⁻

In 2002, CARB reviewed and retained the state standard for sulfates, retaining the concentration level (25 µg/m³) but changing the basis of the standard from a Total Suspended Particulate (TSP) measurement to a PM10 measurement. In their 2002 staff report,¹⁴ CARB reviewed the health studies related to exposure to ambient sulfates, along with particulate matter, and found an association with mortality and the same range of morbidity effects as PM10 and PM2.5, although the associations were not as consistent as with PM10 and PM2.5. The 2009 U.S. EPA *Integrated Science Assessment for Particulate Matter*¹⁵ also contains a review of sulfate studies. A summary of health effects information can also be found in the 2012 AQMP, Appendix I.

Most of the health effects associated with fine particles and SO₂ at ambient levels are also associated with sulfates. Thus, both mortality and morbidity effects have been observed with an increase in ambient sulfate concentrations. However, efforts to

¹⁴ CARB. (2002). Staff Report: Public Hearing to Consider Amendments to the Ambient Air Quality Standards for Particulate Matter and Sulfates. California Air Resources Board, Sacramento, CA.

separate the effects of sulfates from the effects of other pollutants have generally not been successful.

Clinical studies of asthmatics exposed to sulfuric acid suggest that adolescent asthmatics are possibly a subgroup susceptible to acid aerosol exposure. Animal studies suggest that acidic particles such as sulfuric acid aerosol and ammonium bisulfate are more toxic than non-acidic particles like ammonium sulfate. Whether the effects are attributable to acidity or to particles remains unresolved.

Air Quality, SO_4^{2-}

Sulfate from PM10 was measured at 22 stations in 2011, including one in the Coachella Valley. In 2011, the state PM10-sulfate standard was not exceeded anywhere in the Basin or the Coachella Valley. Maximum concentrations by air basin and county are shown in Table 2-14.

Lead (Pb) Specific Information

Health Effects, Pb

The adverse effects of ambient lead exposures on health have been reviewed in the 2006 U.S. EPA document, *Air Quality Criteria for Lead (2006) Final Report*.¹⁶ This document presents a detailed assessment of the available scientific studies and presents conclusions on the causal determination of the health effects of lead, including the justification to lower the federal lead standard.

Fetuses, infants, and children are more sensitive than others to the adverse effects of lead exposure. Exposure to low levels of lead can adversely affect the development and function of the central nervous system, leading to learning disorders, distractibility, inability to follow simple commands, and lower intelligence quotient. In adults, increased lead levels are associated with increased blood pressure.

Lead poisoning can cause anemia, lethargy, seizures, and death. It appears that there are no direct effects of lead on the respiratory system. Lead can be stored in the bone from early-age environmental exposure, and elevated blood lead levels can occur due to breakdown of bone tissue during pregnancy, hyperthyroidism (increased secretion of hormones from the thyroid gland), and osteoporosis (breakdown of bony tissue). Fetuses and breast-fed babies can be exposed to higher levels of lead because of previous environmental lead exposure of their mothers.

Air Quality, Pb

Based on the review of the NAAQS for lead, U.S. EPA has established a new standard of 0.15 $\mu\text{g}/\text{m}^3$ for a rolling 3-month average, effective October 15, 2008 (measured from total suspended particulates, TSP). Except for the source-specific monitoring that is now required under the new standard, there have been no violations of the lead standards at the District's regular air monitoring stations since 1982, as a result of removal of lead from gasoline. However, monitoring at two stations immediately adjacent to stationary sources of lead have recorded exceedances of the standards in localized areas of the Basin in more recent years. Table 2-15 shows the maximum 3-month rolling average concentrations recorded in 2011. In 2011, lead concentrations in the Basin exceeded the new 3-month rolling average standard (0.15 $\mu\text{g}/\text{m}^3$) at one source-specific monitoring site in Los Angeles County, located immediately downwind of a stationary lead source. The federal rolling 3-month and

state 30-day standards for lead were not exceeded in any other area of the District in 2011.

N.D. = No Data. Historical measurements indicate concentrations are well below standards.

COMPARISON TO OTHER U.S. AREAS

The Basin's severe air pollution problem is a consequence of the combination of emissions from the nation's second largest urban area, mountainous terrain surrounding the Basin that traps pollutants as they are pushed inland with the sea breeze, and meteorological conditions which are adverse to the dispersion of those emissions. The average wind speed for Los Angeles is the lowest of the nation's ten largest urban areas. In addition, the summertime daily maximum mixing heights (an index of how well pollutants can be dispersed vertically in the atmosphere) in Southern California are the lowest, on average, in the U.S., due to strong temperature inversions in the lower atmosphere that effectively trap pollutants near the surface. The Southern California area is also an area with abundant sunshine, which drives the photochemical reactions which form pollutants such as ozone and a significant portion of PM_{2.5}.

In the Basin, high concentrations of ozone are normally recorded during the late spring and summer months, when more intense sunlight drives enhanced

photochemical reactions. In contrast, higher concentrations of carbon monoxide are generally recorded in late fall and winter, when nighttime radiation inversions trap the emissions at the surface. High PM10 and PM2.5 concentrations can occur throughout the year, but occur most frequently in fall and winter in the Basin. Although there are changes in emissions by season, the observed variations in pollutant concentrations are largely a result of seasonal differences in weather conditions.

Figures 2-6 and 2-7 show maximum pollutant concentrations in 2011 for the South Coast Air Basin compared to other urban areas in the U.S. and California, respectively. Maximum concentrations in all of these areas exceeded the federal 8-hour ozone standard. The annual PM2.5 standard was exceeded in the Basin and in one other California air basin (San Joaquin Valley). The 24-hour PM2.5 standard, however, was exceeded in a few of the other large U.S. urban areas and in many California air basins. The 24-hour PM10 standard was exceeded in one of the U.S. urban areas shown (Phoenix), although potential flagging of exceptional events may affect the treatment of that data. It is important to note that maximum pollutant concentrations do not necessarily indicate potential nonattainment designations, as the design values that are used for attainment status are based on the form of the standard.

Nitrogen dioxide concentrations exceeded the recently established 1-hour standard in the Basin and Phoenix (on one day each). Denver, Colorado (not shown in Figure 2-7), was the only other U.S. urban area exceeding the NO₂ standard in 2011. Sulfur dioxide concentrations were below the recently established 1-hour federal standard in the Basin and all of the urban areas shown in Figures 2-6 and 2-7. However, the SO₂ standard was exceeded in other U.S. areas, with the highest concentrations recorded in Hawaii, due to volcano emissions. The CO standards were not exceeded in the U.S. in 2011.

FIGURE 2-6

2011 South Coast Air Basin Air Quality Compared to Other U.S. Metropolitan Areas (Maximum Pollutant Concentrations as Percentages of Corresponding Federal Standards)

In 2011, the Central San Bernardino Mountains area in the Basin recorded the highest maximum 1-hour and 8-hour average ozone concentrations in the nation (0.160 and 0.136 ppm, respectively). The highest 8-hour average concentration was more than one and a half times the federal standard level. In 2011, seven out of ten stations with the highest maximum 8-hour average ozone concentrations in the nation were located in the Basin¹⁷. The South Coast Air Basin also exceeded the 8-hour ozone standard on more days (106) than most other urban areas in the country in 2011, with only California’s San Joaquin Valley exceeding on more days (109).

¹⁷ The 10 highest measured ozone concentrations in 2011 included 7 Basin stations: Central San Bernardino Mountains (Crestline), East San Bernardino Valley (Redlands), Central San Bernardino Valley (Fontana and San Bernardino), Santa Clarita Valley (Santa Clarita), Northwest San Bernardino Valley (Upland), and Metropolitan Riverside (Rubidoux).

FIGURE 2-7

2011 South Coast Air Basin Air Quality Compared to Other California Air Basins
(Maximum Pollutant Concentrations as Percentages of Corresponding Federal Standards)

SUMMARY

In 2011, the Basin continued to exceed federal and state standards for ozone and PM2.5. The maximum measured concentrations for these pollutants were among the highest in the country, although significant improvement has been seen in recent years for both 24-hour and annual PM2.5 concentrations and only one location in the Basin is currently exceeding the 24-hour and annual design value form of the PM2.5 federal standards. The Basin’s federal 3-year design values for ozone and PM2.5 have continued to exhibit downward trends through 2011.

The Coachella Valley area in the Riverside County portion of the Salton Sea Air Basin exceeded federal and state standards for ozone and PM10. However, the high PM10 concentrations exceeding the federal 24-hour PM10 standard occurred on days influenced by high-wind natural events, which the District has flagged in the U.S. EPA AQS database so that U.S. EPA will consider excluding such data when

determining the NAAQS attainment status in accordance with U.S. EPA's Exceptional Events Rule. For the stations in the Coachella Valley, the federal 3-year design values for 8-hour ozone have continued to exhibit downward trends through 2011.

The NO₂ concentrations in Los Angeles County exceeded the recently established short-term federal standard on one day at two locations, but did not exceed the standards anywhere on any other day in the Basin. The 98th percentile form of the federal NO₂ standard was not exceeded and the Basin's attainment status remains intact. The Los Angeles County portion of the Basin also exceeded the 3-month rolling average Pb federal standard at one source-specific monitor adjacent to a Pb source. A separate SIP revision has been submitted to address Pb violations. Maximum concentrations for SO₂, CO, and sulfate (measured from PM₁₀) continued to remain below the state and federal standards.

Chapter 3

Base Year and Future Emissions

South Coast Air Quality Management District
Cleaning the air that we breathe...

CHAPTER 3

BASE YEAR AND FUTURE EMISSIONS

Introduction

Emission Inventories

Base Year Emissions

Future Emissions

Impact of Growth

Top Ten Source Categories (2008, 2014, 2023)

INTRODUCTION

This chapter summarizes emissions that occurred in the Basin during the 2008 base year, and projected emissions in the years 2014, 2019, 2023, and 2030. More detailed emission data analyses are presented in Appendix III of the Draft Final 2012 AQMP. The 2008 base year emissions inventory reflects adopted air regulations with current compliance dates as of 2008; whereas future baseline emissions inventories are based on adopted air regulations with both current and future compliance dates. A list of the District and CARB's rules and regulations that are part of the base year and future-year baseline emissions inventories is presented in Appendix III of the Draft Final 2012 AQMP. The District is committed to implement the District rules that are incorporated in the Draft Final 2012 AQMP future baseline emissions inventories.

The emissions inventory is divided into four major classifications: point, area, on-road, and off-road sources. The 2008 base year point source emissions are based principally on reported data from facilities using the District's Annual Emissions Reporting Program. The area source emissions are estimated jointly by CARB and the District. The on-road emissions are calculated by applying CARB's EMFAC2011 emission factors to the transportation activity data provided by Southern California Association of Governments (SCAG) from their adopted 2012 Regional Transportation Plan (2012 RTP). CARB's 2011 In-Use Off-Road Fleet Inventory Model is used for the construction, mining, gardening and agricultural equipment. CARB also provides other off-road emissions, such as ocean-going vessels, commercial harbor craft, locomotives and cargo handling equipment. Aircraft emissions are based on an updated analysis by the District. The future emission forecasts are primarily based on demographic and economic growth projections provided by SCAG. In addition, emission reductions resulting from District regulations adopted by June, 2012 and CARB regulations adopted by August 2011 are included in the baseline.

This chapter summarizes the major components of developing the base year and future baseline inventories. More detailed information, such as CARB's and the District's emission reductions resulting from adopted rules and regulations since the 2007 AQMP, growth factors, and demographic trends, are presented in Appendix III of the Draft Final 2012 AQMP. In addition, the top ten source categories contributing to the 2008, 2014, and 2023 emission inventories are identified in this chapter. Understanding information about the highest emitting source categories leads to the identification of potentially more effective and/or cost effective control strategies for improving air quality.

EMISSION INVENTORIES

Two inventories are prepared for the Draft Final 2012 AQMP for the purpose of regulatory and SIP performance tracking and transportation conformity: an annual average inventory, and a summer planning inventory. Baseline emissions data presented in this chapter are based on average annual day emissions (i.e., total annual emissions divided by 365 days) and seasonally adjusted summer planning inventory emissions. The Draft Final 2012 AQMP uses annual average day emissions to estimate the cost-effectiveness of control measures, to rank control measure implementation, and to perform PM_{2.5} modeling and analysis. The summer planning inventory emissions are developed to capture the emission levels during a poor air quality season, and are used to report emission reduction progress as required by the federal and California Clean Air Acts.

Detailed information regarding the emissions inventory development for the base year and future years, the emissions by major source category of the base year, and future baseline emission inventories are presented in Appendix III of the Draft Final 2012 AQMP. Attachments A and B to Appendix III list the annual average and summer planning emissions by major source category for 2008, 2014, 2017, 2019, 2023 and 2030, respectively. Attachment C to Appendix III has the top VOC and NO_x point sources which emitted greater than or equal to ten tons per year in 2008. Attachment D to the Appendix III contains the on-road emissions by vehicle class and by pollutant for 2008, 2014, 2019, 2023 and 2030. Attachment E to Appendix III shows emissions associated with the combustion of diesel fuel for various source categories.

Stationary Sources

Stationary sources can be divided into two major subcategories: point and area sources. Point sources are large emitters with one or more emission sources at a permitted facility with an identified location (e.g., power plants, refineries). These facilities have annual emissions of 4 tons or more of either Volatile Organic Compounds (VOC), Nitrogen Oxide (NO_x), Sulfur Oxide (SO_x), or total Particulate Matter (PM), or annual emissions of over 100 tons of Carbon Monoxide (CO). Facilities are required to report their criteria pollutant emissions and selected toxics to the District on an annual basis, if any of these thresholds are exceeded.

Area sources consist of many small emission sources (e.g., residential water heaters, architectural coatings, consumer products as well as permitted sources smaller than the above thresholds) which are distributed across the region. There are about 400 area

source categories for which emissions are jointly developed by CARB and the District. The emissions from these sources are estimated using activity information and emission factors. Activity data are usually obtained from survey data or scientific reports (e.g., Energy Information Administration (EIA) reports for fuel consumption other than natural gas fuel, Southern California Gas Company for natural gas consumption, paint suppliers and, District databases). The emission factors are based on rule compliance factors, source tests, Material Safety Data Sheets (MSDS), default factors (mostly from AP-42, U.S. EPA's published emission factor compilation), or weighted emission factors derived from the point source facilities' annual emissions reports. Additionally, the emissions over a given area may be calculated using socioeconomic data.

Appendix III of the Draft Final 2012 AQMP has more detail regarding emissions from specific source categories such as fuel combustion sources, landfills, composting waste, metal-coating operations, architectural coatings, and livestock waste. Since the 2007 AQMP was finalized, new area source categories, such as LPG transmission losses, storage tank and pipeline cleaning and degassing, and architectural colorants, were created and included in the emission inventories. These updates and new additions are listed below:

- Fuel combustion sources: The emissions from commercial and industrial internal combustion engines were updated to include the portable equipment emissions.
- Landfills: The emission estimation methodology for this area source category was revised to incorporate CARB's landfills greenhouse gas (GHG) emission inventory data.
- Composting waste category: The emission estimation methodology for this area source category was revised to include the emissions from green waste composting covered under District Rule 1133.3. The 2007 AQMP only included the emissions from co-composting, as it relates to District Rule 1133.2.
- Metal coating operations: This area source category in the 2007 AQMP only included the emissions from small permitted facilities with VOC emissions below 4 tons per year. As such, emissions from these sources maybe underreported in the 2007 AQMP. During the rule development process for amending Rule 1107, staff discovered numerous small shops using coating materials with compliant high solid concentrations, which are subsequently thinned beyond the allowable limits permitted by Rule 1107. The Draft Final

2012 AQMP revised inventory adjusts the 2007 AQMP inventory to account for excess emissions from these coating activities.

- Architectural coating category: Three new area source categories were added under this category to accurately track the emissions from colorants.
- LPG transmission losses: This newly added area source category was created to include the emissions from LPG storage and fueling losses.
- Livestock waste sources: This inventory was updated to reflect the difference amongst dairy cattle based on the fraction of milking cows, dry cows, calves, and heifers as each has different VOC and NH₃ emission factors based on the quantity of manure production.
- Storage tanks and pipeline cleaning: This new area source category was added to include the emissions from these types of operations.

Mobile Sources

Mobile sources consist of two subcategories: on-road and off-road sources. On-road vehicle emissions are calculated by applying CARB's EMFAC2011 emissions factors to the transportation activity data provided by SCAG from their adopted 2012 RTP. Spatial distribution data from Caltrans' Direct Travel Impact Model (DTIM4) are used to generate the gridded emissions. Off-road emissions are calculated using CARB's 2011 In-Use Off-Road Fleet Inventory model for construction, mining, gardening, and agricultural equipment. Ship, locomotive, and aircraft emissions are excluded from CARB's In-Use Off-Road Fleet Inventory model. Their emissions for 2008 and future years were revised separately based on the most recently available data.

On-Road

CARB's EMFAC2011 has been updated to reflect more recent vehicle population, activity, and emissions data. Light-duty motor vehicle fleet age, vehicle type, and vehicle population are updated based on 2009 California Department of Motor Vehicles data. The model also reflects recently adopted rules and benefits that were not reflected in EMFAC2007. The rules and benefits include on-road diesel fleet rules, the Pavley Clean Car Standards, and the Low Carbon Fuel standard. The most important improvement in the model is the integration of new data and methods to estimate emissions from diesel trucks and buses. CARB's Truck and Bus Regulation for the on-road heavy-duty in-use diesel vehicles applies to nearly all privately owned diesel fueled trucks and privately and publicly owned school buses with a gross vehicle weight rating (GVWR) greater than 14,000 pounds. EMFAC2011 includes the

emissions benefits of the Truck and Bus Rule and previously adopted rules for other on-road diesel equipment. The impacts of the recent recession on emissions, quantified as part of the truck and bus rulemaking, are also included.

EMFAC2011 uses a modular emissions modeling approach that departs from past EMFAC versions. The first module, named EMFAC-LDV, is used as the basis for estimating emissions from gasoline powered on-road vehicles, diesel vehicles below 14,000 pounds GVWR, and urban transit buses. The second module, called EMFAC-HD, is the basis for emissions estimates for diesel trucks and buses with a GVWR greater than 14,000 pounds operating in California. This module is based on the Statewide Truck and Bus Rule emissions inventory that was developed between 2007 and 2010 and approved by the CARB Board in December 2010. The third module is called EMFAC2011SG. It takes the output from EMFAC-LDV and EMFAC-HD and applies scaling factors to estimate emissions consistent with user-defined vehicle miles of travel and vehicle speeds. Together the three modules comprise EMFAC2011.

Several external adjustments were made to EMFAC2011 in the Draft Final 2012 AQMP to reflect CARB's rules and regulations which were adopted after the development of EMFAC2011. The adjustments include the advanced clean cars regulations, reformulated gasoline, and smog check improvement.

Figure 3-1 compares the on-road emissions between EMFAC2007 V2.3 used in the 2007 AQMP and EMFAC2011 used in the Draft Final 2012 AQMP, respectively. It should be noted that the comparison for 2008 reflects changes in methodology whereas the comparison for 2023 includes adopted rules and updated growth projections since the release of EMFAC2007. In general, the emissions are lower in EMFAC2011 as compared to EMFAC2007. The lower emissions can be attributed to additional rules and regulations which result in reduced emissions, revisions to growth projections, and the economic impacts of the recent recession.

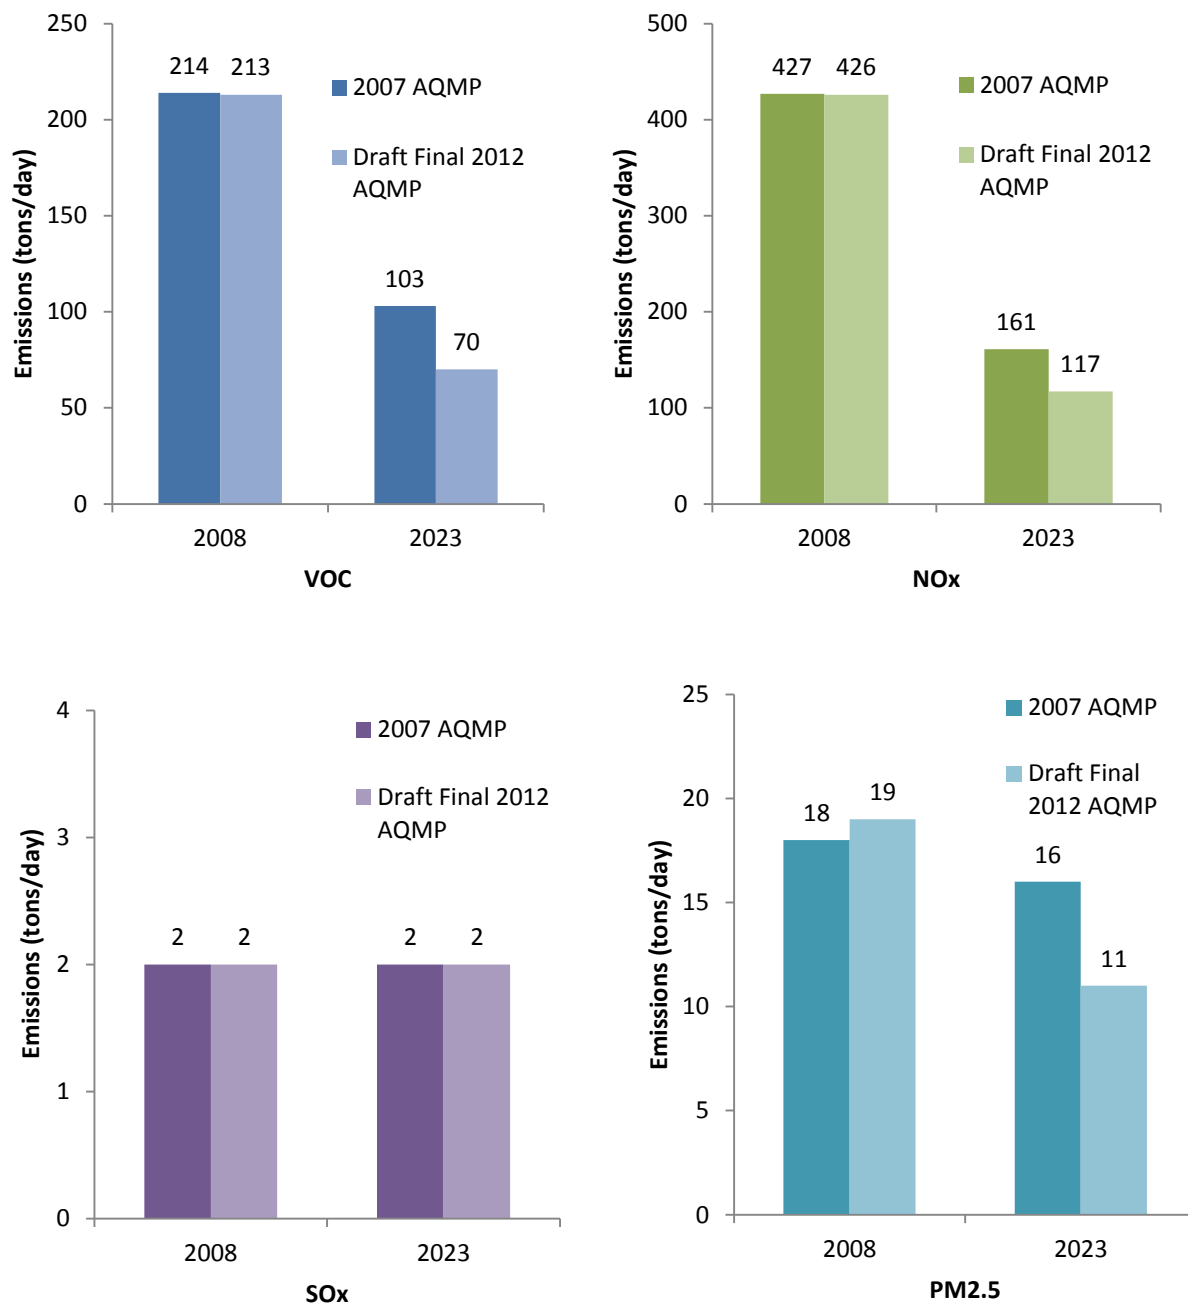

FIGURE 3-1

Comparison of On-Road Emissions Between EMFAC2007 V2.3 (2007 AQMP) and EMFAC2011 (Draft Final 2012 AQMP)

(VOC & NOx – Summer Planning; SOx & PM2.5 – Annual Average Inventory)

Off-Road

Emissions from off-road vehicle categories (construction & mining equipment, lawn & gardening equipment, ground support equipment, agricultural equipment) in CARB's In-Use Off-Road Model were developed primarily based on estimated activity levels and emission factors. Ships, commercial harbor crafts, locomotives, aircrafts, and cargo handling equipment emissions are not included in CARB's In-Use Off-Road Fleet Inventory Model. Separate models or estimations were used for these emissions sources. The off-road source population, activities, and emission factors were re-evaluated and re-estimated since the last AQMP. Consequently, the emissions are modified accordingly.

The major updates and/or improvements to the off-road inventory include:

1. The equipment population in CARB's In-Use Off-Road Fleet Inventory model is updated by using the equipment population reported to CARB for rule compliance. Based on information from CARB, the total population in 2009 was 26% lower than had been anticipated in 2007 due to fleet downsizing during the recent recession.
2. The equipment hours of use in CARB's In-Use Off-Road Fleet Inventory model are updated based on the reported activity data between 2007 and 2009. According to CARB, the new data indicates a 30% or more reduced activity in most cases for 2009 as compared to 2007 due to recession.
3. The equipment load factor in CARB's In-Use Off-Road Fleet Inventory model is updated using a 2009 academic study and information from engine manufacturers. According to CARB, the new data suggests that the load factors should be reduced by 33%.
4. According to CARB, construction activity and emissions have dropped by more than 50% between 2005 and 2011. Future emissions are uncertain and depend on the pace of economic recovery. The future growth in CARB's In-Use Off-Road Fleet Inventory model is projected based on the average of the future forecast scenarios. CARB's data suggest off-road activity and emissions will recover slowly from the recessionary lows.
5. Locomotive inventories reflect the 2008 U.S. EPA Locomotive regulations and adjustments due to economic activity.

6. Cargo handling equipment has been updated for population, activity, recessionary impacts on growth, and engine load. The updates are based on new information collected since 2005. The new information includes CARB's regulatory reporting data which provides an accounting of all the cargo handling equipment in the state including their model year, horsepower and activity. In addition, the Ports of Los Angeles and Long Beach have developed annual emissions inventories and a number of the major rail yards and other ports in the state have completed individual emission inventories.
7. Ocean-going vessel emissions in the Draft Final 2012 AQMP include CARB's fuel regulation for ocean-going vessels and the 2007 shore power regulation. In addition, the improvements and corrections include recoding the model for speed, updating auxiliary engine information, updating ship routing, revising vessel speed reduction compliance rates, and an adjustment factor to estimate the effects of the recession. In March 2010, the International Maritime Organization (IMO) officially designated the waters within 200 miles of the North American Coast as an Emissions Control Area (ECA). Beginning August 2012, IMO requires ships that travel these waters to use fuel with a sulfur content of less than or equal to 1.0% and in 2015 the sulfur limit will be further reduced to 0.1%. Additionally, vessels built after January 1, 2016 will be required to meet the most stringent IMO Tier 3 NO_x emission levels while transiting within the 200 mile ECA zone. Outer Continental Shelf (OCS) emissions (i.e. emissions from vessels beyond the three-mile state waters line) are included in the ships emissions as well.
8. Another improvement is the development of a separate emission category for the commercial harbor craft from a new commercial harbor craft database. CARB approved a regulation to significantly reduce diesel PM and NO_x emissions from diesel-fueled engines on commercial harbor craft vessels. These vessels emit an estimated 3 tons per day of diesel PM and 70 tons per day of NO_x statewide in 2007. The harbor craft database includes emissions from crew & supply, excursion, fishing, pilot, tow boats, barge, and dredge vessels.
9. The aircraft emissions inventory is updated for the 2008 base year and the 2035 forecast year based on the latest available activity data and calculation methodologies. A total of 43 airports were identified as having aircraft operations within the District boundaries including commercial air carrier, air

taxi, general aviation, and military aircraft operations. The sources of activity data include airport operators (for several commercial and military airports), FAA's databases (i.e., Bureau of Transportation Statistics, Air Traffic Activity Data System, Terminal Area Forecast), and SCAG. For commercial air carrier operations, SCAG's 2035 forecast, which is consistent with the forecast adopted for the 2012 RTP, reflects the future aircraft fleet mix. The emissions calculation methodology is primarily based on the application of FAA's Emissions and Dispersion Modeling System (EDMS) model for airports with detailed activity data for commercial air carrier operations (by aircraft make and model). For other airports and aircraft types (i.e., general aviation, air taxi, military), the total number of landing and takeoff activity data is used in conjunction with the U.S. EPA's average emission factors for major aircraft types (e.g., general aviation, air taxi, military). For the intermediate milestone years, the emissions inventories are linearly interpolated between 2008 and 2035.

Several external adjustments to the off-road emissions are made to reflect CARB's rules and regulations and new estimates of activity. The adjustments include locomotives, large spark ignition engines and non-agricultural internal combustion engines.

Figure 3-2 shows a comparison between the off-road baseline emissions in the 2007 AQMP and the Draft Final 2012 AQMP. In general, the emissions are lower in the 2011 In-Use Off-Road Fleet Inventory model, except for 2008 SO_x emissions. The projected 2008 off-road NO_x emissions in the 2007 AQMP were 339 tons per day, while the 2008 base year off-road NO_x emissions in the Draft Final 2012 AQMP are 207 tons per day. The 2011 In-Use Off-Road Fleet Inventory emissions are lower because of the rules and regulations adopted since 2007 OFFROAD model, updated data, future growth corrections and recessionary impacts to commercial and industrial mobile equipment. The higher 2008 estimated SO_x emissions reflect a temporary stay in the implementation of the lower sulfur content marine fuel regulation for a portion of 2008.

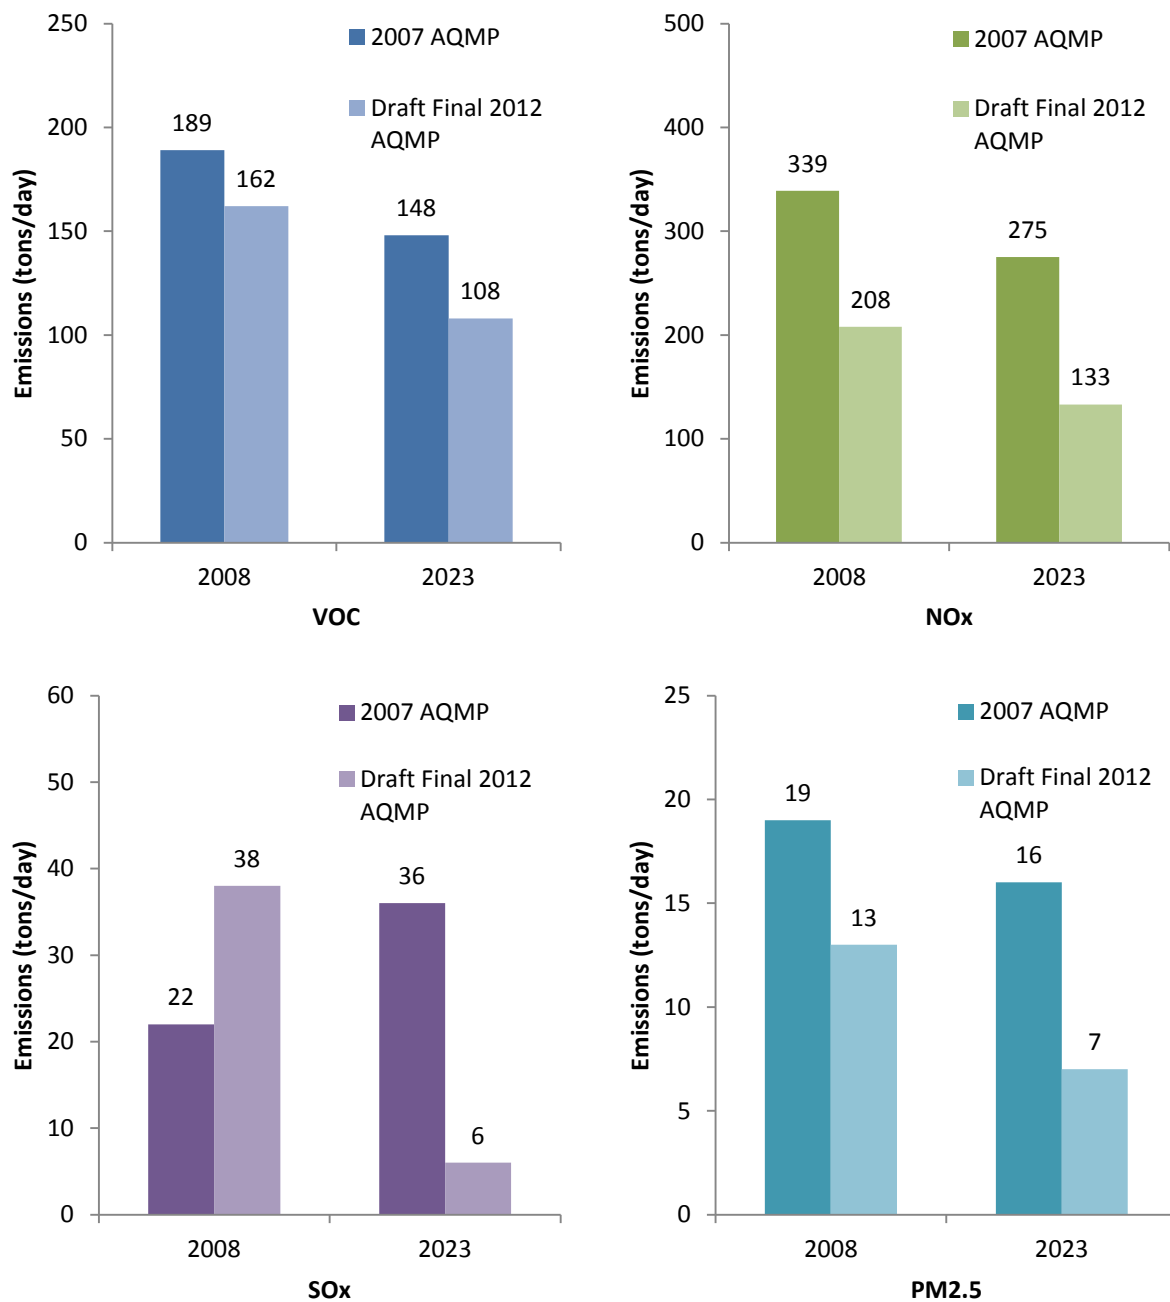

FIGURE 3-2

Comparison of Off-Road Emissions Between 2007 AQMP and Draft Final 2012 AQMP
(VOC & NOx – Summer Planning; SOx & PM2.5 – Annual Average Inventory)

Uncertainty in the Inventory

An effective AQMP relies on a complete and accurate emission inventory. Over the years, significant improvements have been made to quantify emission sources for which control measures are developed. Increased use of continuous monitoring and source tests has contributed to the improvement in point source inventories. Technical assistance to facilities and auditing of reported emissions by the District have also improved the accuracy of the emissions inventory. Area source inventories that rely on average emission factors and regional activities have inherent uncertainty. Industry-specific surveys and source-specific studies during rule development have provided much-needed refinement to the emissions estimates.

Mobile source inventories remain the greatest challenge due to continuously collected new information from the large number and types of equipment and engines. Every AQMP revision provides an opportunity to further improve the current knowledge of mobile source inventories. The Draft Final 2012 AQMP is not an exception. As described earlier, many improvements were included in EMFAC2011 and such work is still ongoing. However, it should be acknowledged that there are still areas that could be significantly improved if better data were available. Technological changes and advancement in the area of electric, hybrid, flexible fuel, fuel cell vehicles coupled with changes in future gasoline prices, all add uncertainty to the on-road emissions inventory.

It is important to note that the recent recession began in 2007, and being unforeseen, its impacts were not included in the 2007 AQMP. As the Draft Final 2012 AQMP is being developed, Southern California is still in the midst of a slow economic recovery. The impact of the recession is deep and is still being felt, and thus adds to the uncertainty in the emissions provided here. Relative to future growth, there are many challenges with making accurate projections, such as where vehicle trips will occur, the distribution between various modes of transportation (such as trucks and trains), as well as estimates for population growth and changes to the number and type of jobs. Forecasts are made with the best information available; nevertheless, they contribute to the overall uncertainty in emissions projections. Fortunately, AQMP updates are generally developed every three to four years; thereby allowing for frequent improvements to the inventories.

Gridded Emissions

For air quality modeling purposes, the region extends to Southern Kern County in the north, the Arizona border in the east, northern Mexico in the south and more than 100

miles offshore to the west. The modeling area is divided into a grid system comprised of 4 km by 4 km grid cells defined by Lambert Conformal coordinates. Both stationary and mobile source emissions are allocated to individual grid cells within this system. In general, the modeling emissions data features daily emissions. Variations in temperature, hours of operation, speed of motor vehicles, or other factors are considered in developing gridded motor vehicle emissions. The “gridded” emissions data used for both PM_{2.5} and ozone modeling applications differ from the average annual day or planning inventory emission data in two respects: (1) the modeling region covers larger geographic areas than the Basin; and (2) emissions represent day-specific instead of average or seasonal conditions. Summary of emissions inventories are generated for the PM_{2.5} and ozone modeling applications. For PM_{2.5}, the annual average day is used, which represents the characteristic of emissions that contribute to year-round particulate impacts. The summer planning inventory focuses on the warmer months (May through October) when evaporative VOC emissions play an important role in ozone formation.

BASE YEAR EMISSIONS

2008 Emission Inventory

Table 3-1A compares the annual average emissions between the 2008 base year in the Draft Final 2012 AQMP and the projected 2008 emissions in the 2007 AQMP by major source category for VOC and NO_x. Table 3-1B compares the annual average emissions between the 2008 base year in the Draft Final 2012 AQMP and the projected 2008 emissions in the 2007 AQMP for SO_x and PM_{2.5}. Due to the economic recession which began in 2007, it is expected that the more recent 2008 base year emissions estimates should be lower than the previously projected 2008 emissions. Yet, several categories show higher emissions in the 2008 base year in the Draft Final 2012 AQMP, such as fuel consumption, waste disposal, petroleum production and marketing for VOC; fuel consumption for NO_x; off-road emissions for SO_x; and industrial processes for PM_{2.5}. The reasons are as follows:

1. Fuel consumption – The emissions from commercial and industrial internal combustion engines were updated to include portable equipment emissions which were overlooked in the 2007 AQMP. The update causes increases in emissions for this category.
2. Waste disposal – Due to erroneous activity data reported by point sources in the 2007 AQMP, landfill emissions increased drastically. In addition, landfill

emission estimation methodology was revised to incorporate CARB's GHG Emission Inventory data to calculate the amount of methane being generated in 2008. Industry stakeholders have requested further evaluation of the emission factors currently used. As a result, the District staff will initiate a working group to undertake this effort.

3. Petroleum production and marketing – Two new area source categories (LPG transmission, storage tanks and pipeline cleaning and degassing) were added to the Draft Final 2012 AQMP. LPG transmission source category tracks the fugitive emissions associated with transfer and dispensing of LPG and is based on emission rates derived from the District source tests conducted in 2008 and 2011, sale volumes provided by the industry association, and category breakdowns. A total of 8.4 tons per day VOC emissions were added to the 2008 inventory. Storage tanks and pipeline cleaning and degassing source category was updated based on Rule 1149 amendments to reflect more frequent degassing events as well as the effectiveness of control techniques. During the amendment, it was determined that the actual degassing events were more than triple the amount that was estimated when the rule was originally developed. It was also assumed that once the degassing rule requirements were fulfilled, there would be no more fugitive emissions; however, a review of degassing logs indicated that sludge and product residual in the storage tanks significantly increase the emissions emanating from the storage tanks. Finally, the source category was expanded to include previously exempted tanks and pipelines. The storage tanks and pipeline source adds 1.4 tons per day VOC to the 2008 base year.
4. Off-road SO_x – CARB adopted a regulation in 2005 to set sulfur content limits on marine fuels for auxiliary diesel engines and diesel-electric engines operated on ocean-going vessels within California waters and 24 nautical miles of the California coastline. The regulation became effective January 1, 2007, and as a result the SO_x reductions were accounted for in the 2007 AQMP. However, pursuant to an injunction issued by a federal district court (district court), CARB ceased enforcing the regulation in the fall of 2007. See *Pacific Merchant Shipping Ass'n v. Thomas A. Cackette* (E.D. Cal. Aug. 30, 2007), No. Civ. S-06 2791-WBS-KJM. CARB filed an appeal with the Ninth Circuit and requested a stay of the injunction pending the appeal. As permitted under the appellate court stay, CARB decided to continue to enforce the regulation while litigation involving the regulation remained active. On May 7, 2008,

CARB issued another announcement to discontinue enforcement of the regulation pursuant to the same injunction after the Court of Appeals issued its decisions which invalidated the 2005 regulation. In the meantime, CARB staff prepared a new Ocean-Going Vessel Clean Fuel Regulation that was approved by its Board on July 24, 2008, and implementation began on July 1, 2009. The 2008 regulation includes the auxiliary engines and also the main engines and auxiliary boilers on ocean-going vessels within the same 24 nautical miles zone as the earlier auxiliary engine rule. The 2008 regulation achieves higher SO_x reductions than the original auxiliary engine rule, primarily due to regulating the main engines and auxiliary boilers in addition to the auxiliary engines.

Tables 3-2A and 3-2B show the 2008 emissions inventory by major source category. Table 3-2A shows annual average emissions, while Table 3-2B shows the summer planning inventory. Stationary sources are subdivided into point (e.g., chemical manufacturing, petroleum production, and electric utilities) and area sources (e.g., architectural coatings, residential water heaters, consumer products, and permitted sources smaller than the emission reporting threshold – generally 4 tpy). Mobile sources consist of on-road (e.g., light-duty passenger cars) and off-road sources (e.g., trains and ships). Entrained road dust is also included.

Figure 3-3 characterizes relative contributions by stationary and mobile source categories. On- and off-road sources continue to be the major contributors for each of the five pollutants. Overall, total mobile source emissions account for 59% of the VOC and 88% of the NO_x emissions for these two ozone-forming pollutants, based on the summer planning inventory. The on-road mobile category alone contributes about 33 and 59% of the VOC and NO_x emissions, respectively, and approximately 68% of the CO for the annual average inventory. For directly emitted PM_{2.5}, mobile sources represent 40% of the emissions with another 10% due to vehicle-related entrained road dust.

Within the category of stationary sources, point sources contribute more SO_x emissions than area sources. Area sources play a major role in VOC emissions, emitting about seven times more than point sources. Area sources, including sources such as commercial cooking, are the predominant source of directly emitted PM_{2.5} emissions (39%).

FUTURE EMISSIONS

Data Development

The milestone years 2008, 2014, 2019, 2023, and 2030 are the years for which inventories were developed as they are relevant target years under the federal CAA and the CCAA. The base year for the attainment demonstration is 2008. 2014 is the attainment year for the federal 2006 24-hour PM_{2.5} standard without an extension, and 2019 represents the latest attainment date with a full five-year extension. The 80 ppb federal 8-hour ozone standard attainment deadline is 2023, and the new 75 ppb 8-hour ozone standard deadline is 2032. A 2030 inventory will be used to approximate this latter year.

Future stationary emissions are divided into RECLAIM and non-RECLAIM emissions. Future NO_x and SO_x emissions from RECLAIM sources are estimated based on their allocations as specified by District Rule 2002 –Allocations for NO_x and SO_x. The forecasts for non-RECLAIM emissions were derived using: (1) emissions from the 2008 base year; (2) expected controls after implementation of District rules adopted by June, 2012, and CARB rules adopted as of August 2011; and (3) activity growth in various source categories between the base and future years.

Demographic growth forecasts for various socioeconomic categories (e.g., population, housing, employment by industry), developed by SCAG for their 2012 RTP, are used in the Draft Final 2012 AQMP. Industry growth factors for 2008, 2014, 2018, 2020, 2023, and 2030 are also provided by SCAG, and interim years are calculated by linear interpolation. Table 3-3 summarizes key socioeconomic parameters used in the Draft Final 2012 AQMP for emissions inventory development.

TABLE 3-3

Baseline Demographic Forecasts in the Draft Final 2012 AQMP

CATEGORY	2008	2023	2023 % GROWTH FROM 2008	2030	2030 % GROWTH FROM 2008
Population (Millions)	15.6	17.3	11%	18.1	16%
Housing Units (Millions)	5.1	5.7	12%	6.0	18%
Total Employment (Millions)	7.0	7.7	10%	8.1	16%
Daily VMT (Millions)	379	396	4%	421	11%

Current forecasts indicate that this region will experience a population growth of 11% between 2008 and 2023, with a 4% increase in vehicle miles traveled (VMT); and a population growth of 16% by the year 2030 with a 11% increase in VMT.

As compared to the projections in the 2007 AQMP, the current 2030 projections in the Draft Final 2012 AQMP show about 1.5 million less population (7.6% less), 900,000 less total employment (10% less), and 32 million miles less in the daily VMT forecast (7.1% less).

Summary of Baseline Emissions

Emissions data by source categories (point, area, on-road mobile and off-road mobile sources) and by pollutants are presented in Tables 3-4 through 3-7 for the years 2014, 2019, 2023, and 2030. The tables provide annual average, as well as summer planning inventories.

Without any additional controls, VOC, NO_x, and SO_x emissions are expected to decrease due to existing regulations, such as controls on off-road equipment, new vehicle standards, and the RECLAIM programs. Figure 3-4 illustrates the relative contribution to the 2023 inventory by source category. A comparison of Figures 3-3 and 3-4 indicates that the on-road mobile category continues to be a major contributor to CO and NO_x emissions. However, due to already-adopted regulations, 2023 on-road mobile sources account for: about 16% of total VOC emissions compared to 33% in 2008; about 36% of total NO_x emissions compared to 59% in 2008; and about 38% of total CO

emissions compared to 68% in 2008. Meanwhile, area sources become the major contributor to VOC emissions from 36% in 2008 to 50% in 2023. See Figures 3-5 through 3-16 for the top ten highest-ranking source categories for 2008, 2014, and 2023.

FIGURE 3-4

Relative Contribution by Source Category to 2023 Emission Inventory
(VOC & NOx – Summer Planning; CO, SOx, & PM2.5 – Annual Average Inventory)

IMPACT OF GROWTH

The Draft Final 2012 AQMP forecasts the 2030 emissions inventories “with growth” through a detailed consultation process with SCAG. The region is likely to see a 16% growth in population, 18% growth in housing units, 16% growth in employment, and 11% growth in vehicle miles traveled between 2008 and 2030. To illustrate the impact of demographic growth on emissions, year 2030 no-growth emissions were estimated by removing the growth factors from the 2030 baseline emissions. Table 3-8 presents the comparison of the projected 2030 emissions with and without growth. It should be noted that in this analysis, the benefit of potential applications of BACT under District’s Reg XIII-New Source Review (NSR) is not included. The growth impacts to year 2030 for VOC, NO_x, CO, SO_x and PM_{2.5} are 77, 76, 311, 5 and 11 tons per day respectively.

Pre-Base-Year Offsets

The District’s growth projections include pre-base year emissions, consistent with the requirements of 40 CFR § 51.165(a)(3)(i)(C)(I). To the extent offsets are required under NSR for permitted facilities to be sited or expanded in this region, pre-2008 emission credits authorized under Reg XIII can be used and are explicitly identified and accounted for in the Draft Final 2012 AQMP through growth projections, up to the amounts shown in Table 3-8. While Table 3-8 includes projected growth in certain sources not subject to NSR, the AQMP does not limit growth to individual source categories. Therefore, Table 3-8 explicitly identifies pre-base-year offsets in the amounts up to the difference between the growth and no-growth projections for the point and area source categories that are potentially subject to NSR and could potentially require the use of pre-base-year offsets. *See 57 Fed. Reg. 13, 498.*

This growth presents a formidable challenge to our air quality improvement efforts since the projected growth will offset the impressive progress made in reducing VOC and NO_x and PM_{2.5} emissions through adopted regulations. Meeting the U.S. EPA’s current and future more-stringent air quality standards will require the continuation of aggressive emissions reduction efforts from all levels of government.

*Annual Average Inventory

TOP TEN SOURCE CATEGORIES (2008, 2014, 2023)

The rankings of the top ten source contributors to the emissions inventories for VOC, NOx, SOx and PM2.5 are listed and briefly discussed in this section. The 2023 summer planning inventory for VOC and NOx, along with the 2008, 2014 and 2023 annual average inventory for VOC, NOx, SOx and PM2.5 are shown in the figures 3-5 to 3-16. These source categories are fairly broad and are intended for illustration purposes only.

Table 3-9 lists the top ten categories for each of the three inventory years for VOCs. Two of top five categories are on-road mobile sources in the 2008 inventory, but none of the on-road categories are found in the top five categories for 2023. This demonstrates the effect of more-stringent on-road standards in the future. Table 3-9 shows that consumer products, off-road equipment, and recreational boats remain as high-emitting categories over time. The top 10 categories account for 78% of the total VOC inventory in 2008 and 71% in 2023.

Table 3-10 shows the top ten categories for NO_x emissions in each of the three years. Mobile source categories remain the predominant contributor to NO_x emissions. Heavy-duty diesel trucks and off-road equipment make the top two on the list for all three years. NO_x RECLAIM and residential fuel combustion are the two non-mobile categories which make it to the top ten list. The top ten categories account for 87% of the total NO_x inventory in 2008, and 78% in 2023.

Table 3-11 shows the top source categories for SOx emissions in the years 2008, 2014 and 2023. The emissions level of SOx is relatively low. Therefore, only the categories that emit more than 0.5 tons per day of SOx are ranked and listed. The top five high emitting source categories remain the same in 2008 and 2023. Ships & Commercial Boats and SOx RECLAIM emissions are the most significant contributors. The top categories represent 93% of the total SOx inventory in 2008 and 81% in 2023.

Table 3-12 shows the top ten source categories in each of the three years for directly emitted PM2.5. Commercial cooking, paved road dust, and residential fuel combustion are the top three highest emitting categories in both 2008 and 2023. The top ten categories represent 71% of the total directly emitted PM2.5 inventory in 2008 and 70% in 2023.

District's SIP Emission Reduction Commitment

Overall Emission Reductions

Implementation

INTRODUCTION

The overall control strategy in the Draft Final 2012 AQMP provides a path to achieving emission reductions and air quality goals. Implementation of the Draft Final 2012 AQMP will be based on a series of control measures and strategies that vary by source type (i.e., stationary or mobile) as well as by the pollutant that is being targeted. Although great strides have been made in air pollution control technologies and emission reduction programs, air quality goals cannot be achieved without significant further emission reductions. The 2012 AQMP is designed to achieve the 2006 24-hour PM_{2.5} standard by 2014. In addition, the sheer magnitude of emission reductions needed for the attainment of the 8-hour ozone national ambient air quality standards (NAAQS) by 2023 and 2032 poses a tremendous challenge to the South Coast Air Basin. This challenge requires an aggressive control strategy and close collaboration with federal, state, and regional governments, local agencies, businesses, and the public. This chapter outlines the proposed control strategy and implementation schedule for the Draft Final 2012 AQMP as required to achieve the air quality goals in the Basin.

OVERALL ATTAINMENT STRATEGY

The overall control strategy for this Plan is designed to meet applicable federal and state requirements, including attainment of ambient air quality standards. The focus of the Draft Final 2012 AQMP is to demonstrate attainment of the federal 2006 24-hour PM_{2.5} ambient air quality standard by the 2014 attainment date, as well as an update to further define measures to meet the federal and state 8-hour ozone standards. The attainment demonstration for the new 8-hour ozone standard (75 ppb) will be addressed in the 2015 ozone plan.

The Draft Final 2012 AQMP provides base year emissions and future baseline emission projections (see Chapter 3 and Appendix III). In doing so, the Draft Final 2012 AQMP relies upon the most recent planning assumptions and the best available information including: CARB's latest emission factors (EMFAC2011) for the on-road mobile source emissions inventory; CARB's 2011 in-use fleet inventory for the off-road mobile source emission inventory; the latest point source inventory; updated area source inventories; and SCAG's forecast growth assumptions based on its recent 2012 Regional Transportation Plan. The baseline emission projections provide a snapshot of the future air quality conditions, including the effects from already adopted rules and regulations, but without a proposed control strategy.

Air quality modeling (see Chapter 5 and Appendix V) is conducted to determine the Basin’s “carrying capacity,” which is the allowable level of emissions to meet the standards. The remaining emissions above the carrying capacity are the amount of emissions that must be reduced in order to achieve the standards. To meet the targeted carrying capacity emissions level, a control strategy has been developed.

The development of the control strategy entails integrated planning to identify, to the extent feasible, co-benefit opportunities in achieving multi-pollutant reductions to meet standards with multiple deadlines. As such, control measures for attainment of one pollutant standard can assist in the attainment of another pollutant standard. For example, some control measures chosen to reduce criteria pollutants can also result in the reduction of greenhouse gases (GHG) and/or toxic emissions. In doing so, implementation of the Draft Final 2012 AQMP control strategy could also assist in reaching the GHG target goals in the AB32 Scoping Plan or the air quality goals in CARB’s Freight Transport Plan.

The control measures were chosen based on technical and economic feasibility, as well as other factors such as promoting fair share responsibility and maximizing private/public partnerships. Table 4-1 provides an overview of the criteria used in evaluating and selecting feasible control measures, in no particular order.

TABLE 4-1

Criteria for Evaluating 2012 AQMP Control Measures (not ranked by priority)

CRITERIA	DESCRIPTION
Cost-Effectiveness	The cost of a control measure to reduce air pollution by one ton [cost includes purchasing, installing, operating and maintaining the control technology].
Emission Reduction Potential	The total amount of pollution that a control measure can actually reduce.
Enforceability	The ability to ensure that polluters comply with a control measure.
Legal Authority	Ability of the District or other adopting agency to implement the measure or the likelihood that local governments and agencies will cooperate to approve a control measure.
Public Acceptability	The likelihood that the public will cooperate in the implementation of a control measure that applies to members of the public.
Rate of Emission Reduction	The time it will take for a control measure to reduce a certain amount of air pollution.
Technological Feasibility	The likelihood that the technology for a control measure will be available as anticipated.

For the Draft Final 2012 AQMP control measure development, District staff conducted an AQMP Technology Symposium in September 2011 to solicit new control concepts and innovative ideas from industry experts, professional consultants, and government specialists. Internal staff suggestions and external recommendations assisted in identifying additional control measures and assessing control measure feasibility. Since the adoption of the 2007 AQMP, the District has made significant strides in achieving further emission reductions from stationary sources. Table 1-2 in Chapter 1 provides a list of rules adopted by the District since adoption of the 2007 AQMP as well as the SIP commitment and the emission reductions achieved for each rule. The proposed control strategy in the Draft Final 2012 AQMP includes some revised and partially implemented measures from the 2007 AQMP, and new measures deemed feasible and necessary to provide additional control opportunities to achieve the air quality standards.

The Draft Final 2012 AQMP is proposing a control strategy that includes emission reductions from both stationary and mobile sources. The proposed stationary source control measures in the Draft Final 2012 AQMP are based on implementation of all feasible control measures through the application of available cleaner technologies, best management practices, incentive programs, as well as development and implementation of zero- and near-zero technologies and control methods. The stationary source control measures presented in the Plan are proposed to further reduce emissions from both point sources (permitted facilities) and area sources (generally small and non-permitted) in addition to smaller permitted sources with emissions less than the reporting threshold in the District's Annual Emissions Reporting Program). The basic principles followed in developing the District's stationary source control measures include: 1) identify PM_{2.5}, ammonia and/or NO_x reduction opportunities and maximize reductions by the 2014 attainment date, and 2) initiate programs or rule making activities for VOC and further NO_x control strategies aiming at maximum reductions by the 2023 timeframe to further implement the ozone plan for the 1997 8-hour ozone standard.

The mobile source strategy includes actions seeking further emission reductions from both on-road and off-road mobile sources, such as accelerated penetration of zero- and near-zero emission vehicles and early retirement of older vehicles. In addition, the mobile source strategy includes research and development of advanced control technologies from various mobile sources. Some of the proposed actions need to be

implemented by several agencies that currently have the statutory authority to implement such measures. For more details about the responsibilities of the other agencies, refer to the last section of this chapter under Implementation.

The Draft Final 2012 AQMP relies on a comprehensive and integrated control approach aimed at achieving the 2006 24-hour PM_{2.5} standard by the 2014 attainment date through implementation of short-term 24-hour PM_{2.5} control measures. For each control measure, the District will seek to achieve the maximum reduction potential that is technically feasible and cost-effective. The overall control strategy provides for attainment of the 2006 24-hour PM_{2.5} standard, with additional ozone measures to further implement the ozone plan for the 8-hour ozone standard.

The following sections provide an overview of the two-part control strategy.

24-Hour PM_{2.5} Strategy

In December 2009, the U.S. EPA designated the Basin as nonattainment for the 2006 24-hour PM_{2.5} NAAQS, and required attainment of the standard by 2014. To develop the Plan's required control strategy for meeting state and federal requirements, an iterative process of technology/strategy review and ambient air quality modeling is utilized. The emission inventories for nonattainment areas include base year (2008) and future years' emissions through the attainment year (see Chapter 3 for detail of the inventory) which include emissions reductions achieved by already-adopted measures. The remaining emissions target is initially defined utilizing air quality modeling that will achieve the ambient air quality standards based on reductions from all sources. Control measures based on existing technologies and advancements are then evaluated to determine their effectiveness in meeting this remaining emissions target. Further modeling analyses are conducted using the actual emissions reductions achieved based on the technology forecast. Ultimately an overall emissions target (i.e., carrying capacity) is determined for achieving the ambient air quality standards and for which controls have been proposed.

Modeling Results

In accordance with U.S. EPA guidelines, the District modeled air quality based on emission reductions achieved due to already-adopted and implemented rules at the federal, state and local levels. This analysis provided the air quality improvements that such programs are projected to offer for the nonattainment area. Future air quality projections for 24-hour PM_{2.5} concentrations as shown in Chapter 5 show an

air quality improvement over time. There are many factors (e.g., current regulations, fleet turnover, etc.) contributing to the downward trend of 24-hour PM_{2.5} levels, but the reductions from already adopted regulations are not enough to meet the attainment date of 2014 at all monitoring stations. The U.S. EPA does allow an area that cannot meet the standard by the attainment date, based on the severity of its nonattainment problem and feasibility of pollution control measures, to request an extension of the initial attainment date for a period of up to five years. As demonstrated in Chapter 5, the inclusion of the control strategy in combination with already adopted measures will enable the region to achieve attainment by 2014.

Sensitivity Analysis

There are five major contributors resulting in the formation of PM_{2.5} including NO_x, SO_x, VOC, directly emitted PM_{2.5}, and ammonia. Various combinations of reductions of these pollutants could provide a path to achieve clean air standards. It is useful to weigh the value in tons per day of emissions reductions relative to ambient concentration improvements of PM_{2.5}, since different pollutant emissions contribute differently to overall PM_{2.5} levels. The Final 2007 AQMP established a set of factors relating regional per ton precursor emissions reductions to microgram per cubic meter improvements of ambient PM_{2.5} for the annual average concentration. The current CMAQ model simulations provide a similar set of factors, but this time related to 24-hour average PM_{2.5}. For 24-hour average PM_{2.5}, the simulations determined that VOC emissions reductions have the lowest benefit in terms of micrograms per cubic meter ambient PM_{2.5} reduced per ton of emissions reduction, a third of NO_x's effectiveness. The analysis further indicated that SO_x emissions were about 7.8 times more effective than NO_x, and that directly emitted PM_{2.5} is approximately 14.8 times more effective than NO_x. It is important to note that the contribution of ammonia emissions is embedded as a component of the SO_x and NO_x factors, since ammonium nitrate and ammonium sulfate are the resultant particulate compounds formed in the ambient chemical process.

Basin-wide and Episodic Short-Term PM_{2.5} Measures

The Basin-wide 24-hour PM_{2.5} attainment strategy is primarily focused on directly-emitted PM_{2.5} and NO_x reductions which can be feasibly achieved by the attainment date of 2014. Direct PM_{2.5} emissions can be substantially reduced by episodically curtailing residential wood burning and open burning from agricultural or prescribed (e.g., brush clearing) sources. NO_x is a precursor to both PM_{2.5} and ozone, and thus NO_x reductions are preferred since they are also needed for ozone. Thus, further

NO_x reductions from RECLAIM facilities are being proposed as a contingency measure if attainment of the 24-hour PM_{2.5} standard is not achieved by 2014. The Basin-wide control strategy also includes a backstop measure for indirect sources at the ports, initiation of control technology assessments, and a measure focused on education and outreach.

8-hour Ozone Strategy

Although the Basin is projected to meet the 2006 24-hour PM_{2.5} standards by the applicable attainment deadlines with the strategy discussed above, significant challenges remain in meeting the federal ozone standards. The next AQMP in 2015 will include a more detailed analysis to demonstrate attainment of the 1997 and 2008 8-hour ozone standards, but it is prudent for both the District and stakeholders to immediately begin development of control strategies for ozone given the looming 2023 deadline. The District will pursue actions that can be implemented over the next two to three years to work towards meeting the 8-hour ozone standards. Ozone reduction strategies and programs need to be continued and accelerated to ensure that the air basin will meet the 8-hour ozone standards by 2024 and 2032. Proposed measures to reduce ozone include emission reductions from coatings, consumer products, and RECLAIM facilities as well as early transitions to cleaner technologies.

To ultimately achieve the ozone ambient air quality standards, significant additional emissions reductions will be necessary from a variety of sources, including those primarily under the jurisdiction of CARB (e.g., on-road motor vehicles, off-road equipment, and consumer products) and U.S. EPA (e.g., aircraft, ships, trains, and pre-empted off-road equipment). Without an adequate and fair-share level of reductions from all sources, the emission reduction burden would unfairly be shifted to sources that have already been doing their part for clean air. Moreover, the District will continue to use its available regulatory authority to further control mobile source emissions where federal or State actions do not meet regional needs.

Overall, the Draft Final 2012 AQMP includes 22 stationary and 17 mobile source measures. The following seven sections discuss the control measures, SIP commitments, overall emission reductions and implementation as outlined below:

- Proposed Short-term PM_{2.5} Control Measures (see Appendix IV-A for detailed descriptions of the District's stationary source control measures)

- Proposed PM_{2.5} Contingency Measures (see Chapter 6 for a detailed discussion of the contingency requirements)
- SCAG's Regional Transportation Strategy and Transportation Control Measures (see Appendix IV-C for detailed descriptions of the regional transportation strategy and control measures)
- Proposed 8-hour Ozone Measures (see Appendix IV-A for detailed descriptions of the District's stationary source control measures and Appendix IV-B for detailed descriptions of the District's mobile source measures)
- District's SIP Emission Reduction Commitment
- Overall Emission Reductions
- Implementation

PROPOSED PM_{2.5} SHORT-TERM CONTROL MEASURES

The proposed short-term PM_{2.5} control measures include stationary source control measures, episodic controls, technology assessments, an indirect source measure and one education measure. As noted earlier in this chapter, a public process to solicit input assisted District staff in developing and proposing feasible control measures and strategies that could be adopted and implemented in the short-term. The assessment considered whether adoption and implementation of control measures could reasonably take place prior to 2014 resulting in attainment of the 2006 24-hour PM_{2.5} standard of 35 µg/m³ by the 2014 attainment year. Each short-term PM_{2.5} control measure was evaluated to determine the potential emission reductions that could be achieved. In some cases, only a range of possible emissions reductions could be determined, and for some others, the magnitude of potential reductions cannot be determined at this time.

Table 4-2 provides a list of the District's short-term PM_{2.5} measures along with the anticipated adoption date, implementation date and emissions reduction. The measures target a variety of source categories: Combustion Sources (CMB), PM Sources (BCM), Indirect Sources (IND), Educational Programs (EDU) and Multiple Component Sources (MCS).

TABLE 4-2

List of District's Adoption/Implementation Dates and Estimated Emission Reductions from Short-Term PM_{2.5} Control Measures

NUMBER	TITLE	ADOPTION	IMPLEMENTATION PERIOD	REDUCTION (TPD)
CMB-01	Further NO _x Reductions from RECLAIM [NO _x] –Phase I (Contingency)	2013	2014	2-3 ^a
BCM-01	Further Reductions from Residential Wood Burning Devices [PM _{2.5}]	2013	2013-2014	7.1 ^b
BCM-02	Further Reductions from Open Burning [PM _{2.5}]	2013	2013-2014	4.6 ^c
BCM-03 (formerly BCM-05)	Emission Reductions from Under-Fired Charbroilers [PM _{2.5}]	Phase I – 2013 (Tech Assessment) Phase II - TBD	TBD	1 ^d
BCM-04	Further Ammonia Reductions from Livestock Waste [NH ₃]	Phase I – 2013-2014 (Tech Assessment) Phase II - TBD	TBD	TBD ^e
IND -01 (formerly MOB-03)	Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources [NO _x , SO _x , PM _{2.5}]	2013	12 months after trigger	N/A ^f
EDU-01 (formerly MCS-02, MCS-03)	Further Criteria Pollutant Reductions from Education, Outreach and Incentives [All Pollutants]	Ongoing	Ongoing	N/A ^f
MCS-01 (formerly MCS-07)	Application of All Feasible Measures Assessment [All Pollutants]	Ongoing	Ongoing	TBD ^e

- Emission reductions are included in the SIP as a contingency measure.
- Winter average day reductions based on episodic conditions and 75 percent compliance rate.
- Reductions based on episodic day conditions.
- Will submit into SIP once technically feasible and cost effective options are confirmed.
- TBD are reductions to be determined once the technical assessment is complete, and inventory and control approach are identified.
- N/A are reductions that cannot be quantified due to the nature of the measure (e.g., outreach, incentive programs) or if the measure is designed to ensure reductions that have been assumed to occur will in fact occur.

Each control measure type relies on a number of control methods. Table 4-3 provides the types of proposed short-term measures and their typical corresponding control methods.

TABLE 4-3

The following text provides a brief description of the District's short-term measures.

Combustion Sources

This category includes a control measure that further reduces NO_x emissions from RECLAIM facilities.

CMB-01 – FURTHER NOX REDUCTIONS FROM RECLAIM (PHASE I):

This proposed control measure is a contingency measure to be automatically triggered if the 24-hour PM_{2.5} standard is not met by the 2014 attainment date. The control measure will seek further reductions of 2 tpd of NO_x allocations if triggered. In addition, staff would seek to identify appropriate approaches during rulemaking to

implement the allocation shaving methodology. The control measure has the ability to produce co-benefits in the reduction of PM_{2.5} and ozone.

PM Sources

This category includes four control measures, including episodic curtailment of residential wood burning and opening burning, PM_{2.5} emission reductions from under-fired charbroilers and ammonia emission reductions from livestock waste. The under-fired charbroiler measure has been carried over from the 2007 AQMP.

BCM-01 - FURTHER REDUCTIONS FROM RESIDENTIAL WOOD BURNING DEVICES: The purpose of this measure would be to seek further PM_{2.5} emissions reductions from residential wood burning fireplaces and wood stoves whenever key areas in the South Coast Air Basin are forecast to approach the federal 24-hour PM_{2.5} standard. A review of other California air district regulations has indicated that the most appropriate amendment to the existing AQMD wood smoke control program would be to decrease the mandatory wood burning curtailment forecast threshold from 35 µg/m³ to a more conservative 30 µg/m³. In addition to the existing sub-regional curtailment program of Rule 445 (based on areas forecast to exceed the existing PM_{2.5} standard), this measure would implement a curtailment that would apply Basin-wide whenever a PM_{2.5} level of greater than 30 µg/m³ is forecast at any monitoring station, which has recorded violations of the design value for the current PM_{2.5} 24-hour standard of 35 µg/m³ for either of the two previous three-year design value periods. Lowering the wood burning curtailment forecast threshold and applying the curtailment to the entire Basin when triggered could potentially reduce Basin-wide ambient PM_{2.5} concentrations on these episodic no-burn days by about 7.1 tons per winter day (assuming 75% rule effectiveness).

BCM-02 - FURTHER REDUCTIONS FROM OPEN BURNING: Rule 444 outlines the criteria and guidelines for agricultural and prescribed burning, as well as training burns, to minimize PM emissions and smoke in a manner that is consistent with state and federal laws. Agricultural burning is open burning of vegetative materials produced from the growing and harvesting of crops. Prescribed burning is a planned open burning of vegetative materials, usually conducted by a fire protection agency and/or department of forestry, to promote a healthier habitat for plants and animals, to prevent plant disease and pests, and to reduce the risk of wild fires. Training burns are hands-on instructional events conducted by fire protection agencies on methods of preventing and/or suppressing fire. Rule 444 currently contains requirements that a no-burn day may be called under a combination of

geographical, meteorological, and air quality conditions. This control measure would potentially increase the number of no-burn days by establishing an additional criteria for no-burn during episodic days as described in control measure BCM-01 by implementing a curtailment that would apply Basin-wide whenever a PM_{2.5} level of greater than 30 µg/m³ is forecast at any monitoring station which has recorded violations of the design value for the current PM_{2.5} 24-hour standard of 35 µg/m³ for either of the two previous three-year design value periods. Enhancing the open burning restrictions with this new threshold criteria and applying a curtailment to the entire Basin could potentially reduce Basin-wide ambient PM_{2.5} concentrations on these episodic no-burn days by about 4.6 tons per winter day. Since the burning would likely be shifted to other days, the total annual emissions would remain the same, but would not occur on days where high PM_{2.5} levels are forecast.

BCM-03 - EMISSION REDUCTIONS FROM UNDER-FIRED CHARBROILERS: This proposed measure seeks emission reductions by potentially requiring new and/or existing medium to large volume restaurants with under-fired charbroilers to install control devices meeting a minimum efficiency requirement. Under-fired charbroilers are responsible for the majority of emissions from restaurant operations – 84 percent of PM and 71 percent of VOC emissions. Several control options are currently being evaluated and tested including electrostatic precipitators (ESP), high efficiency particulate arresting (HEPA) filters, wet scrubbers, and thermal oxidizers. Under-fired charbroilers are one of the largest unregulated sources of directly emitted PM. A technical assessment of potential control technologies is currently ongoing at University of California, Riverside (CE-CERT), to evaluate the efficiency and the cost-effectiveness of various control devices for the capture and control of filterable and/or condensable forms of PM from under-fired charbroilers. The Bay Area AQMD adopted a rule for commercial cooking equipment that controls both chain-driven and under-fired charbroilers. The Bay Area measure will be evaluated to meet the all feasible measures requirement. Technical and economic feasibility, as well as affordability of controls, particularly for existing restaurants relative to retrofit installation and operation/maintenance, will be considered in conjunction with any future rule development to establish requirements for under-fired charbroilers.

BCM-04 – FURTHER AMMONIA REDUCTIONS FROM LIVESTOCK WASTE: This measure seeks to reduce ammonia emissions from livestock operations with emphasis on dairies. Existing Rule 1127 – Emission Reductions from Livestock Waste requires best management practices for dairies and specific

requirements regarding manure removal, handling, and composting; however, the rule does not focus on fresh manure, which is one of the largest dairy sources of ammonia emissions. An assessment will be conducted to evaluate the use of sodium bisulfate (SBS) at local dairies to evaluate the technical and economic feasibility of its application, as well as potential impacts to ground water, and the health and safety of both workers and dairy stock. Reducing pH level in manure through the application of acidulant additives (acidifier), such as SBS, is one of the potential mitigations for ammonia. SBS is currently being considered for use in animal housing areas where high concentrations of fresh manure are located. Research indicates that best results occur when SBS is used on “hot spots”. SBS can also be applied to manure stock piles and at fencelines, and upon scraping manure to reduce ammonia spiking from the leftover remnants of manure and urine. SBS application may be required seasonally or episodically during times when high ambient PM_{2.5} levels are forecast.

Multiple Component Sources

There is one short-term control measure for all feasible measures.

MCS-01: APPLICATION OF ALL FEASIBLE MEASURES ASSESSMENT:

This control measure is to address the state law requirement for all feasible measures for ozone. Existing rules and regulations for pollutants such as VOC, NO_x, SO_x and PM reflect current best available retrofit control technology (BARCT). However, BARCT continually evolves as new technology becomes available that is feasible and cost-effective. Through this proposed control measure, the District would commit to the adoption and implementation of the new retrofit control technology standards. Finally, staff will review actions taken by other air districts for applicability in our region.

Indirect Sources

This category includes a proposed control measure carried over from the 2007 AQMP (formerly MOB-03) that establishes a backstop measure for indirect sources of emissions at ports.

IND-01- BACKSTOP MEASURE FOR INDIRECT SOURCES OF EMISSIONS FROM PORTS AND PORT-RELATED SOURCES: The goal of this measure is to ensure that NO_x, SO_x and PM_{2.5} emissions reductions from port-related sources are sufficient to attain the 24-hr federal PM_{2.5} ambient air quality

standard. If emission levels projected to result from the current regulatory requirements and voluntary reduction strategies specified by the Ports are not realized, the 24-hr federal PM_{2.5} ambient air quality standard may not be achieved. This control measure is designed to ensure that the necessary emission reductions from port-related sources projected in the 2012 AQMP milestone years are achieved or if it is later determined through a SIP amendment that additional region-wide reductions are needed due to the change in Basin-wide carrying capacity for PM_{2.5} attainment. In this case, the ports will be required to further reduce their emissions on a “fair-share” basis.

Educational Programs

There is one proposed educational program within this category.

EDU-01: FURTHER CRITERIA POLLUTANT REDUCTIONS FROM EDUCATION, OUTREACH AND INCENTIVES: This proposed control measure seeks to provide educational outreach and incentives for consumers to contribute to clean air efforts. Examples include the usage of energy efficient products, new lighting technology, “super compliant” coatings, tree planting, and the use of lighter colored roofing and paving materials which reduce energy usage by lowering the ambient temperature. In addition, this proposed measure intends to increase the effectiveness of energy conservation programs through public education and awareness as to the environmental and economic benefits of conservation. Educational and incentive tools to be used include social comparison applications (comparing your personal environmental impacts with other individuals), social media, and public/private partnerships.

PROPOSED PM_{2.5} CONTINGENCY MEASURES

Pursuant to CAA section 172(c)(9), contingency measures are emission reduction measures that are to be automatically triggered and implemented if an area fails to attain the national ambient air quality standard by the applicable attainment date, or fails to make reasonable further progress (RFP) toward attainment. Further detailed descriptions of contingency requirements can be found in Chapter 6 – Clean Air Act Requirements. As discussed in Chapter 6 and consistent with U.S. EPA guidance, the District is proposing to use excess air quality improvement from the proposed control strategy, as well as potential NO_x reductions from CMB-01 listed above, to demonstrate compliance with this federal requirement.

SCAG’s REGIONAL TRANSPORTATION STRATEGY AND TRANSPORTATION CONTROL MEASURES

The Southern California Association of Governments (SCAG), the Metropolitan Planning Organization (MPO) for Southern California, is mandated to comply with federal and state transportation and air quality regulations. Federal transportation law authorizes federal funding for highway, highway safety, transit, and other surface transportation programs. The federal CAA establishes air quality standards and planning requirements for various criteria air pollutants.

Transportation conformity is required under CAA Section 176(c) to ensure that federally supported highway and transit project activities “conform to” the purpose of the SIP. Conformity currently applies to areas that are designated non-attainment, and those re-designated to attainment after 1990 (“maintenance areas” with plans developed under CAA Section 175[A]) for the specific transportation-related criteria pollutants. Conformity to the purpose of the SIP means that transportation activities will not cause new air quality violations, worsen existing violations, or delay timely attainment of the relevant NAAQS. The transportation conformity regulation is found in 40 CFR Part 93.

Pursuant to California Health and Safety Code section 40460, SCAG has the responsibility of preparing and approving the portions of the AQMP relating to regional demographic projections and integrated regional land use, housing, employment, and transportation programs, measures, and strategies. The District combines its portion of the Plan with those prepared by SCAG.

The transportation strategy and transportation control measures (TCMs), included as part of the 2012 PM_{2.5} AQMP and SIP for the South Coast Air Basin, are based on SCAG’s adopted 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) and 2011 Federal Transportation Improvement Program (FTIP). This was developed in consultation with federal, state and local transportation and air quality planning agencies and other stakeholders.

The Regional Transportation Strategy and Transportation Control Measures portion of the 2012 AQMP/SIP consists of the following three related sections.

Section I. Linking Regional Transportation Planning to Air Quality Planning

As required by federal and state laws, SCAG is responsible for ensuring that the regional transportation plan, program, and projects are supportive of the goals and objectives of AQMPs/SIPs. SCAG is also required to develop demographic projections and a regional transportation strategy and control measures for the AQMPs/SIPs.

The RTP/SCS, updated every four years, is a long-range regional transportation plan that provides a vision for transportation investments throughout the SCAG Region. The 2012-2035 RTP/SCS also integrates land use and transportation planning to achieve regional greenhouse gas (GHG) reduction targets set by ARB pursuant to SB375.

SCAG also develops the biennial FTIP. The FTIP is a multimodal program of capital improvement projects to be implemented over a six year period. The FTIP implements the programs and projects in the RTP/SCS.

Section II. Regional Transportation Strategy and Transportation Control Measures

The SCAG Region faces daunting mobility, air quality, and transportation funding challenges. Under the guidance of the goals and objectives adopted by SCAG's Regional Council, the 2012-2035 RTP/SCS was developed to provide a blueprint to integrate land use and transportation strategies to help achieve a coordinated and balanced regional transportation system. The 2012-2035 RTP/SCS represents the culmination of more than two years of work involving dozens of public agencies, 191 cities, hundreds of local, county, regional and state officials, the business community, environmental groups, as well as various nonprofit organizations. The 2012-2035 RTP/SCS was formally adopted by the SCAG Regional Council on April 4, 2012.

The 2012-2035 RTP/SCS contains a host of improvements to every component of the regional multimodal transportation system including:

- Active transportation (non-motorized transportation, such as biking and walking)
- Transportation demand management (TDM)
- Transportation system management (TSM)
- Transit

- Passenger and high-speed rail
- Goods movement
- Aviation and airport ground access
- Highways
- Arterials
- Operations and maintenance

Included within these transportation system improvements are TCM projects that reduce vehicle use or change traffic flow or congestion conditions. TCMs include the following three main categories of transportation improvement projects and programs:

- High occupancy vehicle (HOV) measures,
- Transit and systems management measures, and
- Information-based transportation strategies.

New to this cycle of the RTP is the inclusion of the SCS as required by SB 375. The primary goal of the SCS is to provide a vision for future growth in Southern California that will decrease per capita GHG emissions from passenger vehicles. However, the strategies contained in the 2012-2035 RTP/SCS will produce benefits for the region far beyond simply reducing GHG emissions. The SCS integrates the transportation network and related strategies with an overall land use pattern that responds to projected growth, housing needs, changing demographics, and transportation demands. The regional vision of the SCS maximizes current voluntary local efforts that support the goals of SB 375. The SCS focuses the majority of new housing and job growth in high-quality transit areas and other opportunity areas on existing main streets, in downtowns, and commercial corridors, resulting in an improved jobs-housing balance and more opportunity for transit-oriented development. In addition, SCAG is a strategic partner in a regional effort to accelerate fleet conversion to near-zero and zero-emission transportation technologies, including planning for the expansion of alternative-fuel infrastructure to accommodate the anticipated increase in alternative fueled vehicles.

Section III. Reasonably Available Control Measure (RACM) Analysis for Transportation Control Measures

As required by the CAA, a RACM analysis must be included as part of the overall control strategy in the AQMP/SIP to ensure that all potential control measures are evaluated for implementation and that justification is provided for those measures

that are not implemented. Appendix IV-C contains the RACM TCM component for the Basin's 24-hour PM_{2.5} control strategy. In accordance with U.S. EPA procedures, this analysis considers TCMs in the 2012-2035 RTP/SCS, measures identified by the CAA, and relevant measures adopted in other non-attainment areas of the country. Based on this comprehensive review, it is determined that the TCMs being implemented in the Basin are inclusive of all TCM RACM. None of the candidate measures reviewed and determined to be infeasible meets the criteria for RACM implementation.

The emission benefits associated with the RTP/SCS are reflected in the 2012 AQMP projected emissions. The transportation strategy is estimated to reduce 0.4 ton per day of NO_x and 0.1 ton per day VOC in 2014. The estimated emissions benefits of future TCM projects in 2014 are reductions of 0.7 ton per day of NO_x, 0.3 ton per day of VOC, and 0.1 ton per day of PM_{2.5}.

For a detailed discussion of the regional transportation strategy, refer to Appendix IV-C: Regional Transportation Strategy and Control Measures.

PROPOSED 8-HOUR OZONE MEASURES (TO REDUCE EMISSIONS ASSOCIATED WITH CAA SECTION 182(e)(5) MEASURES)

The 2007 State Implementation Plan (SIP) for the 8-hour ozone NAAQS contains commitments for emission reductions that rely on advancement of technologies, as authorized under Section 182(e)(5) of the federal Clean Air Act. These measures, which have come to be known as the "black box," account for a substantial portion of the NO_x emission reductions needed to attain the federal ozone standards – over 200 tons/day. The deadlines to reduce ozone concentrations in the region are 2023 (to attain the 80 ppb NAAQS), and 2032 (to attain 75 ppb NAAQS)¹. Attaining these standards will require substantial reductions in emissions of NO_x well beyond reductions resulting from current rules, programs, and commercially available technologies. Given the relatively large size of the "black box" measures, it is important to continue to reduce the reliance on Section 182(e)(5) long-term emissions reductions as ozone attainment dates approach. To this end, all feasible

¹ The attainment deadline for the 75 ppb standard (adopted in 2008) for an extreme non-attainment area is December 31, 2032.

ozone control measures are included in this Draft Final 2012 AQMP as an update to the previously approved 2007 8-hour ozone SIP.

Mobile sources emit over 80 percent of regional NO_x and therefore must be the largest part of the solution. As provided in Figure 4-1, on-road truck categories are projected to comprise the single largest contributor to regional NO_x in 2023. Other equipment involved in goods movement, such as marine vessels, locomotives and aircraft, are also substantial NO_x sources.

*Oceangoing vessels = 32 tons/day

**RECLAIM: 320 largest stationary sources, including all refineries and power plants

FIGURE 4-1

Top NO_x Emissions Categories and Corresponding NO_x Emissions (tons per day) in 2023 in the South Coast Air Basin, Annual Average Day

Figure 4-2 shows projections indicating that the region must reduce regional NO_x emissions by about 65% by 2023, and 75% by 2032, to attain the 8-hour ozone NAAQS as required by federal law.

FIGURE 4-2
 Needed NOx Emission Reductions to Achieve
 Federal 8-Hour Ozone Ambient Air Quality Standards

Since most significant emission sources are already controlled by over 90%, attainment of the ozone standards will require broad deployment of zero- and near-zero² emission technologies in the 2023 to 2032 timeframe. On-land transportation sources such as trucks, locomotives, and cargo handling equipment have technological potential to achieve zero- and near-zero emission levels. Current and potential technologies include hybrid-electric, battery-electric, and hydrogen fuel cell

² The term “near-zero emissions” refers to emissions approaching zero and will be delineated for individual source categories through the process of developing the Air Quality Management Plan/State Implementation Plan and subsequent control measures. Based on current analyses, on-land transportation sources will need to achieve zero emissions where possible, and otherwise will need to be substantially below adopted emission standards — including standards with future effective dates. Near-zero emissions technologies can help meet this need, particularly if they support a path toward zero emissions (e.g. electric/fossil fuel hybrids with all-electric range).

on-road vehicle technologies. New types of hybrids could also serve long-term needs while providing additional fuel diversity. These could include, for example, natural gas-electric hybrid technologies for on-road and other applications, particularly if coupled with improved after-treatment technologies. Equipment powered solely by alternative fuels such as natural gas may also play a long-term role in some applications, if those applications are found to pose technological barriers to achieving zero or near-zero emissions. Even in such applications, however, substantial additional emission reductions will be needed through development of new, advanced after-treatment technologies. In addition, alternative fuels will likely play a transitional near-term role. Alternative fuels such as natural gas have historically helped the region make progress toward attaining air quality standards, and -- while not achieving zero or near-zero NO_x emission levels -- they are generally cleaner than conventional fuels. Given the region's need to attain air quality standards in a few short years, alternative fueled engines will continue to play a role. Finally, we emphasize that air quality regulatory agencies have traditionally set policies and requirements that are performance based and technology and fuel neutral -- a policy that the District intends to continue. In short, all technologies and fuels should be able to compete on equal footing to meet environmental needs.

While there has been much progress in developing and deploying transportation technologies with zero- and near-zero emissions (particularly for light-duty vehicles and passenger transit), additional technology development, demonstration and commercialization will be required prior to broad deployment in freight and other applications. This section describes a path to evaluate, develop, demonstrate, fund and deploy such technologies for land-based transportation sources. It also proposes near-term measures to accelerate fleet turnover to the lowest emission units, and require deployment of zero-emission technologies where most feasible.

The District staff believes that a combination of regulatory actions and public funding is the most effective means of achieving these emission reductions. Voluntary incentive programs such as the Carl Moyer Program can help to accelerate turnover to the cleanest commercially available equipment. A majority of the on-road and off-road measures proposed are based on existing funding programs implemented by the District or the California Air Resources Board. However, several of the existing funding programs will sunset in the 2014 – 2015 timeframe. Continued funding beyond 2015 will be needed to reduce the emissions associated with the black box. Developing, demonstrating and deploying new technologies will require public/private partnerships and, in some cases, regulatory actions.

The measures described in this section are a relatively small down payment on the total emission reductions needed to attain the current NAAQS for ozone. The measures proposed in this section and further discussed in Appendix IV-A and IV-B are feasible steps that must commence in the near-term to establish a path toward a broader transition to the technologies that will be needed to attain federal air quality standards. Between now and 2015, the additional measures needed to attain both the 75 and 80 ppb ozone NAAQS will be fleshed out in greater detail as required under the federal Clean Air Act as part of the next AQMP revision (see Chapters 5 and 6 for further discussions). Given the magnitude of needed emission reductions, and the time remaining until attainment deadlines, it is important that progress and momentum to identify, develop, and deploy needed technologies be sustained and accelerated.

The District staff recognizes these are very difficult policy choices the Basin is facing. Transitioning over the next 10 to 20 years to cleaner transportation technologies will involve major costs and effects on the economy. However, adopting sufficient plan measures to attain the ozone air quality standard by 2024 is required by federal law and therefore, failing to do so is not an acceptable public policy. Such failure would also risk adverse health consequences highlighted in recent health studies, not to mention the potential adverse economic impacts on the region due to potential federal sanctions. The following sections summarize the measures to help reduce the emissions associated with the “black box” (Section 182(e)(5)) measures. More detailed discussions are provided in Appendix IV-A and IV-B.

Proposed Stationary Source 8-hour Ozone Measures

The proposed stationary source ozone measures are designed to assist in the attainment of the 8-hour ozone standard. The measures target a number of source categories including Coatings and Solvents (CTS), Combustion Sources (CMB), Petroleum Operations and Fugitive VOC Emissions (FUG), Multiple Component Sources (MCS), Incentive Programs (INC) and Educational Programs (EDU). There are 16 stationary source measures with the majority anticipated to be adopted in the next 2-3 years and implemented after 2015. Table 4-4 provides a list of the District’s 8-hour ozone measures for stationary sources along with the anticipated adoption date, implementation date and emission reduction.

TABLE 4-4

List of the District’s Adoption/Implementation Dates and Estimated Emission Reductions from Stationary Source 8-hour Ozone Measures

NUMBER	TITLE	ADOPTION	IMPLEMENTATION PERIOD	REDUCTION (TPD)
CTS-01	Further VOC Reductions from Architectural Coatings (R1113) [VOC]	2015 - 2016	2018 – 2020	2-4
CTS-02	Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants [VOC]	2013 - 2016	2015 – 2018	1-2
CTS-03	Further VOC Reductions from Mold Release Products [VOC]	2014	2016	0.8 – 2
CTS-04	Further VOC Reductions from Consumer Products [VOC]	2013 - 2015	2018	N/A ^a
CMB-01	Further NOx Reductions from RECLAIM [NOx] – Phase II	2015	2020	1-2 ^b
CMB-02	NOx Reductions from Biogas Flares [NOx]	2015	Beginning 2017	Pending ^c
CMB-03	Reductions from Commercial Space Heating [NOx]	Phase I – 2014 (Tech Assessment) Phase II - 2016	Beginning 2018	0.18 by 2023 0.6 (total)
FUG-01	VOC Reductions from Vacuum Trucks [VOC]	2014	2016	1 ^d
FUG-02	Emission Reduction from LPG Transfer and Dispensing [VOC] – Phase II	2015	2017	1-2
FUG-03	Further Reductions from Fugitive VOC Emissions [VOC]	2015 -2016	2017-2018	1-2
MCS-01	Application of All Feasible Measures Assessment [All Pollutants]	Ongoing	Ongoing	TBD ^e
MCS-02	Further Emission Reductions from Greenwaste Processing (Chipping and Grinding Operations not associated with composting) [VOC]	2015	2016	1 ^d

TABLE 4-4 (concluded)

List of the District’s Adoption/Implementation Dates and Estimated Emission Reductions from Stationary Source 8-hour Ozone Measures

NUMBER	TITLE	ADOPTION	IMPLEMENTATION PERIOD	REDUCTION (TPD)
--------	-------	----------	-----------------------	-----------------

MCS-03 (formerly MCS-06)	Improved Start-up, Shutdown and Turnaround Procedures [All Pollutants]	Phase I – 2012 (<i>Tech Assessment</i>) Phase II - TBD	Phase I – 2013 (<i>Tech Assessment</i>) Phase II – TBD	TBD ^e
INC-01	Economic Incentive Programs to Adopt Zero and Near-Zero Technologies [NOx]	2014	Within 12 months after funding availability	TBD ^e
INC-02	Expedited Permitting and CEQA Preparation Facilitating the Manufacturing of Zero and Near-Zero Technologies [All Pollutants]	2014-2015	Beginning 2015	N/A ^a
EDU-01 (formerly MCS-02, MCS-03)	Further Criteria Pollutant Reductions from Education, Outreach and Incentives [All Pollutants]	Ongoing	Ongoing	N/A ^a

- a. N/A are reductions that cannot be quantified due to the nature of the measure (e.g., outreach, incentive programs) or if the measure is designed to ensure reductions that have been assumed to occur will in fact occur.
- b. If Control Measure CMB-01, RECLAIM Phase I, contingency measure emission reductions are not triggered and implemented, Phase II will target a cumulative 3-5 TPD of NOx emission reductions.
- c. Pending because emission reductions will be provided prior to the Final Draft.
- d. Reductions submitted in SIP once emission inventories are included in the SIP.
- e. TBD are reductions to be determined once the inventory and control approach are identified.

Each control measure type typically relies on a number of control methods. Table 4-5 provides the types of proposed short-term measures and their typical corresponding control methods.

TABLE 4-5

Proposed Short-Term Measure Control Methods

SOURCE CATEGORY	CONTROL METHOD
Coatings and Solvents	<ul style="list-style-type: none"> • Reformulation • Higher Transfer Efficiency • Process Improvements • Add-On Controls • Alternative Coating and Solvent Application Methods • Market Incentives • Improved Housekeeping Practices
Combustion Sources	<ul style="list-style-type: none"> • Add-On Controls • Market Incentives • Process Improvement • Improved Energy Efficiency
Petroleum Operations and Fugitive VOC Emissions	<ul style="list-style-type: none"> • Process Modifications • Add-On Controls Systems • Market Incentives • Enhanced Inspection and Maintenance • Improved Vapor Recovery Systems • Good Management Practices
Multiple Component Sources	<ul style="list-style-type: none"> • Process Modifications and Improvements • Add-On Controls • Best Management Practices • Best Available Control Technology • Market Incentives • Energy Efficiency and Conservation
Incentive Programs	<ul style="list-style-type: none"> • Funding • Investment in Clean Technologies • Private/Public Partnerships
Educational Programs	<ul style="list-style-type: none"> • Increased Awareness • Technical Assistance

The following text provides a brief description of the proposed stationary source 8-hour ozone measures.

Coatings and Solvents

The category of coatings and solvents is primarily targeted at reducing VOC emissions from these VOC-containing products. This category includes four proposed control measures that are based on additional emission reductions from architectural coatings; miscellaneous coatings, solvents, adhesives and lubricants; mold release products; and consumer products with low vapor pressure used by commercial and institutional facilities regulated by CARB.

CTS-01 – FURTHER VOC REDUCTIONS FROM ARCHITECTURAL COATINGS: The District adopted Rule 1113 – Architectural Coatings, in 1977 and it has since undergone numerous amendments. This proposed control measure seeks to reduce the VOC emissions from large volume coating categories such as flat, non-flat and primer, sealer, undercoaters (PSU) and from phasing out the currently exempt use of high-VOC architectural coatings sold in one liter containers or smaller. Additional emission reductions could be achieved from the application of architectural coatings by use of application techniques with greater transfer efficiency. Such transfer efficiency improvements could be achieved through the use of a laser paint targeting system, which has been shown to improve transfer efficiency on average by 30% over equipment not using a targeting system, depending on the size, shape and configuration of the substrate. The proposal is anticipated to be accomplished with a multi-phase adoption and implementation schedule.

CTS-02 – FURTHER VOC REDUCTIONS FROM MISCELLANEOUS COATINGS, ADHESIVES, SOLVENTS, AND LUBRICANTS: This control measure seeks VOC emission reductions by focusing on select coating, adhesive, solvent and lubricant categories by further limiting the allowable VOC content in formulations. Examples of the categories to be considered include but are not limited to, coatings used in aerospace applications; adhesives used in a variety of sealing applications; solvents for graffiti abatement activities; and lubricants used as metalworking fluids to reduce heat and friction to prolong life of the tool, improve product quality and carry away debris. Reductions would be achieved by lowering the VOC content of the coatings, adhesives and lubricants. For solvents, reductions could be achieved with the use of alternative low-VOC products or non-VOC product/equipment at industrial facilities. The proposal is anticipated to be accomplished with a multi-phase adoption and implementation schedule.

CTS-03 – FURTHER VOC REDUCTION FROM MOLD RELEASE PRODUCTS: Metal, fiberglass, composite and plastic products are often manufactured using molds which form the product into a particular configuration. Mold release agents are used to ensure that the parts, as they are made, can be released easily and quickly from the molds. These agents often contain VOC solvent carriers and may also contain toxic components like toluene and xylene. Mold release products are also used for concrete stamping operations to keep the mold from adhering to the fresh concrete. Residential and commercial concrete stamping is a rapidly growing industry, and overall VOC emissions are estimated to be significant. This control measure seeks to reduce emissions from mold release products on metal, fiberglass, composite and plastic products, as well as concrete stamping operations, by requiring the use of low-VOC mold release products.

CTS-04 - FURTHER VOC REDUCTION FROM CONSUMER PRODUCTS: This measure seeks to revise the exemption for low vapor pressure solvents in CARB's consumer products regulation, which exempts low vapor pressure volatile organic compounds (LVP-VOC) from counting towards the compliance obligation for consumer product VOC limits. Recent testing conducted by the District on institutional cleaners found that traditionally formulated consumer products may contain significant amounts of LVP-VOC solvents. In some cases, such as certain multipurpose solvents, the products were 100 percent LVP-VOC solvents. Further testing indicated that many of the LVP-VOC solvents evaporate nearly as quickly as the traditional solvents they were meant to replace and have Maximum Incremental Reactivity (MIR) values well above the threshold considered to be non-reactive, currently based on ethane. Therefore, an evaluation of the continued need for use of LVP-VOC solvents in certain categories is warranted.

Combustion Sources

This category includes three proposed measures for stationary combustion equipment. There is one control measure that further reduces NO_x emissions from RECLAIM facilities. A second proposed measure seeks a reduction from biogas flares, and a third proposed control measure seeks to reduce NO_x emissions from commercial space heaters.

CMB-01 – FURTHER NO_x REDUCTIONS FROM RECLAIM (PHASE II): This proposed control measure will seek further reductions of 1-2 tpd in NO_x allocations by the year 2020. This phase of control is to implement periodic BARCT evaluation as required under the state law. If Control Measure CMB-01, RECLAIM

Phase I, contingency measure emission reductions are not triggered and implemented, Phase II will target a cumulative 3-5 TPD of NO_x emission reductions. The control measure has the ability to produce co-benefits in the reduction of PM_{2.5} and ozone.

CMB-02 – NO_x REDUCTIONS FROM BIOGAS FLARES: There are no source-specific rules regulating NO_x emissions from biogas flares. Flare NO_x emissions are regulated through new source review and BACT. This control measure proposes that, consistent with the all feasible measures measure, older biogas flares be gradually replaced with flares that meet current BACT. Strategies that minimize flaring and associated emissions can also be considered as alternative control options.

CMB-03 – REDUCTIONS FROM COMMERCIAL SPACE HEATING: This control measure applies to natural gas-fired commercial space heaters used for comfort heating. SCAQMD Rule 1111 - NO_x Emissions from Natural Gas-Fired Fan Type Central Furnaces, regulates space heaters with input rates less than 175,000 Btu/hr. This measure proposes to establish a NO_x emission limit for new space heaters for commercial applications, which can be achieved through the use of low-NO_x burners or other technologies.

Petroleum Operations and Fugitive VOC Emissions

This category pertains primarily to operations and materials associated with the petroleum, chemical, and other industries. Within this category, there is one proposed control measure targeting fugitive VOC emissions with improved leak detection and repair. Other proposed measures include reductions from vacuum truck venting, and propane transfer and dispensing.

FUG-01 – VOC REDUCTIONS FROM VACUUM TRUCKS: This control measure seeks to reduce emissions from the venting of vacuum trucks. Emissions from such operations can be further reduced through the utilization of control technologies, including but not limited to, carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers and liquid scrubbers. Additionally, implementation of a leak detection and repair (LDAR) program may further reduce fugitive emissions.

FUG-02 - EMISSION REDUCTION FROM LPG TRANSFER AND DISPENSING: The District recently adopted Rule 1177 - Liquefied Petroleum Gas (LPG) Transfer and Dispensing (June 2012). The rule requires use of low-emission

fixed liquid level gauges or equivalent alternatives during filling of LPG-containing tanks and cylinders, use of low-emission connectors, routine leak checks and repairs of LPG transfer and dispensing equipment. The purpose of this control measure is to reduce fugitive VOC emissions associated with the transfer and dispensing of LPG by expanding rule applicability to include LPG transfer and dispensing at currently exempted facilities such as refineries, marine terminals, natural gas processing plants and pipeline transfer stations, as well as facilities that conduct fill-by-weight techniques.

FUG-03 – FURTHER REDUCTIONS FROM FUGITIVE VOC EMISSIONS:

This control measure seeks to broaden the applicability of improved leak detection and repair (LDAR) programs to remove additional fugitive VOC emissions. Areas for further study may include, but are not limited to, Rule 1142 - Marine Vessel Tank Operations, and wastewater separators. This control measure would explore the opportunity of incorporating a recently developed advanced optical gas imaging technology to detect leaks (Smart LDAR) to more easily identify and repair leaks in a manner that is less time consuming and labor intensive. Additionally, vapor recovery systems are currently required to be 95% control efficient. In an effort to further reduce emissions from these operations, this control measure would explore opportunities and the feasibility of further improving the collection/control efficiency of existing control systems resulting in additional VOC reductions.

Multiple Component Sources

There are a total of three stationary source 8-hour ozone measures proposed in this category. The first measure seeks reductions of all feasible measures after such an assessment is made. Another measure seeks further emission reductions from greenwaste processing, which is chipping and grinding not associated with composting. The third measure seeks to minimize emissions during equipment startup and shutdown and to reduce emissions by applying the state requirement of all feasible control measures.

MCS-01 – APPLICATION OF ALL FEASIBLE MEASURES ASSESSMENT:

This control measure is to address the state law requirement for all feasible measures for ozone. Existing rules and regulations for pollutants such as VOC, NO_x, SO_x and PM reflect current best available retrofit control technology (BARCT). However, BARCT continually evolves as new technology becomes available that is feasible and cost-effective. Through this proposed control measure, the District would commit to the adoption and implementation of the new retrofit control technology

standards. Finally, staff will review actions taken by other air districts for applicability in our region.

MCS-02 - FURTHER EMISSION REDUCTIONS FROM GREENWASTE PROCESSING (CHIPPING AND GRINDING NOT ASSOCIATED WITH COMPOSTING): Chipped or ground greenwaste and/or wood waste has a potential to emit VOCs when being stockpiled or land-applied for various purposes. Chipping and grinding is a process to mechanically reduce the size of greenwaste and wood waste. The District rules currently establish best management practices (BMPs) for greenwaste composting and related operations under Rule 1133.1 – Chipping and Grinding Activities, and Rule 1133.3 – Greenwaste Composting Operations. During rule development, stakeholders raised the need to develop a holistic approach to identifying and accounting for emissions from all greenwaste streams and reducing potential emissions from greenwaste material handling operations at chipping and grinding facilities and other related facilities, and not just the ones associated with composting operations. This control measure would seek to establish additional Best Management Practices (BMPs) for handling processed or unprocessed greenwaste material by greenwaste processors, haulers, and operators who inappropriately stockpile material or directly apply the material to land. The implementation of the control measure would be in two phases. First, the existing database would be reviewed to refine the greenwaste material inventory, and second, staff would potentially develop a rule to incorporate technically feasible and cost-effective BMPs or controls.

MCS-03 - IMPROVED START-UP, SHUTDOWN AND TURNAROUND PROCEDURES: This proposed control measure seeks to reduce emissions during equipment startup, shutdown, and turnaround. Opportunities for further reducing emissions from start-up, shut-down and turnaround activities potentially may exist at refineries as well as other industries. Examples of possible areas for improvement may include best management practices, better engineering and equipment design, diverting or eliminating process streams that are vented to flares, and installation of redundant equipment to increase operational reliability. This measure will be implemented through a two-phase effort to first collect/refine emissions and related data and then, based on the data collected, assess viable controls, if appropriate.

Incentive Programs

There are two proposed incentive programs within this category. The first program seeks to provide incentives for new and existing facilities to install and operate clean,

more-efficient combustion equipment beyond what is currently required. The second program provides expedited permitting processing and development of applicable CEQA documentation if a company manufactures zero or near-zero emission technology.

INC-01: ECONOMIC INCENTIVE PROGRAMS TO ADOPT ZERO AND NEAR-ZERO TECHNOLOGIES: The primary objective of this measure is to develop programs that promote and encourage adoption and installation of cleaner, more-efficient combustion equipment with a focus on zero and near-zero technologies, such as boilers, water heaters and commercial space heating, through economic incentive programs, subject to the availability of public funding. Incentives may include grants for new purchases of equipment as well as loan programs in areas where long-term cost savings from increased efficiency are achieved.

INC-02: EXPEDITED PERMITTING AND CEQA PREPARATION FACILITATING THE MANUFACTURING OF ZERO AND NEAR-ZERO TECHNOLOGIES: This proposed measure is aimed at providing incentives for companies to manufacture zero and near-zero emission technologies locally, thus populating the market, potentially lowering the purchase cost, and increasing demand. With availability and usage of such technologies, air quality benefits will be achieved. This proposed measure focuses on two elements: 1) process the required air permit(s) in an expedited procedure; and 2) prioritize the preparation, circulation and certification of the applicable CEQA document. A stakeholder process will be initiated to design the program and collaborate with other existing District or local programs.

Educational Programs

There is one proposed educational program within this category.

EDU-01: FURTHER CRITERIA POLLUTANT REDUCTIONS FROM EDUCATION, OUTREACH AND INCENTIVES: This proposed control measure seeks to provide educational outreach and incentives for consumers to contribute to clean air efforts. Examples include the usage of energy efficient products, new lighting technology, “super compliant” coatings, tree planting, and the use of lighter colored roofing and paving materials which reduce energy usage by lowering the ambient temperature. In addition, this proposed measure intends to increase the effectiveness of energy conservation programs through public education and

awareness as to the environmental effects and benefits from conservation. Finally, educational and incentive tools to be used include comparison of energy usage and efficiency, social media, public/private partnerships.

Proposed Mobile Source 8-hour Ozone Measures

Depending on the mobile source sector and the proposed control approach, District staff analyzed the need to accelerate the penetration of cleaner engine technologies. The proposed mobile source 8-hour ozone measures are based upon a variety of control technologies that are commercially available and/or technologically feasible to implement in the next several years. The focus of these measures includes accelerated retrofits or replacement of existing vehicles or equipment, acceleration of vehicle turnover through voluntary vehicle retirement programs, and greater use of cleaner fuels in the near-term. In the longer-term, in order to attain the federal ozone ambient air quality standard, there is a need to increase the penetration and deployment of near-zero and zero-emission vehicles such as plug-in hybrids, battery-electric, and fuel cells, even further use of cleaner fuels (either alternative fuels or new formulations of gasoline and diesel fuels), and additional emission reductions from locomotive and aircraft engines.

Ten measures are proposed as actions to reduce mobile source emissions and seven additional measures are proposed to accelerate the development and deployment of near-zero and zero-emission technologies for goods movement related sources and off-road equipment. The measures call for greater emission reductions through accelerated turnover of older vehicles to the cleanest vehicles currently available and increased penetration of commercially-available near-zero and zero-emission technologies through existing incentives programs.

Drawing upon the recent draft “Vision for Clean Air: A Framework for Air Quality and Climate Planning” (or Vision), a document produced jointly between the District staff, the California Air Resources Board, and the San Joaquin Valley Air Pollution Control District, seven measures are proposed to further the development of zero- and near-zero emission technologies for on-road and off-road mobile sources. The draft Vision document discusses the need to accelerate deployment of the cleanest combustion technologies and zero- and near-zero emission technologies earlier to meet federal ambient air quality standards and long-term climate goals. The document provides actions for several key transportation sectors and off-road equipment.

Partial-zero and zero-emission technologies are rapidly being introduced into the on-road light- and medium-duty vehicle categories in large part due to the CARB Low Emission Vehicle (LEV) and the Zero-Emission Vehicle (ZEV) Regulations. In addition, next-generation electric hybrid trucks are being commercialized for light-heavy and medium-heavy heavy-duty on-road vehicles. However, additional research and demonstration are needed to commercialize zero- and near-zero emission technologies for the heavier heavy-duty vehicles (with gross vehicle weight ratings greater than 26,000 lbs.).

For many of the off-road mobile sources such as locomotives, cargo handling equipment, commercial harbor craft, and off-road equipment, some form of “all zero-emission range” is feasible to demonstrate and implement beginning in the latter part of this decade. For other sectors such as marine vessels and aircraft, the development of cleaner combustion technologies beyond existing emission standards will be needed. The Vision document provides a broad discussion of the potential zero- and near-zero technologies or cleaner combustion technologies that could be demonstrated in the near-term. The potential technologies are discussed further in each of the “ADV” measures. A summary of the 17 measures is provided in Table 4-6.

- a. Emission reductions will be determined after projects are identified and implemented.
- b. Reductions achieved locally in Mira Loma region.
- c. Emission reductions provided are updated from the 2007 SIP values reflecting a revised future year base emission levels. The reductions are not included in the 2012 AQMP SIP submittal
- d. Submitted into the SIP once technically feasible and cost effective options are confirmed.
- e. Emission reduction will be quantified after projects are demonstrated.

On-Road Mobile Source Measures

Five on-road mobile source control measures are proposed. The first two measures focus on on-road light- and medium-duty vehicles operating in the South Coast Air Basin. By 2023, it is estimated that about 12 million vehicles will be operating in the Basin. The first measure would implement programs to accelerate the penetration and deployment of partial zero-emission and zero-emission vehicles in the light- and medium-duty vehicles categories. The second control measure would seek to accelerate retirement of older gasoline and diesel powered vehicles up to 8,500 gross

vehicle weight (GVW). These vehicles include passenger cars, sports utility vehicles, vans, and light duty pick-up trucks.

The remaining three measures focus on heavy-duty vehicles. The first of these measures seeks additional emission reductions from the early deployment of partial zero-emission and zero-emission light- and medium-heavy-duty vehicles with gross vehicle weights between 8,501 pounds to 26,000 pounds. The second control measure for heavy-duty vehicles seeks additional emissions reductions from older, pre-2010 heavy-duty vehicles beyond the emission reductions targeted in CARB's Truck and Bus Regulation. Additional emission reductions could be achieved if an additional percentage of the oldest, pre-2010 heavy duty vehicles not subject to the Truck and Bus Regulation are targeted. The fifth on-road measure seeks emission reductions at near-dock railyards through the deployment of zero-emission heavy-duty vehicles. District staff is recommending a minimum funding level of \$85 million per year for incentives to implement on-road mobile source measures.

Off-Road Mobile Source Measures

Five control measures that seek further emission reductions from off-road mobile sources and industrial equipment are proposed. Transportation sources such as aircraft, locomotives, and marine vessels are associated with anticipated economic growth not only in the Basin, but also nationwide. These sources are principally regulated by federal and state agencies. In addition, certain local actions can result in emission reductions beyond the emissions standard setting authority of the state and U.S. EPA. The first measure calls for the continuation of the Surplus Off-Road Opt-In for NO_x (SOON) provision of the statewide In-Use Off-Road Diesel Fleet Regulation beyond 2014. The SOON provision implemented to-date has realized additional NO_x reductions beyond the statewide regulation. The second and third measures call for additional emission reductions from freight and passenger locomotives. The fourth measure seeks additional emission reductions from ocean-going vessels while at berth. The fifth measure recognizes the efforts that the Ports of Los Angeles and Long Beach are implementing to incentivize Tier 2 and Tier 3 ocean-going vessels to call at the ports. District staff is recommending a minimum funding level of \$30 million per year for incentives to implement off-road mobile source measures.

Actions to Deploy Advanced Control Technologies

Seven additional measures are proposed to deploy the cleanest control technologies as early as possible and to foster the development and deployment of near-zero and zero-emission technologies. Many of these actions have already begun. However, additional research and development will be needed that will lead to commercial deployment of control technologies that achieve emission levels below current adopted emission standards. Other near-zero and zero-emission technologies that are commercially available will require infrastructure development to facilitate their deployment.

The term “near-zero” technology is not defined in these actions. The term’s specific meaning could depend on the source category and feasible technologies. The actions needed to deploy zero-emission technologies, “near-zero” emission technologies, and the next generation of cleaner combustion engines will be discussed in the development of the proposed measures and future AQMPs. To initiate the development of cleaner engines (either through in-cylinder or after-treatment controls or in combination with hybrid systems that lead to further criteria pollutant emission reductions), District staff is proposing that optional NO_x standards be adopted. Having such optional standards will facilitate the early development of cleaner technologies and assist to deploy these technologies as soon as possible. They would be set by the level of emission reductions commercially achievable in the near-term. Several of the technologies to achieve emission levels lower than current standards, or zero-emission levels, are currently available and are potentially transferrable to various vehicle vocations and in-use applications. However, further research and demonstration are needed for many of these technologies to evaluate their performance prior to commercialization. Each measure contains a timeline for actions to bring about the zero-emission or cleaner technologies.

The District staff, U.S. Department of Energy, U.S. Environmental Protection Agency, Federal Aviation Administration, California Air Resources Board, California Energy Commission, engine manufacturers, advanced engine control developers, and electric hybrid systems developers have been discussing potential technologies to further reduce engine exhaust emissions or eliminate exhaust emissions entirely. Public forums such as technology symposiums will be used to solicit public input on technology development as part of the proposed actions.

The following text provides a brief description of the District staff's proposed mobile source measures:

ONRD-01 – ACCELERATED PENETRATION OF PARTIAL ZERO-EMISSION AND ZERO EMISSION VEHICLES: This measure proposes to continue incentives for the purchase of zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode. The state Clean Vehicle Rebate Pilot (CVRP) program is proposed to continue from 2015 to 2023 with a proposed funding for up to \$5,000 per vehicle. The proposed measure seeks to provide funding assistance for up to 1,000 zero-emission or partial-zero emission vehicles per year.

ONRD-02 – ACCELERATED RETIREMENT OF OLDER LIGHT- AND MEDIUM-DUTY VEHICLES: This proposed measure calls for promoting the permanent retirement of older eligible vehicles through financial incentives currently offered through local funding incentive programs and the AB 118 Enhanced Fleet Modernization Program (EFMP). The proposed measure seeks to retire up to 2,000 older light- and medium-duty vehicles (up to 8,500 lbs gross vehicle weight) per year. Funding incentives of up to \$2,500 per vehicle are proposed for the scrapping of the vehicle, which may include a replacement voucher for a newer or new vehicle.

ONRD-03 – ACCELERATED PENETRATION OF PARTIAL ZERO-EMISSION AND ZERO-EMISSION LIGHT-HEAVY- AND MEDIUM-HEAVY-DUTY VEHICLES: The objective of the proposed action is to accelerate the introduction of advanced hybrid and zero-emission technologies for Class 4 through 6 heavy-duty vehicles. The state is currently implementing a Hybrid Vehicle Incentives Project (HVIP) program to promote zero-emission and hybrid heavy-duty vehicles. The proposed measure seeks to continue the program from 2015 to 2023 to deploy up to 1,000 zero- and partial-zero emission vehicles per year with up to \$25,000 funding assistance per vehicle. Zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode would be given the highest priority.

ONRD-04 – ACCELERATED RETIREMENT OF OLDER ON-ROAD HEAVY-DUTY VEHICLES: This proposed measure seeks to replace up to 1,000 heavy-duty vehicles per year with newer or new vehicles that at a minimum, meet the 2010 on-road heavy-duty NO_x exhaust emissions standard of 0.2 g/bhp-hr. Given that exceedances of the 24-hour PM_{2.5} air quality standard occur in the Mira Loma region, priority will be placed on replacing older diesel trucks that operate primarily

at the warehouse and distribution centers located in the Mira Loma area. Funding assistance of up to \$35,000 per vehicle is proposed and the level of funding will depend upon the NO_x emissions certification level of the replacement vehicle. In addition, a provision similar to the Surplus Off-Road Option for NO_x (SOON) provision of the statewide In-Use Off-Road Fleet Vehicle Regulation will be sought to ensure that additional NO_x emission reduction benefits are achieved.

ONRD-05 – FURTHER EMISSION REDUCTIONS FROM HEAVY-DUTY VEHICLES SERVING NEAR-DOCK RAILYARDS: This proposed control measure calls for a requirement that any cargo container moved between the Ports of Los Angeles and Long Beach to the nearby railyards (the Intermodal Container Transfer Facility and the proposed Southern California International Gateway) be with zero-emission technologies. The measure would be fully implemented by 2020 through the deployment of zero-emission trucks or any alternative zero-emission container movement system such as a fixed guideway system. The measure calls for CARB to either adopt a new regulation or amend an existing regulation to require such deployment by 2020. To the extent the measure can feasibly be extended beyond near-dock railyards, this would be considered for adoption by CARB.

OFFRD-01 – EXTENSION OF THE SOON PROVISION FOR CONSTRUCTION/INDUSTRIAL EQUIPMENT: This measure seeks to continue the Surplus Off-Road Option for NO_x (SOON) provision of the statewide In-Use Off-Road Fleet Vehicle Regulation beyond 2014 through the 2023 timeframe. In order to implement the SOON program in this timeframe, funding of up to \$30 million per year would be sought to help fund the repower or replacement of older Tier 0 and Tier 1 equipment, with reductions that are considered surplus to the statewide regulation with Tier 4 or cleaner engines.

OFFRD-02 – FURTHER EMISSION REDUCTIONS FROM FREIGHT LOCOMOTIVES: The proposed control measure is to meet the commitment in the 2007 SIP for the accelerated use of Tier 4 locomotives in the South Coast Air Basin. The measure calls for CARB to seek further emission reductions from freight locomotives through enforceable mechanisms within its authority to achieve 95 percent or greater introduction of Tier 4 locomotives by 2023.

OFFRD-03 – FURTHER EMISSION REDUCTIONS FROM PASSENGER LOCOMOTIVES: This measure recognizes the recent actions by the Southern California Regional Rail Authority (SCRRA or Metrolink) to consider replacement of their existing Tier 0 passenger locomotives with Tier 4 locomotives. The SCRRA

adopted a plan that contains a schedule to replace their older existing passenger locomotives with Tier 4 locomotives by 2017. More recently, SCRRRA released a Request for Quotes on the cost of new or newly manufactured passenger locomotives with locomotive engines that meet Tier 4 emission levels.

OFFRD-04 – FURTHER EMISSION REDUCTIONS FROM OCEAN-GOING MARINE VESSELS WHILE AT BERTH: This measure seeks additional emission reductions from ocean-going marine vessels while at berth. The actions would affect ocean-going vessels that are not subject to the statewide Shorepower Regulation or vessel calls that are considered surplus to the statewide regulation. The measure seeks at a minimum to have an additional 25 percent of vessel calls beyond the statewide regulation to deploy shorepower technologies or alternative forms of emissions reduction as early as possible. Such actions could be implemented through additional incentives programs or through the San Pedro Bay Ports as part of the implementation of the Ports Clean Air Action Plan.

OFFRD-05 – EMISSION REDUCTIONS FROM OCEAN-GOING MARINE VESSELS: This measure recognizes the recent actions at the Ports of Los Angeles and Long Beach to initiate an incentives program for cleaner ocean-going vessels to call at the ports. The program has been initiated as part of the San Pedro Bay Ports Clean Air Action Plan. The program will provide financial incentives for cleaner Tier 2 and Tier 3 ocean-going vessels to call at the ports. This measure also recognizes the need to monitor progress under such programs and augment them as necessary to ensure sufficient results. The program will be monitored on annual basis and, if necessary, any adjustments to the program will be made.

ADV-01 –ACTIONS FOR THE DEPLOYMENT OF ZERO- AND NEAR-ZERO EMISSION ON-ROAD HEAVY-DUTY VEHICLES: This measure would continue the efforts underway to develop zero-emission and near-zero emission technologies for on-road heavy-duty vehicle applications. Such technologies include, but not limited to, fuel cell, battery-electric, hybrid-electric with all electric range, and overhead catenary systems. Hybrid-electric systems incorporate an engine powered by conventional fuels or alternative fuels such as natural gas. The actions provided in the proposed measure are based on the SCAG 2012 Regional Transportation Plan.

ADV-02 –ACTIONS FOR THE DEPLOYMENT OF ZERO- AND NEAR-ZERO EMISSION LOCOMOTIVES: This measure calls for the development and deployment of zero-emission and near-zero emission technologies for

locomotives. Such technologies include overhead catenary systems, hybrid locomotives that have some portion of their operation in an “all electric range” mode, and alternative forms of external power such as a battery tender car. The actions provided in the proposed measure are based on the SCAG 2012 Regional Transportation Plan. The zero-emission technologies could apply to freight and passenger locomotives.

ADV-03 –ACTIONS FOR THE DEPLOYMENT OF ZERO- AND NEAR-ZERO EMISSION CARGO HANDLING EQUIPMENT: This measure recognizes the actions underway to develop and deploy zero- and near-zero emission technologies for various cargo handling equipment. The San Pedro Bay Ports are currently demonstrating battery-electric yard tractors. In addition, battery-electric, fuel cell, and hybridized systems could be deployed on smaller cargo handling equipment. In addition, the use of alternative fuels for conventional combustion engines could potentially result in greater emissions benefits.

ADV-04 –ACTIONS FOR THE DEPLOYMENT OF CLEANER EMISSION COMMERCIAL HARBORCRAFT: Several commercial harbor craft operators have begun deployment of hybrid systems in their harbor craft to further reduce criteria pollutant emissions and improve fuel efficiency. Other cleaner technologies include the use of alternative fuels, retrofit of existing older marine engines with selective catalytic converters, and diesel particulate filters. This measure recognizes several efforts between the District and the Ports of Los Angeles and Long Beach to further demonstrate control technologies that could be deployed on commercial harbor craft that could go beyond the statewide Harbor Craft Regulation.

ADV-05 –ACTIONS FOR THE DEPLOYMENT OF CLEANER OCEAN-GOING MARINE VESSELS: The Ports of Los Angeles and Long Beach, CARB, and the District have sponsored research and demonstration of various control technologies to further reduce emissions from ocean-going vessels. In addition, the San Pedro Bay Ports Clean Air Action Plan contains a measure to further demonstrate such technologies on ocean-going vessels. This measure recognizes many of these efforts and the need to further demonstrate retrofit technologies on existing ocean-going vessels.

ADV-06 –ACTIONS FOR THE DEPLOYMENT OF CLEANER OFF-ROAD EQUIPMENT: The District, Mobile Source Air Pollution Reduction Review Committee (MSRC), and CARB have been conducting an off-road “showcase” program for retrofit technologies to further reduce emissions from older off-road

equipment. In addition, several major off-road engine manufacturers are investigating the potential use of hybrid systems to further reduce criteria pollutant and greenhouse gas emissions. Potential advanced technologies include hybrid systems that utilize batteries, fuel cells, or plug-in capabilities, which could result in lower emissions compared to Tier 4 emission levels when combined with future Tier 4 compliant engines. The measure is implemented by the District, CARB and U.S. EPA.

ADV-07 –ACTIONS FOR THE DEPLOYMENT OF CLEANER AIRCRAFT ENGINES: This measure recognizes the efforts of the Federal Aviation Administration’s Continuous Lower Energy, Emissions and Noise (CLEEN) Program. The goal of the CLEEN Program is the development of new aircraft engines that potentially can be up to 60 percent cleaner in NO_x emissions than current aircraft engines. The actions under this measure are to continue the development of cleaner aircraft engines and work with the airlines and local airport authorities to develop mechanisms to route the cleanest aircraft to serve the South Coast Air Basin.

DISTRICT’S SIP EMISSION REDUCTION COMMITMENT

The SIP commitment of the Draft Final 2012 AQMP is structured into two components. Reductions from adopted rules and reductions from the 2012 AQMP control measures are divided into commitments for the 24-hr PM_{2.5} SIP and the 8-hour ozone SIP. Taken together, these reductions are relied upon to demonstrate expeditious progress and attainment of the federal 24-hr PM_{2.5} standard, and implemented to reduce the black box commitment for the 8-hour ozone standard. The following sections first describe the methodology for SIP emission reduction calculations and the creditable SIP reductions, then describe what procedures will be followed to ensure fulfillment of the commitment.

SIP Emission Reduction Tracking

For purposes of tracking progress in emission reductions, the baseline emissions for the year 2014 (annual average) and 2023 (planning inventory) in the Draft Final 2012 AQMP will be used, regardless of any subsequent new inventory information that reflects more recent knowledge. This is to ensure that the same “currency” is used in measuring progress as was used in designing the Plan. This will provide a fair and equitable measurement of progress. Therefore, it makes no difference whether

progress is measured by emission reductions or remaining emissions for a source category. However, the most recent emission inventory information at the time of rule development will continue to be used for calculating reductions, and assessing cost-effectiveness and socioeconomic impacts of the proposed rule. Therefore, for future rulemaking activity, both the most recent and AQMP inventories will be reported.

Any non-mandatory emissions reductions achieved beyond the existing District regulations are creditable only if they are also SIP-enforceable. Therefore, in certain instances, the District may have to adopt regulations to reflect the existing industry practices in order to claim SIP reduction credit, with the understanding that there may not be additional reductions beyond what has already occurred. Exceptions can be made where reductions are real, quantifiable, surplus to the Draft Final 2012 AQMP baseline inventories, and enforceable through other State and/or federal regulations. Also, any emissions inventory revisions, which have gone through a peer review and public review process, can also be SIP creditable.

Reductions from Adopted Rules

A number of control measures contained in the 2007 AQMP have been adopted as rules. These adopted rules and their projected emission reductions become assumptions in developing AQMP's future year inventories. Although they are not part of the control strategy in the Draft Final 2012 AQMP, continued implementation of those rules is essential in achieving clean air goals and maintaining the attainment demonstration. Table 1-2 of Chapter 1 lists the rules adopted by the District since the adoption of the 2007 AQMP and their expected emission reductions.

Reductions from District's Stationary Source Control Measures

For purposes of implementing an approved SIP, the District is committed to adopt and implement control measures that will achieve, in aggregate, emission reductions specified in Tables 4-7 and 4-8 to demonstrate expeditious implementation of measures toward meeting the federal 2006 24-hr PM_{2.5} standard and the 1997 8-hour ozone standard, respectively. Emission reductions achieved in excess of the amount committed to in a given year can be applied to the emission reduction commitments of subsequent years. The District is committed to adopt the control measures in Tables 4-2 and 4-4 unless these measures or a portion thereof are found infeasible and other substitute measures that can achieve equivalent reductions in the same

adoption or implementation timeframes are adopted. Findings of infeasibility will be made at a regularly scheduled meeting of the District Governing Board with proper public notification. For purposes of the SIP commitment, infeasibility means that the proposed control technology is not reasonably likely to be available by the implementation date in question, or achievement of the emission reductions by that date is not cost-effective. It should be noted that the reductions in Tables 4-7 and 4-8 are committed only to the extent needed to achieve attainment by 2014 and if any substitution is needed, the alternative measures will need to achieve the same emission reductions or air quality benefit. The District acknowledges that this commitment is enforceable under Section 304(f) of the federal Clean Air Act. U.S. EPA will not credit SIP reductions unless the control measures are adopted and approved into the SIP at the time of their action on the plan.

Adoption and Implementation of District's Stationary Source Control Measures

As a partial response to concerns raised by the regulated community that costly controls may be required to meet the SIP obligations, the District proposes to establish a threshold of \$16,500 per ton of VOC and \$22,500 per ton of NO_x reduction for tiered levels of analysis. Specifically, proposed rules with an average cost-effectiveness above the threshold will trigger a more rigorous average cost-effectiveness, incremental cost-effectiveness, and socioeconomic impact analysis. A public review and decision process will be instituted to seek lower cost alternatives. In addition, the District staff, with input from stakeholders, will attempt to develop viable control alternatives within the industry source categories that a rule is intended to regulate. If it is determined that control alternatives within the industry source category are not feasible, staff will perform an evaluation of the control measure as described in the next paragraph. Viable alternatives shall be reviewed by the District Governing Board at a public meeting no less than 90 days prior to rule adoption and any needed direction will be given back to staff for further analysis. During this review process, incremental cost-effectiveness scenarios and methodology will be specified, and industry-specific affordability issues will be identified as well as possible alternative control measures. The District Governing Board may adopt the original or an alternative that is consistent with state and federal law. In addition, staff shall include in all set hearing items a notification that proposed rules do or do not exceed the cost threshold.

Adoption and Implementation of Alternative/Substitute Measures

Under the Draft Final 2012 AQMP, the District will be allowed to substitute District stationary source measures in Tables 4-2 and 4-4 with other measures, provided the overall equivalent emission reductions by the adoption and implementation dates in Tables 4-2 and 4-4 are maintained and the applicable measure in Tables 4-2 and 4-4 is deemed infeasible. In order to provide meaningful public participation, when new control concepts are introduced for rule development, the District is committed to provide advanced public notification beyond its regulatory requirements (i.e., through its Rule Forecast Report). The District will also report quantitatively on the AQMP's implementation progress annually at its regularly scheduled Governing Board meetings. Included in the reports will be any new control measures being proposed or measures, or portions thereof, that have been found to be infeasible and the basis of such finding. In addition, at the beginning of the year, any significant emission reduction related rules to be considered would be listed in the Board's Rule Forecast Report. Upon any finding of a new feasible control measure to substitute for a measure deemed infeasible, rule development will be completed no later than 12 months from the adoption date of the control measure substituted, and implementation of the new measure will occur no later than two years from the final implementation date of the measure substituted. The existing rule development outreach efforts such as public workshops, stakeholder working group meetings or public consultation meetings will continue to solicit public input. In addition, if additional technical analysis, including source testing, indicates that actual emissions are less than previously estimated, the reductions would then be creditable toward SIP commitments. In order for reductions from improved emission calculation methodologies to be SIP creditable, a public review process will also be instituted to solicit comments and make appropriate revisions, if necessary.

OVERALL EMISSION REDUCTIONS

A summary of emission reductions for the proposed control measures for the years 2014 and 2023 is provided in Tables 4-10 through 4-11. These reductions reflect the emission reductions associated with implementation of control measures under local, State, and federal jurisdiction. Emission reductions represent the difference between the projected baseline and the remaining emissions. Table 4-10 identifies projected reductions based on the annual average inventory for directly emitted PM_{2.5} and its precursors (NO_x, and SO_x), and VOC for basin-wide stationary and mobile control measures. It represents the level of control needed to achieve the federal 2006 24-hr PM_{2.5} standard by 2014. For attainment of the 1997 ozone standard by 2023, Table 4-11 identifies projected reductions based on the summer planning inventory for VOC and NO_x emissions as an ongoing effort to reduce reliance on the Section 182(e)(5) measures in the 2007 AQMP.

IMPLEMENTATION

Achieving clean air objectives requires the effective and timely implementation of the control measures. Similar to approaches taken by previous AQMPs, the SIP commitment is to bring each control measure for regulatory consideration in a specified time frame. The time frame is based on the ability to implement certain

control strategies that will result in the reductions necessary to demonstrate attainment by the required attainment date. There is a commitment to achieve a total emission reduction target, with the ability to substitute for control measures deemed infeasible, so long as equivalent reductions are met by other means. These measures are also designed to satisfy the federal Clean Air Act requirement of Reasonably Available Control Technologies [Section 172(c)], and the California Clean Air Act requirement of Best Available Retrofit Control Technologies (BARCT) [Health and Safety Code Section 40440(b)(1)].

The adoption and implementation schedule of the control measures proposed in the Draft Final 2012 AQMP can be found in Tables 4-2, 4-4 and 4-6. Multiple agencies are necessary for implementation of the mobile source ozone measures in Table 4-6. This section describes each agency's area of responsibility.

Responsible Agencies

Implementation of the control strategies requires a cooperative partnership of governmental agencies at the federal, state, regional and local level. These agencies form the four cornerstones from which implementation programs will evolve.

At the federal level, the U.S. EPA and sometimes other agencies are charged with reducing emissions from federally controlled sources such as commercial aircraft, trains, marine vessels, and other sources. At the state level, CARB is primarily responsible for reducing emissions from motor vehicles and consumer products.

At the regional level, the District is responsible for the overall development and implementation of the AQMP. The District is specifically authorized to reduce the emissions from stationary, point, and some area sources such as coatings and industrial solvents. Emission reductions are also sought through funding programs designed to accelerate vehicle turnover and the purchase of cleaner vehicles. In addition, the District regulates indirect sources under Health and Safety Code Sections 40716 (a)(1) and 40440(b)(3). As a means of achieving further emission reductions, the District may seek additional authority to regulate sources that have not been completely under the District's jurisdiction in the past such as marine vessels, consumer products, and other on-road and off-road sources. The District implements its responsibilities with participation from the regulated community through an extensive rule development and implementation program. This approach maximizes the input of those parties affected by the proposed rule through consultation meetings, public workshops, and ongoing working groups.

At the regional level, the Southern California Association of Governments (SCAG) assists sub-regional and local governments in playing a formative role in the air quality elements of transportation planning. In addition, local governments serve an important role in developing and implementing the transportation control measures that are included in the Draft Final 2012 AQMP. SCAG is responsible for providing the socioeconomic forecast (e.g., population and growth forecasts) upon which the Plan is based. SCAG also provides assessments for conformity of regionally significant transportation projects with the overall Plan and is responsible for the adoption of the Regional Transportation Plan (RTP) and the Regional Transportation Improvement Program (RTIP) which include growth assumptions and transportation improvement projects that could have significant air quality impacts, and transportation control measures as required by the CAA.

Table 4-12 list the responsibilities of the key agencies involved in the implementation of the 2012 AQMP.

South Coast Air Quality Management District
Cleaning the air that we breathe...

CHAPTER 5

FUTURE AIR QUALITY

Introduction

Background

Modeling Approach

Future Air Quality

Additional Modeling Analyses

Summary and Conclusions

INTRODUCTION

Air quality modeling is an integral part of the planning process to achieve clean air. The attainment demonstrations provided in this Draft Final 2012 AQMP reflect the updated baseline emissions estimates, new technical information, enhanced air quality modeling techniques, and the control strategy provided in Chapter 4 for 24-hour PM_{2.5}. Projections for progress towards meeting the annual PM_{2.5} standard by 2014 and the 1997 8-hour ozone standard by 2023 are also presented in this chapter. These latter two requirements are addressed in the 2007 AQMP.

The Basin is currently designated nonattainment for PM_{2.5}, and extreme nonattainment for ozone. The District's goal is to develop an integrated control strategy which: 1) ensures that ambient air quality standards for all criteria pollutants are met by the established deadlines in the federal Clean Air Act (CAA); and 2) achieves an expeditious rate of progress towards attaining the state air quality standards. The overall control strategy is designed so that efforts to achieve the standard for one criteria pollutant do not cause unnecessary deterioration of another. A two-step modeling process which is consistent with the approach used in the 2007 AQMP has been conducted for the Draft Final 2012 AQMP. First, future year 24-hour PM_{2.5} levels are simulated for 2014 and 2019 to determine the earliest possible date of attainment. If attainment cannot be demonstrated by 2014, U.S. EPA can grant up to an additional five years to demonstrate attainment of the 24-hour standard. However, the length of the extension is contingent upon the earliest year beyond 2014 that the 24-hour average PM_{2.5} standard can be achieved implementing all feasible control measures.

BACKGROUND

During the development of the 2007 AQMP, the District convened a panel of seven experts to independently review the regional air quality modeling. The consensus of the panel was for the District to move to the more current state-of-the-art dispersion platforms and chemistry modules. In keeping with the recommendations of the expert panel as well as the Scientific Technical Modeling Peer Review Committee, the Draft Final 2012 AQMP has continued to move forward to incorporate the current state-of-the-art modeling platforms to conduct regional modeling analyses in support of the PM_{2.5} attainment demonstrations and ozone update. The Draft Final 2012 AQMP PM_{2.5} attainment demonstration has been developed using the U.S. EPA supported Community Multiscale Air Quality (CMAQ) (version 4.7) modeling platform with SAPRC99 chemistry, and the Weather Research and Forecasting Model (WRF) (version 3.3) meteorological fields. Supporting PM_{2.5} and ozone simulations were also conducted

using the most current and publicly available version of CAMx (version 5.3), which also used SAPRC99 chemistry and WRF meteorology, to ensure smooth transition from the CAMx platform used in the 2007 AQMP to CMAQ. The model analyses were conducted on an expanded domain, with increased resolution in the vertical structure, and a finer 4 km grid size.

Detailed information on the modeling approach, data gathering, model development and enhancement, model application, and interpretation of results is presented in Appendix V. The following sections summarize the results of the 24-hour PM_{2.5} attainment demonstration modeling effort and provide an update to the annual PM_{2.5} and future projected Basin ozone levels given new emissions, design values and modeling tools.

MODELING APPROACH

Design Values and Relative Response Factors (RRF)

As first employed in the 2007 AQMP, the Draft Final 2012 AQMP modeling approach to demonstrate attainment of the air quality standards relies heavily on the use of design values and relative response factors (RRF) to translate regional modeling simulation output to the form of the air quality standard. Both PM_{2.5} and ozone have standards that require three consecutive years of monitored data, averaged according to the form of the standard to derive a design value, to assess compliance. The 24-hour PM_{2.5} design value is determined from the three-year average of the 98th percentile of all 24-hour concentrations sampled at a monitoring site. The annual PM_{2.5} design value is based on quarterly average PM_{2.5} concentrations, averaged by year, for a three-year period. In the case of ozone, compliance with the standard is determined from a three-year average of the 4th highest daily ozone 8-hour average concentration.

Design Value Selection

U.S. EPA guidance recommends the use of multiple year averages of design values, where appropriate, to dampen the effects of single year anomalies to the air quality trend due to factors such as adverse or favorable meteorology or radical changes in the local emissions profile. The trend in the Basin 24-hour PM_{2.5} design values, determined from routinely monitored Federal Reference Monitoring (FRM), from 2001 through 2011 (Figure 5-1) depicts sharp reductions in concentrations over the period. The 24-hour PM_{2.5} design value for 2001 was 76 µg/m³ while the 2008 design value (based on data from 2006, 2007 and 2008) is 53 µg/m³. Furthermore, the most current design value computed for 2011 has been reduced to 38 µg/m³. The annual PM_{2.5} design value has demonstrated a reduction of 13.6 µg/m³ over the 10-year period from 2001 through

2011. In each case, the trend in PM2.5 is steadily moving in the direction of air quality improvement. The trend of Basin ozone design values is presented in Figure 5-2. The design values have averaged a reduction of approximately three parts per billion over the 14-year period; however the most recent design value (107 ppb) continues to exceed the 1997 8-hour ozone standard (80 ppb) by 34 percent and the 2006 ozone standard by 43 percent (75 ppb).

FIGURE 5-2

South Coast Air Basin 8-Hour Average Ozone Design Values

Note: Each value represents the 3-year average of the 4th highest 8-Hour Average Ozone concentration

The Draft Final 2012 AQMP relies on a set of five years of particulate data centered on 2008, the base year selected for the emissions inventory development and the anchor year for the future year PM_{2.5} projections. In July, 2010, U.S. EPA proposed revisions to the 24-hour PM_{2.5} modeling attainment demonstration guidance. The new guidance suggests using five years of data, but instead of directly using quarterly calculated design values, the procedure requires the top 8 daily PM_{2.5} concentrations days in each quarter to reconstruct the annual 98th percentile. The logic in the analysis is twofold: by selecting the top 8 values in each quarter the 98th percentile concentration is guaranteed to be included in the calculation. Second, the analysis projects future year concentrations for each of the 32 days in a year (160 days over five years) to test the response of future year 24-hour PM_{2.5} to the proposed control strategy. Since the 32 days in each year include different meteorological conditions and particulate species profiles it is expected those individual days will respond independently to the projected future year emissions profile and that a new distribution of PM_{2.5} concentrations will result. Overall, the process is more robust in that the analysis is examining the impact of the control strategy implementation for a total of 160 days, covering a wide variety of potential meteorology and emissions combinations.

Table 5-1 provides the weighted 2008 annual and 24-hour average PM_{2.5} design values for the Basin.

Relative Response Factors and Future Year Design Values

To bridge the gap between air quality model output evaluation and applicability to the health-based air quality standards, U.S. EPA guidance has proposed the use of relative response factors (RRF). The RRF concept was first used in the 2007 AQMP modeling

attainment demonstrations. The RRF is simply a ratio of future year predicted air quality with the control strategy fully implemented to the simulated air quality in the base year. The mechanics of the attainment demonstration are pollutant and averaging period specific. For 24-hour PM_{2.5}, the top 10 percentile of modeled concentrations in each quarter of the simulation year are used to determine the quarterly RRFs. For the annual average PM_{2.5}, the quarterly average RRFs are used for the future year projections. For the 8-hour average ozone simulations, the aggregated response of multiple episode days to the implementation of the control strategy is used to develop an averaged RRF for projecting a future year design value. Simply stated, the future year design value is estimated by multiplying the non-dimensional RRF by the base year design value. Thus, the simulated improvement in air quality, based on multiple meteorological episodes, is translated as a metric that directly determines compliance in the form of the standard.

The modeling analyses described in this chapter use the RRF and design value approach to demonstrate future year attainment of the standards.

PM_{2.5} Modeling

Within the Basin, PM_{2.5} particles are either directly emitted into the atmosphere (primary particles), or are formed through atmospheric chemical reactions from precursor gases (secondary particles). Primary PM_{2.5} includes road dust, diesel soot, combustion products, and other sources of fine particles. Secondary products, such as sulfates, nitrates, and complex carbon compounds are formed from reactions with oxides of sulfur, oxides of nitrogen, VOCs, and ammonia.

The Draft Final 2012 AQMP employs the CMAQ air quality modeling platform with SAPRC99 chemistry and WRF meteorology as the primary tool used to demonstrate future year attainment of the 24-hour average PM_{2.5} standard. A detailed discussion of the features of the CMAQ approach is presented in Appendix V. The analysis was also conducted using the CAMx modeling platform using the “one atmosphere” approach comprised of the SAPRC99 gas phased chemistry and a static two-mode particle size aerosol module as the particulate modeling platform. Parallel testing was conducted to evaluate the CMAQ performance against CAMx and the results indicated that the two model/chemistry packages had similar performance. The CAMx results are provided in Appendix V as a component of the weight of evidence discussion.

The Draft Final 2012 modeling attainment demonstrations using the CMAQ (and CAMx) platform were conducted in a vastly expanded modeling domain compared with the analysis conducted for the 2007 AQMP modeling attainment demonstration. In this analysis, the PM_{2.5} and ozone base and future simulations were modeled

simultaneously. The simulations were conducted using a Lambert Conformal grid projection where the western boundary of the domain was extended to 084 UTM, over 100 miles west of the ports of Los Angeles and Long Beach. The eastern boundary extended beyond the Colorado river while the northern and southern boundaries of the domain extend to the San Joaquin Valley and the Northern portions of Mexico (3543 UTM). The grid size has been reduced from 5 kilometers squared to 4 kilometers squared and the vertical resolution has been increased from 11 to 18 layers.

The final WRF meteorological fields were generated for the identical domain, layer structure and grid size. The WRF simulations were initialized from National Centers for Environmental Prediction (NCEP) analyses and run for 3-day increments with the option for four dimensional data assimilation (FDDA). Horizontal and vertical boundary conditions were designated using a “U.S. EPA clean boundary profile.”

PM_{2.5} data measured as individual species at six-sites in the AQMD air monitoring network during 2008 provided the characterization for evaluation and validation of the CMAQ annual and episodic modeling. The six sites include the historical PM_{2.5} maximum location (Riverside- Rubidoux), the stations experiencing many of the highest county concentrations (among the 4-county jurisdiction including Fontana, North Long Beach and Anaheim) and source oriented key monitoring sites addressing goods movement (South Long Beach) and mobile source impacts (Central Los Angeles). It is important to note that the close proximity of Mira Loma to Rubidoux and the common in-Basin air flow and transport patterns enable the use of the Rubidoux speciated data as representative of the particulate speciation at Mira Loma. Both sites are directly downwind of the dairy production areas in Chino and the warehouse distribution centers located in the northwestern corner of Riverside County. Speciated data monitored at the selected sites for 2006-2007 and 2009-2010 were analyzed to corroborate the applicability of using the 2008 profiles.

Day-specific point source emissions were extracted from the District stationary source and RECLAIM inventories. Mobile source emissions included weekday, Saturday and Sunday profiles based on CARB’s EMFAC2011 emissions model, CALTRANS weigh-in-motion profiles, and vehicle population data and transportation analysis zone (TAZ) data provided by SCAG. The mobile source data and selected area source data were subjected to daily temperature corrections to account for enhanced evaporative emissions on warmer days. Gridded daily biogenic VOC emissions were provided by CARB using BEIGIS biogenic emissions model. The simulations benefited from enhancements made to the emissions inventory including an updated ammonia inventory, improved emissions characterization that split organic compounds into coarse, fine and primary

particulate categories, and updated spatial allocation of primary paved road dust emissions.

Model performance was evaluated against speciated particulate PM_{2.5} air quality data for ammonium, nitrates, sulfates, secondary organic matter, elemental carbon, primary and total particulate mass for the six monitoring sites (Rubidoux, Central Los Angeles, Anaheim, South Long Beach, Long Beach, and Fontana).

The following section summarizes the PM_{2.5} modeling approach conducted in preparation for this Plan. Details of the PM_{2.5} modeling are presented in Appendix V.

24-Hour PM_{2.5} Modeling Approach

CMAQ simulations were conducted for each day in 2008. The simulations included 8784 consecutive hours from which daily 24-hour average PM_{2.5} concentrations (0000-2300 hours) were calculated. A set of RRFs were generated for each future year simulation. RRFs were generated for the ammonium ion (NH₄), nitrate ion (NO₃), sulfate ion (SO₄), organic carbon (OC), elemental carbon (EC) and a combined grouping of crustal, sea salts and metals (Others). A total of 24 RRFs were generated for each future year simulation (4 seasons and 6 monitoring sites).

Future year concentrations of the six component species were calculated by applying the model generated quarterly RRFs to the speciated 24-hour PM_{2.5} (FRM) data, sorted by quarter, for each of the five years used in the design value calculation. The 32 days in each year were then re-ranked to establish a new 98th percentile concentration. The resulting future year 98th percentile concentrations for the five years were subjected to weighted averaging for the attainment demonstration.

In this chapter, future year PM_{2.5} 24-hour average design values are presented for 2014, and 2019 to (1) demonstrate the future baseline concentrations if no further controls are implemented; (2) identify the amount of air quality improvement needed to advance the attainment date to 2014; and (3) confirm the attainment demonstration given the proposed PM_{2.5} control strategy. In addition, Appendix V will include a discussion and demonstration that attainment will be satisfied for the entire modeling domain.

Weight of Evidence

PM_{2.5} modeling guidance strongly recommends the use of corroborating evidence to support the future year attainment demonstration. The weight of evidence demonstration for the Draft Final 2012 AQMP includes brief discussions of the observed 24-hour

PM2.5, emissions trends, and future year PM2.5 predictions. Detailed discussions of all model results and the weight of evidence demonstration are provided in Appendix V.

FUTURE AIR QUALITY

Under the federal Clean Air Act, the Basin must comply with the federal PM2.5 air quality standards by December, 2014 [Section 172(a)(2)(A)]. An extension of up-to five years (until 2019) could be granted if attainment cannot be demonstrated any earlier with all feasible control measures incorporated.

24-Hour PM2.5

A simulation of 2014 baseline emissions was conducted to substantiate the severity of the 24-hour PM2.5 problem in the Basin. The simulation used the projected emissions for 2014 which included all adopted control measures that will be implemented prior to and during 2014, including mobile source incentive projects under contract (Proposition 1B and Carl Moyer Programs). The resulting 2014 future-year Basin design value ($37.3\mu\text{g}/\text{m}^3$) failed to meet the federal standard. As a consequence additional controls are needed.

Simulation of the 2019 baseline emissions indicates that the Basin PM2.5 will attain the federal 24-hour PM2.5 standard in 2019 without additional controls. With the control program in place, the 24-hour PM2.5 simulations project that the 2014 design value will be $34.3\mu\text{g}/\text{m}^3$ and that the attainment date will advance from 2019 to 2014.

Figure 5-3 depicts future 24-hour PM2.5 air quality projections at the Basin design site (Mira Loma) and six PM2.5 monitoring sites having comprehensive particulate species characterization. Shown in the figure, are the base year design values for 2008 along with projections for 2014 with and without control measures in place. All of the sites with the exception of Mira Loma will meet the 24-hour PM2.5 standard by 2014 without additional controls. With implementation of the control measures, all sites in the Basin demonstrate attainment.

*No such state standard.

FIGURE 5-3

Maximum 24-Hour Average PM2.5 Design Concentrations:
2008 Baseline, 2014 and 2014 Controlled

Spatial Projections of PM2.5 Design Values

Figure 5-4 provides a perspective of the Basin-wide spatial extent of 24-hour PM2.5 impacts in the base year 2008, with all adopted rules and measures implemented. Figures 5-5 and 5-6 provide a Basin-wide perspective of the spatial extent of 24-hour PM2.5 future impacts for baseline 2014 emissions and 2014 with the proposed control program in place. With no additional controls, several areas around the northwestern portion of Riverside and southwestern portion of San Bernardino Counties depict grid

cells with weighted PM_{2.5} 24-hour design values exceeding 35 $\mu\text{g}/\text{m}^3$. By 2014, the number of grid cells with concentrations exceeding the federal standard is restricted to a small region surrounding the Mira Loma monitoring station in northwestern Riverside County. With the control program fully implemented in 2014, the Basin does not exhibit any grid cells exceeding the federal standard.

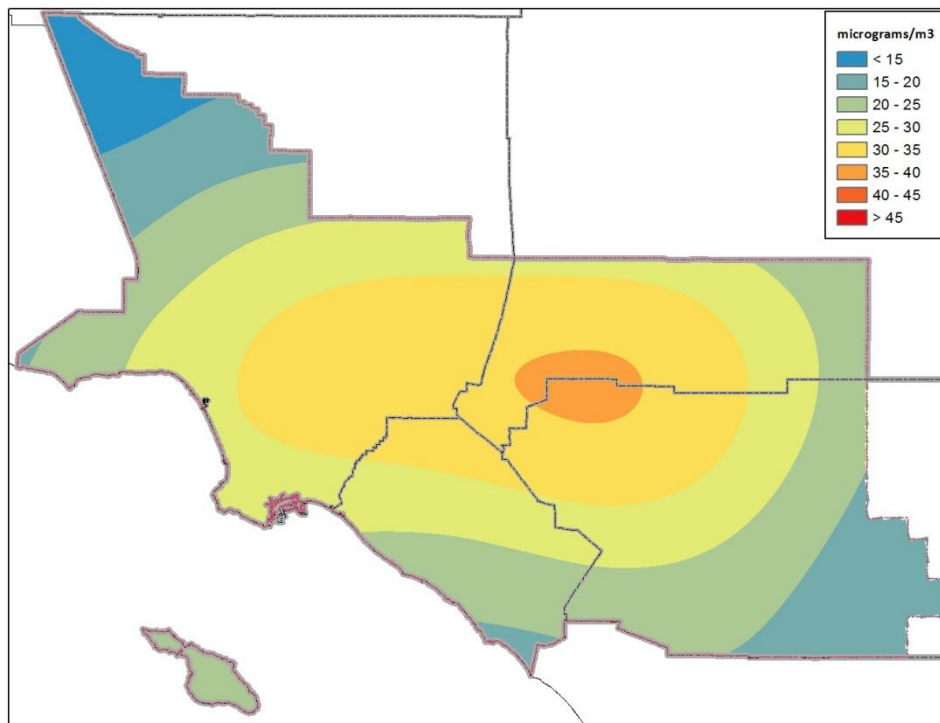

FIGURE 5-5

2014 Baseline 24-Hour PM_{2.5} Design Concentrations (µg/m³)

FIGURE 5-6

2014 Controlled 24-Hour PM_{2.5} Design Concentrations (µg/m³)

Weight of Evidence Discussion

The weight of evidence discussion focuses on the trends of 24-hour PM_{2.5} and key precursor emissions to provide justification and confidence that the Basin will meet the federal standard by 2014.

Figure 5-7 depicts the long term trend of observed Basin 24-hour average PM_{2.5} design values with the CMAQ projected design value for 2014. Also superimposed on the graph is the linear best-fit trend line for the observed 24-hour average PM_{2.5} design values. The observed trend depicts a steady 49 percent decrease in observed design value concentrations between 2001 and 2011. The rate of improvement is just under 4 µg/m³ per year. If the trend is extended beyond 2011, the projection suggests attainment of the PM_{2.5} 24-hour standard in 2013, one year earlier than determined by the attainment demonstration. While the straight-line future year approximation is aggressive in its projection, it offers insight to the effectiveness of the ongoing control program and is consistent with the attainment demonstration.

Figures 5-8 depicts the long term trend of Basin NO_x emissions for the same period. Figure 5-9 provides the corresponding emissions trend for directly emitted PM_{2.5}. Base year NO_x inventories between 2002 (from the 2007 AQMP) and 2008 experienced a 31 percent reduction while directly emitted PM_{2.5} experienced a 19 percent reduction over the 6-year period. The Basin 24-hour average PM_{2.5} design value experienced a concurrent 27 percent reduction between 2002 and 2008. The projected trend of NO_x emissions indicates that the PM_{2.5} precursor associated with the formation of nitrate will continue to be reduced through 2019 by an additional 48 percent. Similarly, the projected trend of directly emitted PM_{2.5} projects a more moderate reduction of 13 percent through 2019. However, as discussed in the 2007 AQMP and in a later section of this chapter, directly emitted PM_{2.5} is a more effective contributor to the formation of ambient PM_{2.5} compared to NO_x. While the projected NO_x and direct PM_{2.5} emissions trends decrease at a reduced rate between 2012 and 2019, it is clearly evident that the overall significant reductions will continue to result in lower nitrate, elemental carbon and direct particulate contributions to 24-hour PM_{2.5} design values.

Trend of Basin PM2.5 Emissions (Controlled)

Control Strategy Choices

PM2.5 has five major precursors that contribute to the development of the ambient aerosol including ammonia, NO_x, SO_x, VOC, and directly emitted PM2.5. Various combinations of reductions in these pollutants could all provide a path to clean air. The 24-hour PM2.5 attainment strategy presented in this Draft Final 2012 AQMP relies on a dual approach to first demonstrate attainment of the federal standard by 2019 and then focuses on controls that will be most effective in reducing PM2.5 to accelerate attainment to the earliest extent. The 2007 AQMP control measures since implemented will result in substantial reductions of SO_x, direct PM2.5, VOC and NO_x emissions. Newly proposed short-term measures, discussed in Chapter 4, will provide additional regional emissions reductions targeting directly emitted PM2.5 and NO_x.

It is useful to weigh the value of the precursor emissions reductions (on a per ton basis) to microgram per cubic meter improvements in ambient PM2.5 levels. As presented in the weight of evidence discussion, trends of PM2.5 and NO_x emissions suggest a direct response between lower emissions and improving air quality. The Final 2007 AQMP established a set of factors to relate regional per ton precursor emissions reductions to PM2.5 air quality improvements based on the annual average concentration. The Draft Final 2012 AQMP CMAQ simulations provided a similar set of factors, but this time directed at 24-hour PM2.5. The analysis determined that VOC emissions reductions have the lowest return in terms of micrograms reduced per ton reduction, one third of the benefit of NO_x reductions. SO_x emissions were about eight times more effective than

NO_x reductions. However, directly emitted PM_{2.5} reductions were approximately 15 times more effective than NO_x reductions. It is important to note that the contribution of ammonia emissions is embedded as a component of the SO_x and NO_x factors since ammonium nitrate and ammonium sulfate are the resultant particulates formed in the ambient chemical process. Table 5-2 summarizes the relative importance of precursor emissions reductions to 24-hour PM_{2.5} air quality improvements based on the analysis. . (A comprehensive discussion of the emission reduction factors is presented in Attachment 8 of Appendix V of this document). Emission reductions due to existing programs and implementation of the 2012 AQMP control measures will result in projected 24-hour PM_{2.5} concentrations throughout the Basin that meet the standard by 2014 at all locations. Basin-wide curtailment of wood burning and open burning when the PM_{2.5} air quality is projected to exceed 30 µg/m³ in Mira Loma will effectively accelerate attainment at Mira Loma from 2019 to 2014. Table 5-3 lists the mix of the four primary precursor's emissions reductions targeted for the staged control measure implementation approach.

TABLE 5-2

Relative Contributions of Precursor Emissions Reductions to Simulated Controlled Future-Year 24-hour PM_{2.5} Concentrations

PRECURSOR	PM_{2.5} COMPONENT (µg/m³)	STANDARDIZED CONTRIBUTION TO AMBIENT PM_{2.5} MASS
VOC	Organic Carbon	Factor of 0.3

ADDITIONAL MODELING ANALYSES

As a component of the Draft Final 2012 AQMP, concurrent simulations were also conducted to update and assess the impacts to annual average PM_{2.5} and 8-hour ozone given the new modeling platform and emissions inventory. This update provides a confirmation that the control strategy will continue to move air quality expeditiously towards attainment of the relevant standards.

Annual PM_{2.5}

Annual PM_{2.5} Modeling Approach

The Draft Final 2012 AQMP annual PM_{2.5} modeling employs the same approach to estimating the future year annual PM_{2.5} as was described in the 2007 AQMP attainment demonstrations. Future year PM_{2.5} annual average air quality is determined using site

and species specific quarterly averaged RRFs applied to the weighted quarterly average 2008 PM_{2.5} design values per U.S. EPA guidance documents.

In this application, CMAQ and WRF were used to simulate 2008 meteorological and air quality to determine Basin annual average PM_{2.5} concentrations. The future year attainment demonstration was analyzed for 2015, the target set by the federal CAA. The 2014 simulation relies on implementation of all adopted rules and measures through 2014. This enables a full year-long demonstration based on a control strategy that would be fully implemented by January 1, 2015. It is important to note that the use of the quarterly design values for a 5-year period centered around 2008 (listed in Table 5-4) continue to be used in the projection of the future year annual average PM_{2.5} concentrations. The future year design reflects the weighted quarterly average concentration calculated from the projections over five years (20 quarters).

Future Annual PM_{2.5} Air Quality

The projections for the annual state and federal standards are shown in Figure 5-10. All areas will be in attainment of the federal annual standard (15.0 µg/m³) by 2014. The 2014 design value is projected to be 9 percent below the federal standard. However, as shown in Figure 5-10, the Draft Final 2012 AQMP does not achieve the California standard of 12 µg/m³ by 2014. Additional controls would be needed to meet the California annual PM_{2.5} standard.

**FIGURE 5-10**

Annual Average PM2.5 Design Concentrations:
2008 and 2014 Controlled

Ozone Modeling

The 2007 AQMP provided a comprehensive 8-hour ozone analysis that demonstrated future year attainment of the 1997 federal ozone standard (80 ppb) by 2023 with implementation of short-term measures and CAA Section 182(e)(5) long term emissions reductions. The analysis concluded that NO_x emissions needed to be reduced approximately 76 percent and VOC 22 percent from the 2023 baseline in order to demonstrate attainment. The 2023 base year VOC and NO_x summer planning emissions inventories included 536 and 506 TPD, respectively.

As presented in Chapter 3, the Draft Final 2012 AQMP controlled 2023 emissions of both precursor pollutants are estimated to be lower than the 2023 baseline established in the 2007 AQMP. The 2023 baseline VOC and NO_x emission summer planning emissions have been revised to 438 and 319 TPD, respectively. The emissions revision incorporated changes made to the on-road truck and off-road equipment categories that resulted from CARB rulemaking. The new emissions inventory also reflects the impact of the economic slowdown and revisions to regional growth estimates. As a consequence, it is important to revisit the projections of 2023 baseline ozone to investigate the impact of the inventory revision on the attainment demonstration and equally important, what is the impact on the size of the proposed long term NO_x emissions reduction commitment.

Ozone Representativeness

As a component of the PM_{2.5} attainment demonstration, the CMAQ modeling provided Basin-wide ozone air quality simulations for each hour in 2008. Past ozone attainment demonstrations evaluated a set of days characterized by restrictive meteorology or episodes occurring during concurrent intensive field monitoring programs. Of great importance, these episodic periods needed to be rated in terms of how representative they were in reference to the ozone standard being evaluated. For the now revoked 1-hour ozone standard, the attainment demonstration focused on a limited number of days closely matching the annual design value. Typically, the analysis addressed fewer than 5 days of simulations. The 2007 AQMP was the first to address the 8-hour ozone standard and the use of the RRFs in the future year ozone projection. To provide a robust characterization of the RRFs for use in the attainment demonstration, the analysis simulated 36 days. The ozone modeling guidance recommends that a minimum of 5-days of simulations meeting modeling acceptance criteria be used in a future year RRF calculation, but recommends incorporating as many days as possible to fully capture both the meteorological variations in the ozone season and the response of ozone formation for different daily emissions profiles.

This update to the future year ozone projection focuses on 91 days of ozone air quality observed during June through August 2008. During this period, seven well defined multiday ozone episodes occurred in the Basin with 75 total days having daily Basin-wide maximum concentrations of 80 ppb or higher. More importantly, when adjusted by a normalized meteorological potential using a regression based weighting covering 30-years of data (1998-2010), summarized in the 2003 AQMP, 8 days during the 2008 period were ranked above the 95th percentile in the long term distribution and another 19 were ranked between the 90th and 94th percentile.

Figure 5-11 depicts the time series of the daily Basin 8-hour maximum and Crestline (the Basin design station) daily maximum 8-hour ozone air quality during the three month period in 2008. The seven primary meteorological episodes which occur primarily between mid June and August are highlighted in the figure. It is important to note that the analysis not only focused on the seven periods or Crestline specifically. All station days meeting the acceptance criteria for calculating a daily RRF were included in the analysis. Several locations in the San Bernardino and Riverside Valleys exhibit similar transport and daily patterns of ozone formation as Crestline. The peak Basin 2008 8-hour average ozone concentration was observed at Santa Clarita on August 2nd at a value of 131 ppb, along a distinctly different transport route.

FIGURE 5-11

Observed Basin and Crestline Daily Maximum 8-Hr Average Ozone Concentrations

(Shaded areas indicate multiple day regional ozone episodes)

Overall, the 91-day period provides a robust description of the 2008 ozone-meteorological season. Table 5-4 lists the number of days each Basin station exceeded the 8-hour ozone standard during the June through August 2008 period. Also listed in Table 5-4 are the 2008, 5-year weighted design values used in the future year ozone projections.

Ozone Modeling Approach

The ozone modeling approach used in this update follows the same criteria employed for the 2007 AQMP attainment demonstration. Briefly, the set of 91 days from June 1 through August 30, 2008, simulated as a subset of the annual PM_{2.5} simulations, were analyzed to determine daily 8-hour average maximum ozone for the 2008 and 2023 emissions inventories. A separate 2023 simulation was conducted to assess future year ozone with VOC and NO_x emissions specified at the levels defined by the 2007 AQMP attainment demonstration carrying capacity (420 TPD VOC and 114 TPD NO_x). Finally, a set of simulations with incremental VOC and NO_x emissions reductions from 2023 baseline emissions was generated to create ozone isopleths for each station in the Basin. The ozone isopleths provide updated guidance to the determination of the future

control strategy, particularly in light of the challenge in meeting the current 75 ppb standard which will require an attainment demonstration to be submitted to U.S. EPA in 2015.

The ozone RRFs were calculated using the ratio methodology described for the PM_{2.5} modeling. Individual station day inclusion in the analysis was determined by three basic criteria: (1) the observed ozone concentration had to be ± 30 percent of the station's weighted design value; (2) the absolute prediction accuracy of the base 2008 simulation for that day was required to be within 20 percent; and (3) the observed daily maximum concentration needed to be greater than 84 ppb. The criteria were designed to eliminate extreme values from entering the analysis and to only focus on station days where model performance met the long-standing criteria for acceptance used in previous attainment demonstrations. Finally, only station days where ozone exceeded the 84 ppb threshold established to demonstrate attainment of the 1997 ozone standard, as specified in the U.S. EPA Modeling Attainment Guidance Document, were included in the analysis.

Future Ozone Air Quality

Table 5-5 summarizes the results of the updated ozone simulations. Included for general comparison are the 2023 ozone baseline and 2023 controlled ozone projections from the 2007 AQMP ozone attainment demonstration modeling analysis approved by U.S. EPA as part of the SIP. The Draft Final 2012 AQMP baseline ozone simulations reflect the changes made to the 2023 baseline inventory. The Draft Final 2012 summer planning inventory has a higher ratio between VOC and NO_x emissions, 1.39 vs. 1.05, although total tonnages of both precursor emissions are lower than presented in the 2007 AQMP. The higher VOC to NO_x ratio is indicative of a more reactive pollutant mix with average projected ozone design concentrations 9 percent higher than previously projected. One implication of this simulation is that moderate VOC emissions reductions in the years between 2014 and 2023 will benefit regional ozone concentrations. Yet, the projected 2023 baseline design value of 108 ppb continues to exceed the federal standard by 35 percent. With the implementation of the Draft Final 2012 AQMP short term control measures and the Section 185(e)(5) long-term control measures, (defined in this update as the difference between the Draft Final 2012 AQMP 2023 base year VOC and NO_x emissions and the corresponding Basin 2007 AQMP ozone attainment demonstration carrying capacity), projected regional ozone design values closely match those defined in the 2007 AQMP ozone attainment demonstration. Regardless, it will still require a 64 percent reduction in NO_x emissions and an additional 3 percent reduction in VOC emissions to attain the 1997 ozone standard.

With controls in place, the updated analysis corroborates the approved 2007 AQMP ozone attainment demonstration in that it is expected that all stations in the Basin will meet the federal 8-hour ozone standard. The east Basin stations in the San Bernardino Valley continue to have among the highest projected 8-hour controlled design values for this update. The 2023 controlled ozone design value at Glendora is also projected to exceed 80 ppb, but all stations show attainment with the federal 8-hour ozone standard (≤ 84 ppb). Glendora, Upland, Fontana and San Bernardino are downwind receptors along the primary wind transport route that moves precursor emissions and developing ozone eastward by the daily sea breeze. The higher projected design value at Glendora reflects the higher VOC to NO_x ratio observed in the baseline inventory relative to the 2007 AQMP 2023 baseline inventory. The 2023 controlled design value at Glendora for the Draft Final 2012 AQMP actually represents a greater response to emissions reductions than in the 2007 AQMP attainment demonstration. Future year projections of ozone for this update along the northerly transport route through the San Fernando Valley indicate that the ozone design value in the Santa Clarita Valley will be approximately 15 percent below the standard.

Note: Attainment with the 1997 Federal 8-hour ozone standard requires 84 ppb or less

Spatial Projections of 8-Hour Ozone Design Values

The spatial distribution of ozone design values for the 2008 base year is shown in Figure 5-12. Future year ozone air quality projections for 2024 with and without implementation of all control measures are presented in Figures 5-13 and 5-14. The predicted ozone concentrations will be significantly reduced in the future years in all parts of the Basin with the implementation of proposed control measures in the South Coast Air Basin.

Appendix V provides base year model performance statistics, grid level spatial plots of simulated ozone (base cases and future year controlled) as well as weight of evidence discussions to support the modeling attainment demonstration.

FIGURE 5-14

Model-Predicted 2023 Controlled 8-Hour Ozone Design Concentrations (ppb)

A First Look at Attaining the 2006 8-Hour Ozone Standard

In 2006, the U.S. EPA lowered the federal 8-hour ozone standard to 75 ppb. Recent 8-hour ozone rule implementation guidance requires that a SIP revision with an updated attainment demonstration and control strategy be submitted to U.S. EPA no later than December 2015. The Basin has been designated as an extreme non-attainment area for the new standard, consistent with the classification of the 80 ppb standard. Thus, the deadline for attainment of the 75 ppb standard is 2032, 8-years after the attainment date for the previous 80 ppb federal standard in 2024. It is critical to conduct preliminary analyses to assess the need for potential adjustments to the overall control strategy considering this new standard and deadline

The preliminary projections, based upon a modeling evaluation of how VOC and NO_x reductions affect the Basin's ozone levels (ozone "isopleths") indicates that that a 75 percent reduction in NO_x emissions beyond the 2023 baseline is needed to meet the 75 ppb level in 2032. The resulting 2032 Basin NO_x carrying capacity could be as low as to 85 tpd. Further discussion of the ozone isopleths and a glance at the potential impact to the control strategy and carrying capacity for potential future revisions to the 8-hour ozone standard is presented in Chapter 8.

SUMMARY AND CONCLUSIONS

Figure 5-15 shows the 2008 observed and model-predicted regional peak concentrations for 24-hour average and annual PM_{2.5} as percentages of the most stringent federal standard, for 2014. The federal 24-hour and annual PM_{2.5} standards are predicted to be met in 2014 with implementation of the Draft Final 2012 AQMP control strategy. The California annual PM_{2.5} standard will not be attained before 2019. (See Figure 5-16).

Given the changes made to the modeling platform, the number of episodes evaluated, and the distinct changes in the projected Draft Final 2012 AQMP 2023 baseline inventory, projected 8-hour ozone design values with implementation of the short- and long-term controls are very consistent with those presented in the 2007 AQMP attainment demonstration. Again, an approximate 65 percent reduction in NO_x emissions in 2023 will be required to meet the 1997 80 ppb standard by 2024.

The challenges of meeting potential future standards for 8-hour ozone and a proposed federal annual PM_{2.5} standard between 12 and 13 µg/m³ are discussed in Chapter 8 of this document.

The challenge of future year attainment of proposed revisions to the federal annual PM_{2.5} standard at a value between 12 and 13 µg/m³ are discussed in Chapter 8 of the Draft Final 2012 AQMP.

FEDERAL & STATE CLEAN AIR ACT REQUIREMENTS

Introduction

Specific 24-Hour PM_{2.5} Planning Requirements

Federal Air Quality Standards for Fine Particulates

Federal Clean Air Act Requirements

California Clean Air Act Requirements

Transportation Conformity Budgets

INTRODUCTION

The purpose of the 2012 revision to the AQMP for the South Coast Air Basin is to set forth a comprehensive program that will assist in leading the Basin and those portions of the Salton Sea Air Basin under the District's jurisdiction into compliance with all federal and state air quality planning requirements. Specifically, the Draft Final 2012 AQMP is designed to satisfy the SIP submittal requirements of the federal CAA to demonstrate attainment of the 24-hour PM_{2.5} ambient air quality standards, the California CAA triennial update requirements, and the District's commitment to update transportation emission budgets based on the latest approved motor vehicle emissions model and planning assumptions. Specific information related to the air quality and planning requirements for portions of the Salton Sea Air Basin under the District's jurisdiction are included in the Draft Final 2012 AQMP and can be found in Chapter 7 – Current and Future Air Quality – Desert Nonattainment Area. The 2012 AQMP will be submitted to U.S. EPA as SIP revisions once approved by the District's Governing Board and CARB.

SPECIFIC 24-HOUR PM_{2.5} PLANNING REQUIREMENTS

In November 1990, Congress enacted a series of amendments to the CAA intended to intensify air pollution control efforts across the nation. One of the primary goals of the 1990 CAA Amendments was to overhaul the planning provisions for those areas not currently meeting the NAAQS. The CAA identifies specific emission reduction goals, requires both a demonstration of reasonable further progress and an attainment demonstration, and incorporates more stringent sanctions for failure to attain or to meet interim milestones. There are several sets of general planning requirements, both for nonattainment areas [Section 172(c)] and for implementation plans in general [Section 110(a)(2)]. These requirements are listed and briefly described in Chapter 1 (Tables 1-4 and 1-5). The general provisions apply to all applicable criteria pollutants unless superseded by pollutant-specific requirements. The following sections discuss the federal CAA requirements for the 24-hour PM_{2.5} standards.

FEDERAL AIR QUALITY STANDARDS FOR FINE PARTICULATES

The U.S. EPA promulgated the National Ambient Air Quality Standards for Fine Particles (PM_{2.5}) in July 1997. Following legal actions, the standards were eventually upheld in March 2002. The annual standard was set at a level of 15 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$), based on the 3-year average of annual mean PM_{2.5} concentrations. The 24-hour standard was set at a level of 65 $\mu\text{g}/\text{m}^3$ based on the 3-year average of the

98th percentile of 24-hour concentrations. U.S. EPA issued designations in December 2004, which became effective on April 5, 2005.

In January 2006, U.S. EPA proposed to lower the 24-hour PM_{2.5} standard. On September 21, 2006, U.S. EPA signed the “Final Revisions to the NAAQS for Particulate Matter.” In promulgating the new standards, U.S. EPA followed an elaborate review process which led to the conclusion that existing standards for particulates were not adequate to protect public health. The studies indicated that for PM_{2.5}, short-term exposures at levels below the 24-hour standard of 65 µg/m³ were found to cause acute health effects, including asthma attacks and breathing and respiratory problems. As a result, the U.S. EPA established a new, lower 24-hour average standard for PM_{2.5} at 35 µg/m³. No changes were made to the existing annual PM_{2.5} standard which remained at 15 µg/m³ as discussed in Chapter 2. On June 14, 2012, U.S. EPA proposed revisions to this annual standard. The annual component of the standard was set to provide protection against typical day-to-day exposures as well as longer-term exposures, while the daily standard protects against more extreme short-term events. For the 2006 24-hour PM_{2.5} standard, the form of the standard continues to be based on the 98th percentile of 24-hour PM_{2.5} concentrations measured in a year (averaged over three years) at the monitoring site with the highest measured values in an area. This form of the standard was set to be health protective while providing a more stable metric to facilitate effective control programs. Table 6-1 summarizes the U.S. EPA’s PM_{2.5} standards.

TABLE 6-1

U.S. EPA’s PM_{2.5} Standards

	1997 STANDARDS		2006 STANDARDS	
	Annual	24-Hour	Annual	24-Hour
PM_{2.5}	15 µg/m ³ Annual arithmetic mean, averaged over 3 years	65 µg/m ³ 24-hour average, 98th percentile, averaged over 3 years	15 µg/m ³ Annual arithmetic mean, averaged over 3 years	35 µg/m ³ 24-hour average, 98th percentile, averaged over 3 years

On December 14, 2009, the U.S. EPA designated the Basin as nonattainment for the 2006 24-hour PM_{2.5} NAAQS. A SIP revision is due to U.S. EPA no later than three years from the effective date of designation, December 14, 2012, demonstrating attainment with the standard by 2014. Under Section 172 of the CAA, U.S. EPA may grant an area an extension of the initial attainment date for a period of up to five years.

With implementation of all feasible measures as outlined in this Plan, the Basin will demonstrate attainment with the 24-hour PM_{2.5} standard by 2014, so no extension is being requested.

FEDERAL CLEAN AIR ACT REQUIREMENTS

For areas such as the Basin that are classified nonattainment for the 2006 24-hour PM_{2.5} NAAQS, Section 172 of subpart 1 of the CAA applies. Section 172(c) requires states with nonattainment areas to submit an attainment demonstration. Section 172(c)(2) requires that nonattainment areas demonstrate Reasonable Further Progress (RFP). Under subpart I of the CAA, all nonattainment area SIPs must include contingency measures. Section 172(c)(1) of the CAA requires nonattainment areas to provide for implementation of all reasonably available control measures (RACM) as expeditiously as possible, including the adoption of reasonably available control technology (RACT). Section 172 of the CAA requires the implementation of a new source review program including the use of “lowest achievable emission rate” for major sources referred to under state law as “Best Available Control Technology” (BACT) for major sources of PM_{2.5} and precursor emissions (i.e., precursors of secondary particulates).

This section describes how the Draft Final 2012 AQMP meets the 2006 24-hour PM_{2.5} planning requirements for the Basin. The requirements specifically addressed for the Basin are:

1. Attainment demonstration and modeling [Section 172(a)(2)(A)];
2. Reasonable further progress [Section 172(c)(2)];
3. Reasonably available control technology (RACT) and Reasonably available control measures (RACM) [Section 172(c)(1)] ;
4. New source review (NSR) [Sections 172(c)(4) and (5)];
5. Contingency measures [Section 172(c)(9)]; and
6. Transportation control measures (as RACM).

Attainment Demonstration and Modeling

Under the CAA Section 172(a)(2)(A), each attainment plan should demonstrate that the area will attain the NAAQS “as expeditiously as practicable,” but no later than five years from the effective date of the designation of the area. If attainment within five years is considered impracticable due to the severity of an area’s air quality problem and the lack

of available control measures, the state may propose an attainment date of more than five years but not more than ten years from designation.

This attainment demonstration consists of: (1) technical analyses that locate, identify, and quantify sources of emissions that contribute to violations of the PM_{2.5} standard; (2) analysis of future year emission reductions and air quality improvement resulting from adopted and proposed control measures; (3) proposed emission reduction measures with schedules for implementation; and (4) analysis supporting the region's proposed attainment date by performing a detailed modeling analysis. Chapter 3 and Appendix III of the Draft Final 2012 AQMP present base year and future year emissions inventories in the Basin, while Chapter 4 and Appendix IV provide descriptions of the proposed control measures, the resulting emissions reductions, and schedules for implementation of each measure. The detailed modeling analysis and attainment demonstration are summarized in Chapter 5 and documented in Appendix V.

Reasonable Further Progress (RFP)

The CAA requires SIPs for most nonattainment areas to demonstrate reasonable further progress (RFP) towards attainment through emission reductions phased in from the time of the SIP submission until the attainment date time frame. The RFP requirements in the CAA are intended to ensure that there are sufficient PM_{2.5} and precursor emission reductions in each nonattainment area to attain the 2006 24-hour PM_{2.5} NAAQS by December 14, 2014.

Per CAA Section 171(1), RFP is defined as “such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date.” As stated in subsequent federal regulation, the goal of the RFP requirements is for areas to achieve generally linear progress toward attainment. To determine RFP for the 2006 24-hour PM_{2.5} attainment date, the plan should rely only on emission reductions achieved from sources within the nonattainment area.

Section 172(c)(2) of the CAA requires that nonattainment area plans show ongoing annual incremental emissions reductions toward attainment, which is commonly expressed in terms of benchmark emissions levels or air quality targets to be achieved by certain interim milestone years. The U.S. EPA recommends that the RFP inventories include direct PM_{2.5}, and also PM precursors (such as SO_x, NO_x, and VOCs) that have been determined to be significant.

40 CFR 51.1009 requires any area that submits an approvable demonstration for an attainment date of more than five years from the effective date of designation to also submit an RFP plan. The Draft Final 2012 AQMP demonstrates attainment with the 24-hour PM_{2.5} standard in 2014, which is five years from the 2009 designation date. Therefore, no separate RFP plan is required.

Reasonably Available Control Measures (RACM) and Reasonably Available Control Technology (RACT) Requirements

Section 172(c)(1) of the CAA requires nonattainment areas to

Provide for the implementation of all reasonably available control measures as expeditiously as practicable (including such reductions in emissions from existing sources in the area as may be obtained through the adoption, at a minimum, of reasonably available control technology) and shall provide for attainment of the national primary ambient air quality standards.

The District staff has completed its RACM analysis as presented in Appendix VI of the Draft Final 2012 AQMP.

The U.S. EPA provided further guidance on the RACM in the preamble and the final “Clean Air Fine Particle Implementation Rule” to implement the 1997 PM_{2.5} NAAQS which were published in the Federal Register on November 1, 2005 and April 25, 2007, respectively.^{1, 2} The U.S. EPA’s long-standing interpretation of the RACM provision stated in the 1997 PM_{2.5} Implementation Rule is that the non-attainment air districts should consider all candidate measures that are available and technologically and economically feasible to implement within the non-attainment areas, including any measures that have been suggested; however, the districts are not obligated to adopt all measures, but should demonstrate that there are no additional reasonable measures available that would advance the attainment date by at least one year or contribute to reasonable further progress (RFP) for the area.

With regard to the identification of emission reduction programs, the U.S. EPA recommends that non-attainment air districts first identify the emission reduction programs that have already been implemented at the federal level and by other states and local air districts. Next, the U.S. EPA recommends that the air districts examine additional RACM/RACTs adopted for other non-attainment areas to attain the ambient air quality standards as expeditiously as practicable. The U.S. EPA also recommends the

¹ See 70FR 65984 (November 1, 2005)

² See 72FR 20586 (April 25, 2007)

air districts evaluate potential measures for sources of direct PM_{2.5}, SO_x and NO_x first. VOC and ammonia are only considered if the area determines that they significantly contribute to the PM_{2.5} concentration in the non-attainment area (otherwise they are pressured not to significantly contribute). The PM_{2.5} Implementation Rule also requires that the air districts establish RACM/RACT emission standards that take into consideration the condensable fraction of direct PM_{2.5} emissions after January 1, 2011. In addition, the U.S. EPA recognizes that each non-attainment area has its own profile of emitting sources, and thus neither requires specific RACM/RACT to be implemented in every non-attainment area, nor includes a specific source size threshold for the RACM/RACT analysis.

A RACM/RACT demonstration must be provided within the SIP. For areas projected to attain within five years of designation, a limited RACM/RACT analysis including the review of available reasonable measures, the estimation of potential emission reductions, and the evaluation of the time needed to implement these measures is sufficient. The areas that cannot reach attainment within five years must conduct a thorough RACM/RACT analysis to demonstrate that sufficient control measures could not be adopted and implemented cumulatively in a practical manner in order to reach attainment at least one year earlier.

In regard to economic feasibility, the U.S. EPA did not propose a fixed dollar per ton cost threshold and recommended that air districts to include health benefits in the cost analysis. As indicated in the preamble of the 1997 PM_{2.5} Implementation Rule:

In regard to economic feasibility, U.S. EPA is not proposing a fixed dollar per ton cost threshold for RACM, just as it is not doing so for RACT...Where the severity of the non-attainment problem makes reductions more imperative or where essential reductions are more difficult to achieve, the acceptable cost of achieving those reductions could increase. In addition, we believe that in determining what are economically feasible emission reduction levels, the States should also consider the collective health benefits that can be realized in the area due to projected improvements.

Subsequently, on March 2, 2012, the U.S. EPA issued a memorandum to confirm that the overall framework and policy approach stated in the PM_{2.5} Implementation Rule for the 1997 PM_{2.5} standards continues to be relevant and appropriate for addressing the 2006 24-hour PM_{2.5} standards.

As described in Appendix VI, the District has concluded that all District rules fulfilled RACT for the 2006 24-hour PM_{2.5} standard. In addition, pursuant to California Health

and Safety Code Section 39614 (SB 656), the District evaluated a statewide list of feasible and cost-effective control measures to reduce directly emitted PM_{2.5} and its potential precursor emissions (e.g., NO_x, SO_x, VOCs, and ammonia). The District has concluded that for the majority of stationary and area source categories, the District was identified as having the most stringent rules in California (see Appendix VI). Under the RACM guidelines, transportation control measures must be included in the analysis. Consequently, SCAG has completed a RACM determination for transportation control measures in the Draft Final 2012 AQMP, included in Appendix IV-C.

New Source Review

New source review (NSR) for major and in some cases minor sources of PM_{2.5} and its precursors are presently addressed through the District's NSR and RECLAIM programs (Regulations XIII and XX). In particular, Rule 1325 has been adopted to satisfy NSR requirements for major sources of directly-emitted PM_{2.5}.

Contingency Measures

Contingency Measure Requirements

Section 172(c)(9) of the CAA requires that SIPs include contingency measures.

Such plan shall provide for the implementation of specific measures to be undertaken if the area fails to make reasonable further progress, or to attain the national primary ambient air quality standard by the attainment date applicable under this part. Such measures shall be included in the plan revision as contingency measures to take effect in any such case without further action by the State or the Administrator.

In subsequent NAAQS implementation regulations and SIP approvals/disapprovals published in the Federal Register, U.S. EPA has repeatedly reaffirmed that SIP contingency measures:

1. Must be fully adopted rules or control measures that are ready to be implemented, without significant additional action (or only minimal action) by the State, as expeditiously as practicable upon a determination by U.S. EPA that the area has failed to achieve, or maintain reasonable further progress, or attain the NAAQS by the applicable statutory attainment date (40 CFR § 51.1012, 73 FR 29184)
2. Must be measures not relied on in the plan to demonstrate RFP or attainment for the time period in which they serve as contingency measures and should provide SIP-creditable emissions reductions equivalent to one year of RFP, based on "generally

linear” progress towards achieving the overall level of reductions needed to demonstrate attainment (76 FR 69947, 73 FR 29184)

3. Should contain trigger mechanisms and specify a schedule for their implementation (72 FR 20642)

Furthermore, U.S. EPA has issued guidance that the contingency measure requirement could be satisfied with already adopted control measures, provided that the controls are above and beyond what is needed to demonstrate attainment with the NAAQS (76 FR 57891).

U.S. EPA guidance provides that contingency measures may be implemented early, i.e., prior to the milestone or attainment date. Consistent with this policy, States are allowed to use excess reductions from already adopted measures to meet the CAA sections 172(c)(9) and 182(c)(9) contingency measures requirement. This is because the purpose of contingency measures is to provide extra reductions that are not relied on for RFP or attainment, and that will provide a cushion while the plan is being revised to fully address the failure to meet the required milestone. Nothing in the CAA precludes a State from implementing such measures before they are triggered.

Thus, an already adopted control measure with an implementation date prior to the milestone year or attainment year would obviate the need for an automatic trigger mechanism.

Air Quality Improvement Scenario

The U.S. EPA Guidance Memo issued March 2, 2012, “Implementation Guidance for the 2006 24-Hour Fine Particle (PM_{2.5}) National Ambient Air Quality Standard (NAAQS)”, provides the following discussion of contingency measures:

The preamble of the 2007 PM_{2.5} Implementation Rule (see 79 FR 20642-20645) notes that contingency measures "should provide for emission reductions equivalent to about one year of reductions needed for reasonable further progress (RFP)." The term "one year of reductions needed for RFP" requires clarification. This phrase may be confusing because all areas technically are not required to develop a separate RFP plan under the 2007 PM_{2.5} Implementation Rule. The basic concept is that an area's set of contingency measures should provide for an amount of emission reductions that would achieve "one year's worth" of air quality improvement proportional to the overall amount of air quality improvement to be achieved by the area's attainment plan; or alternatively, an amount of emission reductions (for all pollutants subject to control measures in the attainment plan) that would achieve one year's worth of emission reductions proportional to the overall amount of emission

reductions needed to show attainment. Contingency measures can include measures that achieve emission reductions from outside the nonattainment area as well as from within the nonattainment area, provided that the measures produce the appropriate air quality impact within the nonattainment area.

The U.S. EPA believes a similar interpretation of the contingency measures requirements under section 172(c)(9) would be appropriate for the 2006 24-hour PM_{2.5} NAAQS.

The March 2, 2012 memo then provides an example describing two methods for determining the required magnitude of emissions reductions to be potentially achieved by implementation of contingency measures:

Assume that the state analysis uses a 2008 base year emissions inventory and a future year projection inventory for 2014. To demonstrate attainment, the area needs to reduce its air quality concentration from 41ug/m³ in 2008 to 35 ug/m³ in 2014, equal to a rate of change of 1 ug/m³ per year. The attainment plan demonstrates that this level of air quality improvement would be achieved by reducing emissions between 2008 and 2014 by the following amounts: 1,200 tons of PM_{2.5}; 6,000 tons of NO_x; and 6,000 tons of SO₂.

Thus, the target level for contingency measures for the area could be identified in two ways:

- 1) The area would need to provide an air quality improvement of 1 ug/m³ in the area, based on an adequate technical demonstration provided in the state plan. The emission reductions to be achieved by the contingency measures can be from any one or a combination of all pollutants addressed in the attainment plan, provided that the state plan shows that the cumulative effect of the adopted contingency measures would result in a 1 ug/m³ improvement in the fine particle concentration in the nonattainment area; and*
- 2) The contingency measures for the area would be one-sixth (or approximately 17%) of the overall emission reductions needed between 2008 and 2014 to show attainment. In this example, these amounts would be the following: 200 tons of PM_{2.5}; 1,000 tons of NO_x; and 1,000 tons of SO₂.*

The two approaches are explicitly mentioned in regulatory form at 40 CFR § 51.1009:

- (g) The RFP plan due three years after designation must demonstrate that emissions for the milestone year are either:*

- (1) At levels that are roughly equivalent to the benchmark emission levels for direct PM_{2.5} emissions and each PM_{2.5} attainment plan precursor to be addressed in the plan; or*
- (2) At levels included in an alternative scenario that is projected to result in a generally equivalent improvement in air quality by the milestone year as would be achieved under the benchmark RFP plan.*

- (h) The equivalence of an alternative scenario to the corresponding benchmark plan must be determined by comparing the expected air quality changes of the two scenarios at the design value monitor location. This comparison must use the information developed for the attainment plan to assess the relationship between emissions reductions of the direct PM_{2.5} emissions and each PM_{2.5} attainment plan precursor addressed in the attainment strategy and the ambient air quality improvement for the associated ambient species.*

The first method in the example and the alternative scenario in the regulation, 40 CFR § 51.1009 (g)(2), base the required amount of contingency measure emission reductions on one year's worth of air quality improvements. The most accurate way of demonstrating that the emissions reductions will lead to air quality improvements is through air quality modeling such as that used in the attainment demonstration (40 CFR § 51.1009 (h) above). If the model results show the required air quality improvements, then the emissions reductions included in the model input are therefore shown to be sufficient to achieve those air quality improvements. The second method in the example, and (g)(1) in the regulation, is based solely on emission reductions, without a direct demonstration that there will be a corresponding improvement in air quality.

Logically, the method based on air quality is more robust than the method based solely on emissions reductions in that it demonstrates that emissions reductions will in fact lead to corresponding air quality improvements, which is the ultimate goal of the CAA and the SIP. The second method relying on overall emissions reductions alone does not account for the spatial and temporal variation of emissions, nor does it account for where and when the reductions will occur. As the relationship between emissions reductions and resulting air quality improvements is complex and not always linear, relying solely on prescribed emission reductions may not ensure that the desired air quality improvements will result when and where they are needed. Therefore, determining the magnitude of reductions required for contingency measures based on air quality improvements, derived from a modeling demonstration, is more effective in achieving the objective of this CAA requirement.

Magnitude of Contingency Measure Air Quality Improvements

The example for determining the required magnitude of air quality improvement to be achieved by contingency measures provided in the March 2, 2012 guidance memo uses the attainment demonstration base year as the base year in the calculation (2008). This is based on the memo's statement that "*contingency measures should provide for an amount of emission reductions that would achieve 'one year's worth' of air quality improvement proportional to the overall amount of air quality improvement to be achieved by the area's attainment plan.* The original preamble (79 FR 20642-20645) states that contingency measures "*should provide for emission reductions equivalent to about one year of reductions needed for reasonable further progress (RFP).*" The term "reasonable further progress" is defined in Section 171(1) of the CAA as "*such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable NAAQS by the applicable date.*"

40 CFR 51.1009 is explicit on how emissions reductions for RFP are to be calculated. In essence, the calculation is a linear interpolation between base-year emissions and attainment-year (full implementation) emissions. The Plan must then show that emissions or air quality in the milestone year (or attainment year) are "roughly equivalent" or "generally equivalent" to the RFP benchmark. As stated earlier in this chapter, given the 2014 attainment year, there are no interim milestone RFP requirements. The contingency measure requirements, therefore, only apply to the 2014 attainment year. In 2014, contingency measures must provide for about one year's worth of reductions or air quality improvement, proportional to the overall amount of air quality improvement to be achieved by the area's attainment plan.

The 2008 base year design value in the 24-hour PM_{2.5} attainment demonstration is 47.9 µg/m³, and the 2014 attainment year design value must be less than 35.5 µg/m³ (see Chapter 5). Linear progress towards attainment over the six year period yields one year's worth of air quality improvements equal to approximately 2 µg/m³. Thus, contingency measures should provide for approximately 2 µg/m³ of air quality improvements to be automatically implemented in 2015 if the Basin fails to attain the 24-hour PM_{2.5} standard in 2014.

Satisfying the Contingency Measure Requirements

As stated above, the contingency measure requirement can be satisfied by already adopted measures resulting in air quality improvements above and beyond those needed

for attainment. Since the attainment demonstration need only show an attainment year concentration below $35.5 \mu\text{g}/\text{m}^3$, any measures leading to improvement in air quality beyond this level can serve as contingency measures. As shown in Chapter 5, the attainment demonstration yields a 2014 design value of $34.28 \mu\text{g}/\text{m}^3$. The excess air quality improvement is therefore approximately $1.2 \mu\text{g}/\text{m}^3$.

In addition to these air quality improvements beyond those needed for attainment, an additional contingency measure is proposed that will result in emissions reductions beyond those needed for attainment in 2014. Control Measure CMB-01 Phase I seeks to achieve an additional two tons per day of NO_x emissions reductions from the RECLAIM market if the Basin fails to achieve the standard by the 2014 attainment date. CMB-01 Phase I is scheduled for near-term adoption and includes the appropriate automatic trigger mechanism and implementation schedule consistent with CAA contingency measure requirements. Taken together with the $1.2 \mu\text{g}/\text{m}^3$ of excess air quality improvement described above, this represents a sufficient margin of “about one year’s of progress” and “generally linear” progress to satisfy the contingency measure requirements. Note that based on the most recent air quality data at the design value site, Mira Loma, the actual measured air quality is already better (by over $4 \mu\text{g}/\text{m}^3$ in 2011) than that projected by modeling based on linear interpolation between base year and attainment year.

To address U.S. EPA’s comments regarding contingency measures, the excess air quality improvements beyond those needed to demonstrate attainment should also be expressed in terms of emissions reductions. This will facilitate their enforceability and any future needs to substitute emissions reductions from alternate measures to satisfy contingency measure requirements. For this purpose, Table 6-2 explicitly identifies the portions of emissions reductions from proposed measures that are designated as contingency measures. Table 6-2 also includes the total equivalent basin-wide NO_x emissions reductions based on the PM_{2.5} formation potential ratios described in Chapter 5.

TABLE 6-2

Emissions Reductions for Contingency Measures (2014)

MEASURE	ASSOCIATED EMISSIONS REDUCTIONS FROM CONTINGENCY MEASURES (TONS/DAY)
BCM-01 – Residential Wood Burning ^{1,2}	2.84(PM2.5)
BCM-02 – Open Burning ^{1,2}	1.84(PM2.5)
CMB-01 – NO _x reductions from RECLAIM	2 (NO _x)
Total	71 (NO _{x(e)}) ³

¹40% of the reductions from these measures, as shown in Table 4-2, are designated for contingency purposes.

² Episodic emissions reductions occurring on burning curtailment days.

³ NO_x equivalent emissions based on PM2.5 formation potentials described in Chapter 5 (Table 5-2). The PM2.5:NO_x ratio is 14.83:1.

Transportation Control Measures

As part of the requirement to demonstrate that RACM has been implemented, transportation control measures meeting the CAA requirements must be included in the plan. Updated transportation control measures included in this plan attainment of the federal 2006 24-hour PM2.5 standard are described in Appendix IV-C – Regional Transportation Strategy & Control Measures.

Section 182(d)(1)(A) of the CAA requires the District to include transportation control strategies (TCS) and transportation control measures (TCM) in its plans for ozone that offset any growth in emissions from growth in vehicle trips and vehicle miles traveled. Such control measures must be developed in accordance with the guidelines listed in Section 108(f) of the CAA. The programs listed in Section 108(f) of the CAA include, but are not limited to, public transit improvement projects, traffic flow improvement

projects, the construction of high occupancy vehicle (HOV) facilities and other mobile source emission reduction programs. While this is not an ozone plan, TCMs may be required if they are RACM.³ TCMs have been developed for the Draft Final 2012 AQMP and are described in Appendix IV-C. TCMs in the Draft Final 2012 AQMP include the capital-based and non-capital-based facilities, projects and programs contained in the Regional Transportation Plan (RTP) and programmed through the Regional Transportation Implementation Plan (RTIP) process. As an additional measure to reduce mobile source emissions, Section 182(d)(1)(B) of the CAA allows the implementation of employer-based trip reduction programs that are aimed at improving the average vehicle occupancy (AVO) rates. As an alternative to trip reduction programs, Section 182(d)(1)(B) also allows the substitution of these programs with alternative programs that achieve equivalent emission reductions. Rule 2202 - On-Road Motor Vehicle Mitigation Options, adopted in December 1995, was developed to comply with CAA Section 182(d)(1)(B).

CALIFORNIA CLEAN AIR ACT REQUIREMENTS

The Basin is designated as nonattainment with the State ambient air quality standards for both PM10 and PM2.5. The California Clean Air Act (CCAA) requires that a plan for attaining the ozone standard be reviewed, and revised as necessary, every three years (Health & Safety Code § 40925). The Draft Final 2012 AQMP satisfies this triennial update requirement. The CCAA established a number of legal mandates to facilitate achieving health-based state air quality standards at the earliest practicable date. The following CCAA requirements do not directly apply to particulate matter plans but are addressed for ozone in the remainder of this chapter:

- (1) Demonstrate the overall effectiveness of the air quality program;
- (2) Reduce nonattainment pollutants at a rate of 5% per year, or include all feasible measures and an expeditious adoption schedule;
- (3) Reduce Population Exposure to severe nonattainment pollutants according to a prescribed schedule; and
- (4) Rank control measures by cost-effectiveness.

³ The District will in the future take actions as required to satisfy ozone TCM provisions when so directed by U.S. EPA.

Plan Effectiveness

The CCAA requires, beginning on December 31, 1994 and every three years thereafter, that the District assess its progress toward attainment of the state ambient air quality standards [Health & Safety Code § 40924(b)] and that this assessment be incorporated into the District's triennial plan revision. To demonstrate the effectiveness of the District's program, air quality trends since 1990 depicting maximum pollutant concentrations are provided in Figure 6-2. While this statute does not apply to particulate matter, it is useful to discuss progress towards attainment of the PM₁₀ and PM_{2.5} standards. Basin maximum annual average PM₁₀ concentrations have decreased continuously since 1990 from a high of nearly 80 µg/m³ to a 2011 level of just above 41 µg/m³. PM_{2.5} annual concentrations have decreased nearly 50% since 1999 to a 2011 level of 15.3 µg/m³. The State annual standards are 20 µg/m³ and 12 µg/m³ for PM₁₀ and PM_{2.5}, respectively.

1-hour ozone concentrations have decreased about 50% since 1990 to a 2011 level of 0.16 ppm. 8-hour ozone concentrations have also decreased continuously from 1990 levels of 0.194 ppm to 2011 levels of 0.136. The State annual standards are 0.09 ppm and 0.07 ppm for 1-hour ozone and 8-hour ozone, respectively.

NO₂ and CO air quality have also improved substantially since 1990. NO₂ and CO metrics are not shown since the Basin currently meets all state and federal NO₂ and CO standards. A comprehensive discussion of local air quality trends can be found in Chapter 2 and Appendix II – Current Air Quality.

Basin Air Quality Trends

FIGURE 6-2

Ozone, PM10, and PM2.5 Trends Since 1990

Emission Reductions

The CCAA requires that each district plan be designed to achieve a reduction in district-wide emissions of 5% or more per year for each covered non-attainment pollutant or its precursors, averaged every consecutive three-year period (Health & Safety Code § 40914). This requirement does not apply to particulate matter, but does apply to ozone. If this cannot be achieved, a plan may instead show that it has implemented all feasible measures as expeditiously as possible. Nevertheless, all feasible measures should be implemented for particulate matter in order to assure attainment as expeditiously as practicable.

It is not practical nor does the federal CAA require an air district to develop an emissions inventory for every year between the base year and attainment year; therefore, consecutive three-year averages have not been explicitly calculated. Furthermore, based on the emissions projections provided in Chapter 3, 5% or more of reductions per year

cannot be achieved for all pollutants and precursors with all feasible measures implemented. As discussed earlier in this chapter with respect to the RACM / RACT analysis, this Plan implements all available feasible measures as expeditiously as possible.

Population Exposure

The CCAA also requires a reduction in overall population exposure to criteria pollutants. Specifically, exposure to the designated severe nonattainment pollutants (i.e., ozone) above standards must be reduced by at least:

- (1) 25 percent by December 31, 1994;
- (2) 40 percent by December 31, 1997; and
- (3) 50 percent by December 31, 2000.

Reductions are to be calculated based on per-capita exposure and the severity of the exceedances. For the Basin, this provision is applicable to ozone [Health & Safety Code § 40920(c)]. The definition of exposure is the number of persons exposed to a specific pollutant concentration level above the State standard times the number of hours exposed. The per-capita exposure is the population exposure (units of pphm-persons-hours) divided by the total population. This requirement for the specific milestone years listed in the CCAA has been shown to have already been satisfied in previous AQMPs.

Cost Effectiveness Ranking

The CCAA requires that each plan revision shall include an assessment of the cost effectiveness of available and proposed control measures and contain a list which ranks the control measures from the least cost-effective to the most cost-effective. Table 6-3 provides a list of stationary source control measures for the 24-hour PM_{2.5} standard ranked by cost-effectiveness. Tables 6-4 and 6-5 provide a list of stationary and mobile source control measures for ozone ranked by cost-effectiveness.

In developing an adoption and implementation schedule for a specific control measure, the District shall consider the relative cost effectiveness of the measure as well as other factors including, but not limited to, technological feasibility, total emission reduction potential, the rate of reduction, public acceptability, and enforceability (Health & Safety Code § 40922). These requirements also do not apply to particulate matter, but provide useful information. The PM_{2.5} control strategy and implementation schedule is provided in Chapter 4.

^b Emissions reductions and costs will be determined after projects are identified and implemented. See Appendix IV-B for cost information for specific measures.

^c Voluntary incentive programs

^d This measure was included in the 2007 Ozone SIP and is included in the Draft Final 2012 AQMP with updated technical information.

TRANSPORTATION CONFORMITY BUDGETS

The Draft Final 2012 AQMP sets forth the strategy for achieving the 2006 24-hour PM_{2.5} and 8-hour ozone standards. For on-road mobile sources, Section 176(c) of the CAA requires that transportation plans and programs do not cause or contribute to any new violation of a standard, increase the frequency or severity of any existing violation,

or delay the timely attainment of the air quality standards. Therefore, on-road mobile sources must "conform" to the attainment demonstration contained in the SIP.

U.S. EPA's transportation conformity rule, found in 40 CFR parts 51 and 93, details the requirements for establishing motor vehicle emissions budgets in SIPs for the purpose of ensuring the conformity of transportation plans and programs with the SIP attainment demonstration. The on-road motor vehicle emissions budgets act as a "ceiling" for future on-road mobile source emissions. Exceedances of the budget indicate an inconsistency with the SIP, and could lead to a conformity "lapse" and its related consequences if not corrected before the next conformity deadline (e.g., during a lapse, certain categories of transportation projects cannot proceed). As required by the CAA, a comparison of regional on-road mobile source emissions to these budgets will occur during the periodic updates of regional transportation plans and programs.

The on-road motor vehicle emissions estimates for the Draft Final 2012 AQMP were analyzed using CARB's EMFAC2011 emission factors for the transportation activity data provided by Southern California Association of Governments (SCAG) from their adopted 2012 Regional Transportation Plan (2012 RTP). For the Draft Final 2012 AQMP, on-road motor vehicle emissions budgets are provided in Table 6-6 for 2014. The PM_{2.5} emissions budgets for PM_{2.5}, and the PM_{2.5} precursors, VOC and NO_x, are derived from the annual average inventory.

This approach is consistent with U.S. EPA's transportation conformity rule, which provides that if emissions budgets rely on new control measures, these measures must be specified in the SIP and the emissions reductions from each control measure must be quantified and supported by agency commitments for adoption and implementation schedules. Moreover, the rule provides that conformity analyses by transportation agencies may not take credit for measures which have not been implemented unless the measures are "projects, programs, or activities" in the SIP supported by written implementation commitments by the responsible agencies (40 CFR 93.122(a)(3)). The emissions budgets for PM_{2.5} are provided for the 2014 attainment year. However, since transportation analyses are needed beyond the attainment dates, the carrying capacities for the PM_{2.5} attainment demonstration also serve as the budgets for future years. For transportation conformity analysis a trading mechanism can be established based on the PM_{2.5} forming potential developed through the modeling analysis for the emission budgets for various pollutants in SCAB.

TABLE 6-6

2014 Motor Vehicle Emissions Budgets: PM2.5
(Annual Average - Tons Per Day)*

PM2.5 Re-entrained Road Dust	--	--	0.58
Road Construction Dust	--	--	0.25
Adjusted Inventory	--	--	19.8
2014 Mobile Source Emission Budget**	116	263	20

* Derived based on EMFAC2011 and external adjustments associated with on-road mobile source incentive programs (Proposition 1B, Carl Moyer, AB1493). 2014 budget is applicable to all future years beyond 2014.

** Rounded up to the nearest whole number

In the Draft Final 2012 AQMP the approximate weighting ratios of the precursor emissions for 24-hour PM_{2.5} formation in equivalent tons per day of NO_x are: VOC: 0.3 (reducing one ton of VOC is equivalent to reducing 0.3 ton of NO_x), NO_x: 1.0, and PM_{2.5}: 14.8 (i.e., reducing one ton of PM_{2.5} is equivalent to reducing 14.8 tons of NO_x). This mechanism allows emissions below the budget for one pollutant to be used to supplement another pollutant exceeding the budget based on the ratios established herein. Clear documentation of the calculations used in the trading should be included in the conformity analysis. This trading approach is consistent with what U.S. EPA approved in 2011 the revisions to the 2007 PM_{2.5} SIP where the precursor substitution methodology was established.

The basic trading ratios are defined by the 24-hour PM_{2.5} regional modeling attainment demonstration. Briefly, NO_x emissions reductions are scaled to the reduction of Basin ammonium nitrate (including water bonding). Similarly, reductions of VOC are scaled to changes in the organic carbon species while reductions in directly emitted particulates are scaled to the projected changes in the elemental carbon and “others” portions of the PM_{2.5} mass. Table 6-7 summarizes the trading equivalencies in TPD:

TABLE 6-7

Trading Equivalencies for PM2.5 Motor Vehicle Emissions Budgets

ONE TON OF	IS EQUIVALENT IN TERMS OF PM2.5 FORMATION TO THIS MANY TONS OF		
	NOx:	VOC:	PM2.5:
NOx	1	3.151	0.067
VOC	0.317	1	0.021
PM2.5	14.833	46.792	1

An example of how the trading mechanism would work follows: If the amount of NOx calculated exceeds the budget by 0.75 TPD then that overage could be offset by trading 2.36 TPD of excess VOC emissions reductions (e.g. $3.151 \text{ VOC}/1 \text{ ton of NOx} \times 0.75 \text{ TPD NOx required} = 2.36 \text{ TPD VOC}$). In this case, “excess” VOC emission reductions would be those beyond what are needed to meet the VOC budget. Similarly 0.050 TPD of directly emitted PM2.5 emissions below the budgeted amount could also be traded to the NOx emissions category and subtracted from the NOx total to allow NOx to meet its budget. In other words, the trading mechanism can be multi-pollutant and multi-directions. It should be noted that the trading calculations are performed prior to the final rounding to demonstrate conformity with the budgets.

It is also important to note that the ratios and equivalencies are targeted for a 2014 application. Ratios beyond 2017 would need to be adjusted based on the projected emissions and regional modeling analyses. A comprehensive discussion of the calculation of the trading ratios is provided in Attachment 8 of Appendix V of this document.

Chapter 7
**Current and Future Air Quality –
Desert Nonattainment Areas**

South Coast Air Quality Management District

Cleaning the air that we breathe...

CHAPTER 7

CURRENT AND FUTURE AIR QUALITY – DESERT NONATTAINMENT AREAS

Introduction

Air Quality Setting

Future Air Quality

Conclusions

INTRODUCTION

The District has jurisdiction over the South Coast Air Basin and the desert portion of Riverside County in the Salton Sea Air Basin. Figure 7-1 shows a map of the area and topography. The Coachella Valley, located in the desert portion of Riverside County does not exceed the federal standard for PM_{2.5}. However, it exceeds the PM₁₀ federal standard on days when high wind events cause transport of windblown dust from both disturbed and natural desert areas (these days can be flagged as exceptional events¹ under U.S. EPA regulations). Also, the Coachella Valley exceeds the federal 8-hour ozone standards, both the 1997 standard (0.08 ppm, or 80 ppb) and the lower 2008 standard (0.075 ppm, or 75 ppb). For both ozone standards, the Coachella Valley is classified as a “severe” ozone nonattainment area. This chapter summarizes the current air quality setting for the Coachella Valley and the most recent updates to the attainment status.

While the 2007 AQMP addressed and satisfied the Clean Air Act (CAA) planning requirements for the Coachella Valley, the 2012 AQMP specifically addresses CAA planning requirements for the 24-hour PM_{2.5} standard in the South Coast Air Basin and not in the Coachella Valley, which is designated by U.S. EPA as unclassifiable/attainment of this standard. Since the Coachella Valley is not in attainment of the federal 8-hour ozone standards, this chapter will address the current status of ozone air quality and provide the latest projections of future ozone levels, based on the latest emissions inventories and modeling efforts. However, the 2007 AQMP adequately addressed and satisfied the CAA planning requirements for ozone in the Coachella Valley, and this chapter is for information only. This AQMP confirms that with the latest emissions and modeling projections, the strategy toward attainment of the federal ozone standards in the Coachella Valley remains effective.

On April 18, 2003, U.S. EPA approved the Coachella Valley State Implementation Plan (2003 CVSIP), which addressed future year attainment of the PM₁₀ standards and incorporated the latest mobile source emissions model results and planning assumptions. Over the past five years, annual average PM₁₀ concentrations have met the levels of the revoked federal annual standard (50 µg/m³), and peak 24-hour

¹The U.S. EPA Exceptional Events Rule, *Treatment of Data Influence by Exceptional Events*, became effective May 21, 2007. The previous U.S. EPA *Natural Events Policy* for Particulate Matter was issued on May 30, 1996. Under the Exceptional Events Rule, U.S. EPA allows certain data to be flagged in the U.S. EPA Air Quality System (AQS) database and not considered for NAAQS attainment status when that data is influenced by exceptional events, such as high winds, wildfires, volcanoes, or some cultural events (Independence Day fireworks) that meet strict requirements.

average PM10 concentrations have not exceeded the current federal standard (150 µg/m³). The Coachella Valley is currently eligible for redesignation as attainment (after high-wind natural events were flagged under the Exceptional Events Rule). Requests have been made to U.S. EPA to redesignate the Coachella Valley and South Coast Air Basin as attainment for PM10; the redesignations are still pending at this time². Since the 2012 AQMP does not include new modeling efforts for PM10, future projections for Coachella Valley PM10 levels in the 2003 CVSIP are still applicable.

Like the South Coast Air Basin, the Coachella Valley is a rapidly growing area, as shown in Table 7-1. By 2030, the population in the Coachella Valley is projected to more than double that of 2000. On a percentage basis, the Coachella Valley growth exceeds that of the Basin. This population growth is taken into account in the emissions projections for future years, used to demonstrate attainment of the air quality standards.

TABLE 7-1

Historic Population and Projections for South Coast Air Basin and Coachella Valley

AREA	1980	1990	2000	2010	2020	2030
South Coast Air Basin	10,500,000	13,022,000	14,681,000	15,759,412	16,901,492	18,129,690
Coachella Valley	139,000	267,000	320,892	439,357	558,321	710,430

² U.S. EPA has requested additional temporary PM10 monitoring in the southeastern Coachella Valley to further assess windblown dust in that area; this project is currently ongoing.

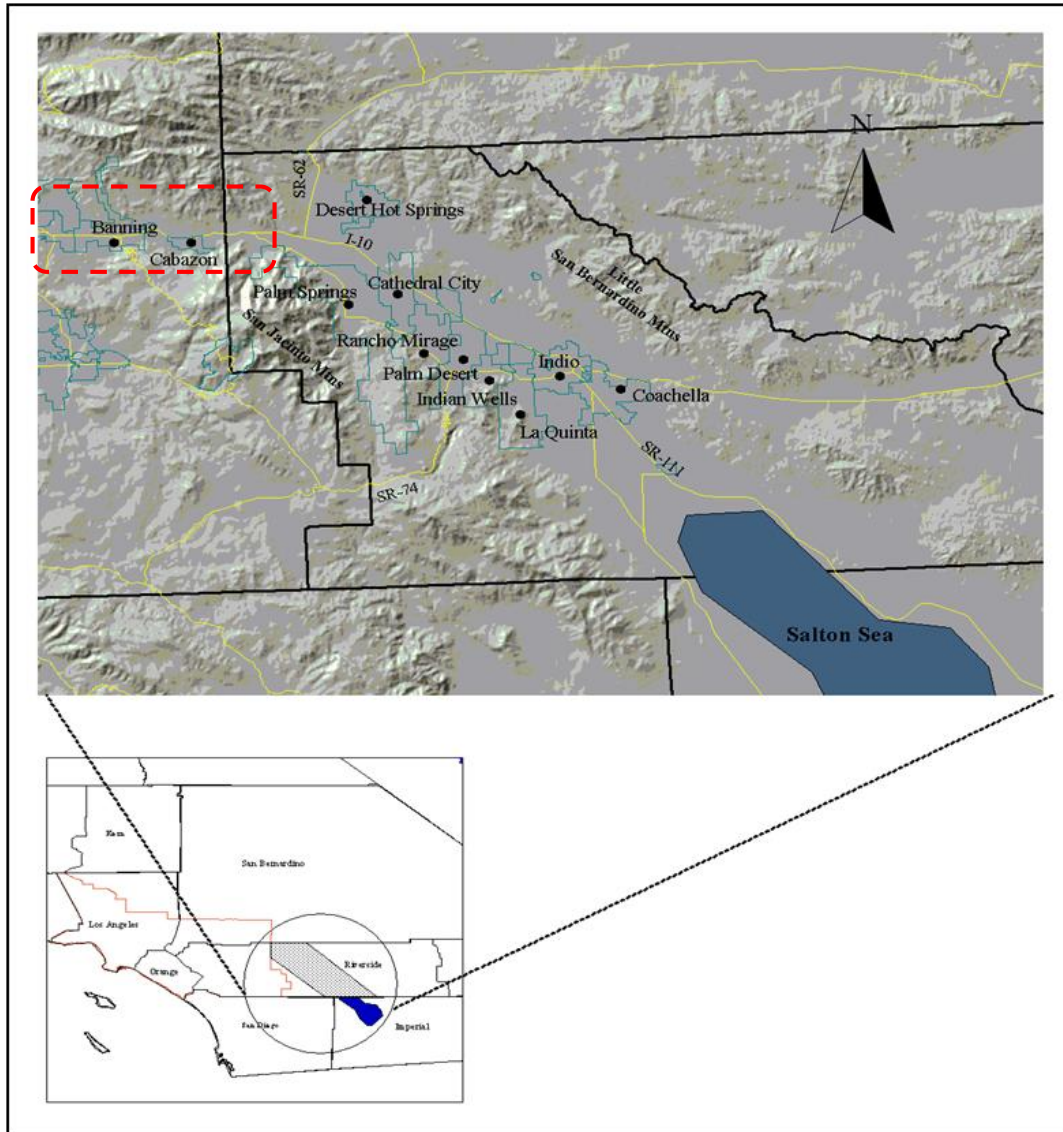

FIGURE 7-1

Location and Topography of the Coachella Valley
(Dashed red box indicates the San Gorgonio Pass;
AQMD Coachella Valley air monitoring stations at Palm Springs and Indio)

AIR QUALITY SETTING

Air Quality Summary

In 2011, the District monitored air quality at two permanent locations in the Riverside county portion of the Salton Sea Air Basin (SSAB), both in the Coachella Valley. One air monitoring station (Palm Springs) is located closer to the San Gorgonio Pass,

predominantly downwind of the densely populated Basin. The other station (Indio) is located further into the Coachella Valley, on the predominant downwind side of the main population areas of the Coachella Valley. A summary of the recent and historic air pollution data collected in the Coachella Valley is included in Appendix II. Information on the health effects associated with criteria air pollutants are summarized in Chapter 2 and detailed in Appendix I.

Attainment Status

In 2011, air pollutant concentrations in the Coachella Valley exceeded state and federal standards for both ozone and PM₁₀. However, the two days that exceeded the federal 24-hour PM₁₀ standard were associated with high-wind natural events and have been flagged in the U.S. EPA Air Quality System (AQS) database to be excluded for comparison to the National Ambient Air Quality Standards (NAAQS), as allowed by the U.S. EPA Exceptional Events Rule. After application of the U.S. EPA Exceptional Event Rule (and its predecessor, the Natural Events Policy) to high wind natural events in the Coachella Valley, no days since the mid-1990s have exceeded the federal 24-hour PM₁₀ standard at Indio or Palm Springs. As a result, the District requested that U.S. EPA redesignate the Coachella Valley from nonattainment to attainment of the PM₁₀ NAAQS. Further action by U.S. EPA on this request is still pending. The current federal NAAQS attainment designations for the Coachella Valley are presented in Table 7-2.

The maximum concentrations of ozone, PM_{2.5}, PM₁₀, nitrogen dioxide (NO₂), carbon monoxide (CO), and sulfate (SO₄²⁻) recorded at these locations in 2011 are shown in Figure 7-2, as percentages of the state and federal standards. Figure 7-3 shows the Coachella Valley design value³ for ozone, PM_{2.5} and PM₁₀ for the 3-year period 2009-2011, as percentages of the current and revoked federal standards.

³ A design value is a statistic that describes the air quality status of a given area relative to the level and form of the National Ambient Air Quality Standards (NAAQS). For most criteria pollutants, the design value is a 3-year average and takes into account the form of the short-term standard (e.g., 98th percentile, fourth high value, etc.).

TABLE 7-2

National Ambient Air Quality Standards (NAAQS) Attainment Status
Coachella Valley Portion of the Salton Sea Air Basin

CRITERIA POLLUTANT	AVERAGING TIME	DESIGNATION ^{a)}	ATTAINMENT DATE ^{b)}
1979 1-Hour Ozone ^{c)}	1-Hour (0.12 ppm)	Nonattainment (Severe-17)	11/15/2007 (not timely attained) ^{c)}
1997 8-Hour Ozone ^{d)}	8-Hour (0.08 ppm)	Nonattainment (Severe-15)	6/15/2019
2008 8-Hour Ozone	8-Hour (0.075 ppm)	Nonattainment (Severe-15)	12/31/2027
CO	1-Hour (35 ppm) 8-Hour (9 ppm)	Unclassifiable/Attainment	Unclassifiable/Attainment
NO₂ ^{e)}	1-Hour (100 ppb)	Unclassifiable/Attainment	Unclassifiable/Attainment
	Annual (0.053 ppm)	Unclassifiable/Attainment	Unclassifiable/Attainment
SO₂ ^{f)}	1-Hour (75 ppb)	Designations Pending	Designations Pending
	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	Unclassifiable/Attainment
PM₁₀	24-hour (150 µg/m ³)	Nonattainment (Serious) ^{g)}	12/31/2006 (redesignation request submitted) ^{g)}
PM_{2.5}	24-Hour (35 µg/m ³) Annual (15.0 µg/m ³)	Unclassifiable/Attainment	Unclassifiable/Attainment
Lead	3-Months Rolling (0.15 µg/m ³)	Unclassifiable/Attainment	Unclassifiable/Attainment

- a) U.S. EPA often only declares Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable
- b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration
- c) 1-hour ozone standard (0.13 ppm) was revoked, effective June 15, 2005; the Southeast Desert Modified Air Quality Management Area, including the Coachella Valley, did not attain this standard based on 2005-2007 data and has some continuing obligations under the former standard (latest 2009-2011 data shows attainment)
- d) 1997 8-hour ozone standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the 1997 ozone standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA
- e) New NO₂ 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO₂ standard retained
- f) The 1971 Annual and 24-hour SO₂ standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO₂ 1-hour standard. Area designations expected in 2012 with Unclassifiable /Attainment designation likely for SSAB Coachella Valley
- g) Annual PM₁₀ standard was revoked, effective December 18, 2006; redesignation request to Attainment of the 24-hour PM₁₀ standard is pending with U.S. EPA

FIGURE 7-2

Coachella Valley 2011 Maximum Pollutant Concentrations as Percent of State and Federal Standards

FIGURE 7-3

Coachella Valley 3-Year (2009-2011) Design Values as Percent of Federal Standards

PM10

PM10 is measured daily at both Indio and Palm Springs by supplementing the (primary) 1-in-3-day Federal Reference Method (FRM) filter sampling at Indio and the 1-in-6-day FRM at Palm Springs with (secondary) continuous hourly Federal Equivalent Method (FEM) measurements at both stations.

Although exceedances of the ozone standard in the Coachella Valley area are due to the transport of ozone from the densely populated areas of the upwind Basin, the same cannot be said for PM10 exceedances. PM10 in the Coachella Valley is primarily due to locally generated sources of fugitive dust (e.g., construction activities, re-entrained dust from paved and unpaved road travel, and natural wind-blown sources) and not as a result of secondary PM generated from precursor gaseous emissions. The Coachella Valley is subject to frequent high winds that generate wind-blown sand and dust, leading to high episodic PM10 concentrations, especially from disturbed soil and natural desert blowsand areas. PM10 is the only pollutant which has sometimes reached higher concentrations in the SSAB than in the Basin. On some of the high days, transport of wind-generated dust and sand occurs with relatively light winds in the Coachella Valley, when deeply entrained dust from desert thunderstorm outflows travels to the Coachella Valley from the desert areas of southeastern California, Arizona, Nevada or northern Mexico. All days in recent years that exceeded the 24-hour federal PM10 standard at Indio or Palm Springs would not have exceeded except for the contribution of windblown dust and sand due to strong winds in the upwind source area (high-wind natural events).

In 2011, two high-wind exceptional events occurred in the Coachella Valley that caused high 24-hour PM10 concentrations (397 and 344 $\mu\text{g}/\text{m}^3$, at Palm Springs and Indio, respectively on July 3; 375 and 265 $\mu\text{g}/\text{m}^3$ at Indio and Palm Springs, respectively on August 28). Both of these days had high PM10 due to strong outflows from thunderstorms over Arizona and northern Mexico that deeply entrained dust and sand and transported it to the Coachella Valley. They have been flagged as high-wind exceptional events in accordance with the U.S. EPA Exceptional Events Rule, with further documentation and U.S. EPA concurrence pending. After flagging these high-wind natural events, the federal 24-hour and former annual PM10 standards were not exceeded in the Riverside County part of the SSAB in 2011. Therefore, the maximum 24-hour and annual average PM10 concentrations were 120 $\mu\text{g}/\text{m}^3$ and 32.6 $\mu\text{g}/\text{m}^3$, 77 percent and 65 percent of the current 24-hour federal PM10

standard ($150 \mu\text{g}/\text{m}^3$) and the revoked annual federal standard ($50 \mu\text{g}/\text{m}^3$), respectively.

When considering the form of the federal PM10 standards, after taking the exceptional events into account, the 3-year (2009-2011) design values for the Coachella Valley are 68 percent of the 24-hour PM10 NAAQS and 56 percent of the revoked annual PM10 NAAQS. For the year 2011 and without the two exceptional events included, the Coachella Valley maximum 24-hour average PM10 concentration ($120 \mu\text{g}/\text{m}^3$) was 77 percent of the federal 24-hour PM10 standard ($150 \mu\text{g}/\text{m}^3$) and 238 percent of the state 24-hour standard ($50 \mu\text{g}/\text{m}^3$). The annual average PM10 concentration ($32.6 \mu\text{g}/\text{m}^3$) was 65 percent of the revoked federal annual PM10 standard ($50 \mu\text{g}/\text{m}^3$) and 151 percent of the state annual PM10 standard ($20 \mu\text{g}/\text{m}^3$).

In 2011, the state 24-hour PM10 standard ($50 \mu\text{g}/\text{m}^3$) was exceeded on a maximum of 19 days (21 days if the high-wind events are included) in the Coachella Valley, which is 5.2 percent of the sampling days (FRM and FEM data combined). The state annual standard ($20 \mu\text{g}/\text{m}^3$) was also exceeded. The maximum annual average PM10 concentration was 151 percent of the state standard. Figure 7-4 shows the trend of the annual average PM10 concentrations in the Coachella Valley for the station showing the highest PM10 measurements from 1990 through 2011.

FIGURE 7-4

Coachella Valley Trend of Annual Average PM2.5 and PM10, 1990-2011

PM2.5

PM2.5 has been measured in Coachella Valley since 1999 when the District began PM2.5 monitoring. It has remained relatively low compared to the South Coast Air Basin due to fewer combustion sources and the increased vertical mixing and horizontal dispersion in the desert area. In 2011, federal PM2.5 standards (35 $\mu\text{g}/\text{m}^3$ 24-hour and 15.0 $\mu\text{g}/\text{m}^3$ annual) were not exceeded at either of the two Coachella Valley air monitoring sites. The Coachella Valley maximum 24-hour average and annual average concentrations recorded in 2011 (35.4 $\mu\text{g}/\text{m}^3$ and 7.2 $\mu\text{g}/\text{m}^3$) were, respectively, 99.7 percent and 48 percent of the federal 24-hour and annual standards. While not technically exceeding the 24-hour federal standard (with rounding, a value of at least 35.5 is needed to exceed the NAAQS), the relatively high 24-hour concentration of 35.4 $\mu\text{g}/\text{m}^3$ was unusual for the Coachella Valley and occurred at Indio on one of the exceptional event days that had extremely high PM10. The second highest 24-hour PM2.5 average for the Coachella Valley was 26.3 $\mu\text{g}/\text{m}^3$ (74 percent of the federal standard), at Palm Springs. When looking at the 3-year design value (2009-2011) that considers the form of the federal standard, the Coachella Valley PM2.5 design value is 42 percent of the PM2.5 24-hour standard and 48 percent of the annual standard.

The annual PM2.5 state standard (12.0 $\mu\text{g}/\text{m}^3$) was not exceeded in the Coachella Valley, with the maximum annual average of 7.2 $\mu\text{g}/\text{m}^3$ (at Palm Springs) at 60 percent of the standard. This gives insight that the Coachella Valley will also be in attainment of the proposed new annual PM2.5 federal standard that will be between 12.0 and 13.0 $\mu\text{g}/\text{m}^3$ (proposed June 14, 2012). Figure 7-4 (above) shows the trend of the annual average PM2.5 concentrations in the Coachella Valley for the station measuring the highest PM2.5 from 1990 through 2011.

Ozone (O₃)

Atmospheric ozone in the Riverside county portion of SSAB is both directly transported from the Basin and formed photochemically from precursors emitted upwind. These precursors are emitted in greatest quantity in the coastal and central Los Angeles County areas of the Basin. The Basin's prevailing sea breeze causes polluted air to be transported inland. As the air is being transported inland, ozone is formed, with peak concentrations occurring in the inland valleys of the Basin, extending from eastern San Fernando Valley through the San Gabriel Valley into the Riverside-San Bernardino area and the adjacent mountains. As the air is transported

still further inland into the desert areas, ozone concentrations typically decrease due to dilution, although ozone standards can be exceeded.

In 2011, the former 1-hour federal ozone standard level was not exceeded in the Coachella Valley. The maximum 1-hour concentration measured was 0.124 ppm, just below (99 percent) the former 1-hour federal standard (0.125 ppm is required to exceed). The 1997 8-hour federal ozone standard (0.08 ppm) was exceeded on 18 days. The most recent (2008) and more stringent 8-hour federal standard (0.075 ppm) was exceeded on 54 days. The maximum 8-hour ozone concentration was 0.098 ppm (129 percent of the 2008 standard and 115 percent of the 1997 standard). Ozone concentrations and the number of days exceeding the federal ozone standard are greatest in summer, with no exceedances during the winter months.

The 1-hour and 8-hour state ozone standards were exceeded on 25 days and 78 days, respectively, in the Coachella Valley in 2011. The 1-hour ozone health advisory level (0.15 ppm) has not been exceeded in the Coachella Valley area since 1999. No 1-hour Stage 1 episode levels (0.20 ppm) have been recorded in the Coachella Valley area since 1989.

Figure 7-5 shows the trend of the annual highest ozone concentrations (1-hour and 8-hour averages) measured in the Coachella Valley between 1990 and 2011. Figure 7-6 shows the annual number of days exceeding federal ozone standards at Coachella Valley monitoring sites for the years 1990-2011.

FIGURE 7-5

Trends of Coachella Valley Maximum 1-hour and 8-hour Ozone Concentrations, 1990-2011

FIGURE 7-6

Coachella Valley Federal and State Ozone Trends, 1990-2011
(Number of Days Exceeding Standards)

Other Criteria Pollutants

Carbon monoxide (CO) was measured at one Coachella Valley air monitoring station (Palm Springs) in 2011. Neither the federal nor state standards were exceeded. The maximum 8-hour average CO concentration recorded in 2011 (0.6 ppm) was less than 7 percent of both the federal and state standards. The maximum 1-hour CO concentration (3.0 ppm) was 8 percent of the federal and 15 percent of the state 1-hour CO standards. Historical carbon monoxide air quality and trends in the Riverside county SSAB area show that the area has not exceeded the federal CO standards in nearly three decades.

Nitrogen dioxide (NO₂) was measured at one station in the Coachella Valley in 2011. The maximum annual average NO₂ concentration (8.0 ppb) was approximately 15 percent of the federal annual standard and 27 percent of the state annual standard. The maximum 1-hour average concentration (44.7 ppb) was 44 percent of the new (2010) federal and 25 percent of the state 1-hour standard.

Sulfur dioxide (SO₂) concentrations were not measured in the Riverside County SSAB in 2011. Historical measurements have shown SO₂ concentrations to be well below the state and federal standards and there are no significant emissions sources in the Coachella Valley.

Sulfate (SO₄²⁻) from PM₁₀ was measured at one station in the Coachella Valley in 2011. The maximum 24-hour average sulfate concentration was 5.7 µg/m³ (23 percent of the 25 µg/m³ state sulfate standard). There is no federal sulfate standard.

Lead (Pb) concentrations were not measured at either of the two Coachella Valley air monitoring stations in 2011. Measurements in past years have shown concentrations to be less than the state and federal standards and no major sources of lead emissions are located in the Coachella Valley.

Pollutant Transport

The pollutant transport pathway from the South Coast Air Basin to the Salton Sea Air Basin is through the San Gorgonio Pass (sometimes referred to as the Banning Pass) to the Coachella Valley.⁴ The transport pathway to the Coachella Valley is well documented and this phenomenon has been studied considerably in the past. An experiment to study this transport pathway concluded that the South Coast Air

⁴ Keith, R.W. 1980. A Climatological Air Quality Profile: California's South Coast Air Basin. Staff Report, South Coast Air Quality Management District.

Basin was the source of the observed high oxidant levels in the Coachella Valley.⁵ Transport from Anaheim to Palm Springs was directly identified with an inert sulfur hexafluoride tracer release.⁶ A comprehensive study of transport from the South Coast Air Basin to the Salton Sea Air Basin confirmed the ozone transport pathways to the Coachella Valley.⁷

Ozone pollutant transport to the Coachella Valley can be demonstrated by examining averaged ozone concentration by time of day for various stations along the transport corridor from Los Angeles County to the Coachella Valley. Figure 7-7 shows the diurnal distribution of averaged 1-hour ozone concentrations for the May-October smog season, by hour for 2011. The Coachella Valley transport route is represented, starting at Central Los Angeles in the main emissions source region and passing through Riverside-Rubidoux and Banning and finally through San Geronio Pass to Palm Springs in the Coachella Valley. Near the source regions, ozone peaks occur just after at mid-day (1:00 to 2:00 p.m. Pacific Standard Time, PST), on average, during the peak of incoming solar radiation and therefore the peak of ozone production. Downwind of the source region, ozone peaks occur later in the day as ozone and ozone precursors are transported downwind and photochemical reactions continue. At Palm Springs, ozone concentration peaks occur between 5:00 and 6:00 p.m. PST. If this peak were locally generated, it would be occurring closer to near mid-day, as it is seen in the major source areas of the South Coast Air Basin, and not in the late afternoon or early evening, as is seen at Palm Springs.

along the Coachella Valley Transport Route

(Hours in Pacific Standard Time, Averaged for the May-October Ozone Season by Hour)

Palm Springs also exhibits an early ozone concentration increase that is not seen in the South Coast Air Basin near the main emissions source areas (i.e., Los Angeles and Rubidoux). The stations in the South Coast have more local NO_x emissions (mostly from mobile sources) to help scavenge the ozone after dark when the ozone production photochemistry ceases. The Coachella Valley has limited local NO_x emissions to help scavenge the ozone at night. This elevated overnight ozone contributes to an early morning bump in the Coachella Valley ozone concentrations, starting around 8 a.m., with the ample sunlight and strong overnight temperature inversions in the desert. Ozone concentrations in this area reach an initial peak before noon and then drop slightly with increased mixing in the early afternoon, before climbing to the daily peak as the normal onshore flow reaches the Coachella Valley through the San Gorgonio Pass, transporting new ozone from the South Coast Air Basin.

Emissions Inventories

For illustrative purposes only, Table 7-3A shows base year (2008) and future-year emission inventories for the Coachella Valley, based on the AQMP inventory methodology as described in Appendix III. Emissions, in tons per day, of volatile organic compounds (VOC), oxides of nitrogen (NO_x), carbon monoxide (CO), sulfur oxides (SO_x), PM₁₀, PM_{2.5} and ammonia (NH₃) are shown. Table 7-3B adds the Coachella Valley emissions for the Competitive Power Ventures, LLC (CPV) Sentinel power plant, as it is projected to be operational in Desert Hot Springs in 2014 and after. The corresponding inventories for the South Coast Air Basin are shown for comparison in Table 7-3C. The South Coast Air Basin emissions, typically upwind of the Coachella Valley, overwhelm the locally-generated emissions. Depending on the pollutant, emissions in the South Coast Air Basin are 10 to over 350 times greater than emissions in the Coachella Valley. It is clear that improved air quality in the Coachella Valley depends on reduced emissions in the South Coast Air Basin. This is further illustrated by the trends in ozone air quality described earlier.

FUTURE AIR QUALITY

In the 2007 AQMP and the subsequent SIP submittal, the District requested that U.S. EPA redesignate the Riverside County portion of the Salton Sea Air Basin from “Serious” nonattainment to “Severe-15” and extend the attainment date of the 1997 8-hour ozone standard (80 ppb) to 2019. This Severe-15 nonattainment redesignation was approved by U.S. EPA and subsequently applied to the nonattainment designation for the new 2008 8-hour ozone standard (75 ppb), for a new attainment date of December 31, 2027. This chapter is intended to update the progress toward attainment of the current ambient air quality standards; it is not an update to the Ozone SIP attainment demonstration. A new Ozone SIP attainment demonstration for the 2008 ozone standard will be required to be submitted to U.S. EPA in 2015.

The CAA requires that ozone nonattainment areas designated as serious and above use a regional photochemical model to demonstrate attainment. To meet this requirement, the Community Multi-scale Air Quality (CMAQ) modeling system is used in this analysis for the Coachella Valley. To provide further confidence with the CMAQ model and to establish consistency with the 2007 AQMP, comparisons were also made with the Comprehensive Air Quality Model with Extensions (CAMx), with comparable results. The complete AQMD modeling system and its application is described in detail in Chapter 5 and Appendix V, along with base and future year results, sensitivity analyses and performance evaluations. To develop relative response factors (RRFs) to project future air quality, CMAQ was run using a full 3-month period (June, July and August of 2008; 91 days) during the peak of the ozone season. During this period, seven well-defined, multi-day high ozone episodes occurred that ranked high in terms of meteorological potential for ozone production. Of the modeled days in 2008, the 1997 8-hour federal ozone standard was exceeded on 75 days in the South Coast Air Basin and 19 days in the Coachella Valley.

The 8-hour average ozone design values (based on a 5-year weighted average as recommended in U.S. EPA modeling guidance) for the Coachella Valley air quality stations, Palm Springs and Indio, in base year 2008 were 96 ppb and 86 ppb, respectively. The baseline emissions inventory assumes no further control beyond existing rules and regulations. Between 2008 and 2019, controls are being implemented in the South Coast Air Basin to reduce emissions.

The results of the CMAQ model simulations and corresponding RRFs using the baseline emissions for 2019 project a maximum 8-hour concentration in the Coachella Valley of 84 ppb, meeting the 1997 federal ozone standard. The CMAQ simulations of the future year ozone using the baseline regional emissions indicate that the 2008

federal 8-hour ozone standard (75 ppb) will not be attained in the Coachella Valley by the 2027 attainment date. However, using the Draft Final 2012 AQMP controlled emissions inventory, the Coachella Valley attains the 2008 federal ozone standard by 2024, in advance of the required attainment date. Further details of the future-year air quality projections in South Coast Air Basin and the Coachella Valley are presented in Appendix V.

CONCLUSIONS

With the Severe-15 ozone nonattainment designation, the Coachella Valley attainment date for the 1997 8-hour federal ozone attainment date is in 2019. Modeling simulations of the ozone episodes indicate that the 1997 federal 8-hour standard will be attained in the Coachella Valley in 2019 with no additional emissions controls. The attainment date for the more stringent 2008 8-hour federal ozone standard is 2027. With future emissions controls in place in the South Coast Air Basin, the 2008 federal 8-hour federal ozone standard will be attained in the Coachella Valley by 2024, three years in advance of the attainment date for that standard. Future emissions reductions implemented in the South Coast Air Basin will ensure timely attainment of existing standards, and also help to achieve potentially more stringent PM_{2.5} and ozone standards in the future.

CHAPTER 8

LOOKING BEYOND CURRENT REQUIREMENTS

Introduction

Potential Changes in the Federal Ozone Standard

Implications of a New Ozone Standard for the Basin

1-Hour Ozone Requirements

Proposed Changes to the Federal Particulate Matter Standards

Implications of the Proposed New PM_{2.5} Standards for the Basin

INTRODUCTION

This Chapter presents additional analyses which are not legally required, but are presented here for informational purposes to initiate stakeholder discussion on future air quality planning and to place the 2012 AQMP in context of long-range transformation needed for this region to meet the health-based air quality standards and provide cobenefits to GHG and air toxic reductions, energy security, and mobility.

POTENTIAL CHANGES IN THE FEDERAL OZONE STANDARD

The Clean Air Act (CAA) requires U.S. EPA to periodically review the existing air quality standards in light of the findings of new and emerging epidemiological and health studies. The CAA sets up a 5-year review cycle for the national ambient air quality standards. The current cycle for ozone began in 2008, and U.S. EPA will revisit the most recent standards in 2013. The Clean Air Scientific Advisory Committee (CASAC) has already begun a new and forthcoming scientific review in preparation of the 2013 review of the ozone standards and U.S. EPA expects to propose potential revisions to the ozone standard in the fall of 2013 and finalize any revisions to the standard in 2014. Based on the previous recommendations by CASAC and the previous reviews and proposals by U.S. EPA, it is anticipated that the 8-hour ozone standard may be lowered to a level between 0.060 ppm and 0.070 ppm (60 – 70 ppb). If finalized in 2014, designations would follow in 2015, and the new attainment date (for extreme non-attainment areas such as the Basin) would be in the 2035 time frame.

IMPLICATIONS OF A NEW OZONE STANDARD FOR THE BASIN

Based on the modeling results presented in Chapter 5 and Appendix V, the Basin can demonstrate attainment with the existing federal 8-hour ozone standards by the corresponding attainment deadlines (2023 and 2032) only by using a provision of the federal CAA Section 182(e)(5) that allows credit for emissions reductions from future improvements in control techniques and technologies. The projected ozone isopleths for the average 8-hour ozone design values at Crestline monitoring station are shown in Figure 8-1 for illustration purpose. The upper right corner represents the projected VOC and NO_x emissions inventory in 2023 with full implementation of all adopted control measures (baseline). Moving down and left on the figure corresponds to relative emissions reductions of NO_x (down) and VOC (left). The curved lines within the figure signify the projected 8-hour ozone design value resulting from those emissions reductions.

Figure 8-1 demonstrates that in order to meet the 80 ppb ozone level in 2023, an approximate 65% reduction (35% remaining) in NO_x emissions will be necessary beyond already adopted measures. VOC reductions are not as effective as NO_x reductions, but concurrent 60% VOC reductions would reduce the needed NO_x reductions to about 60%. Figure 8-1 also indicates that a 75% reduction in NO_x emissions is needed to meet the 75 ppb level in 2032. A full discussion of the emissions reductions needed to meet current ozone standards is included in Chapter 5 and Appendix V.

FIGURE 8-1
 2023 Preliminary 8-hour Average Ozone Basin Design Value Isopleths
 at Crestline Monitoring Station

As stated above, it is anticipated that the 8-hour ozone standard may be lowered to a level between 60 and 70 ppb. Therefore, in order to demonstrate attainment in the 2035

time frame, an additional 80% to 88% NO_x emissions reduction below 2023 baseline would be needed. Assuming the 75 ppb standard is met in 2032 with a 75% NO_x reduction below 2023 baseline helps to illustrate the significant difference between a new 60 ppb 8-hour ozone standard and a 70 ppb standard. A 70 ppb standard represents an approximate 20% NO_x reduction between 2032 and 2035, while a 60 ppb standard requires a 50% NO_x reduction in that three year time span. A standard at 60 ppb is also within 12 ppb of the Basin background level of ozone, which has been estimated to be about 48 ppb by modeling the Basin with all man-made sources removed. Figure 8-1 also demonstrates that the effectiveness of NO_x emission reductions continues to be most effective at these lower ozone levels. It would be the greatest air quality challenge the region has ever faced relative to achieving additional NO_x emission reductions necessary to demonstrate attainment with these potential new standards and would further necessitate transformational technologies with zero or near-zero combustion emissions.

1-HOUR OZONE REQUIREMENTS

The federal 1-hour ozone standard was revoked when the 8-hour standard was established. U.S. EPA guidance indicated that while certain planning requirements remained in effect, a new SIP would not be required if an area failed to attain the standard by the attainment date. However, a recent court decision has led U.S. EPA to propose an action requiring a new 1-hour ozone attainment demonstration for the South Coast Basin. The attainment demonstration would be due within 12 months of publication of the final action. The attainment demonstration would have to show attainment within 5 years with a potential 5-year extension, which would be a similar timeframe as is required for the 1997 8-hr ozone standard (deadline of 2023). However, many new technical issues such as modeling for the attainment demonstration and other CAA requirements would require U.S. EPA's guidance, since the previous preambles and guidelines are no longer directly applicable. Based on previous modeling estimates, the control strategies that are needed to attain the 8-hour ozone standard are nearly identical to those that would be needed to attain the 1-hour ozone standard.

PROPOSED CHANGES TO THE FEDERAL PARTICULATE MATTER STANDARDS

The U.S. EPA revoked the annual PM₁₀ standard of 50 µg/m³ and lowered the 24-hour PM_{2.5} standard from 65 µg/m³ to 35 µg/m³, effective December 17, 2006. At the time,

no changes were made to the existing 24-hour PM₁₀ standard of 150 µg/m³ and the annual PM_{2.5} standard of 15 µg/m³. As part of the requirements of the CAA, every five years, the U.S. EPA must review the ambient air quality standards and propose revisions, if necessary, to “protect public health with an adequate margin of safety,” based on the latest, best-available, science. Under a court order, the U.S. EPA was directed to propose updated standards no later than June 14, 2012. In response to that court order, the U.S. EPA proposed updated national ambient air quality standards for PM_{2.5} on June 14, 2012. U.S. EPA and the litigants have agreed to a proposed consent decree that would require U.S. EPA to issue final standards by December 14, 2012. These proposed revisions to the PM standards also respond to a court remand of two of the existing PM_{2.5} standards, which standards were issued in 2006.

The CAA requires U.S. EPA to set two types of outdoor air quality standards: primary standards, meant to protect public health, and secondary ambient air quality standards, meant to protect the public against adverse environmental effects. When setting air quality standards, the air quality statistics used to determine if an area meets the standard must also be specified. This is known as the “form” of the standard.

The new PM NAAQS rule proposed on June 14, 2012 includes the following:

- **Annual PM_{2.5} standard:** The proposed rule will strengthen the annual PM_{2.5} standard by lowering the level from 15 µg/m³ to a level within the range of 12 µg/m³ to 13 µg/m³. U.S. EPA is also seeking comment and input on alternative levels for the annual PM_{2.5} standard, down to 11 µg/m³. The form of the standard would be unchanged and would be based on the three-year average of an area’s annual average PM_{2.5} concentrations. The current annual PM_{2.5} standard has been in place since 1997.
- **24-hour PM_{2.5} standard:** U.S. EPA is proposing to retain the existing standard of 35 µg/m³ and the current form of the standard, which continues to be based on the 98th percentile of 24-hour PM_{2.5} concentrations measured in a year (averaged over three years) at the monitoring site with the highest measured values in an area. The current 24-hour PM_{2.5} standard has been in place since 2006.
- **24-hour PM₁₀ standard:** U.S. EPA is proposing to retain the existing standard of 150 µg/m³ and the current form of the standard, which continues to be based on the maximum concentrations measured in a year (averaged over three years) at

the monitoring site with the highest measured values in an area. The current 24-hour PM10 standard has been in place since 1987.

Particle pollution causes haze and visibility degradation in cities and some of the country's national parks. Additionally, nitrate and sulfate particles can contribute to acid rain formation, which affects the acidity in water bodies, streams, and rivers, impacting the flora and fauna which rely on those waters for survival. Currently, the secondary PM10 and PM2.5 standards are the same as the primary PM10 and PM2.5 standards, respectively. For secondary standards, the proposed rule includes the following:

- **24-hour PM2.5 secondary standard:** U.S. EPA is proposing to add a 24-hour secondary standard for PM2.5 to protect visibility in urban areas. This standard would be measured in “deciviews”, similar to what is used in the U.S. EPA’s Regional Haze Program. Two alternative levels are being proposed – 30 deciviews and 28 deciviews. The U.S. EPA would calculate a “visibility index” value, using data from fine particle samples that have been analyzed to determine their chemical composition, along with information on the relative humidity of the area. The form of the standard would be the three year average of the 90th percentile of 24-hour visibility index values in one year. U.S. EPA is also seeking additional comment and input on an alternative level, down to 25 deciviews, along with comments on alternate averaging times.
- **Retention of all other secondary standards:** U.S. EPA is proposing to retain all other secondary standards such that they are identical to the primary standards, as discussed previously.

In addition to these revisions, the U.S. EPA is also proposing to revise the public air quality reporting convention, the Air Quality Index (AQI), for PM2.5 by setting the 100 value of the index at the level of the current 24-hour PM2.5 standard, which is 35 µg/m³.

Fine particles come from a variety of sources, including vehicles, and are also formed when emissions from vehicles and other sources undergo atmospheric reactions. The U.S. EPA has proposed changes to the PM2.5 monitoring requirements by including for the first time a requirement for PM2.5 monitoring along heavily traveled roadways in large urban areas. The required monitors, to be located at near-road monitoring sites measuring nitrogen dioxide and carbon monoxide, would have to be operational no later than January 1, 2015.

U.S. EPA anticipates making attainment/nonattainment designations of the new annual PM_{2.5} standard by December 2014, with those designations likely becoming effective in early 2015. States would have until 2020 to meet the new PM_{2.5} NAAQS, with up to a 5-year extension to 2025.

IMPLICATIONS OF THE PROPOSED NEW PM_{2.5} STANDARDS FOR THE BASIN

As presented above, U.S. EPA's proposed rule would strengthen the annual PM_{2.5} standard by lowering the level from 15 µg/m³ to a level within the range of 12 µg/m³ to 13 µg/m³. Based on the baseline modeling performed in Chapter 5, it is projected that the annual PM_{2.5} design value in 2023 will be 13.0 µg/m³ and will occur at the Mira Loma air monitoring station. Thus, the Basin should be able to demonstrate attainment with a 13 µg/m³ NAAQS with already adopted control measures by 2023. With the proposed measures in the Draft Final 2012 AQMP, it may be possible to advance attainment to an earlier date. While the proposed episodic measures are designed to address the 24-hour PM_{2.5} standard, they will also help to achieve annual standards. Alternatively, if the standard is set lower at 12 µg/m³, additional controls may be necessary to demonstrate attainment with the standard by 2025. Whether additional emissions reductions are needed to demonstrate attainment with the potential new primary annual PM_{2.5} NAAQS will depend largely on the level of the standard and other factors, such as economic growth or unfavorable weather. It should also be noted NO_x controls needed for attainment of the 8-hr ozone standard of 80 ppb by 2023 will assist in the attainment of the annual PM_{2.5} standard by 2025 or sooner.

The status of the Basin with regard to the proposed secondary visibility standard cannot be fully assessed until additional implementation guidance is provided by U.S. EPA.

Introduction

Ultrafine Particles

Other Near-Roadway Pollutants

Ambient Measurements

Health Effects

Future Research and Assessment Needs

Planning and Regulatory Issues

District Future Actions

INTRODUCTION

There is growing concern about the potential health effects as caused by exposure for people living near major roadways to criteria pollutants and air toxics emitted from both gasoline and diesel vehicles (HEI, 2010). Recent toxicological and epidemiological studies have identified living near major roadways as a risk factor for respiratory and cardiovascular problems and other health related issues including: asthma and allergic diseases, reduced lung function and growth, low birth weight and pre-term newborns, lung cancer and premature death (Brugge et al., 2007; Kan et al., 2008; Balmes et al., 2009; Jerrett et al., 2009; Andersen et al., 2010; Hoek et al., 2010).

Motor-vehicle emissions consist of a complex mixture of particulate and gaseous pollutants such as fine particulate matter (PM_{2.5}; particles with a diameter less than 2.5 µm), ultrafine particles (UFPs; diameter < 0.1 µm), metals, organic material, black carbon (BC), volatile organic compounds (VOC), nitrogen oxides (NO_x; mostly NO and NO₂) and carbon monoxide (CO). While PM_{2.5} and NO₂ are currently regulated as criteria pollutants, UFPs have been shown to be toxic and have health impacts, but are not specifically regulated.

In 1998, the California Air Resources Board (CARB) classified diesel exhaust PM as a toxic air contaminant, citing its potential to cause cancer and other health problems. The U.S. EPA concluded that long-term exposure to diesel engine exhaust is likely to pose a lung cancer hazard to humans and can also contribute to other acute and chronic health effects.¹ The International Agency for Research on Cancer (IARC), part of the World Health Organization, recently classified diesel exhaust as a human carcinogen (Benbrahim-Tallaa et al., 2012). A recent study conducted by the District suggested that exposure to diesel PM is the major contributor to the remaining air toxics cancer risk in the South Coast Air Basin (Basin), accounting on average for about 84% of the carcinogenic risk attributable to air pollutants (MATES III; AQMD, 2008).²

While substantial effort has been made to characterize the health risks associated with exposure to diesel PM, information about the health impacts of UFPs is just now emerging. These very minute particles (consisting primarily of organic material, soot,

¹ <http://www.epa.gov/ttn/atw/dieselfinal.pdf>

² <http://www.aqmd.gov/prdas/matesIII/matesIII.html>

and trace elements) have a different chemical composition than the larger PM fractions (PM_{2.5} and PM₁₀). Due to their small size, UFPs can penetrate deeply into the human respiratory tract, into the blood stream, and be transported to other critical organs such as the heart and brain. Furthermore, their large surface area may provide a mechanism for delivering potentially toxic adsorbed material into the lung and other organs. This penetration capability is suspected to have human health implications because UFPs' toxic components may initiate or facilitate biological processes that may lead to adverse effects to the heart, lung, and other organs (HEI, 2010).

UFPs are emitted from almost every fuel combustion process, including diesel, gasoline, and jet engines, as well as external combustion processes such as wood burning. Consequently, there is growing concern that people living in close proximity to highly trafficked roadways and other sources of combustion-related pollutants (e.g. airports and rail yards) may be exposed to significant levels of UFPs and other air toxics.

Over the last decade, substantial efforts have been made to better characterize the physical and chemical properties of UFPs and their potential impact on people living in close proximity to roadways and other emissions sources. Two areas of research have received particular attention:

- On-roadways, near-roadways, and in-vehicle measurements: UFP emissions from motor vehicles are not static after leaving the tailpipe and undergo physical transformation and chemical reactions in the atmosphere as they are transported away from the source. In order to study the dynamic nature of UFP formation, evolution and transport, as well as their physical and chemical properties, and human exposure, UFP measurements have been taken at the tailpipe, at different distances from the edge of roadways, and inside vehicles.
- Effect of UFP reduction technologies: As modern engines and emissions controls continue to evolve, the mass of combustion-related PM has been dramatically reduced through sophisticated control of combustion conditions, introduction of ultra low sulfur diesel fuel, and the application of after-treatment control technologies such as diesel particulate filters (DPFs). In some cases, emission controls designed for PM mass have facilitated the formation of a greater number of UFPs. However, properly designed emission control technologies can limit the formation and emission of UFP as well as PM mass.

From a regulatory perspective, the U.S. focus has been on reducing the mass of PM emitted in the ambient air. However, UFPs contribute a very small portion of the overall atmospheric particle mass concentration. Thus, there has been growing interest over the last two decades to study, understand, and regulate the size and number of particles found in PM generated from diesel and other combustion engines. Partly because light-duty diesel vehicles are very common in European countries, the European Union has already adopted standards that phase in particle number limits for passenger car and light-duty vehicle emissions. However, there are still concerns related to the health impacts of non-solid organic UFP components that are not addressed by the European solid particle number standard.

Recently, CARB staff prepared a preliminary discussion paper on proposed amendments to California's Low-Emission Vehicle (LEV III) Regulations, to address UFP emissions from light-duty motor vehicles by promoting a solid particle number based PM compliance strategy (CARB, 2010)³. CARB staff ultimately decided that the complexity of the issues warranted further study and understanding before proceeding. Although the District has limited authority to regulate mobile source pollution in the near-roadway environment, District staff has implemented a variety of measures to assess and reduce the health impacts of near-roadway emissions on local communities. The District continues to demonstrate and incentivize the deployment of zero/near-zero emission technology, has implemented numerous installations of high-efficiency air filtration in schools, and conducts outreach and education on near-roadway health impacts. Furthermore, on July 1, 2012 the District began the next Multiple Air Toxics Exposure Study (MATES IV) to characterize the carcinogenic risk from exposure to air toxics in the Basin. A new focus of MATES IV will be the inclusion of measurements of UFP and BC concentrations across the Basin, and near specific combustion sources (e.g. airports, freeways, rail yards, busy intersections, and warehouse operations) to evaluate the long- and short-term exposures to these pollutants.

This chapter of the AQMP first presents background information on UFPs and other important air pollutants emitted from motor vehicles. Next, recent results from ambient measurement studies conducted near traffic sources, on roadways, and inside vehicles are reviewed, followed by an explanation of the current state of knowledge on the health effects caused by UFPs and near-roadway exposure to pollutants.

³ http://www.arb.ca.gov/msprog/levprog/leviii/meetings/051810/pm_disc_paper-v6.pdf

Finally, potential control, mitigation, and policy strategies for limiting such exposures are discussed with recommendations for future actions to address this emerging and important topic.

ULTRAFINE PARTICLES

Formation and Transport

UFPs are emitted from both natural and anthropogenic sources, although in most urban environments vehicular fossil fuel combustion constitutes the major contributing source. The terms UFPs and nanoparticles (NP; diameter $< 0.05 \mu\text{m}$) are often used interchangeably, and the definitions of each generally vary with the study or application. While PM_{2.5} dominates the mass distribution of atmospheric particles, UFPs account for about 90% of the total particle number (Stanier et al., 2004a and Zhang et al., 2004). For this reason, their concentration is usually expressed in terms of total particle count (i.e. # per cubic centimeter of sampled air, or $\#/ \text{cm}^3$), even though a small fraction of the particles being counted may be above 100 nm.

In the late 1990s, pioneering research by the University of Minnesota (Kittelson, 1998) made significant new progress by identifying three size categories for particles found in diesel engine emissions: 1) coarse mode ($1 \mu\text{m} < d < 10 \mu\text{m}$), 2) accumulation mode ($\sim 0.05 \mu\text{m} < d < 1 \mu\text{m}$), and 3) nuclei mode ($d < 0.05 \mu\text{m}$). As shown in Figure 9-1, UFPs ($d < 0.1 \mu\text{m}$) and NPs in particular dominate the total number concentration (blue line).

Today we know that, typically, three UFP size modes appear in the exhaust of motor vehicles:

- Narrow nucleation mode at around 10 nm that corresponds to nucleated particles that have grown by condensation of gaseous precursors. It is mostly comprised of sulfate particles and semi-volatile organic compounds (SVOCs).
- Larger nucleation mode at around 20 to 30 nm which also contains sulfate particles and SVOCs.
- Accumulation mode at around 60 nm that results from the combustion process and that mostly includes soot and non-volatile organic compounds, but also sulfate and SVOCs. This mode is primarily associated with diesel exhaust.

FIGURE 9-1

Typical Particle Size Distribution for Uncontrolled Diesel Emissions (Kittelson, 1998)

Particles from motor vehicle emissions can be divided into two broad categories, depending on the location of their formation:

- **Primary combustion particles:** formed in the engine or tailpipe, they are mostly sub-micrometer agglomerates of solid phase carbonaceous material ranging in size from 30 to 500 nm. These particles may also contain metallic ash (from lubricating oil additives and from engine wear), adsorbed or condensed hydrocarbons, and sulfur compounds (Morawska et al., 2008).
- **Near-tailpipe UFPs:** as the hot exhaust gases are expelled from the tailpipe, they quickly cool and condense on existing particles or nucleate to form large numbers of very small particles in the air. They consist mainly of hydrocarbons and hydrated sulfuric acid, are generally 30 nm or less in diameter and are most commonly observed near busy freeways, especially those where a large fraction of heavy-duty diesel vehicles is present (Westerdahl et al., 2005; Ntziachristos et al., 2007; eskinen and Ronkko, 2010). These particles are formed very quickly and are distinct from UFPs derived from photochemical nucleation processes occurring in the atmosphere further away from the source (Stanier et al., 2004b).

Once released into the atmosphere, UFPs undergo dilution with ambient air and are subject to chemical reactions and physical processes such as evaporation, condensation, and coagulation. Thus, particles measured away from roadways and other emission sources generally have different characteristics than those measured immediately after formation. Wind speed and direction, precipitation, relative humidity, and temperature are the main meteorological factors affecting UFP transport.

Ambient Diurnal and Seasonal Variations

In ambient urban environments, strong diurnal variations in UFP concentration have been reported in many studies and shown to closely follow the temporal variation in traffic density, with the highest levels observed on weekdays during rush hours (Hussein et al., 2004; Morawska et al., 2008; AQMD, 2012)⁴. Typically, weekdays are characterized by two peaks in UFPs, one early in the morning and another in the afternoon coinciding with traffic rush hours. A wider mid-day peak is usually observed on weekends. Photochemical particle formation also contributes to increasing the afternoon number concentration of UFPs, especially in the summer.

Several meteorological factors contribute to the seasonal variability in the concentration of atmospheric PM and UFPs; these include:

- Lower mixing layer height and greater atmospheric stability in winter, which tend to increase particle levels by not allowing for vertical mixing in the atmosphere.
- Lower winter temperature, which leads to increased nucleation of volatile combustion products, particularly during morning rush hours.
- Higher photochemical activity in the summer, which favors photochemical particle formation.

It should be noted that the effects of these meteorological factors on particle concentration are more pronounced in areas where there are significant meteorological differences between seasons. Pirjola et al. (2006) and Virtanen et al. (2006) showed that the average UFP concentrations in winter in Finland were 2–3 times higher than in the summer, with the highest values observed in February. The highest and lowest monthly average UFP concentrations in Pittsburgh (U.S.A.) reported by Zhang et al. (2004) were measured in December and July, respectively.

⁴ http://www.aqmd.gov/tao/AQ-Reports/I710Fwy_Study.pdf

In the wintertime most of the factors leading to an increase in particle concentration tend to occur early in the morning (i.e. rush hour traffic, low mixing height, low wind speed and temperature). Summer minima are usually associated with increased ambient temperature (which does not favor the nucleation process), although increased photochemical activity can lead to new UFP formation.

Concentration Levels in Different Environments

Morawska et al. (2008) compared particle concentration levels reported for different environments including: road tunnel, on-road, road-side, street canyon, urban, urban background, rural, and clean background (Figure 9-2). The mean and median values for each category were calculated using available literature data and are shown below to illustrate the typical atmospheric variability in UFP number concentration measurements.

FIGURE 9-2

Mean and Median Particle Number Concentrations for Different Environments

In brackets are the numbers of sites for each environment used to calculate the mean and median UFP values. Vertical lines represent standard deviations (from Morawska et al., 2008)

Substantially higher peak particle number levels are expected in each environment over shorter time periods (e.g. seconds to minutes), and in close proximity to specific sources such as roadways and airports. For example, in a recent study conducted by the District near the Santa Monica Airport (SMO; a general aviation airport), 1-min average UFP levels as high as 2,600,000 #/cm³ were measured 35 m downwind of the runway during jet aircraft take-off (AQMD, 2011)⁵. One-minute maxima between 1,500,000 and 2,000,000 #/cm³ (also associated with jet aircraft departures) were observed 100 m downwind of the runway in the backyard of a local residence.

Chemical Composition

Comprehensive knowledge of the chemical composition of UFPs in ambient air is still not available, mostly because of the small amount of mass available for analysis, and because most studies have been conducted using different measurement protocols, sampled particles in different size ranges, and focused on different aspects of their chemical composition (Morawska et al., 2008). However, it is known that engine emissions include sulfur dioxide (SO₂) or sulfur trioxide (SO₃) and NO_x, and that nucleation of these gaseous species into sulfate and nitrate particles is an important mechanism for increasing particle formation near traffic sites.

A few studies have investigated the composition of UFPs in urban environments. Kuhn et al. (2005) showed that UFP samples collected in downtown Pittsburgh were mostly comprised of organic matter (45 to 55% by weight) and salts of ammonium and sulfate (35 to 40%). In a study conducted at two Los Angeles sites (urban and inland), Sardar et al. (2005) found that organic carbon (OC; the amount of carbon present in the collected organic material) ranged from 32 to 69% (by weight), elemental carbon (EC; an indicator of diesel PM and closely related to BC) from 1 to 34%, sulfate from 0 to 24% and nitrate from 0 to 4%. In these and other cases, organic material was found to comprise the larger fraction of UFP by mass especially in the summer, when photochemical formation of organic aerosol is higher. UFP chemistry, including elemental composition, was investigated by Pakkanen et al. (2001) at two sites (urban and rural) in Helsinki (Finland). The most important trace elements at both sites were Ca, Na, Fe, K and Zn (present in higher concentrations), and Ni, V, Cu, and Pb (“heavy metals”). These measured species accounted for less than 1% of the total UFP mass and their presence was probably related to local combustion sources, possibly traffic exhaust, and combustion of heavy fuel oil. Overall, the

⁵ http://www.aqmd.gov/tao/AQ-Reports/Supplement_GA_Report.pdf

chemical composition of UFPs differs significantly from place to place and depends on the types of local sources and their relative contributions.

Measurement Methods

A basic knowledge of the instruments used for monitoring UFPs is critical as the resulting measurements are dependent on the method and measurement principle used. Since there is no “standard” measurement technique or calibration standard by which different instruments can be evaluated and compared, UFP measurements are somewhat operationally defined. Below is a list of the most common instruments that have been used to monitor the mass and number concentration and size distribution of UFPs in the atmosphere and in exhaust streams. For a more comprehensive discussion on the issues associated with measuring UFPs see Maricq and Maldonado (2010) and Robinson et al. (2010).

- Condensation Particle Counter (CPC): it provides the total number concentration of particles above a lower size limit (~3 -20 nm, depending on make and model) in real-time. UFPs are grown through condensation in a controlled super-saturation environment to larger sizes and then measured (counted) using a photodetector. Alcohol or water are usually used as condensing liquids. Although CPCs are the most widely used instruments in most applications, they do not provide any information on the original size of the particles counted.
- Scanning Mobility Particle Sizer (SMPS): particle counters can also be used in conjunction with electrostatic classifiers (used to separate airborne particles according to their size) to characterize the particle size distribution of UFPs. Typically, SMPSs provide size distribution data in almost real-time for particles as small as 10 nm.
- Electrical Low-Pressure Impactors (ELPI): this instrument provides real-time number weighted size distributions in the particle diameter range of 30 to 10,000 nm. ELPIs are very sensitive instruments and measure ambient aerosol concentrations and size distributions. They can be used to measure particle charge distribution in real-time, and also allow for particle collection and direct mass measurements.
- Engine Exhaust Particle Sizer (EEPS): it measures particle size distributions in real time and covers a range from ~3 to 500 nm. It was designed specifically to measure particles emitted from internal combustion engines and motor vehicles,

but newer versions are designed for ambient applications. Its fast response (e.g. ~10 Hz data collection) allows for the measurement of transient signals, but also tracks well with the CPC concentrations and SMPS size distributions.

- Micro Orifice Uniform Deposition Impactor (MOUDI): it provides integrated mass-based size distribution measurements covering particle sizes from ~56 to 10000 nm. Nano MOUDIs are used for smaller particle size ranges (i.e. ~ 10 to 56 nm). Particle samples collected using a MOUDI can also be analyzed for chemical composition in the lab.

Most of the instruments outlined above have been used in engine/vehicle emission testing. Ambient air monitoring of UFPs is also performed using some of the same instrumentation, especially CPCs and SMPSs. It should be noted that different make/model CPCs are characterized by different particle size ranges, sampling flow rates, optical detection techniques, and other instrumental characteristics and, thus, they may provide significantly different results. Therefore, UFP number measurements from different studies should be compared with caution. The District has worked in collaboration with the University of California, Los Angeles (UCLA), CARB, and with various CPC manufacturers to study intra- and inter-model variations in total number concentration measurements taken with several CPC units (Lee et al., submitted).

OTHER NEAR-ROADWAY POLLUTANTS

The majority of air monitoring studies conducted near- and on-roadways in the past decade has focused not only on the measurements of UFPs, but also on the emissions of more traditional and well-studied pollutants. These include:

- Carbon monoxide (CO): ambient concentrations of this pollutant have declined through the adoption of emission control technologies and regulations. However, motor vehicles (especially light-duty, gasoline-powered vehicles) remain the primary source of CO at most locations.
- Oxides of nitrogen (NO_x): although all motor vehicles emit NO_x, the majority of current on-road NO_x emissions occur from diesel vehicles. In terms of primary emissions, the majority of NO_x exhaust is in the form of NO. NO₂ is the focus of concern in terms of health effects and quickly forms by a photochemical reaction from the oxidation of NO. Primary NO_x emissions from heavy-duty diesel engines

with after-treatment devices may contain a greater percentage of NO₂ relative to NO.

- Particulate matter (PM): suspended particles are generally divided in UFP (already discussed), PM_{2.5} and PM₁₀. Significant near-roadway sources of PM mass include direct emissions from motor vehicle combustion (mostly PM_{2.5}), brake and tire wear, and re-suspension of dust from the road surface (mostly PM₁₀ and larger). The atmospheric concentration of PM_{2.5} is mostly affected by contributions from regional sources, and the impact of direct emissions from motor vehicles is generally small in near-roadway environments.
- Volatile organic compounds (VOCs) and carbonyls: these gaseous air toxics are emitted from both natural and anthropogenic sources (including motor vehicles), are involved in the photochemical formation of atmospheric O₃, and some of them have been associated with both short- and long-term toxic health effects. Typical VOCs of concern for near-road monitoring include benzene, toluene, ethylbenzene, xylenes, styrene, formaldehyde, acetaldehyde, and acrolein, all of which are also toxic air contaminants.
- Black (or elemental) carbon (BC or EC): often referred to as “soot,” BC (or EC) is a common constituent emitted from motor vehicles. Both BC and EC are operationally defined and represent the black, graphitic-containing portion of PM. Although BC and EC are often associated with emissions from heavy-duty diesel engines, a portion of all motor vehicle combustion emissions contains these constituents. A recent study conducted by Liggio et al. (2012) has shown that BC emissions from light-duty-gasoline-vehicles may be at least a factor of 2 to 9 times higher than previously thought. Other sources of BC exist in urban areas, but emissions from motor vehicles, primarily diesel trucks, usually dominate these sources in near-roadway environments.

Most near-road studies showed good correlation among the pollutants listed above (with the exception of PM_{2.5}, whose atmospheric concentration is mostly influenced by regional sources), indicating a common traffic origin (Zhu et al., 2002a,b; Sardar et al., 2005; Hagler et al., 2010). In particular, BC is often very well correlated with UFP concentrations in urban air, given that both are emitted from motor vehicles and the larger relative BC content found in the ultrafine particle size range.

AMBIENT MEASUREMENTS

Near-Roadway Studies

The majority of all near-roadway studies conducted to date have focused on the influence of proximity to roadways on outdoor (residential) and indoor exposure to air pollutants. In virtually all of these works, it was found that the outdoor concentrations of primary pollutants emitted from motor-vehicle emissions (UFP and BC in particular) were more strongly correlated with distance from roadways than the outdoor concentrations of species dominated by atmospheric formation or other regional sources (e.g. PM_{2.5}). Measured concentrations of these primary pollutants were typically highest in close proximity to a roadway and decreased exponentially with increasing distance from (and downwind of) the source. In a study conducted in the Los Angeles area in the daytime, Zhu et al. (2002a) found that the concentrations of CO, BC, and UFPs were highest in the immediate vicinity (17 m) of the I-710 (a freeway highly influenced by heavy-duty diesel trucks), and decreased exponentially to upwind background levels after about 300 m (Figure 9-3a). A companion study was carried out next to the I-405 freeway (dominated by gasoline vehicle traffic) with similar results (Zhu et al. 2002b) (Figure 9-3b).⁶ As discussed earlier, the dynamic pollutant mix evolves during transport from the road: nucleation leads to formation of new particles very soon after emission, followed by their growth by condensation, diffusion to surfaces, evaporation and coagulation. Therefore, at the edge of a roadway, particle concentrations are dominated by the smallest particles (in the 6-10 nm range), with the peak in distribution shifting to the larger sizes at greater distances.

⁶ For each air pollutant, upwind and downwind concentrations were normalized to the highest level measured at the edge of the freeway and expressed as relative values (i.e. 0 to 1)

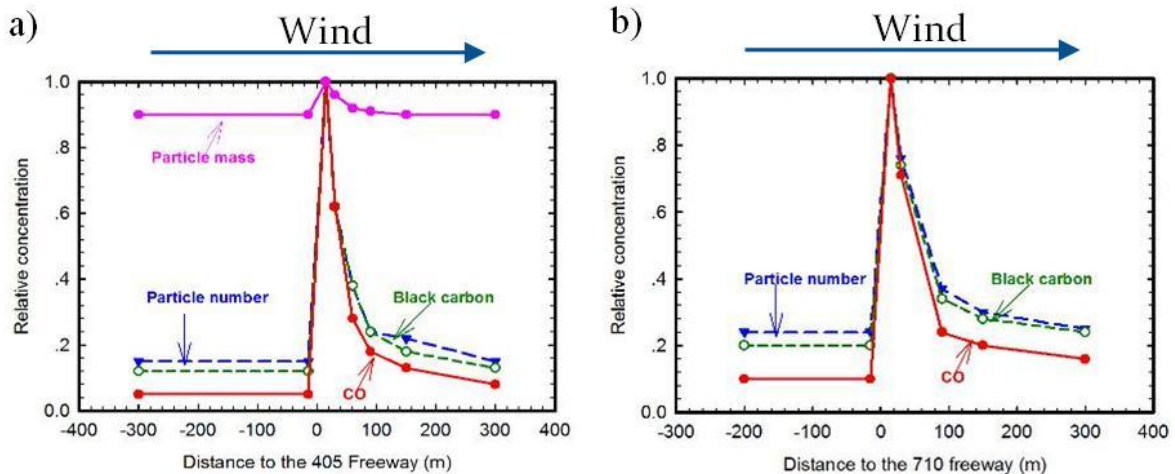

FIGURE 9-3

Relative Black Carbon (BC), Carbon Monoxide (CO), Particle Number (a surrogate for ultrafine particles or UFP), and Particle Mass (PM_{2.5}) Concentrations Upwind and Downwind of the I-405 (a) and I-710 (b) Freeways (from Zhu et al., 2002a; 2002b).

Note that PM_{2.5} was not measured at the I-710.

Measurements conducted in communities adjacent to the Ports of Los Angeles and Long Beach revealed that concentrations of UFP, BC, and NO₂ (mostly from heavy-duty diesel trucks) were frequently elevated two to five times within 150 m downwind of freeways (compared to more than 150 m) and up to two times within 150 m downwind of arterial roads with significant amounts of diesel traffic (Kozawa et al. 2009). In the winter and summer of 2009 the District conducted an intensive study in the vicinity of the I-710 to characterize the spatial and temporal variations of motor vehicle emissions, and their potential impact on the surrounding communities (AQMD, 2012)⁷. Emissions 15 m downwind of the freeway were found to be enriched in BC, UFP, and NO_x, combustion pollutants emitted directly from gasoline and, especially, diesel vehicles. The atmospheric concentration of PM_{2.5} mass and VOCs was not as heavily impacted by proximity to the I-710.

During a recent daytime study conducted in New York City before, during, and after vehicle traffic was excluded from a major street (Park Ave.), Whitlow et al. (2011) showed that the curbside airborne PM_{2.5} level always peaked in the morning regardless of traffic conditions, while UFP number concentration was 58% lower

⁷ http://www.aqmd.gov/tao/AQ-Reports/I710Fwy_Study.pdf

during mornings without traffic. Furthermore, UFP count varied linearly with traffic flow, while PM_{2.5} spiked sharply in response to random traffic events that were weakly correlated with the traffic signal cycle. As expected, UFP concentrations decayed exponentially with distance from the street with unrestricted traffic flow, reaching background levels within 100 m of the source. It is likely that background concentrations of most motor vehicle related pollutants in large urban areas like New York City are more elevated than those found elsewhere.

Karner et al., (2010) summarized data reported in 41 roadside monitoring studies (all conducted during daytime) and found that almost all combustion-related pollutants decay to background by 115-570 m from the edge of road. Changes in pollutant concentrations with increasing distance from the road fell into one of three groups: 1) at least a 50% decrease in peak/edge-of-road concentration by 150 m, followed by consistent but gradual decay toward background (e.g. CO and UFP); 2) consistent decay or change over the entire distance range (e.g. benzene and NO₂); and 3) little or no trend with distance (e.g. PM_{2.5} mass concentrations).

It should be noted that nighttime conditions can lengthen the distance at which near-road pollutant concentrations decay to background. For instance, Hu et al. (2009) observed a wider area of air pollutant impact downwind of the I-10 freeway during pre-sunrise hours. In particular, UFP concentrations peaked immediately downwind of the I-10 and reached background levels only after a distance of about 2600 m (Figure 9-4).⁸ Other combustion related pollutants, such as NO and particle-bound polycyclic aromatic hydrocarbons (p-PAHs), exhibited similar long-distance downwind concentration gradients. The authors associated these elevated pre-sunrise concentrations over a wide area with a nocturnal surface temperature inversion, low wind speeds, and high relative humidity. It should be noted that, occasionally, nighttime near-road UFP number concentrations exceeded daytime conditions, despite reduced traffic volumes.

Further work is needed to integrate daytime and nighttime findings and to assess their relative importance given daytime and nighttime differences in traffic activity, near-road pollutant concentrations, and factors affecting human exposure.

⁸ Upwind and downwind UFP concentrations were normalized to the highest level measured at the edge of the freeway and expressed as relative values (i.e. 0 to 1)

**FIGURE 9-4**

Relative Averaged UFP Concentrations and Gradients During Pre-sunrise Hours along the I-10 (Hu et al., 2009) and the I-710 Freeways (Zhu et al., 2002b)

In the last few years, new powerful instruments have been developed to characterize the physical and chemical characteristics of freshly emitted aerosols in real time. For example, Sun et al. (2012) used a High-Resolution Time-of-Flight Aerosol Mass Spectrometer to study the mass concentrations and chemical composition of sub-micron aerosol species (PM_{10}) in the vicinity (30 m) of a major highway in New York City. The mass spectrometer data (taken at 1-min time resolution) was complemented by rapid measurements (down to 1 Hz) of particle number concentrations and size distributions. Overall, hydrocarbon-like organic (HOA) species dominated the composition of traffic-related PM_{10} especially during periods of high traffic intensity. Significant enhancements in ultrafine organic aerosol mass and particle number concentrations were frequently observed in traffic plumes, suggesting that UFPs are dominated by HOA species from vehicle emissions near highways.

On-road Studies and In-Vehicle Exposure

Several studies have found that, while commuting, individuals are exposed to air toxic levels that are several times higher than the corresponding ambient concentrations measured at fixed near-roadway monitoring sites. Most of these on-road studies have been conducted using zero-emissions mobile platforms outfitted with real-time

instruments to spatially characterize particle and gaseous pollutant concentrations. Fujita et al. (2003) found that concentrations of BC and NO_x in Harbor communities of Wilmington, West Long Beach, and San Pedro (California) were about ten times higher on roadways than at regional air monitoring sites. Similarly, Westerdahl et al. (2005) showed that concentrations of UFP, NO, BC and CO on Los Angeles freeways were often ten times higher than those on residential streets.

Heavily impacted industrial communities are also characterized by increased on-road air pollutant concentrations. For example, elevated UFP, BC, and NO concentrations were observed across the residential neighborhood of Boyle Heights in Los Angeles (Hu et al. 2012). UFP concentrations were nearly uniform spatially, in contrast to other areas in the greater metropolitan area of Los Angeles where UFP concentrations exhibit strong gradients downwind of roadways. This was attributed to the presence of high heavy-duty traffic volumes on the freeways surrounding Boyle Heights, and substantial numbers of high-emitting vehicles on local surface streets. The high density of stop signs and lights, and short block lengths, requiring frequent acceleration of vehicles, may contribute to elevated UFP levels observed in this area.

Fruin et al. (2008) characterized air pollutant concentrations on Los Angeles freeways and arterial roads. On freeways, concentrations of UFPs, BC, NO_x, and p-PAH were generated primarily by diesel emissions, despite the relatively low fraction (~6%) of diesel-powered vehicles. However, UFP concentrations on arterial roads appeared to be driven mainly by proximity to gasoline-fueled cars undergoing hard accelerations. Concentrations were roughly one-third of those on freeways. They concluded that 33 to 45% of total UFP exposure for Los Angeles residents occurs due to time spent traveling in vehicles. A previous study conducted by the same research group showed that time spent in vehicles contributes between 30 and 55% of Californian's total exposure to diesel PM (Fruin et al., 2004). The applicability of these estimates to other regions of the United States is largely unknown.

Due to the high air exchange rates (AERs) of moving cars/trucks, in-vehicle concentrations are typically close to roadway concentrations. Inside-to-outside UFP concentration ratios are best measured under realistic conditions because AERs and other factors influencing these ratios are determined by vehicle speed and ventilation preference, in addition to vehicle characteristics such as age. Two independent studies conducted in Southern California showed that in-cabin concentration of UFPs can be reduced substantially (i.e. up to ~85%) by turning the recirculation fan on (Zhu et al. 2007; Hudda et al. 2011). Evidence suggests that increased ventilation is also a key

determinant of in-cabin UFP concentrations in buses, ferries, and rail modes (Knibbs et al., 2011). Where a vehicle is fitted with a cabin air filter, its particle removal efficiency is a key determinant of what proportion of on-road UFPs reach the cabin (Burtscher et al., 2008; Pui et al., 2008).

Important Factors Affecting Near-Roadway Measurements

The air quality monitoring studies described above measured elevated concentrations of UFPs and other combustion pollutants near roadways. However, most of these studies were conducted under different environmental conditions. In order to interpret results from these and future near-roadway activities and to better evaluate the risks associated with living in close proximity to highly trafficked freeways, it is important to consider all variables influencing the observed monitoring data. These may include:

- **Traffic activity:** parameters such as the total number of vehicles, the fleet mix (e.g., gasoline vs. diesel), and vehicle speeds affect the concentration of near-road pollutants. This information can usually be obtained from local transportation agencies or on the web.⁹
- **Meteorological parameters:** wind speed and direction, temperature, humidity, and atmospheric stability can be used to better evaluate the generation, transformation and transport of traffic-generated emissions and for interpreting near-road air quality data.
- **Roadway type:** proximity to busy freeways has generally been associated with an increase in atmospheric UFPs. However, most urban areas contain arterial roadways that experience regular increases in UFP levels, especially during morning and afternoon rush hours. Increased number of stop-and-go operations from traffic signals, longer idling times, and cold start conditions all contribute to increased UFP emissions.
- **Roadway design:** road grades create an increased load on vehicles ascending the grade, leading to increased exhaust emissions and potential tire wear, while vehicles descending the grade experience increased brake emissions. The presence of ramps, intersections, and lane merge locations can also lead to increased brake

⁹ For example, see Caltrans' Performance Measurement System (PeMS); <http://pems.dot.ca.gov>

wear emissions and idling vehicle conditions due to increased congestion (Baldouf et al., 2009).

- **Roadside structures:** the presence of roadside features such as noise barriers, trees, and buildings can change the dynamics of air pollutant dispersion downwind of a freeway. Results from two recent studies conducted in Raleigh, NC and in Los Angeles indicate that near-roadway concentrations of combustion particles (e.g. UFP and BC) and related gaseous co-pollutants (e.g. CO and NO₂) were lower where a noise barrier was present than in open terrain (Bowker et al., 2007 and Ning et al., 2010). However, a longer downwind distance was generally needed to reach background levels, indicating a larger impact zone of traffic emission sources. Noise barriers adjacent to a roadway may also inhibit air movements off the road, leading to elevated on-road pollutant concentrations (Bowker et al. 2007; Baldauf et al. 2008). The District has several ongoing research efforts to better evaluate the mitigation potential of various roadside features.

HEALTH EFFECTS

Ultrafine Particles

Short- and long-term exposure to particles produced from combustion processes have been associated with numerous adverse health effects in humans including various cardiovascular and respiratory diseases (Pope and Dockery, 2006). It has been hypothesized that the ultrafine portion of atmospheric PM may be responsible for the majority of the observed health effects (Brugge et al., 2007; Balmes et al., 2009; Jarrett et al., 2009; Hoek et al., 2010; Ljubimova et al., 2012). Thus, recent research studies have specifically focused on UFPs and their ability to be absorbed deeply into the lungs, move across cell membranes, and translocate into the bloodstream and other parts of the body. As noted in the preceding sections, the formation and subsequent evolution of UFPs is complex. They are formed and processed on the order of minutes, but their composition continues to change depending on intricate interactions in the exhaust stream and in ambient air. Thus, exposures will vary depending on location within the exhaust plume and with distance from the emission source.

The mechanisms linking UFP exposure to observed health impacts are still not completely understood, but one of the most plausible hypotheses is that many of the adverse health effects may derive from oxidative stress, initiated by the formation

of reactive oxygen species (ROS) within affected cells. Work conducted at the University of California Los Angeles (UCLA) Southern California Particle Center in the past decade has demonstrated that because of their high OC and polycyclic aromatic hydrocarbon (PAH) content, UFPs have the highest potential to generate ROS and to induce oxidative stress in macrophages and epithelial cells (Li et al., 2003). This, in turn, may promote allergic inflammation in the lungs, the progression of atherosclerosis, and precipitation of acute cardiovascular responses ranging from increased blood pressure to myocardial infarction (Delfino et al., 2005; Araujo et al., 2008). From the analysis of summertime ambient PM samples collected near downtown Los Angeles in the morning and in the afternoon, Verma et al. (2009) showed that both primary (traffic dominated) and photochemically formed quasi-ultrafine particles ($d < 250$ nm) possess high reduction-oxidation activity. However, the latter particle type appeared to be more potent in terms of generating oxidative stress and leading to subsequent damage in cells. The semi-volatile component of quasi-ultrafine urban aerosols (mostly OC and PAHs) seems to be responsible for most of the oxidative potential of PM (Verma et al., 2011).

Recent works have examined the health consequences due to UFP exposure on the most susceptible part of the population such as elderly individuals, children and subjects with asthma and diabetes. For example, between 2005 and 2007 the University of California Irvine (UCI) led a multi-disciplinary project (i.e. Cardiovascular Health and Air Pollution Study or CHAPS) to study the health effects of environmental exposure to different PM fractions (including UFPs) in elderly retirees affected by coronary artery disease (Delfino et al. 2008; 2009). Results suggested that traffic-related emissions of primary OC, PAHs, and UFPs were associated with adverse cardio-respiratory responses including elevated blood pressure (Delfino et al., 2010) and increased risk of myocardial ischemia (Delfino et al., 2011).

Other studies tried to elucidate the link between inhalation of UFPs and cardiovascular responses in children and young adults. In most studies, healthy young subjects were exposed to filtered “particle-free” air or UFPs at rest and during exercise (e.g. Shah, et al. 2008; Zareba, et al. 2009; Samet, et al. 2009). Short-term exposure to UFPs did not cause marked changes to the electrocardiography (ECG) parameters, although acute exposure had mild inflammatory and prothrombotic responses. In a recent experiment conducted by Pope et al. (2011), healthy, non-smoking young adults were exposed a) to known amounts of PM_{2.5} (150-200 $\mu\text{g}/\text{m}^3$) from wood and coal combustion, and b) to uncontrolled ambient air. The researchers

did not find any vascular response following the few hours of PM_{2.5} exposure, but noted declines in vascular response with elevated ambient particle exposures, possibly due to the deleterious contributions from mobile source emissions.

There are no long-term studies of human population exposure to ultrafine particles, as there is a lack of a monitoring network in the U.S. There have been several cross sectional epidemiological studies of ultrafine particles, mainly from Europe. Some of these studies found effects on hospital admissions, emergency department visits, for respiratory and cardiovascular effects. Other studies, however, have not found such effects (U.S. EPA, 2009). Concentrations of ultrafine particles can vary geographically, and it is not clear how well central site monitors may capture actual exposures.

The current U.S. EPA Integrated Science Assessment for Particulate Matter (U.S. EPA, 2009)¹⁰ summarized that evidence is inadequate to determine a causal relationship between short-term exposures of UFPs to mortality or central nervous system effects, but that the evidence is suggestive of short-term exposures causing cardiovascular and respiratory effects. The Assessment also concluded that there is inadequate evidence linking long-term exposure of UFPs to health effects, including respiratory, developmental, cancer, and mortality. Overall, epidemiological studies of atmospheric PM suggest that cardiovascular effects are associated with smaller particles, but there are few reports that make a clear link between UFP exposures and increased mortality.

Recently, Hesterberg et al. (2011) hypothesized that the health effects caused by exposure to controlled diesel exhaust will be much less than those from uncontrolled diesel emissions, mostly because particles generated from nucleation of unfiltered sulfur vapors are believed to be less toxic than UFPs emitted from uncontrolled diesel combustion, which are made primarily of organic compounds (Seigneur, 2008). Additional studies are needed to support this hypothesis. The current ongoing Advanced Collaborative Emissions Study (ACES) will provide more data on the health effects of newer diesel engines meeting the U.S. 2007 standards. Similar testing may be necessary for advanced gasoline and alternative fueled engine exhaust as well as for the newer heavy-duty diesel engines meeting the U.S. 2010 standards.

¹⁰ <http://www.epa.gov/ncea/isa/pm.htm>

Considerably more information and data are needed in order to understand the underlying mechanisms and emission properties that affect human health. In 2011, the Health Effects Institute (HEI) convened an expert panel to conduct a critical evaluation of knowledge regarding the potential for UFP and NP to harm human health. The panel's report will be published as part of the HEI Perspective series. The Advanced Collaborative Emissions Study (ACES), which is jointly managed by HEI and the Coordinating Research Council (CRC) has undertaken a major effort to document improvements in vehicle emissions associated with advanced emissions controls. HEI investigators are analyzing the associated health effects.

Near-Roadway Health Impacts

Recent studies have found a positive association between living near busy roadways and asthma exacerbation, decreased lung function, increased heart disease, and other respiratory and cardiovascular effects (Kan et al., 2008; Andersen et al., 2010; HEI, 2010). Exposure to traffic emissions has also been linked to a faster progression of atherosclerosis in subjects living within 100 m of highways in Los Angeles (Künzli et al., 2010), increased risk of low birth weight and premature delivery (Llop et al., 2010; Wilhelm et al., 2011), and lower immune function and increased risk of Type 2 diabetes in post-menopausal women (Krämer et al., 2010; Williams et al., 2011). These studies do not differentiate exactly which pollutant or pollutants may be responsible.

Children are among the most susceptible segment of the population affected by exposure to traffic related pollutants. Their immune, neurological, and respiratory systems are still under development, they typically spend a substantial amount of time playing outdoors, and they have higher breathing rates per body mass. Neighborhood exposure to traffic-related air pollution has been linked to increased medical visits and hospital admissions for childhood asthma, increased wheezing and bronchitis, and the development of new asthma cases (McConnell et al., 2006; 2010; Chang et al., 2010).

In 2005 the District sent an advisory to all school districts under its jurisdiction to bring attention to findings regarding the potential for adverse health effects resulting from exposures to traffic emissions, and to encourage school districts to consider exposure to vehicle emissions when selecting and evaluating sites for new facilities such as schools, playgrounds, and residences (http://www.aqmd.gov/prdas/aqguide/doc/School_Guidance.pdf). As mentioned early in this document, the concentration of vehicle related pollutants drops off to near-background levels after about 300 m from the edge of the roadway (Zhu et al., 2002a;

2002b). A survey of California schools revealed that approximately 2.3% of public schools were located within 150 meters of high-traffic roads (greater than 50,000 vehicles per day), and an additional 7.2 % were within 150 meters of medium traffic roads (25,000 – 50,000 vehicles per day) (Green et al., 2004).

FUTURE RESEARCH AND ASSESSMENT NEEDS

Chemical Composition

Large differences in UFP chemical composition depend on many factors, including vehicle technology, fuel used and after-treatment devices, but also on atmospheric chemical reactions after being emitted. Since particle composition may be a factor determining particle toxicity, there is a need for developing a better knowledge of UFP chemistry near roadways and in different environments.

Processes Leading to Formation

More work is needed to better characterize the mechanisms that lead to UFP formation right after emission and in the atmosphere. Developing a clearer picture of particle formation dynamics in different environments, including those which are influenced by traffic, would greatly assist control measures to regulate emissions of UFPs.

Standardized Measurement Methods and Procedures

Currently, there is no standard method for conducting size-classified or particle-number measurements. The terms UFP and NP are not clearly defined and often used improperly. In addition, the UFP characteristics measured in ambient and emission testing studies (e.g. volatile vs. solid components; mass vs. number concentration) are highly dependent on the measurement instrument/protocol used and its setting. Therefore, there is a need to develop and utilize standardized measurement methods and procedures to enhance meaningful comparison between results from different studies and to guarantee reproducible results.

Increased Measurements at “Hot Spot” Locations

The range of UFP number concentrations between clean and vehicle-affected environments spans over two orders of magnitude. UFPs and NPs are usually not uniformly dispersed in the atmosphere, but concentrated in areas where large numbers of vehicles are operated. Thus, future ambient UFP measurements should be

conducted in areas where concentrations are likely to be higher (“hot spots”). These may include busy roads and intersections, rail yards, airports, etc.

Emission Inventories

Currently vehicle emission factors for different particle size ranges and for particle numbers are highly uncertain, and there are no emission inventories for UFPs from motor vehicles. Also, long-term UFP concentration data in urban environments is scarce. This knowledge is critical for developing management and control strategies for UFP emissions. New estimations of UFP levels should not be derived solely based on vehicle emission factors (which mostly reflect emissions of primary combustion particles), but have to include predictions for UFP formation near the tailpipe and in the atmosphere.

Air Quality Modeling

Exposure assessment of UFPs will require the development of modeling tools to simulate formation and transport over a wide range of atmospheric conditions and emission scenarios. In particular, there is a need to better understand the atmospheric dispersion and transformation of UFP and UFP precursor emissions within the first few hundred meters of the roadway, a region often characterized by complex flow. This complex flow may also affect how pollutants enter multi-story buildings characteristic of higher density environments. Additional new near-roadway studies and laboratory measurements are also necessary to better validate these models.

Health Effects

New toxicological and epidemiological studies targeting exposure to controlled and uncontrolled emissions from gasoline and diesel vehicles are needed to better characterize the exposure-response relationships to UFPs and to help develop health guidelines and potential regulations. The health effects of inorganic (largely related to oil consumption ash constituents) UFP emissions from vehicles are only now starting to receive significant attention.

Other Types of Sources

UFPs are formed through many types of combustion processes. Motor vehicles powered by internal combustion engines are major sources, but stationary source combustion and other processes also contribute significantly to UFP emissions and formation. More work is needed to better understand the size, composition and health impact of these particles near airports, rail-yards, port areas, natural gas electric generators and other potential “hotspot” locations.

PLANNING AND REGULATORY ISSUES

Jurisdiction over Near-Roadway Exposures

The jurisdictional authority for controlling exposure to mobile source pollutants in the near-roadway environment is generally split between 1) federal and state authority over vehicle tailpipe emissions standards; and 2) local government (e.g. cities, counties) authority over land use planning and zoning decisions. In broad terms, tailpipe emission standards affect the source of mobile source emissions, while land use planning affects the exposure to those pollutants. In particular:

- On-road emission standards: U.S. EPA and CARB set standards for the level of pollutants that are allowed from new on-road engines and the fuels used to power them. Chapter 3 and Appendix III details how the emission standards for on-road vehicles are projected to affect total vehicle emissions in future years. While tighter emission standards in the future are expected to lower overall emissions, the near-roadway environment is still expected to have higher concentrations of mobile source pollutants relative to areas further away, especially for ultrafine particles.
- Local land use planning and zoning: local governments maintain the authority to determine the types of land use that are allowed within their jurisdiction. For example, in city General Plans, each parcel of land within that city is given a land use designation (e.g. residential, industrial, etc.). Land use types that do not fall within the General Plan designation are not allowed, with limited exceptions.¹¹ Because the majority of the area within the District jurisdiction has been built out in the past century, many of the current land use patterns are based on historical land use decisions. These legacy decisions have resulted in a large number of residents living in close proximity to freeways. As an example, approximately 691,000 people in Los Angeles County live within 500 feet of a freeway.¹²

¹¹ For example, school districts generally have the authority to supersede local land use authority when determining where to site new schools.

¹² 2012 Regional Transportation Plan, SCAG. Environmental Justice Appendix, Table 40.

Sustainable Communities Strategies

Pursuant to California Senate Bill 375 (SB 375) passed in 2008, CARB developed regional greenhouse gas reduction targets for passenger vehicle emissions in years 2020 and 2035. As required by SB 375, the Southern California Association of Governments (SCAG) used these regional targets¹³ to develop a Sustainable Communities Strategy (SCS) integrating land use, housing, and transportation planning, all as a part of the adopted 2012 Regional Transportation Plan (RTP).

One of the key features of the RTP/SCS is the encouragement of Transit-Oriented Development (TOD) that promotes higher residential and employment densities in High Quality Transit Areas (HQTA)¹⁴. Among the many benefits of well designed TODs, one of their primary purposes under SB 375 is to reduce the total vehicle miles travelled (VMT) in the region by placing homes and jobs closer to public transportation. However, because much of the original and planned transit network lies in close proximity to existing freeways, many of the HQTA areas overlap with freeway proximate areas. For example, with implementation of the RTP/SCS, approximately 282,000 households in the SCAG region will be located both within a HQTA and within 500 feet of a freeway in the year 2035. Some TODs can therefore present a challenge by potentially reducing regional emissions while increasing the exposure of residents in those project areas to elevated pollutant concentrations found in the near-roadway environment.

Enhanced Environmental Analysis

The California Environmental Quality Act (CEQA) requires that all projects requiring discretionary action by a public agency must evaluate and identify the potential environmental impacts of that project, and implement all feasible methods to reduce, avoid, or eliminate any significant adverse impacts.¹⁵ This analysis is reported in CEQA documents such as Negative Declarations or Environmental Impact Reports. Therefore, CEQA requires that a project proponent analyze how the project itself may impact its surrounding environment. For example, if a project includes a new apartment building located adjacent to a freeway, the project will result in new

¹³ 8% reduction below 2005 levels on a per capita basis by 2020, and 13% reduction by 2035

¹⁴ A HQTA is defined as the ½ mile corridor surrounding a fixed bus route with service intervals no longer than 15 minutes during peak commute hours, or the ½ mile area surrounding a rail transit station, ferry terminal served by bus or rail, or the intersection of two or more major bus routes with service intervals no longer than 15 minutes during peak commute periods. See Public Resources Code 21155(b) and 21064.3 for further details.

¹⁵ Public Resources Code §21000 *et seq.*

emissions from vehicles driven by future residents of the apartment building, and these emissions must be evaluated to determine the impact on air quality and the environment.

In a more rigorous CEQA analysis, the impacts from the surrounding environment on people living in the project itself could also be evaluated (Figure 9-5). Using the same example from above, emissions from all of the vehicles on the adjacent freeway would also be evaluated for their potential impact on the proposed apartment residents.

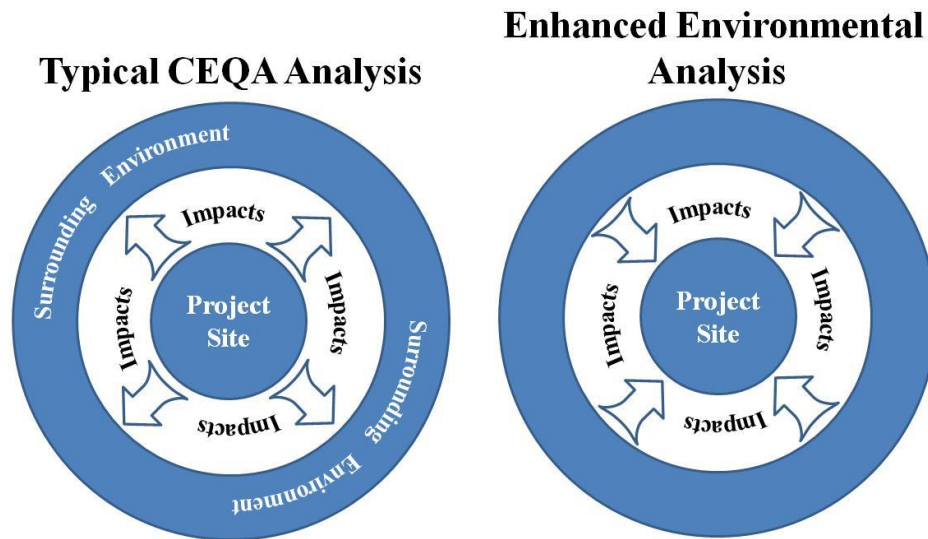

FIGURE 9-5

Example of Typical and Enhanced Environmental Analyses

Although section 15162.2 of the CEQA Guidelines provides that an environmental impact report “shall also analyze any significant environmental effects the project might cause by bringing development and people into the area affected,” recent court rulings have found that CEQA does not require an analysis of the impacts of the environment on a project.¹⁶

¹⁶ *Ballona Wetlands Land Trust v. City of Los Angeles* (2011) 201 Cal.App.4th 455, 473-474 (a revised environmental impact report for a coastal multi-family residential development was not *required* to address impacts on the project from sea-level rise caused by global warming); *see also South Orange County Wastewater Authority v. City of Dana Point* (2011) 196 Cal.App.4th 1604 (analysis of impacts from locating a residential development next to an existing source of noxious odors was not *required*)

However, notwithstanding these court rulings, lead agencies (such as a city or county or air district) that approve CEQA documents retain the authority to include any additional information they deem relevant to assessing and mitigating the environmental impacts of a project. Because of the District's concern about the potential public health impacts of siting sensitive populations within close proximity of freeways, District staff will continue to recommend that, prior to approving the project, lead agencies consider the impacts of air pollutants on people who will live in a new project and provide mitigation where necessary.

Guidance is available for conducting health risk assessments related to mobile sources from the District and from the California Air Pollution Controls Officers Association (CAPCOA).¹⁷

Mitigation Measures

A variety of mitigation measures have been proposed and are under study to reduce exposure to the high concentration of pollutants found in the near-roadway environment. Although some of these exposure controls may have some effectiveness, the solution that would have the greatest effect still lies in source control. Reducing vehicle emissions remains the only way to ensure that all pollutant concentrations in the near-roadway environment can be reduced for everyone, not just for certain pollutants, or for those that can implement mitigation. While emissions from vehicles are expected to continue to decline with existing regulations and fleet turnover, near-roadway environments are still expected to have elevated concentrations of some mobile source pollutants for the foreseeable future. In the interim, there are some measures that may reduce exposure that are briefly described in the table below. All of these conventional methods require further research to determine their effectiveness and feasibility for the variety of land uses found in the near-roadway environment. In addition, District staff will continue to support and monitor the outcome of research on newer technologies such as photocatalytic cement, roadway canopies, and sound barriers with active or passive filtration/ventilation.

Besides buffer zones, none of the measures listed in the table below (Table 9-1) has been found to be effective to reduce all mobile source pollutants to background levels in the near roadway-environment. Because of this limitation, the mitigation

¹⁷ http://www.aqmd.gov/ceqa/handbook/mobile_toxic/mobile_toxic.html
http://www.capcoa.org/wp-content/uploads/2012/03/CAPCOA_HRA_LU_Guidelines_8-6-09.pdf

considered for new land uses may be different than that considered for existing land uses. For example, new land uses could consider buffer zones or site configurations before considering other measures such as enhanced HVAC filtration.

For existing land uses that do not have the same ability to incorporate buffer zones as new land uses, other measures may be considered first, such as encouraging development of outdoor recreation spaces and playgrounds within walking distance but beyond 300 m from a freeway at the same time as considering enhanced filtration in HVAC systems.

Emission Control Technologies

The application of advanced emissions control technologies to both compression-ignition (diesel) and spark-ignition (gasoline, natural gas) engines has led to new concerns about the formation and health effects of UFPs. Since larger accumulation mode particles have effectively been removed from the exhaust of state-of-the-art vehicles, this has eliminated possible condensation surfaces for volatile gases and UFPs. The net result is that while larger-sized particles (accounting for most of the PM mass) are dramatically reduced by control technologies such as diesel particulate filters (DPFs), an increase in the number of UFPs and NP may potentially occur. Additional evaluation regarding a possible increase in UFP and NP number concentration should be addressed. Below is a brief description of the two main PM control technologies in use today:

- Particulate filters are devices capable of achieving over 90% reduction of the solid portion of the total exhaust particles, with some control of the soluble organic fraction (SOF). With most of the solid particles removed, nucleation, rather than condensation, of the remaining gas phase species can occur, potentially increasing particle number emissions (Morawska et al., 2008). However, particulate filters can also be effective in controlling UFPs if designed properly, for example when used in conjunction with an oxidation catalyst.

TABLE 9-1

MITIGATION MEASURE	POLLUTANT TARGETED	RANGE OF REDUCTION	COMMENTS	KEY REFERENCES
Buffer zones	All pollutants	0-100%	Varies with distance. Up to 100% reduction to background levels at 500 feet.	-CARB Air Quality and Land Use Handbook, (2005) (http://www.arb.ca.gov/ch/handbook.pdf)
Enhanced filtration in building Heating, Ventilation, and Air Conditioning (HVAC) systems	PM	30-90% for indoor environments	Effectiveness varies depending upon rating of filter (>MERV 13 recommended near roadways), HVAC design, maintenance of HVAC system, whether doors and windows stay closed, and amount of time people spend outdoors	-AQMD Pilot Study of High Performance Air Filtration for Classroom Applications (http://www.aqmd.gov/rfp/attachments/2010/AQMDPilotStudyFinalReport.pdf) -SCAG 2012 RTP/SCS PEIR Appendix G Measure AQ-19 (http://rtpscs.scag.ca.gov/Documents/peir/2012/final/2012fPEIR_AppendixG_ExampleMeasures.pdf)
Sound walls	All pollutants	15-50% close to barrier at ground level	Effectiveness varies with distance from freeway, with concentrations sometimes increasing >80m downwind of wall. Other site-specific characteristics may significantly alter effectiveness.	-Impact of noise barriers on near-road air quality, Baldauf et al., (2008) -Impact of noise barriers on particle size distributions and pollutant concentrations near freeways, Ning et al., (2010) -The effect of roadside structures on the transport and dispersion of ultrafine particles from highways, Bowker et al., (2007)
Vegetated barriers	PM	Varies	Effectiveness varies with barrier height, thickness, density, and species. Some configurations may increase concentrations.	-Local measures for PM10 hotspots in London, Air Quality Consultants (2009) -Field investigation of roadside vegetative and structural barrier impact on near-road ultrafine particle concentrations under a variety of wind conditions, Hagler et al., (2012)

Common Mitigation Measures Adopted To Reduce Exposure to Motor Vehicle Emissions In Near-Road Environments

- Oxidation catalysts are effective in removing more than 90% of the SOF fraction of total emissions as well as UFPs formed later in the exhaust. Their effectiveness, however, depends on whether the catalyst is formulated to produce little or no sulfate emissions at high temperature. In fact, special catalyst formulations must be employed to hinder the catalytic generation of sulfate particles from SO₂ present in the exhaust gas. While oxidation catalysts are effective in reducing the SOF fraction and smaller particles, it has little effect on larger accumulation or coarse mode particles. An effective control technology should be based on a system addressing both particle mass and number emission reduction.

Testing Protocols

Under the U.S. gravimetric method for certifying heavy-duty engines, exhaust PM mass is collected on inert filters as each engine is operated over official engine dynamometer testing schedules (e.g. the Federal Test Procedure, or FTP). A constant volume sampler (CVS) system collects the exhaust at prescribed conditions (e.g. temperature, dilution ratio). The preconditioned particulate filters are then weighed to obtain the mass of PM emitted over the test cycle. The mass of emitted PM is then normalized according to the work performed over the test cycle in brake horsepower-hour (bhp-hr). The calculated mass emissions values are compared to the PM emissions standard in g/bhp-hr.

Procedures for characterizing emissions from light-duty (diesel) vehicles are similar from the perspective of collecting the PM on preconditioned filters and determining mass emissions. A key difference is that the light-duty vehicle emissions standards are in grams of pollutant per distance driven (g/mile in the U.S.), instead of work performed. Testing of light-duty vehicles is conducted on chassis dynamometers in contrast to heavy-duty engines, which are tested on engine dynamometers prior to vehicle integration.

In the U.S., the focus on measuring and controlling PM emissions has been almost exclusively on the heavy-duty vehicle sector, because overall emissions are dominated by diesel engines. The mass-focused testing methodology described above has worked well for heavy-duty engine technologies meeting PM standards of 0.1 g/bhp-hr (i.e. up to the 2006 engine model year). Such engines emit relatively large amounts of solid material (soot, metals, and ash) from combustion, engine wear, and lube oils. All of this is collected on the preconditioned filters, along with volatiles in the exhaust that condense on the filters including water vapor, sulfates, and other

organics. The net result is that the mass of PM collected during the test cycle over a known amount of work performed can be compared to the PM emissions standard.

However, as more advanced diesel PM control technology was developed and deployed to meet tighter emissions standards (DPFs to meet the U.S. 2007 heavy-duty engine PM standard) the PM mass collected over the FTP was significantly reduced. In some cases, PM mass levels were too low for detection by existing instrumentation in the test methodology. Also, at these low mass levels, testing anomalies can occur due to absorption of semi-volatile gas molecules on sampling filters or on PM already collected, which possibly leads to bias towards higher weight measurements. Similarly, tunnel wall or sampling line losses can also cause erroneous results. The need for better precision at low mass levels led U.S. EPA to revise the protocol to improve accuracy. At the same time, testing in the United States and in Europe shed new light on the characteristics of diesel PM in the exhaust, raising questions as to the relative importance of measuring particle mass versus particle number and/or size (Swanson et al., 2010).

In the late 1990s, the occupational health and safety authorities of Austria, Switzerland and Germany conducted a comprehensive program called Verminderung der Emissionen von Real-Dieselmotoren im Tunnelbau (VERT), which in English stands for Reduction of Diesel-emissions in tunneling to ensure functional and beneficial systems are utilized for the removal of harmful diesel emissions in underground environments. One of the main objectives of VERT was to look at the composition of diesel exhaust in terms of particle size, surface area, and concentration, and to establish whether mass is a good proxy for subsequent exposures and human health effects. PM, primarily BC and UFPs were found to be of major concern to the extent that in tunneling and other major construction sites, particle-traps for diesel equipment/vehicles became mandatory. This work laid the foundation for two additional important programs, the “Particulates Program” and the “Particle Measurement Programme” (PMP), both of which are further discussed below.

- Particulates Program: this program developed a sampling procedure to characterize both the volatile and non-volatile components of exhaust emissions from light- and heavy-duty vehicles. In particular, it developed sampling methodologies capable of assessing the formation of nucleation- and accumulation-mode particles from a minimum size of 7 nm. Figure 9-6 shows the sampling system used in the Particulates Program. The main results for light-duty

and for heavy-duty-vehicle applications are described in Ntziachristos et al. 2004, and in Thompson et al. 2004, respectively.

Figure 9-6

Sampling System used in the Particulates Program (from Samaras et al., 2006)

The basic premise behind the testing protocol was that each vehicle technology can and should be tested under consistent conditions. This enables comparison between the various technologies and fuels used. The procedure entails measuring particle mass, active surface (surrogate for surface area), solid particle number, total particle number, and particle size distribution. Both light-duty and heavy-duty programs investigated the effects of vehicle technology, fuel properties, and driving cycle.

- **Particle Measurement Programme (PMP):** this program is aimed at developing a test protocol to measure only the impact of solid particles in motor vehicle exhaust. The PMP is a collaboration of the United Nations Economic Commission for Europe and GRPE (Working Party on Pollution and Energy). The goal of this program is to find a new approach to measure particle emissions from vehicles that can either replace or coexist with the current mass-based particulate measurements. A result of this work has been the development of instrumentation and methodologies for counting solid (i.e. low-volatility particles that survived evaporation after a residence time of 0.2 seconds at 300 °C) particles down to a size of 23 nm. The PMP was implemented in a number of testing labs in Europe, Japan, and the U.S. The results of the lab emission testing for light- and heavy-duty vehicles is provided by Andersson et al. (2007; 2010). Figure 9-7 shows an example of a PMP setup for particle number count testing. New test requirements

are continuously being added to European light-duty vehicle emissions regulations, including those specific to particle number.

FIGURE 9-7

Schematic of PMP Testing Setup for Particle Number Count (from Kasper et al., 2006)

There have also been a number of related studies or research reports on the evaluation of various components of the PMP methodology. For example, CARB studied this method for light-duty vehicles using the “Golden Vehicle” (GV; a single vehicle that has been shipped to laboratories in Italy, Sweden, United Kingdom, Germany, Greece, Japan, Korea and France for testing) and the Golden Particle Measurement System (GPMS; a set of particle counting instruments that was sent along with the GV) to compare results with the other nine international laboratories that participated in the PMP (CARB, 2008).¹⁸ Additional testing was done on heavy-duty vehicles and results indicated that further study was needed to include a wider range of vehicles and after-treatment systems (Robertson et al., 2007).

The PMP protocol has gained acceptance in Europe and Japan. American regulators, industry and researchers continue to evaluate this methodology. Researchers in the U.S. (e.g., Swanson et al. 2010) favor alternative methods that focus on measuring surface area including solids and volatiles. Kittelson et al. (2011) noted that for engines equipped with particle filters setting the limit to 23 nm effectively regulates all sizes. However, vehicles without filters may emit large concentrations of solid

¹⁸ http://www.arb.ca.gov/research/veh-emissions/pmp-ld/CARB_Golden_Vehicle_PMP_Report_Final-05JAN09.pdf

particles below 23 nm that are not counted by the current method. The next generation of high-efficiency direct injection gasoline engines is also challenged by the current 23 nm limit. They proposed extending solid PM measurements to 10 nm although this may be problematic due to formation of particles as small as 3 nm downstream of the PMP Volatile Particle Remover (VPR) system.¹⁹

As noted, the European PMP protocol has been implemented to include numbers-based particle emission standards. While there is no consensus in the U.S. at present regarding how to standardize particle measurements, research work and regulatory discussions are ongoing among industry and regulatory agencies such as U.S. EPA, CARB, and the District. For now, U.S. EPA and CARB continue to regulate PM mass only.

Emissions Standards

European Standards

Europe's new emission levels for light-duty and medium-duty vehicles are Euro 5 and Euro 6. Euro 5's goal is to reduce the emissions of PM from diesel cars from 25 mg/km to 5 mg/km. Euro 6 will become effective in January 2014, and will reduce the NO_x emissions from diesel cars from 180 mg/km to 80 mg/km. A solid particle number emission limit of 6×10^{11} km⁻¹ became effective in September 2011 for all categories of diesel vehicles. Europe's reason for adopting the number standard is to promote the use of DPF technology. A particle number emissions limit for gasoline vehicles will be determined in 2014.

California Standards

In 2010, CARB considered adopting certain particle number standards as an alternative under the LEV III requirements, and proposed that for all vehicles subject to LEV III, beginning in 2014, manufacturers must select one of two standards to demonstrate compliance (CARB, 2010)²⁰:

1. Federal Test Procedure weighted PM mass emission limit to 0.006 g/mi (2014) and 0.003 g/mi (2017)
2. Federal Test Procedure weighted particle number emission limit to 6.0×10^{12} particles/mi (2014) and 3.0×10^{12} particles/mi (2017)

¹⁹ <http://www.unece.org/fileadmin/DAM/trans/doc/2011/wp29grpe/PMP-26-06e.pdf>

²⁰ http://www.arb.ca.gov/msprog/levprog/leviii/meetings/051810/pm_disc_paper-v6.pdf

CARB's reason for proposing the particle number limit is to take advantage of the latest methodology advances by PMP. The PMP method was considered because it is the only particle emission measurement method that went through extensive international scrutiny and laboratory testing. Excellent sources of information about CARB's LEV III proposals and objectives specific to fine particles can be found on CARB's 2011 publication "LEV III PM Technical Support Document: Development of Particulate Mass Standards for Future Light-Duty Vehicles".²¹

National Standards

The National Ambient Air Quality Standards (NAAQS) set by the U.S. EPA are designed to protect public health and the environment. The standards are developed based on a variety of scientific studies, including the results of epidemiologic studies that evaluate how human health has been affected by pollutant concentrations in the past. These standards are periodically reviewed and updated based on recent scientific developments. Most recently, the NO₂ and CO NAAQS were reviewed and updated, with a new provision that new permanent monitors must be established near roadways. The most recent AQMD monitoring plan provides details about how and where these new monitors may be located.²² The recent PM NAAQS revision proposed on June 14, 2012, by U.S. EPA for the first time includes near-roadway monitoring requirements for PM_{2.5}. Currently, U.S. EPA notes that, in their assessment, there is not sufficient health evidence to support a separate standard for UFPs.

DISTRICT FUTURE ACTIONS

Although the District has limited authority to regulate mobile source pollution in the near-roadway environment, there are a variety of measures that District staff will continue to take to reduce this public health impact.

- The District will continue to fund health effects, exposure, atmospheric chemistry, modeling, and other research activities aimed at investigating the impact of UFPs exposure in communities impacted by traffic emissions. An AQMD-funded study is currently underway to assess potential air quality impacts and the effectiveness of mitigation measures (e.g. sound walls and vegetated barriers) in the near roadway environment. The multi-pronged approach of this study includes a

²¹ <http://www.arb.ca.gov/regact/2012/leviiiighg2012/levappp.pdf>

²² <http://www.aqmd.gov/tao/AQ-Reports/AQMonitoringNetworkPlan/AQnetworkplan.htm>

review of different mitigation techniques implemented throughout the world, pollutant monitoring combined with dispersion modeling of local freeway emissions, development of alternative models, and laboratory-based simulations in flow tanks. The results of this study are expected by early 2013.

- Since the problem of near-roadway exposure can effectively be addressed by controlling tailpipe emissions, the District will continue to encourage U.S.EPA and CARB to set vehicle emission standards for UFP.
- District staff will continue to work with local and state agencies to address near-roadway exposures. This includes outreach and education to local governments and elected officials on the health risks associated with mobile source pollution and recommending measures that can be taken to reduce those risks. As an example, General Plans prepared for a city can include requirements to provide buffer zones, as feasible, between freeways and any new development with sensitive receptors.
- Through the CEQA Intergovernmental Review program, CEQA documents submitted to the District are reviewed during the public comment period. For those projects that may expose sensitive populations to elevated concentrations of mobile source pollution, District staff will recommend that the potential impacts be quantified and that all feasible mitigation measures be considered to reduce this impact below a significant level.
- As part of the Clean Communities Program (CCP), District staff will continue to work in the pilot study areas of Boyle Heights and San Bernardino to address exposure to mobile source pollution and will apply those lessons learned to other areas in the District. Further, as part of CCP Measures Outreach-1 and Agency-01, District staff will prepare a document titled “Proximity Matters” that will provide an additional resource for local agency planners to use when addressing near-roadway exposures.
- On July 1, 2012 the District began MATES IV, a year-long study designed to characterize the carcinogenic risk caused by exposure to air toxics in the Basin. MATES IV will enhance the spatial resolution of previous measurement efforts by characterizing the localized exposure to UFPs and Diesel Particulate Matter in residential, industrial, and commercial communities. Mobile monitoring platforms will be deployed for short-term monitoring at six to eight sites in areas close to mobile sources such as airports, rail yards, freeways and warehouse operations.

- District staff will continue to work with instrument manufacturers, CARB, and U.S. EPA on the evaluation of new technologies for monitoring UFPs, BC and other traffic-related pollutants, and on the development of methods for the standardization of UFP measurements.

Chapter 10

Energy and Climate

South Coast Air Quality Management District
Cleaning the air that we breathe...

CHAPTER 10

ENERGY AND CLIMATE

Introduction

Energy Consumption Inventory and Projections

Recently Implemented State Regulations and Electricity Generation

Natural Gas

Transportation Fuels

Efficiency Impacts on Energy Use

Southern California's Energy Future

INTRODUCTION

In September of 2011, the AQMD Governing Board adopted the AQMD Air Quality-Related Energy Policy. This policy was developed to integrate air quality, energy issues, and climate change in a coordinated holistic manner and provides a review of energy usage within the Basin followed by ten policies and ten actions (Tables 10-1a and 10-1b). One of the action items is to provide an update of energy usage within the District in each AQMP (SCAQMD, 2011). Energy projections made in this chapter reflect past energy usage in the South Coast Basin and energy projections made from utility and other agencies' planning documents. These projections reflect existing policies and regulations. This review does not include an analysis of energy implications from the control measures within this AQMP; this analysis is conducted within the EIR review.

Energy use in Southern California plays a major role in everyone's lives for purposes such as transportation, comfort, goods movement, manufacturing, and entertainment. In the South Coast Basin this reliance on energy was at a cost of over \$50 billion in 2008 and is projected to increase to over \$70 billion on our current path of consumption. Unfortunately our reliance on energy usage is also the main source of criteria pollutants and greenhouse gases in Southern California. In particular, on-road transportation sources are the largest sources of GHG and criteria pollutants, emitting over 80% of the NO_x and 70% of the CO₂ emissions in the Basin.

Technology changes are needed in the transportation sector over the next 10 to 20 years to meet the criteria pollutant standards and 2050 GHG goals. In the jointly developed *Vision for Clean Air: A Framework for Air Quality and Climate Planning*, technology scenarios are outlined for the transportation sector that provide insight relative to pathways forward to achieving criteria pollutant standards and climate change goals. The likely pathways also would result in greater energy independence and less money spent on energy. For example, newer transportation technologies such as hybrid and electric vehicles provide much greater efficiencies than typical internal combustion engines alone.

Despite the large quantities of energy consumed in California, the per capita energy consumption is the fourth lowest in the nation (EIA, 2011). This low per-capita energy consumption is due to California's energy efficiency programs as well as the relatively mild California climate. However, there are large improvements that need

to be made through increased efficiency, renewable fuels, conservation, and renewable energy generation from all sources.

TABLE 10-1a
AQMD Air Quality-Related Energy Policy

POLICIES	
1.	Promote zero and near-zero emission technologies through ultra clean energy strategies, to meet air quality, energy security, and climate change objectives
2.	Promote zero and near-zero emission technologies in both stationary and mobile applications to the extent feasible
3.	Promote diversification of electricity generation technologies to provide reliable, feasible, affordable, sustainable, and zero or near-zero emission electricity supply for the Basin in partnership with local power producers
4.	Promote demand side management programs to manage energy demand growth. Such programs include, but are not limited to, energy conservation, energy efficiency and load-shifting measures
5.	Promote in-Basin distributed electricity generation, with emphasis on distributed renewable electricity generation, to reduce reliance on energy imports or central power plants, and to minimize the air quality, climate and cross-media environmental impacts of traditional power generation
6.	Promote electricity storage technology to improve the supply reliability, availability, and increased generation technology choices
7.	Require any new/repowered in-Basin fossil-fueled generation power plant to incorporate Best Available Control Technology (BACT) as required by District rules, considering energy efficiency for the application. These power plants shall also comply with any requirements adopted by the California Air Resources Board (CARB), California Energy Commission (CEC), Public Utilities Commission (PUC), California Independent System Operator (ISO), or the governing board of a publicly-owned electric utility, as well as state law under the California Environmental Quality Act (CEQA)
8.	Advocate, within the existing CEQA review process, maximum cost effective mitigation in the communities affected by emission increases resulting from the siting of new or repowered power plants
9.	Educate and incentivize the public and businesses to shift toward the lowest emission technologies, considering emissions of criteria pollutants, toxic air contaminants, greenhouse gases, energy efficiency, and the potential to create local jobs
10.	Incorporate energy efficiency and conservation as an emissions reductions strategy for stationary and mobile sources through AQMD's planning, rule making, advocacy, and CEQA commenting activities

TABLE 10-1b

AQMD Air Quality-Related Energy Policy

ACTIONS	
1.	Advocate for, conduct, and/or support detailed technical studies to identify viable zero and near-zero emission technologies and associated energy delivery and capacity needs to support these technologies as part of the clean air strategy for the Basin
2.	Conduct appropriate socioeconomic studies to identify the societal costs and benefits for the implementation of zero and near-zero emissions strategies, including but not limited to, further electrification and impacts on businesses and jobs
3.	Where feasible, develop an AQMD action plan to develop and deploy electrification and other zero and near-zero emissions measures for various sectors, including identification of implementation barriers and strategies to overcome such barriers
4.	Conduct studies to identify measures to reduce emissions from the transportation sector, including incentivizing early introduction of zero and near-zero emission measures and identify potential new transportation funding mechanisms to support substantial penetration of such technologies within the transportation sector
5.	Further develop and demonstrate low emitting biogas technologies and other clean energy sources from biomass
6.	Coordinate this Energy Policy with California state energy policy as promulgated by the California Energy Commission (CEC), California Public Utilities Commission (PUC), and the California Air Resources Board (CARB), and assure that rules and regulations adopted by the Board are not in conflict with state and federal laws. Actively participate in CEC, PUC, and CARB proceedings to promote policies and regulatory actions that further clean air objectives, consistent with state and federal law
7.	Convene a stakeholder working group (including, but not limited to, representatives from the building industry, local fire departments and building departments, and utilities) to develop and recommend standardized installations of electricity recharging, natural gas refueling, and other zero/near-zero emission refueling equipment for residential and commercial building applications to facilitate greater plug-in electric vehicle (PEV), natural gas vehicle (NGV), fuel cell vehicle, and other zero or near-zero emission vehicle market penetration
8.	Advocate for electricity rate structures that incentivize off-peak charging for PEVs through the Statewide PEV Collaborative (comprised of CEC, PUC, CARB, local air districts and utilities) while remaining sensitive to potential impacts on rates for existing customers
9.	Partner with local utilities and local government stakeholders to promote energy conservation and efficiency through local actions
10.	Compile and track Basin-wide energy usage and supply profiles in conjunction with each Air Quality Management Plan (AQMP) update

Many of the recently adopted and existing State regulations developed for energy efficiency, greenhouse gas reductions, and fuel economy will have impacts on the future amounts and types of energy use in Southern California and influence future-year energy consumption projections. This review helps us understand the amounts of energy being used, the associated costs, the historical and projected trends, and the energy-related emissions.

In this chapter, an overview of energy consumption within the District is presented for year 2008 and projected years 2014, 2019 and 2023. This review incorporates recent planning documents from other federal and state agencies, and utility providers. The review also utilizes information presented in other chapters and appendices of the 2012 AQMP. Finally, this chapter includes a discussion of the large benefits efficiency improvements provide and a discussion of the Basin's energy future to meet both criteria and pollutant GHG goals.

ENERGY CONSUMPTION INVENTORY AND PROJECTIONS

In 2008, the end use energy needs of the South Coast Basin were 2.1 quads (1 quadrillion [10^{15}] British Thermal Units) as shown in Figure 10-1. This is equivalent to 2% of the energy consumption within the U.S. The large majority of energy use in the South Coast Basin is devoted to transportation purposes as shown in Figure 10-2. This is the result of several factors related to the region's dense urban population, development structure, and economy. Southern California has two of the largest maritime ports in the United States that account for up to 40% of all U.S. container traffic. This goods movement system includes local distribution networks that require numerous diesel-powered trucks and trains. The Basin also has three large airports that involve both air and ground transportation. Most importantly Southern California is home to approximately 16 million residents that primarily rely on freeway and road infrastructure for mobility. As a result the largest energy use is gasoline consumption. As shown in Figure 10- 1, in 2008, 0.9 quads of gasoline were consumed in the South Coast Basin, approaching 50% of the total energy consumed. End use electricity consumption accounts for the second largest source of energy in Southern California, principally the result of commercial and residential usage.

FIGURE 10-1

Total End Use Energy Consumption in the South Coast Basin by Fuel Type in 2008 and Forecasted Energy Growth

*Natural Gas consumption does not include consumption for electricity generation. Future projections are discussed in each energy type category.

FIGURE 10-2

Share of Energy Use in South Coast Basin in 2008

*Transportation includes off-road sources

The energy usage in Southern California comes with a significant price tag. In 2008, over \$54 billion was spent on energy usage within the Basin. As shown in Figure 10-3, the energy usage is projected to grow relatively slowly and will reach slightly over 2.2 quads in 2023 (i.e., a 0.1 quad increase between 2008 and 2023). Unfortunately, Figure 10-4 shows that the cost of energy consumption within the Basin is projected to increase by 27% in 2023 to \$74 billion (EIA AEO, 2011).

FIGURE 10-3

Projected Basin Energy Usage Growth by Fuel Type Relative to 2008

FIGURE 10-4

Dollars Spent on Energy End Use in 2008 and Projected Years in the South Coast Basin

Note: Prices based on EIA Energy Outlook 2011 reference case for the Pacific except electricity (EIA AEO, 2011); electricity prices based on LADWP and SCE rates for 2008 and projected (CEC Energy Demand, 2009).

While transportation sources accounts for over 50% of the energy use, the majority of NO_x emissions are attributable to transportation sources (Figures 10-5 and 10-6). Within the transportation sector, the majority of the NO_x is emitted from diesel-powered vehicles. This is largely the result of years of effective stationary source and light-duty vehicle controls, the large numbers of vehicles in use, and the slow rate of fleet turnover for diesel-powered vehicles. Increased fleet turnover, fuel economy standards, diesel repowering and other state regulations are projected to lower NO_x emissions. However, these reductions are far from what is needed to achieve ozone standards. Figure 10-7 provides the corresponding data for PM_{2.5} emissions by fuel type. Similarly, the majority of PM_{2.5} emissions are attributable to transportation sources.

FIGURE 10-5

NOx Emissions in Tons per Day by Fuel Type

FIGURE 10-6

Percentage of NOx Emissions by Fuel Type

FIGURE 10-7
PM2.5 Emissions by Fuel Type

In 2008, the carbon dioxide emissions from fuel use were 134 MMT (million metric tons) in the Basin (Figure 10-8). This accounts for 32% of the total 421 MMT of carbon dioxide released in California in 2008 (CARB). The CO₂ emissions from fuel usage in Southern California are dominated by the use of transportation fuels. By 2023, emissions of carbon dioxide are projected to remain relatively flat. This is largely the result of programs and regulations being implemented in California and discussed in further sections.

The carbon dioxide emissions in Figure 10-8 were determined from fuel consumption data and future fuel consumption projections. Sector-specific carbon dioxide emissions can be found in Appendix III – Table F.

**FIGURE 10-8**

Carbon Dioxide Emissions by Fuel Type

*Natural Gas emissions include all combustion sources including electricity generation

Electricity Sources

Within the Basin in 2008, electricity end use accounted for 114,400 GWh of energy usage and 23% of the energy costs. While electricity generated within the Basin accounted for 26,000 GWh or 24% of the total electricity consumed in the Basin (CEC QFER). The generation mix for electricity produced within the Basin as of 2008 was mostly from natural gas fueled power plants (Figure 10-9) as it is for most of California; the majority of electricity in the U.S. derives from coal-fired power plants. As shown in Figure 10-9, the remaining supply of electricity into the Basin from Southern California Edison (SCE) and Los Angeles Department of Water and Power (LADWP) are likewise broken out to show percentages of their electricity from coal-powered plants in 2008. The percentages of power from coal between these two utilities have come down from 12% and 44% for SCE and LADWP to 7% and 39% in 2010 respectively (SB1305). SB 1368 (Perata, Chapter 598, 2006), and its implementing regulations by the CEC and CPUC, has explicit constraints on utilities regarding the development of new coal-powered facilities or contracts for coal-powered generation. Due to this legislation, and as the State's renewable portfolio standard and cap-and-trade program are implemented, the power procurement from coal will continue to decline through time.

FIGURE 10-9

Electricity Generating Mix by Type in 2008

*Wind and Solar not included in Basin generation renewable mix, location data not available;
 ** Includes large hydro not accounted in renewable and fossil derived co-generation

Basin Electricity Consumption

As stated above, total electricity consumption within the Basin was 114,400 GWh in 2008 and is predicted to grow to an estimated 123,600 GWh by 2020 as shown in Figure 10-10. This is determined from the net energy loads for L.A. Basin and LADWP service territories within the CEC California Energy Demand Forecast 2010-2020 (CEC Energy Demand Outlook, 2009). Electricity consumption is recovering from a recent decline due to the economic recession that began in 2008.

The projected electricity use within the Basin is estimated to grow an average of 0.5% per year until 2020. In 2008, \$12 billion was spent on end use electricity deliveries within the Basin. Using the projected electricity rates in the CA Demand Forecasts and anticipated electricity deliveries between SCE and LADWP, it is estimated that \$18 billion will be spent on electricity in the Basin in 2020.

**FIGURE 10-10**

Total Basin End Use Electricity Consumption and Projections
within the South Coast Basin

Electricity Consumption by Sector

The 2008 electricity consumption and future projections within the residential, industrial, and commercial source categories are shown in Figure 10-11 based on the SCE and LADWP service areas in the adopted CEC California energy demand forecasts and prices (CEC Energy Demand Outlook, 2009). These projections include electricity energy efficiency savings of 14,000 GWh in 2008, growing to an estimated 24,000 GWh in 2020. These savings are anticipated from new and existing appliance standards, building standards, and utility programs.

Electricity projections from these two utility service areas correspond closely, but not exactly, to the expected energy use in the Basin. For instance, total electricity consumption in the Basin in 2008 was 114,400 GWh as compared to 129,700 GWh in these service areas. These two utility service area demand forecasts include the local municipal utilities located within the Basin, except for electricity services provided by the Cities of Burbank, Glendale and Pasadena; individual source categories for these power providers were not available.

FIGURE 10-11

Electricity Consumption and Projections for LADWP and SCE Service Areas by Sector

RECENTLY IMPLEMENTED STATE REGULATIONS AND ELECTRICITY GENERATION

There are several state regulations that will impact the sources of electricity, the emissions of GHGs from electricity production, and the demand for repowered or new fossil-fueled plants in the future. These regulations were very recently implemented and represent a groundbreaking shift in how electricity is generated in California. The number of recently adopted regulations that affect the power sources in California, along with future conservation and efficiency programs, will significantly impact energy planning efforts in the future.

SBX 1-2 Renewable Portfolio Standard (RPS) – The expanded RPS was adopted in April 2011 and requires both publicly owned utilities and investor owned utilities to serve 33% of retail electricity sales with renewable generation sources by 2020. Compliance periods monitor the progress of procuring renewable power by California electricity-servicing utilities; the first period ending in 2013 requires utilities to have an average of 20% of sales from eligible renewables; by 2016, 25% must be from renewables; and then 33% by 2020 and beyond. Eligible renewable power sources

that meet the compliance requirements include photovoltaics, wind, geothermal, solar thermal, power from renewable fuels, and small hydroelectric less than 30 MW.

Adding large percentages of renewable power requires changes to the existing grid and generation requirements for fossil-fueled plants. Large solar power generation facilities in the desert areas have required new transmission lines, such as the San Diego Sunrise 500 kV line linking the Imperial Valley solar resources with the San Diego urban area demand. Other implications include providing ancillary services on the grid to account for the intermittency of some renewable power generation sources. New and existing fossil-fueled generation will need to provide some of these services since these generating sources can provide voltage support through inertia and fast ramp rates when needed. Storage technologies and pumped hydro may also help provide the needed ancillary services for supply stability.

Once-Through Cooling (OTC) – In May 2010, the State Water Resources Control Board adopted the Statewide Policy on the Use of Coastal and Estuarine Waters for Power Plant Cooling. This regulation places restrictions on the use of seawater for power plant cooling in order to protect marine life. Using billions of gallons of seawater to cool California’s power plants significantly harms the environment by killing marine life primarily on the lower end of the food chain as they are trapped against the intake screens or drawn into the power plant cooling system where they are exposed to high heat and pressure. In California, nineteen power plants are affected by this regulation. The plants may undertake several options to comply, including incorporating a 93% reduction in their seawater intake, screening, or switching to evaporative cooling, with certain exceptions given to the two nuclear generating facilities. The coastal plants affected by this regulation in Southern California include seven fossil fuel powered plants and the San Onofre Nuclear plant. These Southern California plants provide over 7,000 MW of generating capacity and have varying compliance dates under this regulation (Table 10-2). To comply with this regulation, some of the Southern California fossil-powered generation plants will need repowering and some units are planned for shutdown.

TABLE 10-2

Southern California Fossil-Fueled Power Plants affected by OTC

FACILITY	UNITS	TOTAL MW	OTC REPLACEMENT DATE
Alamitos, Long Beach	Boilers 1-6	1,950	2020
Huntington Beach	Boilers 1-4	880	2020
Redondo Beach	Boilers 5-8	1,310	2020
El Segundo	Boilers 3-4	670	2015
Haynes, Los Angeles	Boilers 1,2,5,6 Turbines 9,10	1,654	2029
Harbor, Los Angeles	Turbines 1,2	364	2029
Scattergood, Playa del Rey	Boilers 1-3	818	2024

SCAB Electricity Needs Assessment (AB-1318) – The passage of AB-1318 required the state power regulatory agencies, in conjunction with CARB, to conduct a needs assessment of electricity generation for the South Coast Basin. This analysis is also needed for implementing the OTC regulation, to determine how many plants will need to be repowered. This analysis is currently being conducted and initial estimates under several base case scenarios indicate the OTC regulation results in new generation needs of 2,400 MW. A draft report is expected in the summer of 2012.

Cap-and-Trade – The Global Warming Solutions Act of 2006 (AB-32) seeks to reduce GHG emissions in California to 1990 levels by 2020. Under the Governor’s Executive Order, an additional goal was established to reduce GHG emissions 80% below 1990 levels by 2050. To achieve the initial 2020 goal CARB has set forth a scoping plan that contains voluntary and regulatory measures to help reduce GHG emissions. One of these measures is to establish a cap on GHG emissions for the largest emitters in the state. The CARB cap-and-trade regulation was adopted in October 2011 and goes into effect in January 2013 for facilities with emissions greater than 25,000 MT CO₂e. This inclusion threshold encompasses most large fossil fueled generating plants. Additionally, the cap-and-trade program also applies to fuel providers and importers of electricity. Participants falling under this regulation must surrender allowances to meet their emissions over three-year compliance periods with some annual monitoring. Allowances under this program will be obtained through direct issuance, available through auctions; or may be partially obtained from allowable GHG offsets. Under this regulation, the electrical distribution utilities will

be given allowances that they must auction, the proceeds from these allowance auctions are then used to help isolate the electricity ratepayers from fee increases (§95892 Cap-and-Trade Regulation). How the utilities will use these proceeds may provide opportunities to further reduce consumption and incentivize clean power through incentives such as efficiency programs and appropriate distributed generation sources while also providing other co-benefits.

NATURAL GAS

Figure 10-12 shows the natural gas consumption by major customer end use categories, including the electricity generating sector, in the Southern California Gas Company’s service area within the District (consumption data and forecast provided by SoCal Gas Co.).

The decline of natural gas prices relative to liquid fuels will likely result in natural gas continuing to be a large component of California’s electricity production and increased usage as a transportation fuel. In addition, natural gas plants will help integrate renewables into the grid by providing peaking assistance, fast ramp rates and other ancillary services. The declining consumption forecast for natural gas in the commercial and industrial sectors is due to improved energy efficiency/conservation programs in place through the CEC and CPUC. This declining consumption is partially offset by a projected increased usage for transportation purposes.

FIGURE 10-12

Natural Gas Consumption in the Basin by Sector

TRANSPORTATION FUELS

The use of transportation fuels in Southern California as shown previously in Figures 10-6 and 10-7 accounts for the majority of NO_x emissions and fuel-related emissions of fine particulate. Diesel fuel use in Southern California is dominated by on-road heavy-duty diesel vehicles. Overall usage of transportation fuels in the Basin is slightly over a staggering 10 billion gallons annually (Figures 10-13 and 10-14).

FIGURE 10-13

Consumption of Transportation Fuels in the Basin in 2008 and Projected Years

FIGURE 10-14

Fuel Consumption by Type

Fuel consumption figures for transportation fuels were obtained from several sources. The on-road portions of diesel and gasoline vehicles were obtained from the annual average emissions in Appendix III within attachment D. An estimation of the jet fuel consumption within the Basin was determined using the EIA sales to California for 2008 and adjusting for the Basin consumption using the NO_x inventory for the Basin relative to the State, then projected to future years using the inventory in Appendix III (CARB Almanac). The diesel consumption estimates for ocean-going vessels were limited to the 100 nm regulatory zone for the Basin ports (CARB OGV). The consumption figures estimated for trains were determined using consumption numbers developed in 2004 for South Coast and grown using inventory numbers for future years (CARB). Other off-road users of diesel were determined from CARB's OFFROAD model.

EFFICIENCY IMPACTS ON ENERGY USE

Energy efficiency is an increasingly important strategy in reducing impacts from volatile and rising energy prices. For example, in 2008 the South Coast Basin consumed over 10 billion gallons of gasoline at a cost of over \$26 billion dollars. Unfortunately, the typical gasoline fueled vehicle utilizes, at best, 20% of the energy contained in a gallon of gasoline for propulsion (fueleconomy.gov). The remaining 80% of the energy content of gasoline is mostly wasted as heat. Small changes in the fuel efficiency of gasoline vehicles can have major impacts on the amount of gasoline consumed and money spent while also providing major emission reductions.

Other benefits of implementing efficiency projects include helping to minimize strains on existing infrastructure, providing positive environmental impacts, helping to promote economic growth, and providing job opportunities. Although the term energy efficiency is often used interchangeably with energy conservation, there are key differences. Energy conservation techniques typically involve reducing the “level of service” consumers derive from energy usage, such as raising thermostat levels in the summer or driving less by foregoing leisure travel. Conservation measures are typically behavior based and more difficult to rely on for meeting a specific air quality or climate objective. Energy efficiency, on the other hand, means obtaining the same level of service while using less energy. An example of an energy efficiency project might be installing a high efficiency air conditioning unit as a replacement for an older less efficient one. The consumer is still obtaining the benefit of a cool house, but

uses less electricity, requiring less power generated, and thus less pollution from such power plants.

In California, incentive funding administered by the CPUC and distributed to ratepayers through utilities for efficiency projects has helped alleviate the need for new power plants while also reducing the infrastructure needs for energy distribution. Since 2010 these efficiency incentives in the South Coast Basin have reduced 3.8 million GWh of electricity and 71,000 MMBTU of natural gas (<http://eega.cpuc.ca.gov/Default.aspx>) consumption, resulting in a reduction of 1.4 million MT of CO₂ from being released into the atmosphere (equivalent to the combustion of 154 million gallons of gasoline) and energy cost savings of well over half a billion dollars (based on \$0.10/kWh and \$2/therm). In addition to energy cost savings, these efficiency projects have reduced criteria pollutant emissions such as PM and NO_x. Other efficiency requirements, such as the Title 24 building standards for residential and non-residential buildings, have saved an estimated \$66 billion in energy costs since 1978. These efforts have helped California's per-capita energy consumption to remain relatively flat since 1973 while the U.S. per-capita consumption has increased over 60% during this time (CEC per capita).

Globally there is an increase in energy use and demand as emerging markets further develop and thus, global energy markets are becoming increasingly volatile. Addressing energy issues through policy and technology improvements is a lengthy process, combining scientific, engineering, economic, social, and political elements that take long periods of time to develop and implement. However, implementing efficiency measures provides for actions that can be taken quickly and provide several immediate benefits. These benefits include emission reductions from electricity generation or process equipment and typically have quick payback periods given the energy cost savings.

Example: Manufacturing, Industrial and Commercial Boilers

The manufacturing and industrial sectors have significant opportunities for additional efficiency gains that can be captured as a compliance strategy for NO_x and GHG reductions. These two sectors account for 20% of energy end use in the United States and 23% within California (IEA). It is estimated that 4.7-7.7 quads of energy can be saved in the United States by 2020 in these sectors through efficiency measures that have rates of return from energy savings of at least 10% (NAS). Of the equipment

within these sectors, boilers account for the largest sources of energy consumption. Efficiency improvements on boilers often have higher initial capital costs but result in quick payback from energy savings. Table 10-3 shows a partial list of efficiency improvements, which when properly applied, have payback periods of less than two years (DOE; Itron).

TABLE 10-3
High Impact Efficiency Measures for Boilers

NATURAL GAS BOILER EFFICIENCY MEASURE	DESCRIPTION	POTENTIAL EFFICIENCY GAIN
Reduce Steam Demand	Optimize process steam requirements	High
Maintenance	Maintain burners and condensate return systems, clean heat transfer surfaces, use proper water treatment, steam trap maintenance	>30%
Economizer	Flue gas heat used to preheat feed water	4-8%
Burner Efficiency	Oxygen trim systems to optimize air-fuel mixture, new burners	2-5%
Load Control	Optimize use of several boilers	3-5%
Improved Insulation	Improving insulation (type, thickness, quality)	6-26%
Scheduling	Optimizing boiler usage	2-8%

Boilers have widespread use to produce steam and provide hot water for industrial processes and commercial buildings. Because boilers are large consumers of fuel, primarily natural gas in Southern California, there are numerous opportunities to implement efficiency measures with quick payback periods from reduced energy use. Nearly 49% of fuel consumed by U.S. manufacturers is used for steam processes (http://www1.eere.energy.gov/manufacturing/tech_deployment/steam.html). In the South Coast Basin there are over 2,000 boilers ranging in size from 5 to greater than 50 MMBtu/hr with an average age greater than 14 years old which consumed 143,000 mmscf of natural gas (2008). This accounts for 20% of natural gas consumed within the South Coast Basin. Figure 10-15 below shows energy usage in 2008 from boilers was 143,000 mmscf of natural gas at a cost of \$1.23 billion dollars. This resulted in emissions of 870 tons of NO_x and 8 million MT of CO₂. (<http://info.ornl.gov/sites/publications/files/Pub25191.pdf>).

FIGURE 10-15

Boiler Energy Usage within the Basin

Note: Current estimated energy use projections accounting for existing efficiency programs and an accelerated one percent per year efficiency increase above projection.

Efficiency programs already in place are projected to decrease the natural gas consumption used in boilers as shown in Figure 10-15. If these efficiency measures can be enhanced to achieve an additional one percent efficiency gain per year, the resulting savings in 2023 will be 16,000 mmscf. This would result in a yearly savings of \$140 million, prevent 87,000 MT of CO₂ emissions, and produce reductions in criteria pollutant emissions.

Waste Heat Recovery

Additional efficiencies can be gained in the commercial, manufacturing and industrial sectors through utilizing waste heat recovery. There are widespread applications of waste heat recovery in the commercial, industrial and manufacturing sectors. Applying waste heat recovery systems can provide a holistic approach to energy use. Some technical approaches to waste heat recovery include the following:

Combined Heat and Power (CHP) - Utilizing CHP takes advantage of both electricity production and thermal energy from one energy source. Efficiency benefits of CHP systems can be achieved through utilizing waste heat of electricity production from small generating sources like a fuel cell or micro turbine to increase the efficiency of another thermal process such as preheating boiler feed water. Combined systems can

achieve overall thermal efficiencies greater than 90%. Certain steam industrial applications may benefit from generating power directly from their steam production using a high pressure steam boiler coupled with a turbine. In California, currently 8,444 MW are online from approximately 1,000 CHP systems (ICF database). In Southern California some of the largest generators of electricity are utilizing waste heat to generate electricity (CEC QFER, large kWh from refinery CHPs).

Waste Heat to Cooling or Refrigeration - Waste heat may also be used to help with cooling or refrigeration needs utilizing absorption chillers.

Heat to Heat – Some applications can use waste heat to supplement another heating process such as supplementing space heating requirements or utilizing an economizer to preheat feed water.

Available Tools to Develop Projects

The DOE has developed a suite of software tools to evaluate existing boiler systems and provide benefit estimates from a suite of efficiency and performance tools. Other resources such as energy assessments on specific industries, best practices, and literature resources are available at the DOE Advanced Manufacturing website (http://www1.eere.energy.gov/manufacturing/tech_deployment/steam.html). The providing local utilities also offer technical assistance in developing efficiency projects.

EFFICIENCY INCENTIVES AND FINANCING

There are many business reasons for undertaking efficiency projects, including rising energy prices, high demand use charges, environmental concerns and regulations, increased productivity, and business sustainability. Despite these strong business cases and potentially short payback periods for capital investments, financing and incentives are necessary to help implement efficiency projects (AP NORC). Implementing efficiency projects on industrial applications often requires a large initial capital outlay, time to implement the project, and personnel to administer the project. Often the largest hurdle is securing the initial capital to undertake the project. Providing efficiency incentives and loan programs can help overcome the limited capital improvement budgets that businesses have for such projects. Additionally, incentive programs also can provide funding and technical assistance in developing a project which also helps limit staff hours allocated to these projects. Incentives

available for efficiency projects include direct rebate incentives often administered through the local utility, tax incentives, and favorable loan terms. Some resources to find available incentives include:

- Flex Your Power: www.fypower.org
- CEC low-interest loans for energy efficiency projects:
www.energy.ca.gov/efficiency/financing/index.html
- Energy Star: http://www.energystar.gov/index.cfm?c=tax_credits.tx_index
- WRCOG HERO program: <http://herofinancing.com/HEROFinancing/>

SOUTHERN CALIFORNIA'S ENERGY FUTURE

The energy use projections presented above represent a base case scenario of energy use in the South Coast Basin in the near future. The control measures proposed as SIP commitments for the PM_{2.5} attainment and progress toward the ozone standard do not in themselves cause substantial change in current energy consumption. However, in order to meet the ozone standards and GHG goals, energy consumption related NO_x and carbon emissions would need to be reduced. In the transportation sector, fleet turnover along with newer emission control designs will help reduce criteria pollutants from this sector but as shown in Figure 10-5 these reductions alone will not be enough to meet federal ozone standards by the 2023 deadline.

To greatly impact energy usage, attain healthful air quality levels, and meet the 2050 climate change goals, significant technology shifts are needed in the transportation sector, including efficiency shifts and increased renewable sources of energy, especially for electricity production.

Transportation and goods movement are our largest energy consumption sectors, responsible for 80% of NO_x emissions and 70% of the CO₂. The majority of our transportation and goods movement activities rely on the internal combustion engine, which has dominated these sectors for well over the past hundred years and is inherently energy inefficient. Reliance on internal combustion engines results in a vehicle fleet that utilizes only 20% of the gasoline energy consumed for mobility while the rest is lost primarily to wasted heat. From the over \$26 billion spent on gasoline in 2008 within the South Coast Basin, this significant inefficiency means over \$20 billion in gasoline costs was wasted as unused heat. On a national level in 2008, \$455 billion was spent on gasoline, thus wasting \$364 billion dollars as unused heat. Other transportation fuels for the most part have a slightly higher efficiency than gasoline; however, a similar situation applies, resulting in the vast majority of the

fuel being wasted as heat. This wastefulness in transportation fuels represents a dramatic opportunity for efficiency increases in the transportation and goods movement sector that would reduce criteria and toxic pollutant emissions, GHG emissions and provide many other co-benefits.

Currently, emerging global markets are developing infrastructures reliant on existing transportation technologies. As these are implemented, more people globally are being exposed to the same transportation-related emissions and will encounter the negative effects of volatile energy prices. It will not take long for the cost benefits of a cleaner more efficient transportation system to be realized, especially when looking at the energy cost savings. The business-as-usual scenario without these changes may cause significant increases and will certainly delay decreases in air pollution related health problems as the population increases, both in California and the rest of the world.

New fuel economy standards will eventually help improve the effectiveness of transportation fuels in providing mobility. More transportation choices are coming into the marketplace providing higher efficiencies that utilize electricity either solely or in hybrid applications. In the jointly developed Vision for Clean Air: A Framework for Air Quality and Climate Planning, information is presented that shows the benefits of implementing these new technologies and renewable energy sources.

As outlined earlier, more renewable power sources will be put online as utilities work toward meeting their obligations under the Renewable Portfolio Standard. Coupling renewable electricity sources with transportation can mean large reductions in the total amount of energy spent for transportation, provide emission reductions in all areas, and support energy independence along with buffering from increasingly volatile transportation fuel prices. Under AB32, there is also a need to implement renewable sources of transportation fuels which would help with GHG reductions.

Transformation of the Energy Sector

The recent shutdown of the San Onofre Nuclear Generating Station has required temporary return to service of two units at the Huntington Beach natural gas plant which had been voluntarily shut down. This event demonstrates the vulnerabilities in the current energy planning process. The planning and investments in the energy infrastructure must consider reliability; reductions in criteria pollutants, air toxics, and greenhouse gases; provide energy security, energy diversity, and energy cost

certainty. The transformation of the energy sector to maximize these co-benefits can start with:

- Coordinated planning efforts – Agencies such as the CEC, CPUC, CARB, AQMD, EPA, and CalISO need to be working closely together in planning and regulatory efforts. A holistic, integrated approach, considering the objectives, constraints, and legal responsibilities of all agencies, needs to be addressed. Regulations and actions by one agency can negatively impact the other agencies. A coordinated planning strategy would not only help to avoid such conflicts, but also identify synergies whereby the goals of multiple agencies could be furthered simultaneously.
- Scheduling for infrastructure and technology needs – New and existing mobile source technologies can provide a more efficient means of mobility and goods movement. Implementing these technologies requires the supporting energy infrastructure to allow acceptance and greater use, similar to the Actions to Deploy Advanced Control Technologies (ADV) measures in Chapter 4 and Appendix IV-B. These efforts should also be implemented in a coordinated manner with multi-agency participation and support.

To achieve these planning objectives, the District will enhance its outreach and coordination efforts with the appropriate state and federal agencies. Through scheduled public hearing testimony, as well as meetings, conferences, workshops, and the formation of interagency working groups, the District desires to help catalyze the coordinated planning efforts that are needed to achieve air quality, climate and energy goals.

Chapter 11 **Public Process and Participation**

South Coast Air Quality Management District

Cleaning the air that we breathe...

CHAPTER 11

PUBLIC PROCESS AND PARTICIPATION

Introduction

Outreach Program

Outreach Results

Summary of Outreach Activities

INTRODUCTION

The development of the 2012 AQMP has been a regional and multi-agency effort including the District Governing Board, CARB, SCAG, and U.S. EPA. The AQMP includes control strategies and contingency measures that demonstrate attainment with NAAQS by specified deadlines. The 2012 AQMP incorporates the latest scientific and technological information and planning assumptions, including SCAG's 2012 Regional Transportation Plan/Sustainable Communities Strategy, an updated emission inventory and modeling methodologies for various source categories.

A 2012 AQMP Advisory Group was formed to provide feedback and recommendations on the development of the plan, including policy and control measure strategies. The Advisory Group represents a diverse cross section of stakeholders such as large and small businesses, government agencies, environmental and community groups, and academia. In addition, a Scientific, Technical, and Modeling Peer Review (STMPR) Advisory Group convened to make recommendations on air quality modeling, emissions inventory and socioeconomic modeling and analysis. Both Advisory Groups meet monthly throughout the AQMP development process and those meetings have been open to the public. There has been ongoing close coordination between U.S. EPA, CARB, SCAG and AQMD staff on all elements of AQMP development.

The 2012 AQMP Outreach Program is designed to go above and beyond the usual Advisory Group, public workshop and public hearing mandates in order to more broadly disseminate information and engage a wider range of stakeholders. The approach aims to achieve multiple goals, such as:

- Reach a broader and more diverse audience
- Ensure greater transparency in the process
- Facilitate greater participation and engagement
- Develop partnerships with stakeholder groups

The outreach approach has been designed to help formulate the policy debate by ensuring all stakeholders share a common set of essential facts, understand the federal requirements, and thus have adequate information to make informed comments on the AQMP.

The clean air goals in the 2012 AQMP will not be achieved solely by the actions of the District. The proposed control strategy will require participation from affected businesses, local communities, and government agencies. Achieving the mutual goals of

protecting public health, providing environmental equity and promoting robust and sustainable economic development can only be accomplished through strong partnerships. Thus, it was critical to inform and engage a wide range of stakeholders on the requirements, approach, goals, and impacts of the 2012 AQMP.

OUTREACH PROGRAM

Audience

Stakeholders for the 2012 AQMP include community members, businesses, trade associations, environmental organizations, health advocates and local, regional, state and federal governmental entities. Table 11-1 lists specific stakeholder groups targeted for outreach efforts. The stakeholders were notified of all Advisory Group meetings, workshops and hearings, as well as invited to participate in various activities designed to assist in the communication and development of the 2012 AQMP.

TABLE 11-1

Stakeholders Targeted for Outreach Efforts

Public Agencies	<ul style="list-style-type: none"> • CARB • California Energy Commission • California Public Utility Commission • California ISO • CalWaste • U.S. EPA • U.S. Department of Transportation • U.S. Department of Energy
Local/Regional Government	<ul style="list-style-type: none"> • Councils of Governments • SCAG • Transportation Commissions • Local Planning Departments • Building and Fire Departments • Tribal Governments

TABLE 11-1 (concluded)
Stakeholders Targeted for Outreach Efforts

Special Districts	<ul style="list-style-type: none"> • School Districts • Sanitation Districts • Water Districts
Health Advocates	<ul style="list-style-type: none"> • Medical Practitioners • Health Researchers • Health Providers
Community/Health/Environmental Groups	<ul style="list-style-type: none"> • Public Health Departments • Environmental Justice Organizations • Environmental Advocacy Groups • Faith-based Organizations • Labor Organizations
Academia	<ul style="list-style-type: none"> • Universities • National Laboratories
Business	<ul style="list-style-type: none"> • Energy Industry (Electricity, Petroleum Refining, Natural Gas, Biofuels, Renewables, etc.) • Green Technologies • Goods Movement and Logistics (Warehousing, Trucking, Railroads, Ports) • Dairy Operations • Printing/Coating Industry • Airport/Airline Operations • Engine Technologies • After-treatment Technologies • Building and Construction Industry • Chambers of Commerce/ Business Councils • Small Businesses

Format

A variety of formats and communication outreach methods were utilized as part of the Outreach Program. The format used for specific activities were tailored to the particular audience or venue where information was being presented and discussed.

Formats and methods include:

- AQMD Advisory Groups and Committee meetings
- Workshops
- Air Quality Institutes
- Open houses and community meetings
- Panel discussions
- Conference calls
- Invited presentations at conferences, seminars, board/council meetings, etc.
- Printed materials such as the Advisor newsletter and collaterals
- Dissemination of information through stakeholder newsletters, websites and other communication tools
- Clean Air Connection email blasts
- Distribution at the AQMD Public Information Center
- AQMD website including postings and links from partner organizations
- Social media
- Telephone “hold” message
- Radio telephone operators

Outreach Activities

As in previous AQMPs, multiple public workshops will be held throughout the District. Mandatory public hearings will also be held as required. In addition, the following specific activities are planned to fulfill the goals of the Outreach Program:

- Key agency coordination meetings (CARB, US EPA, SCAG)
- Local stakeholder meetings
- Topical workshops
- Public agency engagement (CEC, CPUC, solid waste agencies, sanitation districts, transportation agencies, etc.)
- Focus groups
- Peer review
- General public outreach

Key Agency Coordination Meetings

Throughout the 2012 AQMP development process, staff has and continues to hold frequent coordination meetings with the key AQMP partner agencies (CARB, US EPA and SCAG). Meetings occurred several times per month to raise and discuss technical and control strategy issues.

Local Stakeholder Meetings

Meetings with specific stakeholder groups have been held to communicate the purpose and scope of the 2012 AQMP, discuss the concerns of the representatives, solicit recommendations for inclusion, and gather further outreach suggestions. Stakeholders include all those listed in Table 13-1, such as regional council of governments (COGs), county transportation commissions, labor organizations, Chambers of Commerce, business councils, trade groups and associations, environmental and health advocates, community groups, and faith-based organizations. Outreach methods included agendized AQMD presentations at COGs, participation at conferences and seminars, and face-to-face meetings as requested.

Topical Workshops

In addition to the regional workshops/hearings, topical workshops have been held to focus on specific AQMP related topics such as economics, incentives, employment impacts, health benefits, modeling issues, climate/energy, transportation, environmental justice, and goods movement. Attendance at the public workshops has been comprised of experts and interested parties from various stakeholder groups, but focused on a particular aspect of the AQMP. These topical workshops provided a forum where different opinions on specific topics could be shared and discussed.

Focus Groups

Focus groups have been formed to address specific issues including the evaluation and development of the emission inventory and certain control measures. The control measure topics included, but were not limited to, coatings and solvents, petroleum operations, combustion sources, energy, transportation, mobile sources and incentive programs. The focus groups were comprised of experts for the particular inventory or control technology under evaluation, including equipment manufacturers and suppliers. The focus groups met as often as necessary to provide any recommendations.

Peer Review

In addition to the feedback provided by the 2012 AQMP Advisory Group and the STMPR Advisory Group, additional expert peer review of specific 2012 AQMP components has been sought. One specific example is the focused peer review of the socioeconomic/health impacts and a cost-benefit analysis of the 2012 AQMP and associated control strategy. Another review was focused on modeling methods and assumptions, including growth and emissions projections. Expert reviewers were from a diverse range of institutions and perspectives. All results of the peer reviews have and will be made public to ensure full transparency and open discussion of any issues raised.

General Public Outreach

The 2012 AQMP has been included in the District's extensive community outreach activities – including, but not limited to events, community forums and other meetings – to promote better public awareness of its purpose and significance. Non-technical brochures have been created and distributed at events at which AQMD participates. Furthermore, web-based and social media communication tools have been utilized to distribute AQMP information and provide an opportunity for interactive feedback.

OUTREACH RESULTS

As of the release of the Draft Final 2012 AQMP, twenty-two (22) Focus Groups convened, including: Ports of LA and Long Beach, CCEEB, The Gas Company, SoCal Edison, Regulatory Flexibility Group, Sanitation Districts (4 counties), Manufacturer's of Emission Control Association (MECA), Construction Industry Air Quality Coalition (CIAQC), American Coatings Association, Environmental and Health Community, the Environmental Justice Advisory Group (EJAG), Western States Petroleum Association (WSPA), Home Rule Advisory Group (HRAG), Compost/Greenwaste Processing/Composting, Mobile Source Committee, and Mira Loma Focus Group.

Seven (7) topical workshops took place with: Technology Symposium, Transportation Research Board, Independent Lubricant Manufacturing Association (ILMA), Valley Green Building Education Conference and Expo, and AQMD Student Interns.

Eight (8) meetings with key agencies were coordinated with: SCAG, CARB, U.S. EPA, and San Joaquin Valley APCD (SJVAPCD).

Thirty-eight (38) meetings with local stakeholders occurred with: WRCOG (Executive Council), Santa Monica City Council Task Force on the Environment, LA Chamber of Commerce (Energy, Water and Environmental), WRCOG (Technical Advisory Committee), Valley Industrial Commerce Association (VICA), ALA/Inland Empire Air Quality Committee, Inland Action Committee, Loma Linda Chamber of Commerce, San Gabriel Valley Economic Partnership (Legislative Action), SCAG (Energy and Environment), San Fernando Valley COG, STEM Learning Institute, San Bernardino Association of Governments (Major Projects), Orange County COG, San Gabriel Valley COG (Energy, Environment and Natural Resources), South Bay Cities COG, Gateway COG, SCAG (Regional Council), City of Los Angeles, Orange County (OC) COG Technical Advisory Committee, OC Business Council, U.S. Forest Service, Jurupa Valley Parks/ Chamber of Commerce/ Rotary Club, DWP, SoCal Edison, SoCal Gas, Department of Housing and Community Development, City of Redondo Beach, AEP, Environmental Groups, BizFed, SCAG GLUE Council, Association of CA Cities of Orange County (ACCOG), Assembly Budget Committee/ Assemblymember Blumenfield's office, and Inland Action Committee.

Approximately 65 presentations were given regarding the development of 2012 AQMP.

SUMMARY OF OUTREACH ACTIVITIES

Table 11-2 provides the specific efforts conducted to implement the outreach program for the 2012 AQMP. The table provides the outreach format (e.g., an air quality institute, key agency coordination meeting, etc.), the date the activity took place, with what organization(s), what was discussed or accomplished, and the type of activity (e.g., conference, meeting, presentation, etc.). In addition to meeting and giving presentations, AQMD staff also attended a number of meetings conducted by other organizations (e.g., cities, councils of government, chambers, etc.) where a brief announcement regarding the 2012 AQMP was made. These types of announcement include any information in regards to the date, time and location of the next AQMP Advisory meeting or the latest status in the development of the 2012 AQMP. That list is provided in Table 11-3.

Glossary

South Coast Air Quality Management District
Cleaning the air that we breathe...

GLOSSARY

GLOSSARY

AAQS (Ambient Air Quality Standards): Health and welfare based standards for clean outdoor air that identify the maximum acceptable average concentrations of air pollutants during a specified period of time. (See NAAQS)

Acute Health Effect: An adverse health effect that occurs over a relatively short period of time (e.g., minutes or hours).

Aerosol: Particles of solid or liquid matter that can remain suspended in air for long periods of time because of their small size and light weight.

Air Pollutants: Amounts of foreign and/or natural substances occurring in the atmosphere that may result in adverse effects on humans, animals, vegetation, and/or materials.

Air Quality Simulation Model: A computer program that simulates the transport, dispersion, and transformation of compounds emitted into the air and can project the relationship between emissions and air quality.

Air Toxics: A generic term referring to a harmful chemical or group of chemicals in the air. Typically, substances that are especially harmful to health, such as those considered under EPA's hazardous air pollutant program or California's AB 1807 toxic air contaminant program, are considered to be air toxics. Technically, any compound that is in the air and has the potential to produce adverse health effects is an air toxic.

Airborne Toxic Control Measure (ATCM): A type of control measure, adopted by the CARB (Health and Safety Code Section 39666 et seq.), which reduces emissions of toxic air contaminants from nonvehicular sources.

Alternative Fuels: Fuels such as methanol, ethanol, hydrogen, natural gas, and liquid propane gas that are cleaner burning and help to meet mobile and stationary emission standards.

Ambient Air: The air occurring at a particular time and place outside of structures. Often used interchangeably with "outdoor" air.

APCD (Air Pollution Control District): A county agency with authority to regulate stationary, indirect, and area sources of air pollution (e.g., power plants, highway construction, and housing developments) within a given county, and governed by a district air pollution control board composed of the elected county supervisors and in most cases, representatives of cities within the district.

AQMD (Air Quality Management District): A group or portions of counties, or an individual county specified in law with authority to regulate stationary, indirect, and area sources of air pollution within the region and governed by a regional air pollution control board comprised mostly of elected officials from within the region.

AQMP (Air Quality Management Plan): A Plan prepared by an APCD/AQMD, for a county or region designated as a nonattainment area, for the purpose of bringing the area into compliance with the requirements of the national and/or California Ambient Air Quality Standards. AQMPs designed to attain national ambient air quality standards are incorporated into the State Implementation Plan (SIP).

Area-wide Sources (also known as "area" sources): Smaller sources of pollution, including permitted sources smaller than the districts's emission reportin threshold and those that do not receive permits (e.g. water heaters, gas furnace, fireplaces, woodstoves, architectural coatings) that often are typically associated with homes and non-industrial sources. The CCAA requires districts to include area sources in the development and implementation of the AQMPs.

Atmosphere: The gaseous mass or envelope surrounding the earth.

Attainment Area: A geographic area which is in compliance with the National and/or California Ambient Air Quality Standards (NAAQS OR CAAQS).

Attainment Plan: In general, a plan that details the emission reducing control measures and their implementation schedule necessary to attain air quality standards. In particular, the federal Clean Air Act requires attainment plans for nonattainment areas; these plans must meet several requirements, including requirements related to enforceability and adoption deadlines.

BACT (Best Available Control Technology): The most up-to-date methods, systems, techniques, and production processes available to achieve the greatest feasible emission reductions for given regulated air pollutants and processes. BACT is a requirement of NSR (New Source Review) and PSD (Prevention of Significant Deterioration). BACT as used in federal law under PSD applies to permits for sources of attainment pollutants and other regulated pollutants is defined as an emission limitation based on the maximum degree of emissions reductions allowable taking into account energy, environmental & economic impacts and other costs. [(CAA Section 169(3)]. The term BACT as used in state law means an emission limitation that will achieve the lowest achievable emission rates, which means the most stringent of either the most stringent emission limits contained in the SIP for the class or category of source, (unless it is demonstrated that the limitation is not achievable) or the most stringent emission limit

achieved in practice by that class in category of source. “BACT” under state law is more stringent than federal BACT and is equivalent to federal LAER (lowest achievable emission rate) which applies to nonattainmentNSR permit actions.

BAR (Bureau of Automotive Repair): An agency of the California Department of Consumer Affairs that manages the implementation of the motor vehicle Inspection and Maintenance Program.

CAA (Federal Clean Air Act): A federal law passed in 1970 and amended in 1977 and 1990 which forms the basis for the national air pollution control effort. Basic elements of the act include national ambient air quality standards for major air pollutants, air toxics standards, acid rain control measures, and enforcement provisions.

CAAQS (California Ambient Air Quality Standards): Standards set by the State of California for the maximum levels of air pollutants which can exist in the outdoor air without unacceptable effects on human health or the public welfare. These are more stringent than NAAQS.

CARB (California Air Resources Board): The State's lead air quality agency, consisting of a nine-member Governor-appointed board. It is responsible for attainment and maintenance of the State and federal air quality standards, and is primarily responsible for motor vehicle pollution control. It oversees county and regional air pollution management programs.

CCAA (California Clean Air Act): A California law passed in 1988 which provides the basis for air quality planning and regulation independent of federal regulations. A major element of the Act is the requirement that local APCDs/AQMDs in violation of state ambient air quality standards must prepare attainment plans which identify air quality problems, causes, trends, and actions to be taken to attain and maintain California's air quality standards by the earliest practicable date.

CEQA (California Environmental Quality Act): A California law which sets forth a process for public agencies to make informed decisions on discretionary project approvals. The process aids decision makers to determine whether any environmental impacts are associated with a proposed project. It requires significant environmental impacts associated with a proposed project to be identified, disclosed, and mitigated to the maximum extent feasible.

CFCs (Chlorofluorocarbons): Any of a number of substances consisting of chlorine, fluorine, and carbon. CFCs are used for refrigeration, foam packaging, solvents, and propellants. They have been found to cause depletion of the atmosphere's ozone layer.

Chronic Health Effect: An adverse health effect which occurs over a relatively long period of time (e.g., months or years).

CO (Carbon Monoxide): A colorless, odorless gas resulting from the incomplete combustion of fossil fuels. Over 80% of the CO emitted in urban areas is contributed by mobile sources. CO interferes with the blood's ability to carry oxygen to the body's tissues and results in numerous adverse health effects. CO is a criteria air pollutant.

Community Multiscale Air Quality Model (CMAQ): A computer modeling system designed to address air quality as a whole by including state-of-the-science capabilities for modeling multiple air quality issues, including tropospheric ozone, fine particles, toxics, acid deposition, and visibility degradation.

Comprehensive Air Quality Model with Extensions (CAMx): An open-source modeling system for multi-scale integrated assessment of gaseous and particulate air pollution.

Conformity: Conformity is a process mandated in the federal Clean Air Act to insure that federal actions do not impede attainment of the federal health standards. General conformity sets out a process that requires federal agencies to demonstrate that their actions are air quality neutral or beneficial. Transportation conformity sets out a process that requires transportation projects that receive federal funding, approvals or permits to demonstrate that their actions are air quality neutral or beneficial and meet specified emissions budgets in the SIP.

Congestion Management Program: A state mandated program (Government Code Section 65089a) that requires each county to prepare a plan to relieve congestion and reduce air pollution.

Consumer Products: Products for consumer or industrial uses such as detergents, cleaning compounds, polishes, lawn and garden products, personal care products, and automotive specialty products which are part of our everyday lives and, through consumer use, may produce air emissions which contribute to air pollution.

Contingency Measure: Contingency measures are statute-required back-up control measures to be implemented in the event of specific conditions. These conditions can include failure to meet interim milestone emission reduction targets or failure to attain the standard by the statutory attainment date. Both state and federal Clean Air Acts require that District plans include contingency measures.

Electric Motor Vehicle: A motor vehicle which uses a battery-powered electric motor as the basis of its operation. Such vehicles emit virtually no air pollutants. Hybrid electric

motor vehicles may operate using both electric and gasoline powered motors. Emissions from hybrid electric motor vehicles are also substantially lower than conventionally powered motor vehicles.

EMFAC: The EMISSION FACTOR model used by CARB to calculate on-road mobile vehicle emissions. The 2012 AQMP is based on the latest version, EMFAC2011.

Emission Inventory: An estimate of the amount of pollutants emitted from mobile and stationary sources into the atmosphere over a specific period such as a day or a year.

Emission Offset (also known as an emission trade-off): A regulatory requirement whereby approval of a new or modified stationary source of air pollution is conditional on the reduction of emissions from other existing stationary sources of air pollution or banked reductions. These reductions are required in addition to reductions required by BACT.

Emission Standard: The maximum amount of a pollutant that is allowed to be discharged from a polluting source such as an automobile or smoke stack.

FIP (Federal Implementation Plan): In the absence of an approved State Implementation Plan (SIP), a plan prepared by the EPA which provides measures that nonattainment areas must take to meet the requirements of the Federal Clean Air Act.

Fugitive Dust: Dust particles which are introduced into the air through certain activities such as soil cultivation, off-road vehicles, or any vehicles operating on open fields or dirt roadways.

Goods Movement: An event that causes movement of commercial materials or stock typically at ports, airports, railways, highways, including dedicated truck lanes and logistics centers.

Greenhouse Gases (GHGs): A gas in an atmosphere that absorbs long-wave radiant energy reflected by the earth, which warms the atmosphere. GHGs also radiate long-wave radiation both upward to space and back down toward the surface of the earth. The downward part of this long-wave radiation absorbed by the atmosphere is known as the “greenhouse effect.”

Growth Management Plan: A plan for a given geographical region containing demographic projections (i.e., housing units, employment, and population) through some specified point in time, and which provides recommendations for local governments to better manage growth and reduce projected environmental impacts.

Hybrid Electric Vehicles (HEV): Hybrids commercially available today combine an internal combustion engine with a battery and electric motor.

Hydrocarbon: Any of a large number of compounds containing various combinations of hydrogen and carbon atoms. They may be emitted into the air as a result of fossil fuel combustion, fuel volatilization, and solvent use, and are a major contributor to smog. (Also see VOC)

Hydrogen Fuel Cell Vehicles (HFCV): Vehicles that produce zero tailpipe emissions and run on compressed hydrogen fed into a fuel cell "stack" that produces electricity to power the vehicle.

Incentives – tax credits, financial rebates/discounts, or non-monetary conveniences offered to encourage further use of advanced technology and alternative fuels for stationary and mobile sources.

Indirect Source: Any facility, building, structure, or installation, or combination thereof, which generates or attracts mobile source activity that results in emissions of any pollutant (or precursor). Examples of indirect sources include employment sites, shopping centers, sports facilities, housing developments, airports, commercial and industrial development, and parking lots and garages.

Indirect Source Control Program: Rules, regulations, local ordinances and land use controls, and other regulatory strategies of air pollution control districts or local governments used to control or reduce emissions associated with new and existing indirect sources.

Inspection and Maintenance Program: A motor vehicle inspection program implemented by the BAR. It is designed to identify vehicles in need of maintenance and to assure the effectiveness of their emission control systems on a biennial basis. Enacted in 1979 and strengthened in 1990. (Also known as the "Smog Check" program.)

Low Emission Vehicle (LEV): A vehicle which is certified to meet the CARB 1994 emission standards for low emission vehicles.

Maintenance Plan: In general, a plan that details the actions necessary to maintain air quality standards. In particular, the federal Clean Air Act requires maintenance plans for areas that have been redesignated as attainment areas.

Mobile Sources: Moving sources of air pollution such as automobiles, motorcycles, trucks, off-road vehicles, boats and airplanes.

Model Year: Model year refers to the actual annual production period (year) as determined by the manufacturer.

NAAQS (National Ambient Air Quality Standards): Standards set by the federal U.S. EPA for the maximum levels of air pollutants which can exist in the outdoor air without unacceptable effects on human health or the public welfare.

Near-Zero Emission Technologies: Refers to emissions approaching zero and will be delineated for individual source categories through the process of developing the Air Quality Management Plan/State Implementation Plan and subsequent control measures.

Nitrogen Oxides (Oxides of Nitrogen, NO_x): A general term pertaining to compounds of nitric acid (NO), nitrogen dioxide (NO₂), and other oxides of nitrogen. Nitrogen oxides are typically created during combustion processes, and are major contributors to smog formation and acid deposition. NO₂ is a criteria air pollutant, and may result in numerous adverse health effects; it absorbs blue light, resulting in a brownish-red cast to the atmosphere and reduced visibility.

Nonattainment Area: A geographic area identified by the U.S. EPA and/or CARB as not meeting either NAAQS or CAAQS standards for a given pollutant.

NSR (New Source Review): A program used in development of permits for new or modified industrial facilities which are in a nonattainment area, and which emit nonattainment criteria air pollutants. The two major requirements of NSR are Best Available Control Technology and Emission Offsets.

Ozone: A strong smelling reactive toxic chemical gas consisting of three oxygen atoms. It is a product of the photochemical process involving the sun's energy. Ozone exists in the upper atmosphere ozone layer as well as at the earth's surface. Ozone at the earth's surface causes numerous adverse health effects and is a criteria air pollutant. It is a major component of smog.

Ozone Precursors: Chemicals such as hydrocarbons and oxides of nitrogen, occurring either naturally or as a result of human activities, which contribute to the formation of ozone, a major component of smog.

Partial Zero Emission Vehicle (PZEV): A vehicle emissions rating within California's exhaust emission standards. Cars that are certified as PZEVs meets the Super Ultra Low Emission Vehicle exhaust emission standard and has zero evaporative emissions from its fuel system.

Permit: Written authorization from a government agency (e.g., an air quality management district) that allows for the construction and/or operation of an emissions generating facility or its equipment within certain specified limits.

PIC (Particle-in-Cell) Model: An air quality simulation model that is used to apportion sulfate and nitrate PM10 concentrations to their precursor emissions sources. The PIC model uses spatially and temporally resolved sources of NOx and SOx emissions, with meteorological, physical, and simplified chemical processes, to calculate the contributions from various emission source categories.

Plug-in Electric Vehicle (PEV): Vehicles that can be recharged from any external source of electricity and the electricity is stored in a rechargeable battery pack to drive or contribute to drive the wheels.

Plug-in Hybrid Electric Vehicle (PHEV): Vehicles similar to traditional hybrids but are also equipped with a larger, more advanced battery that allows the vehicle to be plugged in and recharged in addition to refueling with gasoline. This larger battery allows the car to drive on battery alone, gasoline alone, or a combination of electric and gasoline fuels.

PM (Particulate Matter): Solid or liquid particles of soot, dust, smoke, fumes, and aerosols.

PM10 (Particulate Matter less than 10 microns): A major air pollutant consisting of tiny solid or liquid particles of soot, dust, smoke, fumes, and aerosols. The size of the particles (10 microns or smaller, about 0.0004 inches or less) allows them to easily enter the air sacs in the lungs where they may be deposited, resulting in adverse health effects. PM10 also causes visibility reduction and is a criteria air pollutant.

PM2.5 (Particulate Matter less than 2.5 microns): A major air pollutant consisting of tiny solid or liquid particles, generally soot and aerosols. The size of the particles (2.5 microns or smaller, about 0.0001 inches or less) allows them to easily enter the air sacs deep in the lungs where they may cause adverse health effects, as noted in several recent studies. PM2.5 also causes visibility reduction,

PSD (Prevention of Significant Deterioration): A program used in development of permits for new or modified industrial facilities in an area that is already in attainment. The intent is to prevent an attainment area from becoming a non-attainment area. This program, like require BACT as defined in the Clean Air Act and, if an AAQS is projected to be exceeded, Emission Offsets.

Public Workshop: A workshop held by a public agency for the purpose of informing the public and obtaining its input on the development of a regulatory action or control measure by that agency.

Regional Transportation Plan (RTP): The long-range transportation plan developed by the Southern California Association of Governments that provides a vision for transportation investments throughout the South Coast region. The RTP considers the role of transportation in the broader context of economic, mobility, environmental, and quality-of-life goals for the future, identifying regional transportation strategies to address regional mobility needs.

ROG (Reactive Organic Gas): A reactive chemical gas, composed of hydrocarbons, that may contribute to the formation of smog. Also sometimes referred to as Non-Methane Organic Compounds (NMOCs). (Also see VOC)

Salton Sea Air Basin (SSAB): Area comprised of a central portion of Riverside County (the Coachella Valley) and Imperial County. The Riverside county portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley.

SIP (State Implementation Plan): A document prepared by each state describing existing air quality conditions and measures which will be taken to attain and maintain national ambient air quality standards (see AQMP).

Smog: A combination of smoke, ozone, hydrocarbons, nitrogen oxides, and other chemically reactive compounds which, under certain conditions of weather and sunlight, may result in a murky brown haze that causes adverse health effects. The primary source of smog in California is motor vehicles. **Smog Check Program:** (See Inspection and Maintenance Program.)

Smoke: A form of air pollution consisting primarily of particulate matter (i.e., particles). Other components of smoke include gaseous air pollutants such as hydrocarbons, oxides of nitrogen, and carbon monoxide. Sources of smoke may include fossil fuel combustion, agricultural burning, and other combustion processes.

SO₂ (Sulfur Dioxide): A strong smelling, colorless gas that is formed by the combustion of fossil fuels. Ocean-going vessels, which may use oil high in sulfur content, can be major sources of SO₂. SO₂ and other sulfur oxides contribute to ambient PM_{2.5}. SO₂ is also a criteria pollutant.

South Coast Air Basin (SCAB or Basin): Area bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto Mountains to the north and east. It includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties.

Stationary Sources: Non-mobile sources such as power plants, refineries, and manufacturing facilities which emit air pollutants; can include area sources depending on context.

Super Ultra Low Emission Vehicle (SULEV): A vehicle emissions rating within California's LEV 1 and LEV 2 exhaust emission standards.

Sustainable Communities Strategy (SCS): Planning element in the RTP that integrates land use and transportation strategies that will achieve CARB's greenhouse gas emissions reduction targets.

Toxic Air Contaminant: An air pollutant, identified in regulation by the CARB, which may cause or contribute to an increase in deaths or in serious illness, or which may pose a present or potential hazard to human health. TACs are considered under a different regulatory process (California Health and Safety Code Section 39650 et seq.) than pollutants subject to CAAQS. Health effects due to TACs may occur at extremely low levels, and it is typically difficult to identify levels of exposure which do not produce adverse health effects.

Transportation Control Measure (TCM): Under Health & Safety Code Section 40717, any control measure to reduce vehicle trips, vehicle use, vehicle miles traveled, vehicle idling, or traffic congestion for the purpose of reducing motor vehicle emissions. TCMs can include encouraging the use of carpools and mass transit. Under federal law, includes, but is not limited to those measures listed in CAA Section 108(f).

Ultrafine Particles (UFP): Particles with a diameter less than 0.1 μm (or 100nm).

Ultra Low Emission Vehicle (ULEV): Vehicles with low emission ratings within California's LEV 1 or LEV 2 exhaust emission standards. The LEV 1 emission standards typically apply to cars from 1994-2003. The LEV 2 emission standards were adopted in 1998 and typically apply to cars from 2004-2010.

U.S. EPA (United States Environmental Protection Agency): The federal agency charged with setting policy and guidelines, and carrying out legal mandates for the protection of national interests in environmental resources.

VMT: Total vehicle miles traveled by all or a subset of mobile sources.

Visibility: The distance that atmospheric conditions allow a person to see at a given time and location. Visibility reduction from air pollution is often due to the presence of sulfur and nitrogen oxides, as well as particulate matter.

VOCs (Volatile Organic Compounds): Hydrocarbon compounds that exist in the ambient air. VOCs contribute to the formation of smog and/or may themselves be toxic. VOCs often have an odor, and some examples include gasoline, alcohol, and the solvents used in paints.

Zero-Emission Technologies: Advanced technology or control equipment that generates zero end-use emissions from stationary or mobile source applications.

Zero Emission Vehicle (ZEV): A vehicle that produces no emissions from the on-board source of power.

INTRODUCTION

This document presents a summary of scientific findings on the health effects of ambient air pollutants. The California Health and Safety Code Section 40471(b) requires that the South Coast Air Quality Management District prepare a report on the health impacts of particulate matter in the South Coast Air Basin (SCAB) in conjunction with the preparation of the Air Quality Management Plan revisions. This document, which was prepared to satisfy that requirement, also includes the effects of the other major pollutants.

HEALTH EFFECTS OF AIR POLLUTION

Ambient air pollution is a major public health concern. Excess deaths and increases in illnesses associated with high air pollution levels have been documented in several episodes as early as 1930 in Meuse Valley, Belgium; 1948 in Donora, Pennsylvania; and 1952 in London. Although levels of pollutants that occurred during these acute episodes are now unlikely in the United States, ambient air pollution continues to be linked to increases in illness and other health effects (morbidity) and increases in death rates (mortality).

The adverse health effects associated with air pollution are diverse and include:

- Premature mortality
- Cardiovascular effects
- Increased health care utilization (hospitalization, physician and emergency room visits)
- Increased respiratory illness and other morbidity (symptoms, infections, and asthma exacerbation)
- Decreased lung function (breathing capacity)
- Lung inflammation
- Potential immunological changes

- Increased airway reactivity to a known pharmacological agent exposure - a method used in laboratories to evaluate the tendency of airways to have an increased possibility of developing an asthmatic response
- A decreased tolerance for exercise.
- Adverse birth outcomes such as low birth weights

The evidence linking these effects to air pollutants is derived from population-based observational and field studies (epidemiological) as well as controlled laboratory studies involving human subjects and animals. There have been an increasing number of studies focusing on the mechanisms (that is, on learning how specific organs, cell types, and biomarkers are involved in the human body's response to air pollution) and specific pollutants responsible for individual effects. Yet the underlying biological pathways for these effects are not always clearly understood.

Although individuals inhale pollutants as a mixture under ambient conditions, the regulatory framework and the control measures developed are pollutant-specific for six major outdoor pollutants covered under Sections 108 and 109 of the clean Air Act. This is appropriate, in that different pollutants usually differ in their sources, their times and places of occurrence, the kinds of health effects they may cause, and their overall levels of health risk. Different pollutants, from the same or different sources, oftentimes occur together. Evidence for more than additive effects have not been strong and, as a practical matter, health scientists, as well as regulatory officials, usually must deal with one pollutant at a time in adopting air quality standards. To meet the air quality standards, comprehensive plans are developed such as the Air Quality Management Plan (AQMP), and to minimize toxic exposure a local air toxics control plan is also prepared. These plans examine multiple pollutants, cumulative impacts, and transport issues related to attaining healthful air quality. A brief overview of the effects observed and attributed to various air pollutants is presented in this document.

This summary is drawn substantially from reviews presented previously (SCAQMD, 1996, 2003, 2007), and from reviews on the effects of air pollution by the American Thoracic Society (ATS, 1996), the U.S. EPA reviews for ozone (U.S. EPA, 2006), Carbon Monoxide (U.S. EPA, 2010), and Particulate Matter (U.S. EPA, 2004, 2009), from a published review of the health effects of air pollution (Brunekreef and Holgate, 2002), and from reviews prepared by the California Air Resources Board and the California EPA Office of the Environmental Health Hazard Assessment for

Particulate Matter (CARB, 2002), for Ozone (CARB, 2005) and for NO₂ (CARB 2007). Additional materials are from EPA’s current and ongoing review of the ozone standard and health effects (EPA, 2012c, d). More detailed citations and discussions on air pollution health effects can be found in these references.¹

Also included are are tables showing summaries of the EPA conclusions regarding the causality of air pollution health effects. The TABLE 1-1 below shows the five descriptors used by EPATABLE 1-1

Weight of evidence descriptions for causal determination

DETERMINATION	WEIGHT OF EVEDENCE
Causal Relationship	Evidence is sufficient to conclude that there is a causal relationship with relevant pollutant exposures. That is, the pollutant has been shown to result in health effects in studies in which chance, bias, and confounding could be ruled out with reasonable confidence. For example: a) controlled human exposure studies that demonstrate consistent effects; or b) observational studies that cannot be explained by plausible alternatives or are supported by other lines of evidence (e.g., animal studies or mode of action information). Evidence includes replicated and consistent high-quality studies by multiple investigators. Evidence is sufficient to conclude that there is a causal relationship with relevant pollutant exposures. That is, the pollutant has been shown to result in effects in studies in which chance, bias, and confounding could be ruled out with reasonable confidence. Controlled exposure studies (laboratory or small-to medium-scale field studies) provide the strongest evidence for causality, but the scope of inference may be limited. Generally, determination is based on multiple studies conducted by multiple research groups, and evidence that is considered sufficient to infer a causal relationship is usually obtained from the joint consideration of many lines of evidence that reinforce each other.
Likely To Be A Causal Relationship	Evidence is sufficient to conclude that a causal relationship is likely to exist with relevant pollutant exposures, but important uncertainties remain. That is, the pollutant has been shown to result in health effects in studies in which chance and bias can be ruled out with reasonable confidence but potential issues remain. For example: a) observational studies show an association, but copollutant exposures are difficult to address and/or other lines of evidence (controlled human exposure, animal, or mode of action information) are limited or inconsistent; or b) animal toxicological evidence from multiple studies from different

¹ Most of the studies referred to in this appendix are cited in the above sources. Only more recent specific references selected references to provide examples of the types of health effects will be cited in this summary.

DETERMINATION	WEIGHT OF EVIDENCE
	laboratories that demonstrate effects, but limited or no human data are available. Evidence generally includes replicated and high-quality studies by multiple investigators.
Suggestive Of A Causal Relationship	Evidence is suggestive of a causal relationship with relevant pollutant exposures, but is limited because chance, bias and confounding cannot be ruled out. For example, at least one high-quality epidemiologic study shows an association with a given health outcome but the results of other studies are inconsistent.
Inadequate To Infer A Causal Relationship	Evidence is inadequate to determine that a causal relationship exists with relevant pollutant exposures. The available studies are of insufficient quantity, quality, consistency or statistical power to permit a conclusion regarding the presence or absence of an effect.
Not Likely To Be A Causal Relationship	Evidence is suggestive of no causal relationship with relevant pollutant exposures. Several adequate studies, covering the full range of levels of exposure that human beings are known to encounter and considering susceptible populations, are mutually consistent in not showing an effect at any level of exposure.

Adapted from EPA 2009

OZONE

Ozone is a highly reactive compound, and is a strong oxidizing agent. When ozone comes into contact with the respiratory tract, it can react with tissues and cause damage in the airways. Since it is a gas, it can penetrate into the gas exchange region of the deep lung.

The EPA primary standard for ozone, adopted in 2008, is 0.075 ppm averaged over eight hours. The California Air Resources Board (CARB) has established standards of 0.09 ppm averaged over one hour and at 0.070 ppm averaged over eight hours.

A number of population groups are potentially at increased risk for ozone exposure effects. In the ongoing review of ozone, the EPA has identified populations as having adequate evidence for increased risk from ozone exposures include individuals with asthma, younger and older age groups, individuals with reduced intake of certain nutrients such as Vitamins C and E, and outdoor workers. There is suggestive evidence for other potential factors, such as variations in genes related to oxidative metabolism or inflammation, gender, socioeconomic status, and obesity. However further evidence is needed.

The adverse effects reported with short-term ozone exposure are greater with increased activity because activity increases the breathing rate and the volume of air reaching the lungs, resulting in an increased amount of ozone reaching the lungs. Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher specific ventilation rate than adults (i.e. after normalization for body mass).

A number of adverse health effects associated with ambient ozone levels have been identified from laboratory and epidemiological studies (EPA, 1996; 2006, 2011; ATS, 1996). These include increased respiratory symptoms, damage to cells of the respiratory tract, decrease in lung function, increased susceptibility to respiratory infection, an increased risk of hospitalization, and increased risk of mortality.

Increases in ozone levels are associated with increased numbers of absences from school. The Children's Health Study, conducted by researchers at the University of Southern California, followed a cohort of children that live in 12 communities in Southern California with differing levels of air pollution for several years. A publication from this study reported that school absences in fourth graders for respiratory illnesses were positively associated with ambient ozone levels. An increase of 20 ppb ozone was associated with an 83% increase in illness-related absence rates (Gilliland, 2001).

The number of hospital admissions and emergency room visits for all respiratory causes (infections, respiratory failure, chronic bronchitis, etc.) including asthma shows a consistent increase as ambient ozone levels increase in a community. These excess hospital admissions and emergency room visits are observed when hourly ozone concentrations are as low as 0.06 to 0.10 ppm.

Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations are strongest during warmer months but overall persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).

Multicity studies of short-term ozone exposures (days) and mortality have also examined regional differences. Evidence was provided that there were generally higher ozone-mortality risk estimates in northeastern U.S. cities, with the southwest and urban mid-west cities showing lower or no associations (Smith, 2009; Bell, 2008). Another long-term study of a national cohort found that long-term exposures

to ozone were associated with respiratory-related causes of mortality, but not cardiovascular-related causes, when PM_{2.5} exposure were also included in the analysis.

In the ongoing EPA review, it was concluded that there is adequate evidence for asthmatics to be a potentially at risk population (EPA, 2012c). Several population-based studies suggest that asthmatics are at risk from ambient ozone levels, as evidenced by changes in lung function, increased hospitalizations and emergency room visits.

Laboratory studies have also compared the degree of lung function change seen in age and gender-matched healthy individuals versus asthmatics and those with chronic obstructive pulmonary disease. In studies of individuals with chronic obstructive pulmonary disease, the degree of change evidenced did not differ significantly. That finding, however, may not accurately reflect the true impact of exposure on these respiration-compromised individuals. Since the respiration-compromised group may have lower lung function to begin with, the same total change may represent a substantially greater relative adverse effect overall. Other studies have found that subjects with asthma are more sensitive to the short term effects of ozone in terms of lung function and inflammatory response.

Another publication from the Children's Health Study focused on children and outdoor exercise. In southern California communities with high ozone concentrations, the relative risk of developing asthma in children playing three or more sports was found to be over three times higher than in children playing no sports (McConnell, 2002). These findings indicate that new cases of asthma in children may be associated with performance of heavy exercise in communities with high levels of ozone. While it has long been known that air pollution can exacerbate symptoms in individuals with preexisting respiratory disease, this is among the first studies that indicate ozone exposure may be causally linked to asthma onset.

In addition, human and animal studies involving both short-term (few hours) and long-term (months to years) exposures indicate a wide range of effects induced or associated with ambient ozone exposure. These are summarized in Table I-1.

TABLE I-2

Adverse Health Effects of Ozone (O₃) - Summary of Key Findings

O₃ CONCENTRATION AND EXPOSURE HR., PPM	HEALTH EFFECT
<p>Ambient air containing 0.10 - 0.15 daily 1-h max over days to weeks;</p> <p>< 0.06 (Max 8 hour average)</p> <p>< 0.069 (Mean 8 hour average)</p>	<p>Decreased breathing capacity, in children, adolescents, and adults exposed to O₃ outdoors</p> <p>Positive associations of ambient O₃ with respiratory hospital admissions and ED visits in the U.S., Europe, and Canada with supporting evidence from single city studies. Generally, these studies had mean 8-h max O₃ concentrations less than 60 ppb.</p> <p>Positive associations between short-term exposure to ambient O₃ and respiratory symptoms (e.g., cough, wheeze, and shortness of breath) in children with asthma. Generally, these studies had mean 8-h max O₃ concentrations less than 69 ppb.</p>
<p>≥0.12 (1-3h)</p> <p>≥0.06 (6.6h)</p> <p>(chamber exposures)</p>	<p>Decrements in lung function (reduced ability to take a deep breath), increased respiratory symptoms (cough, shortness of breath, pain upon deep inspiration), increased airway responsiveness and increased airway inflammation in exercising adults</p> <p>Effects are similar in individuals with preexisting disease except for a greater increase in airway responsiveness for asthmatic and allergic subjects</p> <p>Older subjects (>50 yrs old) have smaller and less reproducible changes in lung function</p> <p>Attenuation of response with repeated exposure</p>
<p>≥0.12 with prolonged, repeated exposure (chamber exposures)</p>	<p>Changes in lung structure, function, elasticity, and biochemistry in laboratory animals that are indicative of airway irritation and inflammation with possible development of chronic lung disease</p> <p>Increased susceptibility to bacterial respiratory infections in laboratory animals</p>

From: SCAQMD, 1996; EPA, 2007, EPA, 2012c, Kim 2011

Some lung function responses (volume and airway resistance changes) observed after a single exposure to ozone exhibit attenuation or a reduction in magnitude with repeated exposures. Although it has been argued that the observed shift in response

is evidence of a probable adaptation phenomenon, it appears that while functional changes may exhibit attenuation, biochemical and cellular changes which may be associated with episodic and chronic exposure effects may not exhibit similar adaptation. That is, internal damage to the respiratory system may continue with repeated ozone exposures, even if externally observable effects (chest symptoms and reduced lung function) disappear. Additional argument against adaptation is that after several days or weeks without ozone exposures, the responsiveness in terms of lung function as well as symptoms returns.

In a laboratory, exposure of human subjects to low levels of ozone causes reversible decrease in lung function as assessed by various measures such as respiratory volumes, airway resistance and reactivity, irritative cough and chest discomfort. Lung function changes have been observed with ozone exposure as low as 0.06 to 0.12 ppm for 6-8 hours under moderate exercising conditions. Similar lung volume changes have also been observed in adults and children under ambient exposure conditions (0.10 - 0.15 ppm 1-hour average). The responses reported are indicative of decreased breathing capacity and are reversible.

The results of several studies where human volunteers were exposed to ozone for 6.6 hours at levels between 0.04 and 0.12 ppm were recently summarized (Brown, 2008). As shown in the figure below, there is an increasing response on lung function with increasing exposure levels in moderately exercising subjects. A more recent study (Kim, 2010) exposed young healthy adults to 0.06 ppm ozone for 6.6 hours while engaging in intermittent moderate exercise. The subjects exhibited a reduction in lung function (FEV1) after exposure.

**FIGURE I-1**

Comparison of mean ozone-induced decrements in lung function following 6.6 hours of ozone exposure (from Brown, 2008)

In addition to controlled laboratory conditions, studies of individuals exercising outdoors, including children attending summer camp, have shown associations of reduced lung function with ozone exposure. There were wide ranges in responses among individuals. EPA's recent review indicates reductions of <1 to 4% in lung function when standardized to an increase of 0.03 ppm for an 8-hour maximum (EPA 2012).

Results of epidemiology studies support the relationship between ozone exposure and respiratory effects. Several, but not all, studies have found associations of short-term ozone levels and hospital admissions and emergency department admissions for respiratory-related conditions (EPA, 2011).

In laboratory studies, cellular and biochemical changes associated with respiratory tract inflammation have also been consistently found in the airway lining after low level exposure to ozone. These changes include an increase in specific cell types and in the concentration of biochemical mediators of inflammation and injury such as Interleukin-1, Tumor Necrosis Factor α , and fibronectin. Indications of lung injury

and inflammatory changes have been observed in healthy adults exposed to ozone in the range of 0.06 to 0.10 ppm for up to 6.6 hours with intermittent moderate exercise.

There may be interactions between ozone and other ambient pollutants. The susceptibility to ozone observed under ambient conditions could be modified due to the combination of pollutants that coexist in the atmosphere or ozone might sensitize these subgroups to the effects of other pollutants.

Some animal studies show results that indicate possible chronic effects including functional and structural changes of the lung. These changes indicate that repeated inflammation associated with ozone exposure over a lifetime may result in cumulative damage to respiratory tissue such that individuals later in life may experience a reduced quality of life in terms of respiratory function and activity level achievable. An autopsy study involving Los Angeles County residents, although conducted many years ago when pollutant levels were higher than currently measured, provided supportive evidence of lung tissue damage (structural changes) attributable to air pollution.

A study of birth outcomes in southern California found an increased risk for birth defects in the aortic and pulmonary arteries associated with ozone exposure in the second month of pregnancy (Ritz et al., 2002). This was the first study linking ambient air pollutants to birth defects in humans. Studies conducted since mostly focusing on cardiac and oral cleft defects have found mixed results, with some showing associations, but others did not.

In summary, adverse effects associated with ozone exposures have been well documented. Although the specific mechanisms of actions are not fully identified, there is a strong likelihood that oxidation of key enzymes and proteins and inflammatory responses play important roles.

It may be instructive to provide the overall EPA staff preliminary conclusions on the causality on ozone health effects for the health outcomes evaluated (EPA, 2011). These are provided in the two tables below. On the basis of the most recent evaluations of ozone health effects, EPA's Clean Air Scientific Advisory Committee has recommended that the NAAQS for ozone be reduced and recommended a range in which 0.070 ppm would be the upper limit. This would be consistent with the California air quality standard.

TABLE I-3

Summary of Causal Determinations for Short-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Effects on Liver and Xenobiotic Metabolism	Inadequate to infer a causal relationship
Effects on Cutaneous and Ocular Tissues	Inadequate to infer a causal relationship
Mortality	Likely to be a causal relationship

From EPA, 2011

TABLE I-4

Summary of Causal Determinations for Long-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Likely to be a causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Reproductive and Developmental Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Carcinogenicity and Genotoxicity	Inadequate to infer a causal relationship
Mortality	Suggestive of a causal relationship

PARTICULATE MATTER

Airborne particulates are a complex group of pollutants that vary in source, size and composition, depending on location and time. The components include nitrates, sulfates, elemental carbon, organic carbon compounds, acid aerosols, trace metals, and material from the earth's crust. Substances of biological origin, such as pollen and spores, may also be present.

The National Ambient Air Quality Standard for particulate matter was established in 1971, and set limits on the ambient level of Total Suspended Particulates (TSP). In 1987, the national particulate matter standards were revised to cover particles sized 10 μm (micrometers) aerodynamic diameter and smaller. These can be inhaled through the upper airways and deposited in the lower airways and gas exchange tissues in the lung. These particles are referred to as PM₁₀. EPA initially promulgated ambient air quality standards for PM₁₀ of 150 $\mu\text{g}/\text{m}^3$ averaged over a 24-hour period, and 50 $\mu\text{g}/\text{m}^3$ for an annual average. EPA has since rescinded the annual PM₁₀ standard, but kept the 24-hour standard.

In more recent years additional focus has been placed on particles having an aerodynamic diameter of 2.5 μm or less (PM_{2.5}). A greater fraction of particles in this size range can penetrate and deposit deep in the lungs. The EPA established standards for PM_{2.5} in 1997 and in 2006 lowered the air quality standards for PM_{2.5} to 35 $\mu\text{g}/\text{m}^3$ for a 24-hour average and reaffirmed 15 $\mu\text{g}/\text{m}^3$ for an annual average standard. There was considerable controversy and debate surrounding the review of particulate matter health effects and the consideration of ambient air quality standards (Kaiser, 1997; Vedal, 1997) when the EPA promulgated the initial PM_{2.5} standards in 1997. The California Air Resources Board adopted an air quality standard for PM_{2.5} in 2002 at 12 $\mu\text{g}/\text{m}^3$ annual average.

Since that time, numerous studies have been published, and some of the key studies were closely scrutinized and the data reanalyzed by additional investigators. The reanalyses confirmed the findings of significant result, and there are now substantial new data confirming and extending the range of the adverse health effects of PM_{2.5} exposures.

There are also differences in the composition and sources of particles in the different size ranges that may have implications for health effects. The particles larger than 2.5 μm (often referred to as the coarse fraction) are mostly produced by mechanical processes. These include automobile tire wear, industrial processes such as cutting and grinding, and resuspension of particles from the ground or road surfaces by wind and human activities.

In contrast, particles smaller than 2.5 μm are mostly derived from combustion sources, such as automobiles, trucks, and other vehicle exhaust, as well as from stationary combustion sources. The particles are either directly emitted or are formed in the atmosphere from gases that are emitted. Components from material in the

earth's crust, such as dust, are also present, with the amount varying in different locations.

Attention to another range of very small particles has been increasing over the last few years. These are generally referred to as "ultrafine" particles, with diameters of 0.1 μm or less. These particles are mainly from fresh emissions of combustion sources, but are also formed in the atmosphere by condensation of vapors that are emitted or by chemical or photochemical reactions with other contaminants in the air.

Ultrafine particles have relatively short half lives (minutes to hours) and rapidly grow through condensation and coagulation process into larger particles within the PM_{2.5} size range. These particles are garnering interest since a limited number of epidemiological and some laboratory studies, though not all, indicate that their toxicity may be higher on a mass basis than larger particles. There is also evidence that these small particles, or toxic components carried on their surface, can translocate from the lung to the blood and to other organs of the body.

There have been several reviews of the health effects of ambient particulate matter (ATS, 1996; Brunekreef, 2002; U.S. EPA, 2004; U.S. EPA, 2009; Brook, 2012). In addition, the California Air Resources Board (CARB) and the Office of Environmental Health and Hazard Assessment (OEHHA) have reviewed the adequacy of the California Air Quality Standards for Particulate Matter (Cal EPA, 2002).

The major types of effects associated with particulate matter include:

- Increased mortality
- Exacerbation of respiratory disease and of cardiovascular disease as evidenced by increases in:
 - Respiratory symptoms
 - Cardiovascular symptoms, non-fatal myocardial infarction
 - Hospital admissions and emergency room visits
 - Physician office visits
 - School absences
 - Adverse birth outcomes

- Effects on lung function
- Changes in lung morphology

The California Air Resources Board has also set air quality standards for particulate matter. The current federal and California standards are listed below:

TABLE I-5

Ambient Air Quality Standards for Particulate Matter

STANDARD	FEDERAL	CALIFORNIA
PM10 24-Hour average	150 $\mu\text{g}/\text{m}^3$	50 $\mu\text{g}/\text{m}^3$
PM10 Annual Average	--	20 $\mu\text{g}/\text{m}^3$
PM 2.5 24-Hour Average	35 $\mu\text{g}/\text{m}^3$	--
PM 2.5 Annual Average	15 $\mu\text{g}/\text{m}^3$	12 $\mu\text{g}/\text{m}^3$

Short-Term Exposure Effects

Epidemiological studies have provided evidence for most of the effects listed above. An association between increased daily or several-day-average concentrations of PM10 and excess mortality and morbidity is consistently reported from studies involving communities across the U.S. as well as in Europe, Asia, and South America. A review and analysis of epidemiological literature for acute adverse effects of particulate matter was published by the American Thoracic Society in 1996. Several adverse effects were listed as associated with daily PM10 exposures, as listed in Table I-5. It also appears that individuals who are elderly or have preexistent lung or heart disease are more susceptible than others to the adverse effects of PM10 (ATS, 1996).

Since then many more recent studies have confirmed that excess mortality and morbidity are associated with short term particulate matter levels (Pope, 2006).

Estimates of mortality effects from studies of PM10 exposures range from 0.3 to 1.7% increase for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 levels. The National Morbidity, Mortality, and Air Pollution Study (NMMAPS), a study of 20 of the largest U.S. cities, determined a combined risk estimate of about a 0.5% increase in total mortality for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 (Samet, 2000a). This study also analyzed

the effects of gaseous co-pollutants. The results indicated that the association of PM10 and mortality were not confounded by the presence of the gaseous pollutants. When the gaseous pollutants were included in the analyses, the significance of the PM10 estimates remained. The PM10 effects were reduced somewhat when O₃ was also considered and tended to be variably decreased when NO₂, CO, and SO₂ were added to the analysis. These results argue that the effects are likely due to the particulate exposures; they cannot readily be explained by coexisting weather stresses or other pollutants.

TABLE I-6

Combined Effect Estimates of Daily Mean Particulate Pollution (PM10)

	% CHANGE IN HEALTH INDICATOR PER EACH 10 µg/m³ INCREASE IN PM10
Increase in Daily Mortality	
Total deaths	1.0
Respiratory deaths	3.4
Cardiovascular deaths	1.4
Increase in Hospital Usage (all respiratory diagnoses)	
Admissions	1.4
Emergency department visits	0.9
Exacerbation of Asthma	
Asthmatic attacks	3.0
Bronchodilator use	12.2
Emergency department visits*	3.4
Hospital admissions	1.9
Increase in Respiratory Symptom Reports	
Lower respiratory	3.0
Upper respiratory	0.7
Cough	2.5
Decrease in Lung Function	
Forced expiratory volume	0.15
Peak expiratory flow	0.08

* One study only

(Source: American Journal of Respiratory and Critical Care Medicine, Vol. 153, 113-50, 1996)

An expansion of the NMMAPS study to 90 U.S. Cities also reported association with PM10 levels and mortality (Samet 2000b; HEI, 2003). It was discovered that this study was one that used a software package with inappropriate default settings. The investigators have reanalyzed the data using corrected settings for the software (Dominici, 2002a, Dominici 2002b). When the estimates for the 90 cities in the study were recalculated, the estimate changed from 0.41% increase in mortality for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 to a 0.27% increase. There remained a strong positive association between acute exposure to PM10 and mortality. When an alternate model was used, the average estimate was 0.21% increase in mortality per 10 $\mu\text{g}/\text{m}^3$ increase in PM10 (HEI, 2003). Thus while the quantitative estimate was reduced, the major findings of the study did not change.

Studies of short term exposures to PM2.5 have also found associations with increases in mortality. The NMMAPS study conducted a national analysis of PM2.5 mortality association for 1999-2000. The risk estimates were 0.29% for all-cause mortality and 0.38% for cardio-respiratory mortality (Dominici, 2007). In its recent review EPA determined that estimates for PM2.5 generally are in the range of 0.29 to 1.21% increase in total deaths per 10 $\mu\text{g}/\text{m}^3$ increase in 24-hour PM2.5 levels. The estimates for cardiovascular related mortality range from 0.03 to 1.03% per 10 $\mu\text{g}/\text{m}^3$, and for respiratory mortality estimates range from 1.01 to 2.2% per 10 $\mu\text{g}/\text{m}^3$ 24-hour PM2.5 (EPA,2009). FIGURE I-2 shows a summary of recent studies of mortality and short term PM2.5 exposures.

Several studies have attempted to assess the relative importance of particles smaller than 2.5 μm and those between 2.5 μm and 10 μm (PM10-2.5). While some studies report that PM2.5 levels are better predictors of mortality effects, others suggest that PM10-2.5 is also important. Most of the studies found higher mortality associated with PM2.5 levels than with PM10-2.5. For example, a study of six cities in the U.S. found that particulate matter less than 2.5 μm was associated with increased mortality, but that the larger particles were not. In the EPA review, (EPA, 2009) several studies were presented that found associations of PM10-2.5 and mortality. Some of the studies showed differences by region of the U.S. In one study of 47 U.S. cities that had both PM2.5 and PM10 data available to calculate PM10-2.5 as a difference. Overall, the study found a significant association between

the computed PM10—2.5 and all cause, cardiovascular, and respiratory mortality. The study also reported difference by season and climate area.

FIGURE I-2

Summary of nonaccidental mortality per 10 µg/m³ increase in PM_{2.5} short- term exposures (from EPA 2009)

The relative importance of both PM_{2.5} and PM_{10-2.5} may vary in different regions depending on the relative concentrations and components, which can also vary by season. A major knowledge gap is the relative paucity of direct measurements of

PM2.5-10. Most estimates are made by subtracting PM2.5 from PM10 measured at co-located samplers, a process that is subject to errors that are inherent in the subtracting of one relatively large number from another. More research is needed to better assess the relative effects of fine (PM2.5) and coarse (PM10-2.5) fractions of particulate matter on mortality. A graph from the EPA review is included below to demonstrate ranges of mortality findings.

FIGURE I-3

Summary of percent increase in total (nonaccidental) and cause-specific mortality per 10 µg/m³ increase in PM10-2.5 (from EPA. 2009)

A number of studies have evaluated the association between particulate matter exposure and indices of morbidity such as hospital admissions, emergency room visits or physician office visits for respiratory and cardiovascular diseases. The effects estimates are generally higher than the effects for mortality. The effects are associated with measures of PM10 and PM2.5. Effects are also associated with PM10-2.5.

In the NMMAPS study, hospital admissions for those 65 years or older were assessed in 14 cities. Several models were compared to estimate associations of hospital

admissions for specific disease categories and short term PM10 levels. Hospital admissions showed an increase ranging from 0.68 – 1.47% for cardiovascular diseases, a range of 1.46 – 2.88% increase for chronic obstructive pulmonary disease, and a range of 1.31 – 2.86% increase for pneumonia per 10 $\mu\text{g}/\text{m}^3$ increase in PM10. (Samet, 2000) In the reanalysis of the study, (HEI 2003), it was found that using different models the pollution coefficients were on average lower. However the authors note that most of the conclusions of associations with PM10 exposures and hospital admissions held.

Similarly, school absences, lost workdays and restricted activity days have also been used in some studies as indirect indicators of acute respiratory conditions. The results are suggestive of both immediate and delayed impact on these parameters following elevated particulate matter exposures. These observations are consistent with the hypothesis that increased susceptibility to infection follows particulate matter exposures, which is consistent with mechanistic studies that show PM exposures may suppress the immune system.

Some studies have reported that short-term particulate matter exposure is associated with changes in lung function (lung capacity and breathing volume); upper respiratory symptoms (hoarseness and sore throat); and lower respiratory symptoms (increased sputum, chest pain and wheeze). The severity of these effects is widely varied and is dependent on the population studied, such as adults or children with and without asthma. Sensitive individuals, such as those with asthma or pre-existing respiratory disease, may have increased or aggravated symptoms associated with short-term particulate matter exposures. Several studies have followed the number of medical visits associated with pollutant exposures. A range of increases from 1 to 4% for medical visits for respiratory illnesses was found corresponding to a 10 $\mu\text{g}/\text{m}^3$ change in PM10. A number of studies also looked at levels of PM2.5 or PM10-2.5. The findings suggest that both the fine and coarse fractions may have associations with some respiratory symptoms (EPA, 2009).

The biological mechanisms by which particulate matter can produce health effects are being investigated in laboratory studies. Inflammatory responses in the respiratory system in humans and animals exposed to concentrated ambient particles have been measured. These include effects such as increases in neutrophils in the lungs. Other changes reported include increased release of cytokines and interleukins, chemicals released as part of the inflammatory process. The effects of particulate matter may be mediated in part through the production of reactive oxygen species

during the inflammatory process. Several reviews discuss mechanistic studies in more detail (Brunekreef, 2002; Brook, 2004, Brook, 2010).

Long-Term Exposure Effects

While most studies have evaluated the acute effects, some studies specifically focused on evaluating the effects of chronic exposure to PM10 and PM2.5. Studies have analyzed the mortality of adults living in different U.S. cities. After adjusting for important risk factors, taken as a whole these studies found a positive association of deaths and exposure to particulate matter. A similar association was observable in both total number of deaths and deaths due to specific causes. The largest effects were observed from cardiovascular causes and ischemic heart disease. A shortening of lifespan was also reported in these studies.

Since the initial promulgation by EPA of the National Ambient Air Quality Standards for PM2.5, controversy has remained over the association of mortality and exposures to PM2.5. Thus an expanded discussion of this issue is presented below.

Significant associations for PM2.5 for both total mortality and cardiorespiratory mortality were reported in a study following a national cohort recruited by the American Cancer Society for its Cancer Preventions Study II over several years. A re-analysis of the data from this study confirmed the initial finding (Krewski, 2000). In this study, mortality rates and PM2.5 levels were analyzed for 51 metropolitan areas of the U.S. Average levels from monitors in each area were used to estimate exposures. At these levels of aggregation, regional differences in the association of PM2.5 and mortality were noted, with higher associations in the Northeast, and lower or non-significant associations in the West.

The Harvard Six Cities Study evaluated several size ranges of particulate matter and reported significant associations with PM15, PM2.5, sulfates, and non-sulfate particles, but not with coarse particles (PM15 – PM2.5). An extension of the Harvard Six Cities Cohort confirmed the association of mortality with PM2.5 levels (Laden, 2006). These studies provide evidence that the fine particles, as measured by PM2.5, may be more strongly associated with mortality effects from long-term particulate matter exposures than are coarse compounds. An update to this study covering a follow-up over the years 1974 to 2009 (Lepeule, 2012) was recently published. Findings indicated a linear relationship of PM2.5 levels and mortality from all causes, cardiovascular causes, and from lung cancer. According to the

authors, the PM_{2.5} levels decreased over time, but no evidence of a threshold for these effects was found.

A recent study conducted in Canada on long term particulate exposures and mortality found a 15% increase in all-cause mortality and a 31 % increase in ischemic heart disease mortality for a 10 µg.m³ increase in PM_{2.5}. The mean concentration among all study subjects was 8.7 µg/m³ (Crouse, 2012)

A follow-up study of the American Cancer Society cohort confirmed and extended the findings in the initial study. The researchers estimated that, on average, a 10 µg/m³ increase in fine particulates was associated with approximately a 4% increase in total mortality, a 6% increase in cardiopulmonary mortality, and an 8% increase risk of lung cancer mortality (Pope, 2002). The magnitude of effects is larger in the long-term studies than in the short-term investigations. In an additional re analysis and extension of the American Cancer Society cohort from 1982 to 2000 (Krewski, 2009), and including additional metropolitan areas for the most recent years, effects estimates on mortality were similar, though somewhat higher, than those reported previously. The extended analyses included an additional 11 years of cohort follow-up. The authors reported positive and significant association between a 10 µg/m³ change in PM_{2.5} level and all cause, cardiopulmonary disease, and ischemic heart disease deaths. Mortality from ischemic heart disease was associated with the largest risk estimates.

Other national studies include an analysis of mortality and PM_{2.5} exposures in a Medicare population. Zeger and Associates (2008) assembled a Medicare cohort by including all Medicare enrollees residing in zip codes with centroids within 6 miles of a PM_{2.5} monitor. PM_{2.5} data was obtained from the monitoring stations, and mean annual levels were called for the zip codes within six miles of each monitor. The estimated associations between exposures to PM_{2.5} and mortality for the eastern and central portions of the U.S were similar to those previously published in the Six Cities Study and the American Cancer Society cohorts. The authors reported that there were no significant associations between zip code levels of PM_{2.5} and mortality rates in the western region of the U.S. This lack of association was attributed largely to the higher PM_{2.5} levels in Los Angeles area counties compared to other western urban areas, but there were not higher mortality rates in these counties. The authors further reported that they found no associations of PM_{2.5} with mortality in persons aged 85 years or higher.

FIGURE I-4

Mortality risk estimates, long-term exposure to PM_{2.5} in recent cohort studies

From EPA, 2009

Analyses of mortality and PM_{2.5} levels specific to California have also been reported. A cohort of elderly individuals (average age of 65 yr in 1973) recruited from 11 California counties was followed over several years (Enstrom, 2005). An association for exposure with all cause deaths was reported from 1973–1982. However, no significant association was found in the later time period of 1983–2002. Pollutant levels were taken from ambient monitors and averaged over each county to estimate exposures.

Two recent reports have been released looking at air pollution and health effects in California cohorts. One study (Lipsett, 2011) followed school teachers recruited in 1995, and followed through 2005. Pollutant exposures at the subject residence were estimated using data from ambient monitors, and extrapolated using a distance weighted method. The authors reported significant association of PM_{2.5} levels and mortality from ischemic heart disease, but no associations were found with all cause, cardiovascular, or respiratory disease.

The second study (Jerrett, 2011) followed individuals in California from the American Cancer Society II cohort recruited starting in 1982, with follow up to 2000. Pollutant levels at subject residences were estimated using several methods and models. All but one of the methods found no association of all-cause mortality with PM_{2.5} levels. All exposure estimation methods were reported to have found significant associations with ischemic heart disease mortality, however. The authors noted that mortality rates differ in urban areas compared to non-urban areas, and so included a variable for this in a land use regression model to estimate effects on mortality. When the authors applied the land use regression model including an urban indicator to estimate exposures, all-cause mortality, mortality from cardiovascular disease, and mortality from ischemic heart disease were all significantly associated with PM_{2.5} levels.

Some other studies have focused on particulate matter exposure and health effects in residents of Southern California. Two analyses of the American Cancer Society cohort, for example, focused specifically on the Los Angeles Metropolitan area using methods to estimate exposures on a finer geographical scale than previous studies that used geographic scales at the county or metropolitan area. Using data from monitoring stations in the Los Angeles area, one study applied interpolation methods (Jerrett, 2005) and another applied land use regression techniques (Krewski, 2009) to estimate exposures to the study individuals. Significant associations of PM_{2.5} with mortality from all causes and cardiopulmonary disease were reported, with the

magnitude of risks being higher than those from the national studies of the American Cancer Society cohort. This provides evidence that using methods to provide more detailed exposure estimates can result in stronger associations of PM_{2.5} and mortality. It should be noted that various analyses were presented in these, as well as other, studies to estimate the influence on various individual level and ecologic variables that might also be related to health effects risks. Including such variable generally reduces the association of PM_{2.5} and mortality. It may be illustrative to describe some of the estimates from the various calculations as presented by the authors of the Los Angeles area cohort (Krewski, 2009). In the descriptions below, HR refers to Hazard Ratio expressed for a 10 ug/m³ change in PM_{2.5} exposure, followed by the 95% Confidence Interval. For example, if the Hazard Ratio is 2, the risk would be twice as high, and conversely if the Hazard Ratio is 0.5, the risk would be one half of that of the reference group. Several of the analyses results follow as excerpted from Krewski, 2009. The analyses listed all include PM_{2.5}, plus various additional individual and ecological variables.

TABLE I- 7

Influence of Adding Confounding Variables (From Krewski, 2009)	
Variable Included	Hazard Ratio
PM _{2.5} alone (stratified for age, sex, and race)	1.197 (95% CI, 1.082–1.325);
PM _{2.5} with 44 individual-level covariates	1.143 (95% CI, 1.033–1.266)
With 44 individual-level covariates and the ecologic covariate of unemployment	1.127 (95% CI, 1.015–1.252)
With 44 individual-level covariates and social factors extracted from the principal component analysis (which account for 81% of the total variance in the social variables)	1.142 (95% CI, 1.026–1.272).
With 44 individual-level covariates and all ecologic covariates that were individually associated with mortality in bivariate models with PM _{2.5} exposure	1.115 (95% CI, 1.003–1.239)
Parsimonious model that included 44 individual-level covariates and ecologic confounder variables that both reduced the pollution coefficient and had associations with mortality	1.126 (95% CI, 1.014–1.251)

Another study looked at measuring of atherosclerosis in Southern California residents (Kunzli, 2005). An assessment of the carotid intima-media thickness (CIMT) was used as a measure of subclinical atherosclerosis. The subjects' residential areas were geocoded and a geospatial extrapolation of ambient monitoring data was used to assign annual mean concentrations of ambient PM_{2.5}. The authors report results of an association between atherosclerosis and ambient air pollution as measured by PM_{2.5}. The associations of PM_{2.5} and CIMT were strongest in women ≥ 60 years of age.

The U.S. EPA has recently proposed to lower the annual National Ambient Air Quality Standard for PM_{2.5} (U.S. EPA, 2012a). EPA also released a Regulatory Impact Analysis (U.S. EPA 2012b) which looked at the costs and benefits of alternate PM_{2.5} stand levels. As part of the analysis, EPA also looked at California specific studies regarding PM_{2.5} and mortality published in the scientific literature. The EPA analysis concluded "most of the cohort studies conducted in California report central effect estimates similar to the (nation-wide) all-cause mortality risk estimate we applied from Krewski et al. (2009) and Laden et al. (2006) albeit with wider confidence intervals. A couple cohort studies conducted in California indicate higher risks than the risk estimates we applied." Thus in EPA's judgment the California related studies provided estimates of mortality consistent with or higher than those from the national studies.

Other studies report evidence indicating that particulate matter exposure early in pregnancy may be associated with lowered birth weights (Bobak, 1999). Studies from the U.S., the Czech Republic and Mexico City have reported that neonatal and early postnatal exposure to particulate matter may lead to increased infant mortality. A more recent study in Southern California found increased risks for infant deaths associated with exposures to particulates and other pollutants (Ritz, 2006). These results suggest that fetuses and infants may be subgroups affected by particulate matter exposures.

In addition, some long-term effect studies have reported an increased risk of mortality from lung cancer associated with particulate matter exposures. A study involving California Seventh Day Adventists (very few of whom smoke) has reported an association of lung cancer mortality with PM₁₀ levels. It is not clear from these studies whether the association relates to causation of disease, or whether individuals with cancer are more susceptible to other effects of particles leading to the observed mortality association. A study that followed a large number of

individuals living in the largest U.S. cities found elevated lung cancer risk associated with long-term average PM_{2.5} levels (Pope, 2002).

Several studies have assessed the effects of long-term particulate matter exposure on respiratory symptoms and lung function changes. Associations have been found with symptoms of chronic bronchitis and decreased lung function. A study of school children in 12 communities in Southern California showed significant association of particulate matter with bronchitis or phlegm in children with asthma. These effects were also associated with NO₂ and acid vapor levels (McConnell, 1999).

A cohort of fourth graders from the Southern California communities was followed over a period of four years by the Children's Health Study. A lower rate of growth in lung function was found in children living in areas with higher levels of particulate pollution (Gauderman, 2000). Decreases in lung function growth were associated with PM₁₀, PM_{2.5}, PM_{10-2.5}, acid vapor, and NO₂. There was no association with ozone levels. The investigators were not able to identify independent effects of the pollutants, but noted that motor vehicle emissions are a major source of the pollutants.

A follow-up study on a second cohort of children confirmed the findings that decreased lung function growth was associated with particulates, nitric oxides, and elemental carbon levels (Gauderman, 2002). Elemental carbon is often used as a measure for diesel particulate. Additionally, children who moved to areas with less air pollution were found to regain some of the lung function growth rate (Avol, 2001). By the time the fourth graders graduated from high school, a significant number showed lower lung function. The risk of lower lung function was about five times higher in children with the highest PM_{2.5} exposure when compared to the lowest exposure communities (Gauderman, 2004). These deficits are likely to persist since the children were at the end of their growth period.

Despite data gaps, the extensive body of epidemiological studies has both qualitative and quantitative consistency suggestive of causality. A considerable body of evidence from these studies suggests that ambient particulate matter, alone or in combination with other coexisting pollutants, is associated with significant increases in mortality and morbidity in a community.

In summary, the scientific literature indicates that an increased risk of mortality and morbidity is associated with particulate matter at ambient levels. The evidence for particulate matter effects is mostly derived from population studies with supportive

evidence from clinical and animal studies. Although most of the effects are attributable to particulate matter, co-pollutant effects cannot be ruled out on the basis of existing studies. The difficulty of separating the effects may be due to the fact that particulate levels co-vary with other combustion source pollutants. That is, the particle measurements serve as an index of overall exposure to combustion-related pollution, and some component(s) of combustion pollution other than particles might be at least partly responsible for the observed health effects.

EPA staff has presented conclusions on the particulate matter causal determination of several health effects based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the Tables below.

TABLE I-8

Summary of Causal Determination of PM10-2.5 by Exposure Duration and Health Outcome

SHORT-TERM EXPOSURES	
Health Outcome	Causality Determination
Cardiovascular effects	Suggestive
Respiratory effects	Suggestive
Mortality	Suggestive
LONG-TERM EXPOSURES	
Health Outcome	Causality Determination
Cardiovascular effects	Inadequate
Respiratory effects	Inadequate
Mortality	Inadequate
Reproductive and developmental	Inadequate

From EPA, 2009

TABLE I- 9

Summary of Causal Determination of PM2.5 by Exposure Duration and Health Outcome

SHORT-TERM EXPOSURES	
Health Outcome	Causality Determination
Cardiovascular effects	Causal
Respiratory effects	Likely to be causal
Central nervous system	Inadequate information to assess
Mortality	Causal
LONG-TERM EXPOSURES	
Health Outcome	Causality Determination
Cardiovascular effects	Causal
Respiratory effects	Likely to be causal
Mortality	Causal
Reproductive and developmental	Suggestive of a causal relationship
Cancer, Mutagenicity, Genotoxicity	Suggestive of a causal relationship

From EPA, 2009

In terms of estimating health burdens of air pollution exposure, CARB has conducted analyses in the past estimating exposures and quantitative health effects from exposures to particulate matter, as well as other pollutants. The most recent assessment focused on premature mortality and PM2.5 (CARB 2010). The analysis used the EPA's risk assessment methodology for calculating premature mortality, and used ambient air quality measurements averaged over a three year period of 2006-2008. The analysis indicated that PM2.5 related premature deaths in California as 9,200 with an uncertainty range of 7,300 – 11,000. Estimates were also made at for the California Air Basins. For the South Coast Air Basin, the estimate was 4,900 with an uncertainty range of 3,900 – 6,000. These estimates were calculated using the associations of cardiopulmonary mortality and PM2.5 from the second exposure period from Krewski (2009). The associations from the first exposure period from Krewski, 2009 as well as other cause of death estimates were also presented.

Another analysis of health impacts in the South Coast was conducted as part of the Draft Socioeconomic Report for the 2012 AQMP. The analysis estimates the

anticipated costs and benefits of adopting the measures in the Draft 2012 AQMP. Adopting these measures is projected to result in attainment of the national PM2.5 standards by 2014. The total average annual quantifiable benefits associated with implementing the Draft 2012 AQMP were calculated and represent the currently quantifiable benefit of moving beyond today’s regulations to the level needed to meet the federal PM2.5 standards. The table below shows the number of avoided cases (or person-days) by health effect when the Basin attains the PM2.5 standard in 2014 and also in 2023 that result (SCAQMD 2012). The estimates pertain to the projected PM2.5 reductions only.

TABLE I-10

Changes in Number of Health Effects for Future Years*
for Measures contained in the Draft 2012 AQMP

Health Outcome	Number of Avoided Cases	
	2014	2023
Mortality	668	275
Acute Bronchitis	597	186
Non-Fatal Heart Attacks	29 - 261	12 – 105
Lower & Upper Respiratory Symptoms	18,384	5,750
Emergency Room Visits	153	53
Hospital Admissions	151	62
Minor Restricted Activity Days	287,447	95,093
Work Loss Days	48,805	16,055
Asthma Attacks	26,910	3,628

*Changes reflect differences in base and control cases for a given year. Positive numbers are reductions in symptoms due to the Draft 2012 AQMP.

**Person-days.

ULTRAFINE PARTICLES

As noted above, numerous studies have found association of particulate matter levels with adverse effects, including mortality, hospital admissions, and respiratory disease symptoms. The vast majority of these studies used particle mass of PM10 or PM2.5

as the measure of exposure. Some researchers have postulated, however, that ultrafine particles may be responsible for some of the observed associations of particulate matter and health outcomes (Oberdorster, et al, 1995; Seaton, et al, 1995). Ultrafine particles that have aerodynamic diameter of less than 0.1 μm .

Several potential mechanisms have been brought forward to suggest that the ultrafine portion may be important in determining the toxicity of ambient particulates, some of which are discussed below.

For a given mass concentration, ultrafine particles have much higher numbers and surface area compared to larger particles. Particles can act as carriers for other adsorbed agents, such as trace metals and organic compounds; and the larger surface area may transport more of such toxic agents than larger particles.

Smaller particles can also be inhaled deep into the lungs. As much as 50% of 0.02 μm diameter particles are estimated to be deposited in the alveolar region of the lung. There is complex nature of the relation between deposition and particle size. The ultrafine particles generally have higher fractional deposition in the alveolar region. However, for the smaller nucleation mode (particles less than 0.01 μm size) the deposition in the alveolar region declines, but increases in the extrathoracic region.

Exposures of laboratory animals to ultrafine particles have found cardiovascular and respiratory effects. Using an animal model of atherosclerotic disease, mice exposed to concentrated ultrafine particles near a roadway in Southern California showed larger early atherosclerotic lesions than mice exposed to concentrated PM_{2.5} or to filtered air (Araujo, 2008). In a mouse allergy model, exposures to concentrated ultrafine particles resulted in a greater response to antigen challenge to ovalbumin (Li, 2010), indicating that vehicular traffic exposure could exacerbate allergic inflammation in already-sensitized animals.

Controlled exposures of human volunteers to ultrafine particles either laboratory generated or as products of combustion, such as diesel exhaust containing particles, have found physiological changes related to vascular effects. Mills, 2011, for example found exposure to diesel exhaust particulate attenuated both acetylcholine and sodium-nitroprusside -induced vasorelaxation.

There are no long-term studies of human population exposure to ultrafine particle, as there is a lack of a monitoring network in the U.S. There have been several cross sectional epidemiological studies of ultrafine particles, mainly from Europe. Some of these studies found effects on hospital admissions, emergency department visits, for respiratory and cardiovascular effects. Other studies, however, have not found

such effects (EPA, 2009). Concentrations of ultrafine particles can vary geographically, and it is not clear how well central site monitors may capture actual exposures.

EPA staff has presented conclusions on causal determination of several health effects of ultrafine PM based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the table below.

Additional discussion on the sources and health effects of ultrafine particles can be found in Chapter 9 of the 2012 AQMP.

CARBON MONOXIDE

The high affinity of carbon monoxide (CO) to bond with oxygen-carrying proteins (hemoglobin and myoglobin) results in reduced oxygen supply in the bloodstream of exposed individuals. The reduced oxygen supply is responsible for the toxic effects

of CO which are typically manifested in the oxygen-sensitive organ systems. The effects have been studied in controlled laboratory environments involving exposure of humans and animals to CO, as well as in population-based studies of ambient CO exposure effects. People with deficient blood supply to the heart (ischemic heart disease) are known to be susceptible to the effects of CO. Protection of this group is the basis of the existing National Ambient Air Quality Standards for CO at 35 ppm for one hour and 9 ppm averaged over eight hours. The health effects of ambient CO have been recently reviewed (U.S. EPA, 2000, 2010).

Inhaled CO has no known direct toxic effect on lungs but rather exerts its effects by interfering with oxygen transport through the formation of carboxyhemoglobin (COHb, a chemical complex of CO and hemoglobin). Exposure to CO is often evaluated in terms of COHb levels in blood measured as percentage of total hemoglobin bound to CO. COHb levels in non-smokers range between 0.3 and 0.7% and 5 to 10% in smokers. COHb levels in excess of 1.5% in a significant proportion of urban non-smoking populations can be considered as evidence of widespread exposure to environmental CO.

Under controlled laboratory conditions, healthy subjects exposed to CO sufficient to result in 5% COHb levels exhibited reduced duration of maximal exercise performance and consumption of oxygen. Studies involving subjects with coronary artery disease who engaged in exercise during CO exposures have shown that COHb levels as low as 2.4% can lead to earlier onset of electrocardiograph changes indicative of deficiency of oxygen supply to the heart. Other effects include an earlier onset of chest pain, an increase in the duration of chest pain, and a decrease in oxygen consumption.

Findings of epidemiologic studies have observed associations between ambient CO concentration and emergency department visits and hospital admissions for ischemic heart disease and other cardiovascular diseases.

Animal studies associated with long-term exposure to CO resulting in COHb levels that are equivalent to those observed in smokers have shown indication of reduction in birth weight and impaired neurobehavior in the offspring of exposed animals.

Epidemiological studies conducted in Southern California have indicated an association with CO exposure during pregnancy to increases in pre-term births (Ritz, 2000). However, the results were not consistent in different areas studied. The increase in the pre-term births was also associated with PM10 levels. Another study found increased risks for cardiac related birth defects with carbon monoxide exposure in the second month of pregnancy (Ritz, 2002). Toxicological studies in

laboratory animals with higher than ambient levels of CO have also reported decrements in birth weight and prenatal growth.

EPA staff has presented conclusions on causal determination of the health effects of carbon monoxide based on a recent review of the available scientific studies (EPA, 2010). These are depicted in the table below.

TABLE I-12

Causal Determination for Health Effects of Carbon Monoxide

SHORT-TERM EXPOSURES	
Health Outcome	Causality Determination
Cardiovascular morbidity	Likely to be a causal relationship
Central nervous system	Suggestive
Respiratory morbidity	Suggestive
Mortality	Suggestive
LONG-TERM EXPOSURES

Cardiovascular morbidity	Inadequate
Central nervous system	Suggestive
Birth outcomes and developmental effects	Suggestive
Respiratory morbidity	Inadequate
Mortality	Not likely to be a causal relationship

From EPA, 2010

NITROGEN DIOXIDE

The U.S. EPA has recently reviewed the health effects of nitrogen dioxide (U.S. EPA, 2008a). Evidence for low-level nitrogen dioxide (NO₂) exposure effects is derived from laboratory studies of asthmatics and from epidemiological studies. Additional supportive evidence is derived from animal studies.

Some epidemiological studies using the presence of an unvented gas stove as a surrogate for indoor NO₂ exposures suggest an increased incidence of respiratory infections or symptoms in children. However the evidence is mixed.

Recent studies related to outdoor exposure have found health effects associated with ambient NO₂ levels, including respiratory symptoms, respiratory illness, decreased lung function, increased emergency room visits for asthma, and cardiopulmonary mortality. However, since NO₂ exposure generally occurs in the presence of other pollutants, such as particulate matter, these studies are often unable to determine the specific role of NO₂ in causing effects.

The Children's Health Study in Southern California found associations of air pollution, including NO₂, PM₁₀, and PM_{2.5}, with respiratory symptoms in asthmatics (McConnell, 1999). Particles and NO₂ were correlated, and effects of individual pollutants could not be discerned. A subsequent analysis indicated a stronger role for NO₂ (McConnell, 2002).

Ambient levels of NO₂ were also associated with a decrease in lung function growth in a group of children followed for eight years. In addition to NO₂, the decreased growth was also associated with particulate matter and airborne acids. The study authors postulated this may be a result of a package of pollutants from traffic sources (Gauderman, 2004).

Results from controlled exposure studies of asthmatics demonstrate an increase in the tendency of airways to contract in response to a chemical stimulus (bronchial reactivity) or after inhaled allergens. Effects were observed with exposures from 0.1 to 0.3 ppm NO₂ for periods ranging from 30 minutes to 3 hours. A similar response is reported in some studies with healthy subjects at higher levels of exposure (1.5 - 2.0 ppm). Mixed results have been reported when people with chronic obstructive lung disease are exposed to low levels of NO₂.

Short-term controlled studies of animals exposed to NO₂ over a period of several hours indicate cellular changes associated with allergic and inflammatory response and interference with detoxification processes in the liver. In some animal studies

the severity of the lung structural damage observed after relatively high levels of short-term ozone exposure is observed to increase when animals are exposed to a combination of ozone and NO₂.

In animals, longer-term (3-6 months) repeated exposures at 0.25 ppm appear to decrease one of the essential cell-types (T-cells) of the immune system. Non-specific changes in cells involved in maintaining immune functions (cytotoxic T-cells and natural killer cells) have been observed in humans after repeated exposure (4-6 days) to >0.6 ppm of NO₂ (20 min. - 2 hours). All these changes collectively support the observation reported both in population and animal studies of increased susceptibility to infections, as a result of NO₂ exposure.

The U.S. EPA recently adopted a new short-term standard of 100 ppb (0.1 ppm) averaged over 1 hour. The standard was designed to protect against increases in airway reactivity in individuals with asthma observed in controlled exposure studies, as well as respiratory symptoms observed in epidemiological studies. The new standard also requires additional monitoring for NO₂ near roadways.

SULFUR DIOXIDE

Controlled laboratory studies involving human volunteers have clearly identified asthmatics as a very sensitive group to the effects of ambient sulfur dioxide (SO₂) exposures. Healthy subjects have failed to demonstrate any short-term respiratory functional changes at exposure levels up to 1.0 ppm over 1-3 hours.

In exercising asthmatics, brief exposure (5-10 minutes) to SO₂ at levels between 0.2-0.6 ppm can result in significant alteration of lung function, such as increases in airway resistance and decreases in breathing capacity. In some, the exposure can result in severe symptoms necessitating the use of medication for relief. The response to SO₂ inhalation is observable within 2 minutes of exposure, increases further with continuing exposure up to 5 minutes then remains relatively steady as exposure continues. SO₂ exposure is generally not associated with any delayed reactions or repetitive asthmatic attacks.

In epidemiologic studies, associations of SO₂ levels with increases in respiratory symptoms, increases in emergency department visits and hospital admissions for respiratory-related causes have been reported. Coupled with the human clinical studies, these data suggest that SO₂ can trigger asthmatic episodes in individuals with pre-existing asthma.

The U.S. EPA has recently revised the SO₂ air quality standard. The previous 24-hour standard was rescinded and replaced with a new 1-hour standard at 75 ppb (0.075 ppm) to protect against acute asthma attacks in sensitive individuals.

Animal studies have shown that despite SO₂ being a respiratory irritant, it does not cause substantial acute or chronic toxicity in animals exposed at ambient concentrations. However, relatively high exposures (10 ppm of SO₂ for 72 hours) in mice can lead to tissue damage, fluid accumulation and sloughing of respiratory lining. Sensitization to allergies is observable in guinea pigs repeatedly exposed to high levels (72 ppm) of SO₂. This effect needs further evaluation in clinical and population studies to identify any chronic exposure impact on both asthmatic incidence and attacks in a population.

Some epidemiological studies indicate that the mortality and morbidity effects associated with the fine fraction of particles show a similar association with ambient SO₂ levels. In these studies, efforts to separate the effects of SO₂ from fine particles have not been successful. Thus, it is not clear whether the two pollutants act synergistically, or whether being generated from similar combustion sources, they represent the same pollution index for the observed effects.

SULFATES

Based on a level determined necessary to protect the most sensitive individuals, the California Air Resources Board (CARB) in 1976 adopted a standard of 25 µg/m³ (24-hour average) for sulfates. There is no federal air quality standard for sulfates.

In recent years, a vast majority of effects (mortality and morbidity) associated with fine particles (PM_{2.5}) and sulfur dioxide have shown a similar association with ambient sulfate levels in some population studies. The efforts to fully separate the effects of sulfates from other coexisting pollutants have not been successful. This may be due to the fact that these pollutants covary under ambient conditions, having been emitted from common sources; and the effects observed may be due to the combination of pollutants, rather than a single pollutant.

A clinical study involving exposure of human subjects to sulfuric acid aerosol indicated that adolescent asthmatics may be a susceptible population subgroup with some changes in lung function observed with exposures below 100 µg/m³. In

general, however, laboratory exposures of human volunteers to sulfates at or near ambient levels have not found significant changes in lung function.

Results from animal studies involving exposures to sulfuric acid aerosol, ammonium bisulfate and ammonium sulfate indicate that acidic particles (former two) are more toxic than non-acidic particles (latter). In addition, the severity or magnitude of both mortality and morbidity effects is relatively higher in population studies of the eastern United States and Canada where sulfate concentrations are higher than for those observed in the western United States. Mixed results have been reported from studies which attempted to ascertain the role of acidity in determining the observed toxicity.

LEAD

The U.S. EPA has recently reviewed the health effects of ambient lead exposures in conjunction with a review of the NAAQS for lead. (U.S. EPA 2006b; U.S. EPA 2007b). The following summary is taken from these reviews.

There are a number of potential public health effects at low level exposures. The health implications are generally indexed by blood lead levels, which are related to lead exposures both from inhalation as well as from ingestion. As identified by EPA, effects include impacts on population IQ, as well as heart disease and kidney disease. The array of health effects includes the following.

- Heme biosynthesis and related functions;
- Neurological development and function;
- Reproduction and physical development;
- Kidney function;
- Cardiovascular function
- Immune function

Children appear to be sensitive to the neurological toxicity of lead, with effects observed at blood lead concentration ranges of 5 – 10 µg/dL, or possibly lower. No clear threshold has yet been established for such effects.

According to the EPA review, the most important effects observed are neurotoxic effects in children and cardiovascular effects in adults. The effects in children include impacts on intellectual attainment and school performance.

EPA has recently revised the NAAQS for lead to a level of 0.15 $\mu\text{g}/\text{m}^3$ averaged over a rolling 3 month period to protect against lead toxicity. The following two charts, taken from the U.S. EPA review, depict the health effects of lead in relation to blood levels. In the figure, the question marks indicate that there are no demonstrated threshold blood lead levels for health effects. The Centers for Disease Control (CDC) has recently revised their lead hazard information and replaced their level of concern for adverse effects of 10 $\mu\text{g}/\text{dL}$ blood lead level with a childhood blood lead level reference value of 5 $\mu\text{g}/\text{dL}$ to identify children and environments associated with lead-exposure hazards (CDC, 2012).

Lowest Observed Effect Blood Lead Level	Neurological Effects	Hematological Effects	Immune Effects
30 $\mu\text{g}/\text{dL}$		Increased urinary δ -aminolevulinic acid	
15 $\mu\text{g}/\text{dL}$	Behavioral disturbances (e.g., inattention, delinquency) Altered electrophysiological responses	Erythrocyte protoporphyrin (EP) elevation	
10 $\mu\text{g}/\text{dL}$	Effects on neuromotor function CNS cognitive effects (e.g., IQ deficits)	Inhibition of δ -aminolevulinic acid dehydratase (ALAD) Pyrimidine-5'-nucleotidase (Py5N) activity inhibition	Effects on humoral (\uparrow serum IgE) and cell-mediated (\downarrow T-cell abundance) immunity
5 $\mu\text{g}/\text{dL}$	↓ (???)	↓ (???)	
0 $\mu\text{g}/\text{dL}$			

FIGURE I-5

Summary of Lowest Observed Effect Levels for Key Lead- Induced Health Effects in Children (From U.S. EPA 2007b)

Lowest Observed Effect Blood Lead Level	Neurological Effects	Hematological Effects	Cardiovascular Effects	Renal Effects
30 µg/dL	Peripheral sensory nerve impairment	Erythrocyte protoporphyrin (EP) elevation in males		Impaired Renal Tubular Function
20 µg/dL	Cognitive impairment			
15 µg/dL	Postural sway	Erythrocyte protoporphyrin (EP) elevation in females		
10 µg/dL		Increased urinary δ-aminolevulinic acid	Elevated blood pressure	
5 µg/dL		Inhibition of δ-aminolevulinic acid dehydratase (ALAD)	↓ (???)	Elevated serum creatine (↓ creatine clearance)
0 µg/dL

Summary of Lowest Observed Effect Levels for Key Lead- Induced Health Effects in Adults
(From U.S. EPA 2007b)

TOXIC AIR CONTAMINANTS

Toxic air contaminants are pollutants for which there generally are no ambient air quality standards. The Toxic Air Contaminant Identification and Control Act (AB1807, Tanner 1983) created California’s program to reduce exposures to air toxics. The air Toxics “Hot Spots” Information and Assessment Act (AB2588, Connelly 1987) supplements the program by requiring statewide air toxics inventories, notification of people exposure to significant health risks, and facility plans to reduce these risks. Under California’s Air Toxics Program, CARB staff and Office of Environmental Health Hazard Assessment (OEHHA) assess the health effects of substances that may pose a risk of adverse health effects. These effects are usually an increased risk for cancer, adverse birth outcomes and respiratory effects. After review by the state Scientific Review Panel, CARB holds a public hearing on whether to formally list substances that may pose a significant risk to public health as a Toxic Air Contaminant.

OEHHA also establishes potency factors for air toxics that are carcinogenic. The potency factors can be used to estimate the additional cancer risk from ambient levels of toxics. This estimate represents the chance of contracting cancer in an individual

over a lifetime exposure to a given level of an air toxic and is usually expressed in terms of additional cancer cases per million people exposed.

For non-cancer health effects, OEHHA has developed acute and chronic Reference Exposure Levels (RELs). RELs are concentrations in the air below which adverse health effects are not likely to occur. Acute RELs refer to short-term exposures, generally of one-hour duration. Chronic RELs refer to long-term exposures of several years. OEHHA has also established 8-hour RELs for several substances. The ratio of ambient concentration to the appropriate REL can be used to calculate a Hazard Index. A Hazard Index of less than one would not be expected to result in adverse effects. The measured levels from the most recent study were below the applicable Reference Exposure Levels.

The District conducted studies on the ambient concentrations and estimated the potential health risks from air toxics (SCAQMD, 2008). In the latest study, a two year monitoring program was undertaken at 10 sites throughout the SCAB over the time period 2004-2006. Over 30 substances were measured, and annual average levels were calculated. The results showed that the overall risk for excess cancer from a 70-year lifetime exposure to the levels of air toxics calculated as the average level at the 10 sites was about 1,200 in a million. The largest contributor to this risk was diesel particulate matter, accounting for about 84% of the air toxics risk. A breakdown of the major contributors to the air toxics risk is shown in the figure below. The average levels measured were also compared to the non-cancer Reference Exposure Levels. The measurements were below the established RELs.

The California Air Resources Board listed Diesel Particulate Matter as a Toxic Air Contaminant in 1989. The International Agency for Research on Cancer, an arm of the World Health Organization, classified diesel exhaust as probably carcinogenic to humans in 1989. Recently IARC convened an international panel of scientists to review the published literature since the initial classification regarding the carcinogenicity of diesel combustion emissions. The panel concluded that Diesel Exhaust is a substance that causes lung cancer in humans (Benbrahim-Tallaa, 2012).

FIGURE I-7

Major Pollutants Contributing to Air Toxics Cancer Risk in the South Coast Air Basin

The key air toxics contributing to risk from mobile and stationary sources are listed in the table below.

TABLE I-13

Key Toxic Air Contaminants in the SCAB

MOBILE SOURCES	STATIONARY SOURCES
Acetaldehyde	Hexavalent Chromium
Benzene	Methylene Chloride
1,3 Butadiene	Nickel
Diesel Particulate Matter	Perchloroethylene
Formaldehyde	Trichloroethylene

CONCLUSION

A large body of scientific evidence shows that the adverse impacts of air pollution in human and animal health are clear. A considerable number of population-based and laboratory studies have established a link between air pollution and increased morbidity and, in some instances, earlier mortality.

As the scientific methods for the study of air pollution health effects has progressed over the past decades, adverse effects have been shown to occur at lower levels of exposure. For some pollutants, no clear thresholds for effects have been demonstrated. The new findings have, in turn, led to the revision and lowering of National Ambient Air Quality Standards which, in the judgment of the Administrator of the U.S. EPA, are necessary to protect public health. The figures below are meant to convey some of the historical context to recent revisions to the NAAQS for ozone and for particulate matter.

To: Jean Ospital
Cc: Herner, Jorn@ARB
Subject: RE: AQMD Advisory Council Update and Meeting on October 11, 2012

Jean,

Thank you for the opportunity to review and comment on Appendix I of the SC AQMP. Overall, it is a well-written document on the health effects of exposure to the major air pollutants, summarizing the most important literature in the field. Our comments, which are embedded in the document (attached), are brief. There are a few suggestions for improving clarity, and we noted a few minor errors in fact that should be corrected.

Please contact me if you have any questions, and thanks, again. I hope this email finds you well.

Regards,
Linda

RE: Update on Draft Appendix I Review

Greetings to all.

At the July 11, 2012 meeting of the Advisory Council the group requested that another meeting be held to review Appendix I and any revisions that might be made. We have scheduled a meeting of the Advisory Council for October 11, 2012. Details are below.

2012 AQMP Advisory Council meeting
October 11, 2012
10 am - noon
Room CC8
AQMD Offices
21865 Copley Drive,
Diamond Bar, CA

An interim updated draft has been posted to the AQMD website at <http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/AppI.pdf>. Additions to the initial draft were made based on suggestions from the advisory group, and include a brief summary of lead health effects, an expansion of the conclusion section to reflect how health studies support revisions to the National Ambient Air Quality Standards, information on EPA's proposed revisions to the PM2.5 NAAQS, and the recent finding from the International Agency for Research on Cancer regarding the carcinogenicity of diesel exhaust.

We have also received one public comment to the AQMP that is relevant to the draft Appendix I, which I attach for your information. A member of the public also distributed a handout at a meeting of the AQMP Advisory Group relevant to the draft Appendix I, and the handout is also attached for your information. Prior to the October 11 meeting, we will be providing you another interim draft version of Appendix I, which will be prepared in conjunction with CARB. Additionally, we expect to have additional outside reviews of the draft Appendix by the end of this month. We will attach any additional comments relative to the draft Appendix as we receive them so that they will also be available to you prior to the October 11 meeting.

If any of you have additional comment on the draft Appendix I, please forward to me by the end of this month (Sept 30, 2012) if possible, but at the latest prior to the next meeting of the Advisory Council on October 11, 2012.

Revisions to the current draft made as a result of comments received by the end of September will be sent to you prior to the October 11 Advisory Council meeting for your review. Additionally, the revised draft will have all comments received as attachments.

Additional information regarding the Draft 2012 AQMP is available at <http://www.aqmd.gov/aqmp/2012aqmp/index.htm>.

Lastly, a reminder that the Advisory Council is subject to the California open meetings regulations. Please do not copy other Advisory Council members regarding any comments or correspondence. There will be opportunity for discussion at the meeting on October 11.

Thanks.

INTRODUCTION

This document presents a summary of scientific findings on the health effects of ambient air pollutants. The California Health and Safety Code Section 40471(b) requires that the South Coast Air Quality Management District prepare a report on the health impacts of particulate matter in the South Coast Air Basin (SCAB) in conjunction with the preparation of the Air Quality Management Plan revisions. This document, which was prepared to satisfy that requirement, also includes the effects of the other major pollutants.

HEALTH EFFECTS OF AIR POLLUTION

Ambient air pollution is a major public health concern. Excess deaths and increases in illnesses associated with high air pollution levels have been documented in several episodes as early as 1930 in Meuse Valley, Belgium; 1948 in Donora, Pennsylvania; and 1952 in London. Although levels of pollutants that occurred during these acute episodes are now unlikely in the United States, ambient air pollution continues to be linked to increases in illness (morbidity) and increases in death rates (mortality).

The adverse health effects associated with air pollution are diverse and include:

- Increased mortality
- Increased health care utilization (hospitalization, physician and emergency room visits)
- Increased respiratory illness (symptoms, infections, and asthma exacerbation)
- Decreased lung function (breathing capacity)
- Lung inflammation
- Potential immunological changes
- Increased airway reactivity to a known chemical exposure - a method used in laboratories to evaluate the tendency of airways to have an increased possibility of developing an asthmatic response
- A decreased tolerance for exercise.

The evidence linking these effects to air pollutants is derived from population-based observational and field studies (epidemiological) as well as controlled laboratory studies involving human subjects and animals. There have been an increasing number of studies focusing on the mechanisms (that is, on learning how specific organs, cell types, and biochemicals are involved in the human body's response to air pollution) and specific pollutants responsible for individual effects. Yet the underlying biological pathways for these effects are not always clearly understood.

Although individuals inhale pollutants as a mixture under ambient conditions, the regulatory framework and the control measures developed are mostly pollutant-specific. This is appropriate, in that different pollutants usually differ in their sources, their times and places of occurrence, the kinds of health effects they may cause, and their overall levels of health risk. Different pollutants, from the same or different sources, may sometimes act together to harm health more than they would acting separately. Nevertheless, as a practical matter, health scientists, as well as regulatory officials, usually must deal with one pollutant at a time in determining health effects and in adopting air quality standards. To meet the air quality standards, comprehensive plans are developed such as the Air Quality Management Plan (AQMP), and to minimize toxic exposure a local air toxics control plan is also prepared. These plans examine multiple pollutants, cumulative impacts, and transport issues related to attaining healthful air quality. A brief overview of the effects observed and attributed to various air pollutants is presented in this document.

This summary is drawn substantially from reviews presented previously (SCAQMD, 1996, 2003, 2007), and from reviews on the effects of air pollution by the American Thoracic Society (ATS, 1996), the U.S. EPA reviews for ozone (U.S. EPA, 2006), Carbon Monoxide (U.S. EPA, 2010), and Particulate Matter (U.S. EPA, 2004, 2009), from a published review of the health effects of air pollution (Brunekreef and Holgate, 2002), and from reviews prepared by the California EPA Office of Environmental Health Hazard Assessment for Particulate Matter (Cal EPA, 2002) and for Ozone (Cal EPA, 2005). Additional materials are from EPA's current review of the ozone standard and health effects (EPA, 2011). More detailed citations and discussions on air pollution health effects can be found in these references.¹

¹ Most of the studies referred to in this appendix are cited in the above sources. Only more recent specific references will be cited in this summary.

OZONE

Ozone is a highly reactive compound, and is a strong oxidizing agent. When ozone comes into contact with the respiratory tract, it can react with tissues and cause damage in the airways. Since it is a gas, it can penetrate into the gas exchange region of the deep lung.

The EPA primary standard for ozone, adopted in 2008, is 0.075 ppm averaged over eight hours. The California Air Resources Board (CARB) has established standards of 0.09 ppm averaged over one hour and at 0.070 ppm averaged over eight hours.

The major subgroups of the population considered to be at increased risk from ozone exposure are outdoor exercising individuals, including children, and people with preexisting respiratory disease(s) such as asthma. The data base identifying the former group as being at increased risk to ozone exposure is much stronger and more quantitative than that for the latter group, probably because of a larger number of studies conducted with healthy individuals. The adverse effects reported with short-term ozone exposure are greater with increased activity because activity increases the breathing rate and the volume of air reaching the lungs, resulting in an increased amount of ozone reaching the lungs. Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher ventilation rate than adults.

A number of adverse health effects associated with ambient ozone levels have been identified from laboratory and epidemiological studies (EPA, 1996; 2006, 2011; ATS, 1996). These include increased respiratory symptoms, damage to cells of the respiratory tract, decrease in lung function, increased susceptibility to respiratory infection, and increased risk of hospitalization.

Increases in ozone levels are associated with elevated absences from school. The Children's Health Study, conducted by researchers at the University of Southern California, followed a cohort of children that live in 12 communities in Southern California with differing levels of air pollution for several years. A publication from this study reported that school absences in fourth graders for respiratory illnesses were associated with ambient ozone levels. An increase of 20 ppb ozone was associated with an 83% increase in illness-related absence rates (Gilliland, 2001).

The number of hospital admissions and emergency room visits for all respiratory causes (infections, respiratory failure, chronic bronchitis, etc.) including asthma

shows a consistent increase as ambient ozone levels increase in a community. These excess hospital admissions and emergency room visits are observed when hourly ozone concentrations are as low as 0.06 to 0.10 ppm.

Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).

Multicity studies of short-term ozone exposures (days) and mortality have also examined regional differences. Evidence was provided that there were generally higher ozone-mortality risk estimates in northeastern U.S. cities, with the southwest and urban mid-west cities showing lower or no associations (Smith, 2009; Bell, 2008). Another long-term study of a national cohort found that long-term exposures to ozone were associated with respiratory-related causes of mortality, but not cardiovascular-related causes, when PM2.5 exposure were also included in the analysis.

Several population-based studies suggest that asthmatics are more adversely affected by ambient ozone levels, as evidenced by increased hospitalizations and emergency room visits. Laboratory studies have attempted to compare the degree of lung function change seen in age and gender-matched healthy individuals versus asthmatics and those with chronic obstructive pulmonary disease. While the degree of change evidenced did not differ significantly, that finding may not accurately reflect the true impact of exposure on these respiration-compromised individuals. Since the respiration-compromised group may have lower lung function to begin with, the same degree of change may represent a substantially greater adverse effect overall.

Another publication from the Children's Health Study focused on children and outdoor exercise. In communities with high ozone concentrations, the relative risk of developing asthma in children playing three or more sports was found to be over three times higher than in children playing no sports (McConnell, 2002). These findings indicate that new cases of asthma in children are associated with heavy exercise in communities with high levels of ozone. While it has long been known that air pollution can exacerbate symptoms in individuals with respiratory disease, this is among the first studies that indicate ozone exposure may be causally linked to asthma onset.

Author: Administrator Subject: Sticky Note Date: 9/14/2012 1:58:20 PM
This is a rather strong conclusion given that there is only one study that supports the statement.

In addition, human and animal studies involving both short-term (few hours) and long-term (months to years) exposures indicate a wide range of effects induced or associated with ambient ozone exposure. These are summarized in Table I-1.

TABLE I-1

Adverse Health Effects of Ozone (O₃) - Summary of Key Studies

O ₃ CONCENTRATION AND EXPOSURE HR., PPM	HEALTH EFFECT
Ambient air containing 0.10 - 0.15 daily 1-h max over days to weeks; ≥ 0.05 (8 hour average)	Decreased breathing capacity, in children, adolescents, and adults exposed to O ₃ outdoors Exacerbation of respiratory symptoms (e.g., cough, chest pain) in individuals with preexisting disease (e.g., asthma) with low ambient exposure, decreased temperature, and other environmental factors resulting in increased summertime hospital admissions and emergency department visits for respiratory causes
≥0.12 (1-3h) ≥0.06 (6.6h) (chamber exposures)	Decrements in lung function (reduced ability to take a deep breath), increased respiratory symptoms (cough, shortness of breath, pain upon deep inspiration), increased airway responsiveness and increased airway inflammation in exercising adults Effects are similar in individuals with preexisting disease except for a greater increase in airway responsiveness for asthmatic and allergic subjects Older subjects (>50 yrs old) have smaller and less reproducible changes in lung function Attenuation of response with repeated exposure
≥0.12 with prolonged, repeated exposure (chamber exposures)	Changes in lung structure, function, elasticity, and biochemistry in laboratory animals that are indicative of airway irritation and inflammation with possible development of chronic lung disease Increased susceptibility to bacterial respiratory infections in laboratory animals

From: SCAQMD, 1996; EPA, 2007

Some lung function responses (volume and airway resistance changes) observed after a single exposure to ozone exhibit attenuation or a reduction in magnitude with repeated exposures. Although it has been argued that the observed shift in response is evidence of a probable adaptation phenomenon, it appears that while functional changes may exhibit adaptation, biochemical and cellular changes which may be

- Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:19:55 AM
 We are not aware of any studies that report reduced pulmonary function and symptoms in people exposed to 0.05 ppm ozone. Only a small percentage of studied subjects show these effects with exposure to 0.06 ppm (5% of fewer of the total number studied to date).
- Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:20:39 AM
 Respiratory symptoms have also been noted in healthy children and younger adults with this sort of exposure, although not in healthy older adults.
- Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:20:23 AM
 This is an incorrect usage of the work "adaptation". Adaptation implies a permanently altered biological process, which is not the case with ozone. The correct term here is "attenuation" because the altered biological response only persists so long as regular ozone exposures continue.

associated with episodic and chronic exposure effects may not exhibit similar adaptation. That is, internal damage to the respiratory system may continue with repeated ozone exposures, even if externally observable effects (chest symptoms and reduced lung function) disappear.

In a laboratory, exposure of human subjects to low levels of ozone causes reversible decrease in lung function as assessed by various measures such as respiratory volumes, airway resistance and reactivity, irritative cough and chest discomfort. Lung function changes have been observed with ozone exposure as low as 0.06 to 0.12 ppm for 6-8 hours under moderate exercising conditions. Similar lung volume changes have also been observed in adults and children under ambient exposure conditions (0.10 - 0.15 ppm). The responses reported are indicative of decreased breathing capacity and are reversible.

The results of several studies where human volunteers were exposed to ozone for 6.6 hours at levels between 0.04 and 0.12 ppm were recently summarized (Brown, 2008). As shown in the figure below, there is an increasing response on lung function with increasing exposure levels in moderately exercising subjects.

FIGURE I-1

Comparison of mean ozone-induced decrements in lung function following 6.6 hours of ozone exposure (from Brown, 2008)

Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:21:08 AM
Please specify the averaging time and whether or not the subjects were exercising, and if so, the ventilation rate. The total inhaled dose is the important factor, not just the ambient concentration.

In addition to controlled laboratory conditions, studies of individuals exercising outdoors, including children attending summer camp, have shown associations of reduced lung function with ozone exposure. There were wide ranges in responses among individuals.

Results of epidemiology studies support the relationship between ozone exposure and respiratory effects. Several, but not all, studies have found associations of short-term ozone levels and hospital admissions and emergency department admissions for respiratory-related conditions (EPA, 2011).

In laboratory studies, cellular and biochemical changes associated with respiratory tract inflammation have also been consistently reported in the airway lining after low level exposure to ozone. These changes include an increase in specific cell types and in the concentration of biochemical mediators of inflammation and injury such as cytokines and fibronectin. Indications of lung injury and inflammatory changes have been observed in healthy adults exposed to ozone in the range of 0.06 to 0.10 ppm.

The susceptibility to ozone observed under ambient conditions could be due to the combination of pollutants that coexist in the atmosphere or ozone may actually sensitize these subgroups to the effects of other pollutants.

Some animal studies show results that indicate possible chronic effects including functional and structural changes of the lung. These changes indicate that repeated inflammation associated with ozone exposure over a lifetime may result in sufficient damage to respiratory tissue such that individuals later in life may experience a reduced quality of life in terms of respiratory function and activity level achievable. An autopsy study involving Los Angeles County residents provided supportive evidence of lung tissue damage (structural changes) attributable to air pollution.

A study of birth outcomes in southern California found an increased risk for birth defects in the aortic and pulmonary arteries associated with ozone exposure in the second month of pregnancy (Ritz et al., 2002). This is the first study linking ambient air pollutants to birth defects in humans. Studies conducted since mostly focusing on cardiac and oral cleft defects have found mixed results, with some showing associations, but others did not. Confirmation by further studies is needed.

In summary, adverse effects associated with ozone exposures have been well documented, although the specific causal mechanism is still somewhat unclear.

This page contains no comments

It may be instructive to provide the overall EPA staff preliminary conclusions on the causality on ozone health effects for the health outcomes evaluated (EPA, 2011). These are provided in the two tables below.

TABLE I-2

Summary of Causal Determinations for Short-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Effects on Liver and Xenobiotic Metabolism	Inadequate to infer a causal relationship
Effects on Cutaneous and Ocular Tissues	Inadequate to infer a causal relationship
Mortality	Likely to be a causal relationship

From EPA, 2011

TABLE I-3

Summary of Causal Determinations for Long-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Likely to be a causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Reproductive and Developmental Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Carcinogenicity and Genotoxicity	Inadequate to infer a causal relationship
Mortality	Suggestive of a causal relationship

From EPA, 2011

PARTICULATE MATTER

Airborne particulates are a complex group of pollutants that vary in source, size and composition, depending on location and time. The components include nitrates, sulfates, elemental carbon, organic carbon compounds, acid aerosols, trace metals, and material from the earth's crust. Substances of biological origin, such as pollen and spores, may also be present.

Until several years ago, the health effects of particulates were focused on those sized 10 µm (micrometers) aerodynamic diameter and smaller. These can be inhaled through the upper airways and deposited in the lower airways and gas exchange tissues in the lung. These particles are referred to as PM10. EPA initially promulgated ambient air quality standards for PM10 of 150 µg/m³ averaged over a 24-hour period, and 50 µg/m³ for an annual average. EPA has since rescinded the annual PM10 standard, but kept the 24-hour standard.

In recent years additional focus has been placed on particles having an aerodynamic diameter of 2.5 µm or less (PM2.5). A greater fraction of particles in this size range can penetrate and deposit deep in the lungs. The EPA recently lowered the air quality standards for PM2.5 to 35 µg/m³ for a 24-hour average and reaffirmed 15 µg/m³ for an annual average standard. There was considerable controversy and debate surrounding the review of particulate matter health effects and the consideration of ambient air quality standards (Kaiser, 1997; Vedal, 1997) when the EPA promulgated the initial PM2.5 standards in 1997.

Since that time, numerous studies have been published, and some of the key studies were closely scrutinized and analyses repeated. The result is that there are now substantial data confirming the adverse health effects of PM2.5 exposures.

There are also differences in the composition and sources of particles in the different size ranges that may have implications for health effects. The particles larger than 2.5 µm (often referred to as the coarse fraction) are mostly produced by mechanical processes. These include automobile tire wear, industrial processes such as cutting and grinding, and resuspension of particles from the ground or road surfaces by wind and human activities.

In contrast, particles smaller than 2.5 µm are mostly derived from combustion sources, such as automobiles, trucks, and other vehicle exhaust, as well as from stationary combustion sources. The particles are either directly emitted or are formed

Author: pwong Subject: Sticky Note Date: 9/26/2012 10:21:25 AM
While the California PM standards values are mentioned in table I-4, there is no discussion or mention in the text unlike ozone.

Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:18:05 AM
You might mention that a new annual average PM2.5 standard is expected by the end of the year. US EPA is considering a range of 12-13 ug/m3.

in the atmosphere from gases that are emitted. Components from material in the earth's crust, such as dust, are also present, with the amount varying in different locations.

Attention to another range of very small particles has been increasing over the last few years. These are generally referred to as "ultrafine" particles, with diameters of 0.1 µm or less. These particles are mainly from fresh emissions of combustion sources, but are also formed in the atmosphere from photochemical reactions. Ultrafine particles have relatively short half lives (minutes to hours) and rapidly grow through condensation and coagulation process into larger particles within the PM2.5 size range. These particles are garnering interest since laboratory studies indicate that their toxicity may be higher on a mass basis than larger particles, and there is evidence that these small particles can translocate from the lung to the blood and to other organs of the body.

There have been several reviews of the health effects of ambient particulate matter (ATS, 1996; Brunekreef, 2002; U.S. EPA, 2004; U.S. EPA, 2009). In addition, the California Air Resources Board (CARB) and the Office of Environmental Health and Hazard Assessment (OEHHA) have reviewed the adequacy of the California Air Quality Standards for Particulate Matter (Cal EPA, 2002).

The major types of effects associated with particulate matter include:

- Increased mortality
- Exacerbation of respiratory disease and of cardiovascular disease as evidenced by increases in:
 - Respiratory symptoms
 - Hospital admissions and emergency room visits
 - Physician office visits
 - School absences
 - Work loss days 
- Effects on lung function
- Changes in lung morphology

The current federal and California standards are listed below:

Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:21:48 AM
We don't think that the work loss days paper specifies the reason for work loss in terms of exacerbated chronic disease. This should be verified with the Ostro paper.

TABLE I-4

Ambient Air Quality Standards for Particulate Matter

STANDARD	FEDERAL	CALIFORNIA
PM10 24-Hour average	150 µg/m ³	50 µg/m ³
PM10 Annual Average	--	20 µg/m ³
PM 2.5 24-Hour Average	35 µg/m ³	--
PM 2.5 Annual Average	15 µg/m ³	12 µg/m ³

Short-Term Exposure Effects

Epidemiological studies have provided evidence for most of the effects listed above. An association between increased daily or several-day-average concentrations of PM10 and excess mortality and morbidity is consistently reported from studies involving communities across the U.S. as well as in Europe, Asia, and South America. A review and analysis of epidemiological literature for acute adverse effects of particulate matter was published by the American Thoracic Society in 1996. Several adverse effects were listed as associated with daily PM10 exposures, as listed in Table I-5. ~~undertaken by Doekery and Pope to estimate these effects as percent increase in mortality associated with each incremental increase of PM10 by 10 µg/m³. The estimates are presented in Table I-5.~~ It also appears that individuals who are elderly or have preexistent lung or heart disease are more susceptible than others to the adverse effects of PM10 (ATS, 1996). Since then many more recent studies have confirmed that excess mortality and morbidity are associated with short term particulate matter levels (Pope, 2006).

Estimates of mortality effects from these studies of PM10 exposures range from 0.3 to 1.7% increase for a 10 µg/m³ increase in PM10 levels. The National Morbidity, Mortality, and Air Pollution Study (NMMAPS), a study of 20 of the largest U.S. cities, determined a combined risk estimate of about a 0.5% increase in total mortality for a 10 µg/m³ increase in PM10 (Scahill, 2000a). This study also analyzed the effects of gaseous co-pollutants. The results indicated that the association of PM10 and mortality were not confounded by the presence of the gaseous pollutants. When the gaseous pollutants were included in the analyses, the significance of the PM10 estimates remained. The PM10 effects were reduced somewhat when O₃ was also considered and tended to be variably decreased when NO₂, CO, and SO₂ were

Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:22:38 AM
 The author should cite the reanalysis of the original NMMAPS studies that were sponsored by HEI. The statistical package used for the original analyses was found to not converge correctly. This led to incorrect RR and standard errors. The corrected papers are from 2003, and all reanalyzed papers that were affected by this statistical problem are in a volume published by HEI, and available on their website. In the case of NMMAPS, the RR dropped to about 0.25% with a 10 ug/m3 change in PM10.

added to the analysis. These results argue that the effects are likely due to the particulate exposures; they cannot readily be explained by coexisting weather stresses or other pollutants.

An expansion of the NMMAPS study to 90 U.S. Cities also reported association with PM10 levels and mortality (Samet 2006). It was discovered that this study was one that used a flawed statistical software package. The investigators have reanalyzed the data using corrected settings for the software (Dominici, 2002a, Dominici 2002b). When the estimates for the 90 cities in the study were recalculated, the estimate changed from 0.41% increase in mortality for a 10 µg/m³ increase in PM10 to a 0.27% increase. There remained a strong positive association between acute exposure to PM10 and mortality. Thus while the quantitative estimate was reduced, the major findings of the study did not change.

TABLE I-5

Combined Effect Estimates of Daily Mean Particulate Pollution (PM10)

% CHANGE IN HEALTH INDICATOR PER EACH 10 µg/m ³ INCREASE IN PM10	
Increase in Daily Mortality	
Total deaths	1.0
Respiratory deaths	3.4
Cardiovascular deaths	1.4
Increase in Hospital Usage (all respiratory diagnoses)	
Admissions	1.4
Emergency department visits	0.9
Exacerbation of Asthma	
Asthmatic attacks	3.0
Bronchodilator use	12.2

(Source: American Journal of Respiratory and Critical Care Medicine, Vol. 153, 113-50, 1996)

Studies of PM2.5 also find associations with elevated mortality. The estimates for PM2.5 generally are in the range of 2.0 to 8.5% increase in total deaths per 25 µg/m³ increase in 24-hour PM2.5 levels. The estimates for cardiovascular related mortality range from 3.0 to 7.0% per 25 µg/m³ 24-hour PM2.5, and for respiratory mortality estimates range from 2.0 to 7.0% per 25 µg/m³ 24-hour PM2.5.

Several studies have attempted to assess the relative importance of particles smaller than 2.5 µm and those between 2.5 µm and 10 µm (PM10-2.5). While some studies report that PM2.5 levels are better predictors of mortality effects, others suggest that PM10-2.5 is also important. Most of the studies found higher mortality associated with PM2.5 levels than with PM10-2.5. For example, a study of six cities in the U.S. found that particulate matter less than 2.5 µm was associated with increased mortality, but that the larger particles were not. Other studies in Mexico City and Santiago, Chile reported that PM10-2.5 was as important as PM2.5. Overall effects estimates for PM10-2.5 fall in the range of 0.5 to 6.0 % excess mortality per 25 µg/m³ 24-hour average.

The relative importance of both PM2.5 and PM10-2.5 may vary in different regions depending on the relative concentrations and components, which can also vary by season. More research is needed to better assess the relative effects of fine (PM2.5) and coarse (PM10-2.5) fractions of particulate matter on mortality.

A number of studies have evaluated the association between particulate matter exposure and indices of morbidity such as hospital admissions, emergency room

visits or physician office visits for respiratory and cardiovascular diseases. The effects estimates are generally higher than the effects for mortality. The effects are associated with measures of PM10 and PM2.5. Effects are also associated with PM10-2.5. Thus, it appears that when a relatively small number of people experience severe effects, larger numbers experience milder effects, which may relate either to the coarse or to the fine fraction of airborne particulate matter.

In the NMMAPS study, hospital admissions for those 65 years or older were assessed in 14 cities. Hospital admissions for these individuals showed an increase of 6% for cardiovascular diseases and a 10% increase for respiratory disease admissions, per $\mu\text{g}/\text{m}^3$ increase in PM10. The excess risk for cardiovascular disease ranges from 3-10% per 50 $\mu\text{g}/\text{m}^3$ PM10 and from 4-10% per 25 $\mu\text{g}/\text{m}^3$ PM2.5 or PM10-2.5.

Similarly, school absences, lost workdays and restricted activity days have also been used in some studies as indirect indicators of acute respiratory conditions. The results are suggestive of both immediate and delayed impact on these parameters following elevated particulate matter exposures. These observations are consistent with the hypothesis that increased susceptibility to infection follows particulate matter exposures.

Some studies have reported that short-term particulate matter exposure is associated with changes in lung function (lung capacity and breathing volume); upper respiratory symptoms (hoarseness and sore throat); and lower respiratory symptoms (increased sputum, chest pain and wheeze). The severity of these effects is widely varied and is dependent on the population studied, such as adults or children with and without asthma. Sensitive individuals, such as those with asthma or pre-existing respiratory disease, may have increased or aggravated symptoms associated with short-term particulate matter exposures. Several studies have followed the number of medical visits associated with pollutant exposures. A range of increases from 3% to 42% for medical visits for respiratory illnesses was found corresponding to a 50 $\mu\text{g}/\text{m}^3$ change in PM10. A limited number of studies also looked at levels of PM2.5 or PM10-2.5. The findings suggest that both the fine and coarse fractions may have associations with some respiratory symptoms.

The biological mechanisms by which particulate matter can produce health effects are being investigated in laboratory studies. Inflammatory responses in the respiratory system in humans and animals exposed to concentrated ambient particles have been measured. These include effects such as increases in neutrophils in the lungs. Other changes reported include increased release of cytokines and interleukins,

chemicals released as part of the inflammatory process. The effects of particulate matter may be mediated in part through the production of reactive oxygen species during the inflammatory process. Recent reviews discuss mechanistic studies in more detail (Brunekreef, 2002; Brook, 2004).

Long-Term Exposure Effects

While most studies have evaluated the acute effects, some studies specifically focused on evaluating the effects of chronic exposure to PM10 and PM2.5. Studies have analyzed the mortality of adults living in different U.S. cities. After adjusting for important risk factors, taken as a whole these studies found a positive association of deaths and exposure to particulate matter. A similar association was observable in both total number of deaths and deaths due to specific causes. The largest effects were observed from cardiovascular causes and ischemic heart disease. A shortening of lifespan was also reported in these studies.

Since the initial promulgation by EPA of the National Ambient Air Quality Standards for PM2.5, controversy has remained over the association of mortality and exposures to PM2.5. Thus an expanded discussion of these studies is presented below.

Significant associations for PM2.5 for both total mortality and cardiorespiratory mortality were reported in a study following a national cohort recruited by the American Cancer Society for a Cancer Prevention Study over several years. A re-analysis of the data from this study confirmed the initial finding (Krewski, 2000). In this study, mortality rates and PM2.5 levels were analyzed for 51 metropolitan areas of the U.S. Average levels from monitors in each area were used to estimate exposures. At these levels of aggregation, regional differences in the association of PM2.5 and mortality were noted, with higher associations in the Northeast, and lower or non-significant associations in the West.

The Harvard Six Cities Study evaluated several size ranges of particulate matter and reported significant associations with PM15, PM2.5, sulfates, and non-sulfate particles, but not with coarse particles (PM15 – PM2.5). An extension of the Harvard Six Cities Cohort confirmed the association of mortality with PM2.5 levels (Laden, 2006). These studies provide evidence that the fine particles, as measured by PM2.5, may be more strongly associated with mortality effects from long-term particulate matter exposures than are coarse compounds. An update to this study covering a follow-up over the years 1974 to 2009 (Lepeule, 2012) was recently published. Findings indicated a linear relationship of PM2.5 levels and mortality

This page contains no comments

This page contains no comments

from all causes, cardiovascular causes, and from lung cancer. According to the authors, the PM2.5 levels decreased over time, but no evidence of a threshold for these effects was found.

A follow-up study of the American Cancer Society cohort confirmed and extended the findings in the initial study. The researchers estimated that, on average, a 10 ug/m3 increase in fine particulates was associated with approximately a 4% increase in total mortality, a 6% increase in cardiopulmonary mortality, and an 8% increase risk of lung cancer mortality (Pope, 2002). The magnitude of effects is larger in the long-term studies than in the short-term investigations. In an additional re analysis and extension of the American Cancer Society cohort from 1982 to 2000 (Krewski, 2009), and including additional metropolitan areas for the most recent years, effects estimates on mortality were similar, though somewhat higher, than those reported previously.

Other national studies include an analysis of mortality and PM2.5 exposures in a Medicare population. Zeger and Associates (2008) assembled a Medicare cohort by including all Medicare enrollees residing in zip codes with centroids within 6 miles of a PM2.5 monitor. PM2.5 data was obtained from the monitoring stations, and mean annual levels were called for the zip codes within six miles of each monitor. The estimated associations between exposures to PM2.5 and mortality for the eastern and central portions of the U.S were similar to those previously published in the Six Cities Study and the American Cancer Society cohorts. The authors reported that there were no significant associations between zip code levels of PM2.5 and mortality rates in the western region of the U.S. This lack of association was attributed largely to the higher PM2.5 levels in Los Angeles area counties compared to other western urban areas, but there were not higher mortality rates in these counties. The authors further reported that they found no associations of PM2.5 with mortality in persons aged 85 years or higher.

Analyses of mortality and PM2.5 levels specific to California have also been reported. A cohort of elderly individuals (average age of 65 yr in 1973) recruited from 11 California counties was followed over several years (Enstrom, 2005). An association for exposure with all cause deaths was reported from 1973–1982. However, no significant association was found in the later time period of 1983–2002. Pollutant levels were taken from ambient monitors and averaged over each county to estimate exposures.

Two analyses of the American Cancer Society cohort focused [specifically](#) on the Los Angeles [Metropolitan](#) area using methods to estimate exposures on a finer geographical scale than previous studies that used geographic scales at the county or metropolitan area. Using data from monitoring stations in the Los Angeles area, one study applied interpolation methods (Jerrett, 2005) and another applied land use regression techniques (Krewski, 2009) to estimate exposures to the study individuals. Significant associations of PM2.5 with mortality from all causes and cardiopulmonary disease were reported, with the magnitude of risks being up to [one](#) times higher than those from the national studies of the American Cancer Society cohort. This provides evidence that using methods to provide more detailed exposure estimates can result in stronger associations of PM2.5 and mortality.

Two recent reports have been released looking at air pollution and health effects in California. One study (Lipsett, 2011) followed school teachers recruited in 1995, and followed through 2005. Pollutant exposures at the subject residence were estimated using data from ambient monitors, and extrapolated using a distance weighted method. The authors reported significant association of PM2.5 levels and mortality from ischemic heart disease, but no associations were found with all cause, cardiovascular, or respiratory disease.

The second study (Jerrett, 2011) followed individuals in ~~the Los Angeles area~~ [California](#) from the American Cancer Society cohort recruited starting in 1982, with follow up to 2000. Pollutant levels at subject residences were estimated using several methods. All but one of the methods found no association of all-cause mortality with PM2.5 levels. All exposure estimation methods were reported to have found significant associations with ischemic heart disease mortality, however. The authors noted that mortality rates differ in urban areas compared to non-urban areas, and so included a variable for this in a land use regression model to estimate effects on mortality. When the authors applied the land use regression model including an urban indicator to estimate exposures, all-cause mortality, mortality from cardiovascular disease, and mortality from ischemic heart disease were all significantly associated with PM2.5 levels.

[The U.S. EPA has recently proposed to lower the annual National Ambient Air Quality Standard for PM2.5 \(U.S. EPA, 2012a\). EPA also released a Regulatory Impact Analysis \(U.S. EPA 2012b\) which looked at the costs and benefits of alternate PM2.5 stand levels. As part of the analysis, EPA also looked at California specific studies regarding PM2.5 and mortality published in the scientific literature. The EPA](#)

Author: Administrator Subject: Sticky Note Date: 9/26/2012 10:23:52 AM
When comparing the relative risks from the LA and national studies, we recommend that both the national and the LA studies be adjusted to account for ozone exposure. Adjustment for ozone reduced the RR from three to about 1.5 times the national studies, which still suggest that the RR is greater in LA.

This page contains no comments

[analysis concluded "most of the cohort studies conducted in California report central effect estimates similar to the \(nation-wide\) all-cause mortality risk estimate we applied from Krewski et al. \(2009\) and Laden et al. \(2006\) albeit with wider confidence intervals. A couple cohort studies conducted in California indicate higher risks than the risk estimates we applied." Thus in EPA's judgment the California related studies provided estimates of mortality consistent with or higher than those from the national studies.](#)

Other studies report evidence indicating that particulate matter exposure early in pregnancy may be associated with lowered birth weights (Bobak, 1999). Studies from the U.S., the Czech Republic and Mexico City have reported that neonatal and early postnatal exposure to particulate matter may lead to increased infant mortality. A more recent study in Southern California found increased risks for infant deaths associated with exposures to particulates and other pollutants (Ritz, 2006). These results suggest that infants may be a subgroup affected by particulate matter exposures.

In addition, some long-term effect studies have reported an increased risk of mortality from lung cancer associated with particulate matter exposures. A study involving California Seventh Day Adventists (very few of whom smoke) has reported an association of lung cancer mortality with PM₁₀ levels. It is not clear from these studies whether the association relates to causation of disease, or whether individuals with cancer are more susceptible to other effects of particles leading to the observed mortality association. A study that followed a large number of individuals living in the largest U.S. cities found elevated lung cancer risk associated with long-term average PM_{2.5} levels (Pope, 2002).

Several studies have assessed the effects of long-term particulate matter exposure on respiratory symptoms and lung function changes. Associations have been found with symptoms of chronic bronchitis and decreased lung function. A study of school children in 12 communities in Southern California showed significant association of particulate matter with bronchitis or phlegm in children with asthma. These effects were also associated with NO₂ and acid vapor levels.

A cohort of fourth graders from the Southern California communities was followed over a period of four years by the Children's Health Study. A lower rate of growth in lung function was found in children living in areas with higher levels of particulate pollution (Gauderman, 2000). Decreases in lung function growth were associated with PM₁₀, PM_{2.5}, PM_{10-2.5}, acid vapor, and NO₂. There was no association with

This page contains no comments

ozone levels. The investigators were not able to identify independent effects of the pollutants, but noted that motor vehicle emissions are a major source of the pollutants.

A follow-up study on a second cohort of children confirmed the findings that decreased lung function growth was associated with particulates, nitric oxides, and elemental carbon levels (Gauderman, 2002). Elemental carbon is often used as a measure for diesel particulate. Additionally, children who moved to areas with less air pollution were found to regain some of the lung function growth rate (Avol, 2001). By the time the fourth graders graduated from high school, a significant number showed lower lung function. The risk of lower lung function was about five times higher in children with the highest PM_{2.5} exposure when compared to the lowest exposure communities (Gauderman, 2004). These deficits are likely to persist since the children were at the end of their growth period.

Despite data gaps, the extensive body of epidemiological studies has both qualitative and quantitative consistency suggestive of causality. A considerable body of evidence from these studies suggests that ambient particulate matter, alone or in combination with other coexisting pollutants, is associated with significant increases in mortality and morbidity in a community.

In summary, the scientific literature indicates that an increased risk of mortality and morbidity is associated with particulate matter at ambient levels. The evidence for particulate matter effects is mostly derived from population studies with supportive evidence from clinical and animal studies. Although most of the effects are attributable to particulate matter, co-pollutant effects cannot be ruled out on the basis of existing studies. The difficulty of separating the effects may be due to the fact that particulate levels co-vary with other combustion source pollutants. That is, the particle measurements serve as an index of overall exposure to combustion-related pollution, and some component(s) of combustion pollution other than particles might be at least partly responsible for the observed health effects.

EPA staff has presented conclusions on causal determination of several health effects based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the Table below.

ULTRAFINE PARTICLES

As noted above, numerous studies have found association of particulate matter levels with adverse effects, including mortality, hospital admissions, and respiratory disease symptoms. The vast majority of these studies used particle mass of PM₁₀ or PM_{2.5} as the measure of exposure. Some researchers have postulated, however, that ultrafine particles may be responsible for some of the observed associations of particulate matter and health outcomes (Oberdorster, et al, 1995; Seaton, et al, 1995). Ultrafine particles are generally classified of 0.1 μm and small diameter.

Several potential mechanisms have been brought forward to suggest that the ultrafine portion may be important in determining the toxicity of ambient particulates, some of which are discussed below.

For a given mass concentration, ultrafine particles have much higher numbers and surface area compared to larger particles. Particles can act as carriers for other adsorbed agents, such as trace metals and organic compounds; and the larger surface area may transport more of such toxic agents than larger particles.

Smaller particles can also be inhaled deep into the lungs. As much as 50% of 0.02 μm diameter particles are estimated to be deposited in the alveolar region of the lung. There is complex nature of the relation between deposition and particle size. The ultrafine particles generally have higher fractional deposition in the alveolar region. However, for the smaller nucleation mode (particles less than 0.01 μm size) the deposition in the alveolar region declines, but increases in the extrathoracic region.

Exposures of laboratory animals to ultrafine particles have found cardiovascular and respiratory effects. Mice exposed to concentrated near roadway ultrafine particles showed larger early atherosclerotic lesions than mice exposed to PM_{2.5} or filtered air (Arujo, 2008). In a mouse allergy model, exposures to concentrated ultrafine particles resulted in a greater response to antigen challenge to ovalbumin (Li, 2010), indicating that vehicular traffic exposure could exacerbate allergic inflammation in already-sensitized animals.

Controlled exposures of human volunteers to ultrafine particles either laboratory generated or as products of combustion, such as diesel exhaust containing particles, have found physiological changes related to vascular effects. Mills, 2011, for example found exposure to diesel exhaust particulate attenuated both acetylcholine and sodium-nitroprusside-induced vasorelaxation.

There are no long-term studies of human population exposure to ultrafine particle, as there is a lack of a monitoring network in the U.S. There have been several cross sectional epidemiological studies of ultrafine particles, mainly from Europe. Some of these studies found effects on hospital admissions, emergency department visits, for respiratory and cardiovascular effects. Other studies, however, have not found such effects (EPA, 2009). Concentrations of ultrafine particles can vary geographically, and it is not clear how well central site monitors may capture actual exposures.

EPA staff has presented conclusions on causal determination of several health effects of ultrafine PM based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the table below.

[Additional discussion on the sources and health effects of ultrafine particles can be found in Chapter 9 of the 2012 AQMP.](#)

CARBON MONOXIDE

The high affinity of carbon monoxide (CO) to bond with oxygen-carrying proteins (hemoglobin and myoglobin) results in reduced oxygen supply in the bloodstream of exposed individuals. The reduced oxygen supply is responsible for the toxic effects of CO which are typically manifested in the oxygen-sensitive organ systems. The effects have been studied in controlled laboratory environments involving exposure of humans and animals to CO, as well as in population-based studies of ambient CO exposure effects. People with deficient blood supply to the heart (ischemic heart disease) are known to be susceptible to the effects of CO. Protection of this group is the basis of the existing National Ambient Air Quality Standards for CO at 35 ppm for one hour and 9 ppm averaged over eight hours. The health effects of ambient CO have been recently reviewed (U.S. EPA, 2000, 2010).

Inhaled CO has no known direct toxic effect on lungs but rather exerts its effects by interfering with oxygen transport through the formation of carboxyhemoglobin (COHb, a chemical complex of CO and hemoglobin). Exposure to CO is often evaluated in terms of COHb levels in blood measured as percentage of total hemoglobin bound to CO. COHb levels in non-smokers range between 0.3 and 0.7% and 5 to 10% in smokers. COHb levels in excess of 1.5% in a significant proportion of urban non-smoking populations can be considered as evidence of widespread exposure to environmental CO.

Under controlled laboratory conditions, healthy subjects exposed to CO sufficient to result in 5% COHb levels exhibited reduced duration of maximal exercise performance and consumption of oxygen. Studies involving subjects with coronary artery disease who engaged in exercise during CO exposures have shown that COHb levels as low as 2.4% can lead to earlier onset of electrocardiograph changes indicative of deficiency of oxygen supply to the heart. Other effects include an earlier onset of chest pain, an increase in the duration of chest pain, and a decrease in oxygen consumption.

Findings of epidemiologic studies have observed associations between ambient CO concentration and emergency department visits and hospital admissions for ischemic heart disease and other cardiovascular diseases.

Animal studies associated with long-term exposure to CO resulting in COHb levels that are equivalent to those observed in smokers have shown indication of reduction in birth weight and impaired neurobehavior in the offspring of exposed animals.

This page contains no comments

Epidemiological studies conducted in Southern California have indicated an association with CO exposure during pregnancy to increases in pre-term births. (Ritz, 2000). However, the results were not consistent in different areas studied. The increase in the pre-term births was also associated with PM10 levels. Another study found increased risks for cardiac related birth defects with carbon monoxide exposure in the second month of pregnancy (Ritz, 2002). Toxicological studies in laboratory animals with higher than ambient levels of CO have also reported decrements in birth weight and prenatal growth.

EPA staff has presented conclusions on causal determination of the health effects of carbon monoxide based on a recent review of the available scientific studies (EPA, 2010). These are depicted in the table below.

NITROGEN DIOXIDE

The U.S. EPA has recently reviewed the health effects of nitrogen dioxide (U.S. EPA, 2008a). Evidence for low-level nitrogen dioxide (NO₂) exposure effects is derived from laboratory studies of asthmatics and from epidemiological studies. Additional supportive evidence is derived from animal studies.

Epidemiological studies using the presence of an unvented gas stove as a surrogate for indoor NO₂ exposures suggest an increased incidence of respiratory infections or symptoms in children.

Recent studies related to outdoor exposure have found health effects associated with ambient NO₂ levels, including respiratory symptoms, respiratory illness, decreased lung function, increased emergency room visits for asthma, and cardiopulmonary mortality. However, since NO₂ exposure generally occurs in the presence of other pollutants, such as particulate matter, these studies are often unable to determine the specific role of NO₂ in causing effects.

The Children's Health Study in Southern California found associations of air pollution, including NO₂, PM₁₀, and PM_{2.5}, with respiratory symptoms in asthmatics (McConnell, 1999). Particles and NO₂ were correlated, and effects of individual pollutants could not be discerned. A subsequent analysis indicated a stronger role for NO₂ (McConnell, 2002).

Ambient levels of NO₂ were also associated with a decrease in lung function growth in a group of children followed for eight years. In addition to NO₂, the decreased growth was also associated with particulate matter and airborne acids. The study authors postulated that these may be a measure of a package of pollutants from traffic sources. (Gauderman, 2004).

Results from controlled exposure studies of asthmatics demonstrate an increase in the tendency of airways to contract in response to a chemical stimulus (bronchial reactivity). Effects were observed with exposures from 0.1 to 0.3 ppm NO₂ for periods ranging from 30 minutes to 3 hours. A similar response is reported in some studies with healthy subjects at higher levels of exposure (1.5 - 2.0 ppm). Mixed results have been reported when people with chronic obstructive lung disease are exposed to low levels of NO₂.

Short-term controlled studies of animals exposed to NO₂ over a period of several hours indicate cellular changes associated with allergic and inflammatory response and interference with detoxification processes in the liver. In some animal studies

This page contains no comments

the severity of the lung structural damage observed after relatively high levels of short-term ozone exposure is observed to increase when animals are exposed to a combination of ozone and NO₂.

In animals, longer-term (3-6 months) repeated exposures at 0.25 ppm appear to decrease one of the essential cell-types (T-cells) of the immune system. Non-specific changes in cells involved in maintaining immune functions (cytotoxic T-cells and natural killer cells) have been observed in humans after repeated exposure (4-6 days) to >0.6 ppm of NO₂ (20 min. - 2 hours). All these changes collectively support the observation reported both in population and animal studies of increased susceptibility to infections, as a result of NO₂ exposure.

The U.S. EPA recently adopted a new short-term standard of 100 ppb (0.1 ppm) averaged over 1 hour. The standard was designed to protect against increases in airway reactivity in individuals with asthma observed in controlled exposure studies, as well as respiratory symptoms observed in epidemiological studies.

SULFUR DIOXIDE

Controlled laboratory studies involving human volunteers have clearly identified asthmatics as the most sensitive group to the effects of ambient sulfur dioxide (SO₂) exposures. Healthy subjects have failed to demonstrate any short-term respiratory functional changes at exposure levels up to 1.0 ppm over 1-3 hours.

In exercising asthmatics, brief exposure (5-10 minutes) to SO₂ at levels between 0.2-0.6 ppm can result in significant alteration of lung function, such as increases in airway resistance and decreases in breathing capacity. In some, the exposure can result in severe symptoms necessitating the use of medication for relief. The response to SO₂ inhalation is observable within 2 minutes of exposure, increases further with continuing exposure up to 5 minutes then remains relatively steady as exposure continues. SO₂ exposure is generally not associated with any delayed reactions or repetitive asthmatic attacks.

In epidemiologic studies, associations of SO₂ levels with increases in respiratory symptoms, increases in emergency department visits and hospital admissions for respiratory-related causes have been reported.

The U.S. EPA has recently revised the SO₂ air quality standard. The previous 24-hour standard was rescinded and replaced with a new 1-hour standard at 75 ppb (0.075 ppm) to protect against high short-term exposures.

This page contains no comments

Animal studies have shown that despite SO₂ being a respiratory irritant, it does not cause substantial acute or chronic toxicity in animals exposed at ambient concentrations. However, relatively high exposures (10 ppm of SO₂ for 72 hours) in mice can lead to tissue damage, fluid accumulation and sloughing of respiratory lining. Sensitization to allergies is observable in guinea pigs repeatedly exposed to high levels (72 ppm) of SO₂. This effect needs further evaluation in clinical and population studies to identify any chronic exposure impact on both asthmatic incidence and attacks in a population.

Some epidemiological studies indicate that the mortality and morbidity effects associated with the fine fraction of particles show a similar association with ambient SO₂ levels. In these studies, efforts to separate the effects of SO₂ from fine particles have not been successful. Thus, it is not clear whether the two pollutants act synergistically, or whether being generated from similar combustion sources, they represent the same pollution index for the observed effects.

SULFATES

Based on a level determined necessary to protect the most sensitive individuals, the California Air Resources Board (CARB) in 1976 adopted a standard of 25 µg/m³ (24-hour average) for sulfates. There is no federal air quality standard for sulfates.

In recent years, a vast majority of effects (mortality and morbidity) associated with fine particles (PM_{2.5}) and sulfur dioxide have shown a similar association with ambient sulfate levels in some population studies. The efforts to fully separate the effects of sulfates from other coexisting pollutants have not been successful. This may be due to the fact that these pollutants covary under ambient conditions, having been emitted from common sources; and the effects observed may be due to the combination of pollutants, rather than a single pollutant.

A clinical study involving exposure of human subjects to sulfuric acid aerosol indicated that adolescent asthmatics may be a susceptible population subgroup with some changes in lung function observed with exposures below 100 µg/m³. In general, however, laboratory exposures of human volunteers to sulfates at or near ambient levels have not found significant changes in lung function.

Results from animal studies involving exposures to sulfuric acid aerosol, ammonium bisulfate and ammonium sulfate indicate that acidic particles (former two) are more toxic than non-acidic particles (latter). In addition, the severity or magnitude of both

mortality and morbidity effects is relatively higher in population studies of the eastern United States and Canada where sulfate concentrations are higher than for those observed in the western United States. Mixed results have been reported from studies which attempted to ascertain the role of acidity in determining the observed toxicity.

LEAD

The U.S. EPA has recently reviewed the health effects of ambient lead exposures in conjunction with a review of the NAAQS for lead. (U.S. EPA 2006b; U.S. EPA 2007b). The following summary is taken from these reviews.

There are a number of potential public health effects at low level exposures. The health implications are generally indexed by blood lead levels, which are related to lead exposures both from inhalation as well as from ingestion. As identified by EPA, effects include impacts on population IQ, as well as heart disease and kidney disease. The array of health effects includes the following.

- Heme biosynthesis and related functions;
- Neurological development and function;
- Reproduction and physical development;
- Kidney function;
- Cardiovascular function
- Immune function

Children appear to be sensitive to the neurological toxicity of lead, with effects observed at blood lead concentration ranges of 5 – 10 µg/dL, or possibly lower. No clear threshold has yet been established for such effects.

According to the EPA review, the most important effects observed are neurotoxic effects in children and cardiovascular effects in adults. The effects in children include impacts on intellectual attainment and school performance.

EPA has recently revised the NAAQS for lead to a level of 0.15 µg/m³ averaged over a 3 month period to protect against lead toxicity. The following two charts, taken from the U.S. EPA review, depict the health effects of lead in relation to blood levels.

Author: pwong Subject: Sticky Note Date: 9/26/2012 10:25:49 AM

The report (maybe intentionally) does not discuss any recent studies, similar to PM/ozone, regarding inhaled lead which may have been used for the updated NAAQS designation. There is no mention or discussion on the California lead standard which is a 30 day average (1.5 ug/m3). It may helpful to mention that this is the concentration of lead in total suspended particles.

Author: pwong Subject: Sticky Note Date: 9/26/2012 10:25:10 AM

It may also be good to mention that the NAAQS is a "rolling" 3-month average

TOXIC AIR CONTAMINANTS

Toxic air contaminants are pollutants for which there generally are no ambient air quality standards. Under California's Air Toxics Program, CARB staff and Office of Environmental Health Hazard Assessment (OEHHA) assess the health effects of substances that may pose a risk of adverse health effects. These effects are usually an increased risk for cancer or adverse birth outcome. After review by the state Scientific Review Panel, CARB holds a public hearing whether to formally list substances that may pose a significant risk to public health as a Toxic Air Contaminant.

CARB and OEHHA also establish potency factors for air toxics that are carcinogenic. The potency factors can be used to estimate the additional cancer risk from ambient levels of toxics. This estimate represents the chance of contracting cancer in an individual over a lifetime exposure to a given level of an air toxic and is usually expressed in terms of additional cancer cases per million people exposed.

The District conducted studies on the ambient concentrations and estimated the potential health risks from air toxics (SCAQMD, 2008). In the latest study, a two year monitoring program was undertaken at 10 sites throughout the SCAB over the time period 2004-2006. Over 30 substances were measured, and annual average levels were calculated. The results showed that the overall risk for excess cancer from a 70-year lifetime exposure to the levels of air toxics calculated as the average level at the 10 sites was about 1,200 in a million. The largest contributor to this risk was diesel exhaust particulate matter, accounting for about 84% of the air toxics risk. A breakdown of the major contributors to the air toxics risk is shown in **FIGURE I-2** **FIGURE I-4**.

[While the California Air Resources Board listed Diesel Particulate Matter as a Toxic Air Contaminant in 1989, the International Agency for Research on Cancer, an arm of the World Health Organization, recently convened an international panel of scientists to review the published literature regarding the carcinogenicity of diesel combustion emissions. The panel concluded that Diesel Exhaust is a substance that causes cancer in humans \(Benbrahim-Tallaa, 2012\).](#)

- Author: pwong Subject: Sticky Note Date: 9/26/2012 10:26:17 AM
The respiratory system appears to be a more frequent target than the reproductive system (<http://www.oehha.ca.gov/air/allrels.html>) and thus should be listed as well.
- Author: pwong Subject: Sticky Note Date: 9/26/2012 10:26:24 AM
OEHHA calculates the potency factors.
- Author: Administrator Subject: Sticky Note Date: 9/14/2012 5:28:36 PM
It was 1999, not 1989.
- Author: pwong Subject: Sticky Note Date: 9/26/2012 10:26:44 AM
This gives the impression that IARC only recently began to review diesel. It might be better to discuss the original 1988 IARC designation and the recent update.

FIGURE I-42

Major Pollutants Contributing to Air Toxics Cancer Risk in the South Coast Air Basin

For non-cancer health effects, OEHHA has developed acute and chronic Reference Exposure Levels (RELs). RELs are concentrations in the air below which adverse health effects are not likely to occur. Acute RELs refer to short-term exposures, generally of one-hour duration. Chronic RELs refer to long-term exposures of several years. The ratio of ambient concentration to the appropriate REL can be used to calculate a Hazard Index. A Hazard Index of less than one would not be expected to result in adverse effects. The measured levels from the most recent study were below the applicable Reference Exposure Levels.

The key air toxics contributing to risk from mobile and stationary sources are listed in TABLE I-9.

This page contains no comments

TABLE I-9

Key Toxic Air Contaminants in the SCAB

MOBILE SOURCES	STATIONARY SOURCES
Acetaldehyde	Hexavalent Chromium
Benzene	Methylene Chloride
1,3 Butadiene	Nickel
Diesel Exhaust Particulate Matter	Perchloroethylene
Formaldehyde	Trichloroethylene

CONCLUSION

A large body of scientific evidence shows that the adverse impacts of air pollution in human and animal health are clear. A considerable number of population-based and laboratory studies have established a link between [air pollution and](#) increased morbidity and, in some instances, earlier mortality ~~and air pollution~~.

[As the scientific methods for the study of air pollution health effects has progressed over the past decades, adverse effects have been shown to occur at lower levels of exposure. For some pollutants, no clear thresholds for effects have been demonstrated. The new findings have, in turn, led to the revision and lowering of National Ambient Air Quality Standards which, in the judgment of the Administrator of the U.S. EPA, are necessary to protect public health. The figures below are meant to convey some of the historical context to recent revisions to the NAAQS for ozone and for particulate matter.](#)

Sent: Monday, October 01, 2012 4:25 PM
To: Jean Ospital
Subject: FW: Review of Draft 2012 AQMP Appendix I

Hi Jean – Bart and staff reviewed the report and have comments embedded in the pdf. They note that there are many more recent studies that are not cited. May be worth adding more, particularly where they note in the comments.

Hope this is helpful,

Melanie

Subject: RE: Review of Draft 2012 AQMP Appendix I

Here it is. My general assessment is that for Pm and ozone many of the refs are old and a lot of new studies (2005 on) are not included...I'm not sure how much time Jean wants to put into this. We made some suggested refs along the way but there are dozens more that could be included in an a more current review. b

Subject: Review of Draft 2012 AQMP Appendix I

Melanie,

Thank you for your willingness to provide a review of the Draft Appendix I of the District's 2012 Air Quality Management Plan.

As background, the California Health and Safety Code Section 40471 calls for the District to prepare a report on the health impacts of particulate matter pollution in the South Coast Air Basin as part of the preparation of air quality management plans. Appendix I of the AQMP is a review of air pollution health effects, with the section dealing with particulate matter intended to fulfill this requirement. The current draft is available at the following link. <http://www.aqmd.gov/aqmp/2012aqmp/draft/Appendices/Appxl.pdf>. Additional materials related to the AQMP are available at <http://www.aqmd.gov/aqmp/2012aqmp/index.htm>.

As we discussed today, receiving the review before the end of this month would be most helpful for us.

Please give me a call if I can provide any additional information.

Best regards,

Jean

INTRODUCTION

This document presents a summary of scientific findings on the health effects of ambient air pollutants. The California Health and Safety Code Section 40471(b) requires that the South Coast Air Quality Management District prepare a report on the health impacts of particulate matter in the South Coast Air Basin (SCAB) in conjunction with the preparation of the Air Quality Management Plan revisions. This document, which was prepared to satisfy that requirement, also includes the effects of the other major pollutants.

HEALTH EFFECTS OF AIR POLLUTION

Ambient air pollution is a major public health concern. Excess deaths and increases in illnesses associated with high air pollution levels have been documented in several episodes as early as 1930 in Meuse Valley, Belgium; 1948 in Donora, Pennsylvania; and 1952 in London. Although levels of pollutants that occurred during these acute episodes are now unlikely in the United States, ambient air pollution continues to be linked to increases in illness (morbidity) and increases in death rates (mortality).

The adverse health effects associated with air pollution are diverse and include:

- Increased mortality
- Increased health care utilization (hospitalization, physician and emergency room visits)
- Increased respiratory illness (symptoms, infections, and asthma exacerbation)
- Decreased lung function (breathing capacity)
- Lung inflammation
- Potential immunological changes
- Increased airway reactivity to a known chemical exposure - a method used in laboratories to evaluate the tendency of airways to have an increased possibility of developing an asthmatic response
- A decreased tolerance for exercise

The evidence linking these effects to air pollutants is derived from population-based observational and field studies (epidemiological) as well as controlled laboratory studies involving human subjects and animals. There have been an increasing number of studies focusing on the mechanisms (that is, on learning how specific organs, cell types, and biochemicals are involved in the human body's response to air pollution) and specific pollutants responsible for individual effects. Yet the underlying biological pathways for these effects are not always clearly understood.

Although individuals inhale pollutants as a mixture under ambient conditions, the regulatory framework and the control measures developed are mostly pollutant-specific. This is appropriate, in that different pollutants usually differ in their sources, their times and places of occurrence, the kinds of health effects they may cause, and their overall levels of health risk. Different pollutants, from the same or different sources, may sometimes act together to harm health more than they would acting separately. Nevertheless, as a practical matter, health scientists, as well as regulatory officials, usually must deal with one pollutant at a time in determining health effects and in adopting air quality standards. To meet the air quality standards, comprehensive plans are developed such as the Air Quality Management Plan (AQMP), and to minimize toxic exposure a local air toxics control plan is also prepared. These plans examine multiple pollutants, cumulative impacts, and transport issues related to attaining healthful air quality. A brief overview of the effects observed and attributed to various air pollutants is presented in this document.

This summary is drawn substantially from reviews presented previously (SCAQMD, 1996, 2003, 2007), and from reviews on the effects of air pollution by the American Thoracic Society (ATS, 1996), the U.S. EPA reviews for ozone (U.S. EPA, 2006), Carbon Monoxide (U.S. EPA, 2010), and Particulate Matter (U.S. EPA, 2004, 2009), from a published review of the health effects of air pollution (Brunekreef and Holgate, 2002), and from reviews prepared by the California EPA Office of the Environmental Health Hazard Assessment for Particulate Matter (Cal EPA, 2002) and for Ozone (Cal EPA, 2005). Additional materials are from EPA's current review of the ozone standard and health effects (EPA, 2011). More detailed citations and discussions on air pollution health effects can be found in these references.¹

OZONE

Ozone is a highly reactive compound, and is a strong oxidizing agent. When ozone comes into contact with the respiratory tract, it can react with tissues and cause damage in the airways. Since it is a gas, it can penetrate into the gas exchange region of the deep lung.

The EPA primary standard for ozone, adopted in 2008, is 0.075 ppm averaged over eight hours. The California Air Resources Board (CARB) has established standards of 0.09 ppm averaged over one hour and at 0.070 ppm averaged over eight hours.

The major subgroups of the population considered to be at increased risk from ozone exposure are outdoor exercising individuals, including children, and people with preexisting respiratory disease(s) such as asthma. The data base identifying the former group as being at increased risk to ozone exposure is much stronger and more quantitative than that for the latter group, probably because of a larger number of studies conducted with healthy individuals. The adverse effects reported with short-term ozone exposure are greater with increased activity because activity increases the breathing rate and the volume of air reaching the lungs, resulting in an increased amount of ozone reaching the lungs. Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher ventilation rate than adults.

A number of adverse health effects associated with ambient ozone levels have been identified from laboratory and epidemiological studies (EPA, 1996; 2006, 2011; ATS, 1996). These include increased respiratory symptoms, damage to cells of the respiratory tract, decrease in lung function, increased susceptibility to respiratory infection, and increased risk of hospitalization.

Increases in ozone levels are associated with elevated absences from school. The Children's Health Study, conducted by researchers at the University of Southern California, followed a cohort of children that live in 12 communities in Southern California with differing levels of air pollution for several years. A publication from this study reported that school absences in fourth graders for respiratory illnesses were associated with ambient ozone levels. An increase of 20 ppb ozone was associated with an 83% increase in illness-related absence rates (Gilliland, 2001).

The number of hospital admissions and emergency room visits for all respiratory causes (infections, respiratory failure, chronic bronchitis, etc.) including asthma

shows a consistent increase as ambient ozone levels increase in a community. These excess hospital admissions and emergency room visits are observed when hourly ozone concentrations are as low as 0.06 to 0.10 ppm.

Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).

Multicity studies of short-term ozone exposures (days) and mortality have also examined regional differences. Evidence was provided that there were generally higher ozone-mortality risk estimates in northeastern U.S. cities, with the southwest and urban mid-west cities showing lower or no associations (Smith, 2009; Bell, 2008). Another long-term study of a national cohort found that long-term exposures to ozone were associated with respiratory-related causes of mortality, but not cardiovascular-related causes, when PM2.5 exposure were also included in the analysis.

Several population-based studies suggest that asthmatics are more adversely affected by ambient ozone levels, as evidenced by increased hospitalizations and emergency room visits. Laboratory studies have attempted to compare the degree of lung function change seen in age and gender-matched healthy individuals versus asthmatics and those with chronic obstructive pulmonary disease. While the degree of change evidenced did not differ significantly, that finding may not accurately reflect the true impact of exposure on these respiration-compromised individuals. Since the respiration-compromised group may have lower lung function to begin with, the same degree of change may represent a substantially greater adverse effect overall.

Another publication from the Children's Health Study focused on children and outdoor exercise. In communities with high ozone concentrations, the relative risk of developing asthma in children playing three or more sports was found to be over three times higher than in children playing no sports (McConnell, 2002). These findings indicate that new cases of asthma in children are associated with heavy exercise in communities with high levels of ozone. While it has long been known that air pollution can exacerbate symptoms in individuals with respiratory disease, this is among the first studies that indicate ozone exposure may be causally linked to asthma onset.

You could include long-term exposures and resp mortality (Jerrett) and Mortality among those with pre-existing chronic disease (Zanobetti & Schwartz, 2011)

This page contains no comments

In addition, human and animal studies involving both short-term (few hours) and long-term (months to years) exposures indicate a wide range of effects induced or associated with ambient ozone exposure. These are summarized in Table I-1.

TABLE I-1

Adverse Health Effects of Ozone (O₃) - Summary of Key Studies

O ₃ CONCENTRATION AND EXPOSURE HR., PPM	HEALTH EFFECT
Ambient air containing 0.10 - 0.15 daily 1-h max over days to weeks; ≥ 0.05 (8 hour average)	Decreased breathing capacity, in children, adolescents, and adults exposed to O ₃ outdoors Exacerbation of respiratory symptoms (e.g., cough, chest pain) in individuals with preexisting disease (e.g., asthma) with low ambient exposure, decreased temperature, and other environmental factors resulting in increased summertime hospital admissions and emergency department visits for respiratory causes
≥0.12 (1-3h) ≥0.06 (6.6h) (chamber exposures)	Decrements in lung function (reduced ability to take a deep breath), increased respiratory symptoms (cough, shortness of breath, pain upon deep inspiration), increased airway responsiveness and increased airway inflammation in exercising adults Effects are similar in individuals with preexisting disease except for a greater increase in airway responsiveness for asthmatic and allergic subjects Older subjects (>50 yrs old) have smaller and less reproducible changes in lung function Attenuation of response with repeated exposure
≥0.12 with prolonged, repeated exposure (chamber exposures)	Changes in lung structure, function, elasticity, and biochemistry in laboratory animals that are indicative of airway irritation and inflammation with possible development of chronic lung disease Increased susceptibility to bacterial respiratory infections in laboratory animals

From: SCAQMD, 1996; EPA, 2007

Some lung function responses (volume and airway resistance changes) observed after a single exposure to ozone exhibit attenuation or a reduction in magnitude with repeated exposures. Although it has been argued that the observed shift in response is evidence of a probable adaptation phenomenon, it appears that while functional changes may exhibit adaptation, biochemical and cellular changes which may be

This page contains no comments

associated with episodic and chronic exposure effects may not exhibit similar adaptation. That is, internal damage to the respiratory system may continue with repeated ozone exposures, even if externally observable effects (chest symptoms and reduced lung function) disappear.

In a laboratory, exposure of human subjects to low levels of ozone causes reversible decrease in lung function as assessed by various measures such as respiratory volumes, airway resistance and reactivity, irritative cough and chest discomfort. Lung function changes have been observed with ozone exposure as low as 0.06 to 0.12 ppm for 6-8 hours under moderate exercising conditions. Similar lung volume changes have also been observed in adults and children under ambient exposure conditions (0.10 - 0.15 ppm). The responses reported are indicative of decreased breathing capacity and are reversible.

The results of several studies where human volunteers were exposed to ozone for 6.6 hours at levels between 0.04 and 0.12 ppm were recently summarized (Brown, 2008). As shown in the figure below, there is an increasing response on lung function with increasing exposure levels in moderately exercising subjects.

FIGURE I-1

Comparison of mean ozone-induced decrements in lung function following 6.6 hours of ozone exposure (from Brown, 2008)

This page contains no comments

In addition to controlled laboratory conditions, studies of individuals exercising outdoors, including children attending summer camp, have shown associations of reduced lung function with ozone exposure. There were wide ranges in responses among individuals.

Results of epidemiology studies support the relationship between ozone exposure and respiratory effects. Several, but not all, studies have found associations of short-term ozone levels and hospital admissions and emergency department admissions for respiratory-related conditions (EPA, 2011).

In laboratory studies, cellular and biochemical changes associated with respiratory tract inflammation have also been consistently reported in the airway lining after low level exposure to ozone. These changes include an increase in specific cell types and in the concentration of biochemical mediators of inflammation and injury such as cytokines and fibronectin. Indications of lung injury and inflammatory changes have been observed in healthy adults exposed to ozone in the range of 0.06 to 0.10 ppm.

The susceptibility to ozone observed under ambient conditions could be due to the combination of pollutants that coexist in the atmosphere or ozone may actually sensitize these subgroups to the effects of other pollutants.

Some animal studies show results that indicate possible chronic effects including functional and structural changes of the lung. These changes indicate that repeated inflammation associated with ozone exposure over a lifetime may result in sufficient damage to respiratory tissue such that individuals later in life may experience a reduced quality of life in terms of respiratory function and activity level achievable. An autopsy study involving Los Angeles County residents provided supportive evidence of lung tissue damage (structural changes) attributable to air pollution.

A study of birth outcomes in southern California found an increased risk for birth defects in the aortic and pulmonary arteries associated with ozone exposure in the second month of pregnancy (Ritz et al., 2002). This is the first study linking ambient air pollutants to birth defects in humans. Studies conducted since mostly focusing on cardiac and oral cleft defects have found mixed results, with some showing associations, but others did not. Confirmation by further studies is needed.

In summary, adverse effects associated with ozone exposures have been well documented, although the specific causal mechanism is still somewhat unclear.

This page contains no comments

It may be instructive to provide the overall EPA staff preliminary conclusions on the causality on ozone health effects for the health outcomes evaluated (EPA, 2011). These are provided in the two tables below.

TABLE I-2

Summary of Causal Determinations for Short-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Effects on Liver and Xenobiotic Metabolism	Inadequate to infer a causal relationship
Effects on Cutaneous and Ocular Tissues	Inadequate to infer a causal relationship
Mortality	Likely to be a causal relationship

TABLE I-3

Summary of Causal Determinations for Long-Term Exposures to Ozone

HEALTH CATEGORY	CAUSAL DETERMINATION
Respiratory Effects	Likely to be a causal relationship
Cardiovascular Effects	Suggestive of a causal relationship
Reproductive and Developmental Effects	Suggestive of a causal relationship
Central Nervous System Effects	Suggestive of a causal relationship
Carcinogenicity and Genotoxicity	Inadequate to infer a causal relationship
Mortality	Suggestive of a causal relationship

From EPA, 2011

PARTICULATE MATTER

Airborne particulates are a complex group of pollutants that vary in source, size and composition, depending on location and time. The components include nitrates, sulfates, elemental carbon, organic carbon compounds, acid aerosols, trace metals, and material from the earth's crust. Substances of biological origin, such as pollen and spores, may also be present.

Until several years ago, the health effects of particulates were focused on those sized 10 μm (micrometers) aerodynamic diameter and smaller. These can be inhaled through the upper airways and deposited in the lower airways and gas exchange tissues in the lung. These particles are referred to as PM10. EPA initially promulgated ambient air quality standards for PM10 of 150 $\mu\text{g}/\text{m}^3$ averaged over a 24-hour period, and 50 $\mu\text{g}/\text{m}^3$ for an annual average. EPA has since rescinded the annual PM10 standard, but kept the 24-hour standard.

In recent years additional focus has been placed on particles having an aerodynamic diameter of 2.5 μm or less (PM2.5). A greater fraction of particles in this size range can penetrate and deposit deep in the lungs. The EPA recently lowered the air quality standards for PM2.5 to 35 $\mu\text{g}/\text{m}^3$ for a 24-hour average and reaffirmed 15 $\mu\text{g}/\text{m}^3$ for an annual average standard. There was considerable controversy and debate surrounding the review of particulate matter health effects and the consideration of ambient air quality standards (Kaiser, 1997; Vedal, 1997) when the EPA promulgated the initial PM2.5 standards in 1997.

Since that time, numerous studies have been published, and some of the key studies were closely scrutinized and analyses repeated. The result is that there are now substantial data confirming the adverse health effects of PM2.5 exposures.

There are also differences in the composition and sources of particles in the different size ranges that may have implications for health effects. The particles larger than 2.5 μm (often referred to as the coarse fraction) are mostly produced by mechanical processes. These include automobile tire wear, industrial processes such as cutting and grinding, and resuspension of particles from the ground or road surfaces by wind and human activities.

In contrast, particles smaller than 2.5 μm are mostly derived from combustion sources, such as automobiles, trucks, and other vehicle exhaust, as well as from stationary combustion sources. The particles are either directly emitted or are formed

in the atmosphere from gases that are emitted. Components from material in the earth's crust, such as dust, are also present, with the amount varying in different locations.

Attention to another range of very small particles has been increasing over the last few years. These are generally referred to as "ultrafine" particles, with diameters of 0.1 μm or less. These particles are mainly from fresh emissions of combustion sources, but are also formed in the atmosphere from photochemical reactions. Ultrafine particles have relatively short half lives (minutes to hours) and rapidly grow through condensation and coagulation process into larger particles within the PM_{2.5} size range. These particles are garnering interest since laboratory studies indicate that their toxicity may be higher on a mass basis than larger particles, and there is evidence that these small particles can translocate from the lung to the blood and to other organs of the body.

There have been several reviews of the health effects of ambient particulate matter (ATS, 1996; Brunekreef, 2002; U.S. EPA, 2004; U.S. EPA, 2009). In addition, the California Air Resources Board (CARB) and the Office of Environmental Health and Hazard Assessment (OEHHA) have reviewed the adequacy of the California Air Quality Standards for Particulate Matter (Cal EPA, 2002).

The major types of effects associated with particulate matter include:

- Increased mortality
- Exacerbation of respiratory disease and of cardiovascular disease as evidenced by increases in:
 - Respiratory symptoms
 - Hospital admissions and emergency room visits
 - Physician office visits
 - School absences
 - Work loss days
- Effects on lung function
- Changes in lung morphology

The current federal and California standards are listed below:

PM10 Annual Average	--	20 µg/m ³
PM 2.5 24-Hour Average	35 µg/m ³	--
PM 2.5 Annual Average	15 µg/m ³	12 µg/m ³

Author: BOstro Subject: Sticky Note Date: 10/1/2012 3:39:19 PM
 Unfortunately this 1996 is very dated. The 2010 Brook study and later Pope and Dockery review are more relevant. The brook focuses on PM2.5 long and short term studies and is an excellent review of the epi, tox, clinical studies as well as mechanisms.

Short-Term Exposure Effects

Epidemiological studies have provided evidence for most of the effects listed above. An association between increased daily or several-day-average concentrations of PM10 and excess mortality and morbidity is consistently reported from studies involving communities across the U.S. as well as in Europe, Asia, and South America. A review and analysis of epidemiological literature for acute adverse effects of particulate matter was published by the American Thoracic Society in 1996. Several adverse effects were listed as associated with daily PM10 exposures, as listed in Table I-5, undertaken by Dockery and Pope to estimate these effects as percent increase in mortality associated with each incremental increase of PM10 by 10 µg/m³. The estimates are presented in Table I-5. It also appears that individuals who are elderly or have preexistent lung or heart disease are more susceptible than others to the adverse effects of PM10 (ATS, 1996). Since then many more recent studies have confirmed that excess mortality and morbidity are associated with short term particulate matter levels (Pope, 2006).

Estimates of mortality effects from these studies of PM10 exposures range from 0.3 to 1.7% increase for a 10 µg/m³ increase in PM10 levels. The National Morbidity, Mortality, and Air Pollution Study (NMMAPS), a study of 20 of the largest U.S. cities, determined a combined risk estimate of about a 0.5% increase in total mortality for a 10 µg/m³ increase in PM10 (Samet, 2000a). This study also analyzed the effects of gaseous co-pollutants. The results indicated that the association of PM10 and mortality were not confounded by the presence of the gaseous pollutants. When the gaseous pollutants were included in the analyses, the significance of the PM10 estimates remained. The PM10 effects were reduced somewhat when O₃ was also considered and tended to be variably decreased when NO₂, CO, and SO₂ were

This page contains no comments

added to the analysis. These results argue that the effects are likely due to the particulate exposures; they cannot readily be explained by coexisting weather stresses or other pollutants.

An expansion of the NMMAPS study to 90 U.S. Cities also reported association with PM10 levels and mortality (Samet 2000b). It was discovered that this study was one that used a flawed statistical software package. The investigators have reanalyzed the data using corrected settings for the software (Dominici, 2002a, Dominici 2002b). When the estimates for the 90 cities in the study were recalculated, the estimate changed from 0.41% increase in mortality for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 to a 0.27% increase. There remained a strong positive association between acute exposure to PM10 and mortality. Thus while the quantitative estimate was reduced, the major findings of the study did not change.

TABLE I-5

Combined Effect Estimates of Daily Mean Particulate Pollution (PM10)

	% CHANGE IN HEALTH INDICATOR PER EACH 10 $\mu\text{g}/\text{m}^3$ INCREASE IN PM10
Increase in Daily Mortality	
Total deaths	1.0
Respiratory deaths	3.4
Cardiovascular deaths	1.4
Increase in Hospital Usage (all respiratory diagnoses)	
Admissions	1.4
Emergency department visits	0.9
Exacerbation of Asthma	
Asthmatic attacks	3.0
Bronchodilator use	12.2
Emergency department visits*	3.4
Hospital admissions	1.9
Increase in Respiratory Symptom Reports	
Lower respiratory	3.0
Upper respiratory	0.7

TABLE I-5 (concluded)

Combined Effect Estimates of Daily Mean Particulate Pollution

	% CHANGE IN HEALTH INDICATOR PER EACH 10 µg/m³ INCREASE IN PM10
Cough	2.5
Decrease in Lung Function	
Forced expiratory volume	0.15
Peak expiratory flow	0.08

* One study only

(Source: American Journal of Respiratory and Critical Care Medicine, Vol. 153, 113-50, 1996)

Studies of PM2.5 also find associations with elevated mortality. The estimates for PM2.5 generally are in the range of 2.0 to 8.5% increase in total deaths per 25 µg/m³ increase in 24-hour PM2.5 levels. The estimates for cardiovascular related mortality range from 3.0 to 7.0% per 25 µg/m³ 24-hour PM2.5, and for respiratory mortality estimates range from 2.0 to 7.0% per 25 µg/m³ 24-hour PM2.5.

Several studies have attempted to assess the relative importance of particles smaller than 2.5 µm and those between 2.5 µm and 10 µm (PM10-2.5). While some studies report that PM2.5 levels are better predictors of mortality effects, others suggest that PM10-2.5 is also important. Most of the studies found higher mortality associated with PM2.5 levels than with PM10-2.5. For example, a study of six cities in the U.S. found that particulate matter less than 2.5 µm was associated with increased mortality, but that the larger particles were not. Other studies in Mexico City and Santiago, Chile reported that PM10-2.5 was as important as PM2.5. Overall effects estimates for PM10-2.5 fall in the range of 0.5 to 6.0 % excess mortality per 25 µg/m³ 24-hour average.

The relative importance of both PM2.5 and PM10-2.5 may vary in different regions depending on the relative concentrations and components, which can also vary by season. More research is needed to better assess the relative effects of fine (PM2.5) and coarse (PM10-2.5) fractions of particulate matter on mortality.

A number of studies have evaluated the association between particulate matter exposure and indices of morbidity such as hospital admissions, emergency room

Please add citations.

visits or physician office visits for respiratory and cardiovascular diseases. The effects estimates are generally higher than the effects for mortality. The effects are associated with measures of PM10 and PM2.5. Effects are also associated with PM10-2.5. Thus, it appears that when a relatively small number of people experience severe effects, larger numbers experience milder effects, which may relate either to the coarse or to the fine fraction of airborne particulate matter.

In the NMMAPS study, hospital admissions for those 65 years or older were assessed in 14 cities. Hospital admissions for these individuals showed an increase of 6% for cardiovascular diseases and a 10% increase for respiratory disease admissions, per 50 $\mu\text{g}/\text{m}^3$ increase in PM10. The excess risk for cardiovascular disease ranges from 3-10% per 50 $\mu\text{g}/\text{m}^3$ PM10 and from 4-10% per 25 $\mu\text{g}/\text{m}^3$ PM2.5 or PM10-2.5.

Similarly, school absences, lost workdays and restricted activity days have also been used in some studies as indirect indicators of acute respiratory conditions. The results are suggestive of both immediate and delayed impact on these parameters following elevated particulate matter exposures. These observations are consistent with the hypothesis that increased susceptibility to infection follows particulate matter exposures.

Some studies have reported that short-term particulate matter exposure is associated with changes in lung function (lung capacity and breathing volume); upper respiratory symptoms (hoarseness and sore throat); and lower respiratory symptoms (increased sputum, chest pain and wheeze). The severity of these effects is widely varied and is dependent on the population studied, such as adults or children with and without asthma. Sensitive individuals, such as those with asthma or pre-existing respiratory disease, may have increased or aggravated symptoms associated with short-term particulate matter exposures. Several studies have followed the number of medical visits associated with pollutant exposures. A range of increases from 3% to 42% for medical visits for respiratory illnesses was found corresponding to a 50 $\mu\text{g}/\text{m}^3$ change in PM10. A limited number of studies also looked at levels of PM2.5 or PM10-2.5. The findings suggest that both the fine and coarse fractions may have associations with some respiratory symptoms.

The biological mechanisms by which particulate matter can produce health effects are being investigated in laboratory studies. Inflammatory responses in the respiratory system in humans and animals exposed to concentrated ambient particles have been measured. These include effects such as increases in neutrophils in the lungs. Other changes reported include increased release of cytokines and interleukins,

chemicals released as part of the inflammatory process. The effects of particulate matter may be mediated in part through the production of reactive oxygen species during the inflammatory process. Recent reviews discuss mechanistic studies in more detail (Brunekreef, 2002; Brook, 2004).

Long-Term Exposure Effects

While most studies have evaluated the acute effects, some studies specifically focused on evaluating the effects of chronic exposure to PM10 and PM2.5. Studies have analyzed the mortality of adults living in different U.S. cities. After adjusting for important risk factors, taken as a whole these studies found a positive association of deaths and exposure to particulate matter. A similar association was observable in both total number of deaths and deaths due to specific causes. The largest effects were observed from cardiovascular causes and ischemic heart disease. A shortening of lifespan was also reported in these studies.

Since the initial promulgation by EPA of the National Ambient Air Quality Standards for PM2.5, controversy has remained over the association of mortality and exposures to PM2.5. Thus an expanded discussion of these studies is presented below.

Significant associations for PM2.5 for both total mortality and cardiorespiratory mortality were reported in a study following a national cohort recruited by the American Cancer Society for a Cancer Prevention Study over several years. A re-analysis of the data from this study confirmed the initial finding (Krewski, 2000). In this study, mortality rates and PM2.5 levels were analyzed for 51 metropolitan areas of the U.S. Average levels from monitors in each area were used to estimate exposures. At these levels of aggregation, regional differences in the association of PM2.5 and mortality were noted, with higher associations in the Northeast, and lower or non-significant associations in the West.

The Harvard Six Cities Study evaluated several size ranges of particulate matter and reported significant associations with PM15, PM2.5, sulfates, and non-sulfate particles, but not with coarse particles (PM15 – PM2.5). An extension of the Harvard Six Cities Cohort confirmed the association of mortality with PM2.5 levels (Laden, 2006). These studies provide evidence that the fine particles, as measured by PM2.5, may be more strongly associated with mortality effects from long-term particulate matter exposures than are coarse compounds. An update to this study covering a follow-up over the years 1974 to 2009 (Lepeule, 2012) was recently published. Findings indicated a linear relationship of PM2.5 levels and mortality

This page contains no comments

from all causes, cardiovascular causes, and from lung cancer. According to the authors, the PM2.5 levels decreased over time, but no evidence of a threshold for these effects was found.

A follow-up study of the American Cancer Society cohort confirmed and extended the findings in the initial study. The researchers estimated that, on average, a 10 ug/m3 increase in fine particulates was associated with approximately a 4% increase in total mortality, a 6% increase in cardiopulmonary mortality, and an 8% increase risk of lung cancer mortality (Pope, 2002). The magnitude of effects is larger in the long-term studies than in the short-term investigations. In an additional re analysis and extension of the American Cancer Society cohort from 1982 to 2000 (Krewski, 2009), and including additional metropolitan areas for the most recent years, effects estimates on mortality were similar, though somewhat higher, than those reported previously.

Other national studies include an analysis of mortality and PM2.5 exposures in a Medicare population. Zeger and Associates (2008) assembled a Medicare cohort by including all Medicare enrollees residing in zip codes with centroids within 6 miles of a PM2.5 monitor. PM2.5 data was obtained from the monitoring stations, and mean annual levels were called for the zip codes within six miles of each monitor. The estimated associations between exposures to PM2.5 and mortality for the eastern and central portions of the U.S were similar to those previously published in the Six Cities Study and the American Cancer Society cohorts. The authors reported that there were no significant associations between zip code levels of PM2.5 and mortality rates in the western region of the U.S. This lack of association was attributed largely to the higher PM2.5 levels in Los Angeles area counties compared to other western urban areas, but there were not higher mortality rates in these counties. The authors further reported that they found no associations of PM2.5 with mortality in persons aged 85 years or higher.

Analyses of mortality and PM2.5 levels specific to California have also been reported. A cohort of elderly individuals (average age of 65 yr in 1973) recruited from 11 California counties was followed over several years (Enstrom, 2005). An association for exposure with all cause deaths was reported from 1973–1982. However, no significant association was found in the later time period of 1983–2002. Pollutant levels were taken from ambient monitors and averaged over each county to estimate exposures.

Author: sgreen Subject: Sticky Note Date: 9/26/2012 1:59:40 PM
Also can add a recent study conducted in Canada by Crouse et al. 2012 (EHP 120:965-970). Study found 15% increase in all-cause mortality and 31% increase in ischemic heart disease mortality for each 10ug/m3 increase in PM 2.5. Mean concentration among all study subjects was only 8.7 ug/m3.

Two analyses of the American Cancer Society cohort focused [specifically](#) on the Los Angeles [Metropolitan](#) area using methods to estimate exposures on a finer geographical scale than previous studies that used geographic scales at the county or metropolitan area. Using data from monitoring stations in the Los Angeles area, ~~one~~ study applied interpolation methods (Jerrett, 2005) and another applied land use regression techniques (Krewski, 2009) to estimate exposures to the study individuals. Significant associations of PM2.5 with mortality from all causes and cardiopulmonary disease were reported, with the magnitude of risks being up to three times higher than those from the national studies of the American Cancer Society cohort. This provides evidence that using methods to provide more detailed exposure estimates can result in stronger associations of PM2.5 and mortality.

~~Two~~ recent reports have been released looking at air pollution and health effects in California. One study (Lipsett, 2011) followed school teachers recruited in 1995, and followed through 2005. Pollutant exposures at the subject residence were estimated using data from ambient monitors, and extrapolated using a distance weighted method. The authors reported significant association of PM2.5 levels and mortality from ischemic heart disease, but no associations were found with all cause, cardiovascular, or respiratory disease.

The second study (Jerrett, 2011) followed individuals in ~~the Los Angeles area~~ [California](#) from the American Cancer Society cohort recruited starting in 1982, with follow up to 2000. Pollutant levels at subject residences were estimated using several methods. All but one of the methods found no association of all-cause mortality with PM2.5 levels. All exposure estimation methods were reported to have found significant associations with ischemic heart disease mortality, however. The authors noted that mortality rates differ in urban areas compared to non-urban areas, and so included a variable for this in a land use regression model to estimate effects on mortality. When the authors applied the land use regression model including an urban indicator to estimate exposures, all-cause mortality, mortality from cardiovascular disease, and mortality from ischemic heart disease were all significantly associated with PM2.5 levels.

[The U.S. EPA has recently proposed to lower the annual National Ambient Air Quality Standard for PM2.5 \(U.S. EPA, 2012a\). EPA also released a Regulatory Impact Analysis \(U.S. EPA 2012b\) which looked at the costs and benefits of alternate PM2.5 stand levels. As part of the analysis, EPA also looked at California specific studies regarding PM2.5 and mortality published in the scientific literature. The EPA](#)

[analysis concluded "most of the cohort studies conducted in California report central effect estimates similar to the \(nation-wide\) all-cause mortality risk estimate we applied from Krewski et al. \(2009\) and Laden et al. \(2006\) albeit with wider confidence intervals. A couple cohort studies conducted in California indicate higher risks than the risk estimates we applied." Thus in EPA's judgment the California related studies provided estimates of mortality consistent with or higher than those from the national studies.](#)

Other studies report evidence indicating that particulate matter exposure early in pregnancy may be associated with lowered birth weights (Bobak, 1999). Studies from the U.S., the Czech Republic and Mexico City have reported that neonatal and early postnatal exposure to particulate matter may lead to increased infant mortality. A more recent study in Southern California found increased risks for infant deaths associated with exposures to particulates and other pollutants (Ritz, 2006). These results suggest that infants may be a subgroup affected by particulate matter exposures.

In addition, some long-term effect studies have reported an increased risk of mortality from lung cancer associated with particulate matter exposures. A study involving California Seventh Day Adventists (very few of whom smoke) has reported an association of lung cancer mortality with PM10 levels. It is not clear from these studies whether the association relates to causation of disease, or whether individuals with cancer are more susceptible to other effects of particles leading to the observed mortality association. A study that followed a large number of individuals living in the largest U.S. cities found elevated lung cancer risk associated with long-term average PM2.5 levels (Pope, 2002).

Several studies have assessed the effects of long-term particulate matter exposure on respiratory symptoms and lung function changes. Associations have been found with symptoms of chronic bronchitis and decreased lung function. A study of school children in 12 communities in Southern California showed significant association of particulate matter with bronchitis or phlegm in children with asthma. These effects were also associated with NO₂ and acid vapor levels.

A cohort of fourth graders from the Southern California communities was followed over a period of four years by the Children's Health Study. A lower rate of growth in lung function was found in children living in areas with higher levels of particulate pollution (Gauderman, 2000). Decreases in lung function growth were associated with PM10, PM2.5, PM10-2.5, acid vapor, and NO₂. There was no association with

Author: sgreen Subject: Sticky Note Date: 9/26/2012 1:53:20 PM
Please add the reference here.

This page contains no comments

ozone levels. The investigators were not able to identify independent effects of the pollutants, but noted that motor vehicle emissions are a major source of the pollutants.

A follow-up study on a second cohort of children confirmed the findings that decreased lung function growth was associated with particulates, nitric oxides, and elemental carbon levels (Gauderman, 2002). Elemental carbon is often used as a measure for diesel particulate. Additionally, children who moved to areas with less air pollution were found to regain some of the lung function growth rate (Avol, 2001). By the time the fourth graders graduated from high school, a significant number showed lower lung function. The risk of lower lung function was about five times higher in children with the highest PM_{2.5} exposure when compared to the lowest exposure communities (Gauderman, 2004). These deficits are likely to persist since the children were at the end of their growth period.

Despite data gaps, the extensive body of epidemiological studies has both qualitative and quantitative consistency suggestive of causality. A considerable body of evidence from these studies suggests that ambient particulate matter, alone or in combination with other coexisting pollutants, is associated with significant increases in mortality and morbidity in a community.

In summary, the scientific literature indicates that an increased risk of mortality and morbidity is associated with particulate matter at ambient levels. The evidence for particulate matter effects is mostly derived from population studies with supportive evidence from clinical and animal studies. Although most of the effects are attributable to particulate matter, co-pollutant effects cannot be ruled out on the basis of existing studies. The difficulty of separating the effects may be due to the fact that particulate levels co-vary with other combustion source pollutants. That is, the particle measurements serve as an index of overall exposure to combustion-related pollution, and some component(s) of combustion pollution other than particles might be at least partly responsible for the observed health effects.

EPA staff has presented conclusions on causal determination of several health effects based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the Table below.

ULTRAFINE PARTICLES

As noted above, numerous studies have found association of particulate matter levels with adverse effects, including mortality, hospital admissions, and respiratory disease symptoms. The vast majority of these studies used particle mass of PM₁₀ or PM_{2.5} as the measure of exposure. Some researchers have postulated, however, that ultrafine particles may be responsible for some of the observed associations of particulate matter and health outcomes (Oberdorster, et al, 1995; Seaton, et al, 1995). Ultrafine particles are generally classified of 0.1 µm and small diameter.

Several potential mechanisms have been brought forward to suggest that the ultrafine portion may be important in determining the toxicity of ambient particulates, some of which are discussed below.

For a given mass concentration, ultrafine particles have much higher numbers and surface area compared to larger particles. Particles can act as carriers for other adsorbed agents, such as trace metals and organic compounds; and the larger surface area may transport more of such toxic agents than larger particles.

This page contains no comments

Smaller particles can also be inhaled deep into the lungs. As much as 50% of 0.02 µm diameter particles are estimated to be deposited in the alveolar region of the lung. There is complex nature of the relation between deposition and particle size. The ultrafine particles generally have higher fractional deposition in the alveolar region. However, for the smaller nucleation mode (particles less than 0.01 µm size) the deposition in the alveolar region declines, but increases in the extrathoracic region.

Exposures of laboratory animals to ultrafine particles have found cardiovascular and respiratory effects. Mice exposed to concentrated near roadway ultrafine particles showed larger early atherosclerotic lesions than mice exposed to PM_{2.5} or filtered air (Arujo, 2008). In a mouse allergy model, exposures to concentrated ultrafine particles resulted in a greater response to antigen challenge to ovalbumin (Li, 2010), indicating that vehicular traffic exposure could exacerbate allergic inflammation in already-sensitized animals.

Controlled exposures of human volunteers to ultrafine particles either laboratory generated or as products of combustion, such as diesel exhaust containing particles, have found physiological changes related to vascular effects. Mills, 2011, for example found exposure to diesel exhaust particulate attenuated both acetylcholine and sodium-nitroprusside -induced vasorelaxation.

There are no long-term studies of human population exposure to ultrafine particle, as there is a lack of a monitoring network in the U.S. There have been several cross sectional epidemiological studies of ultrafine particles, mainly from Europe. Some of these studies found effects on hospital admissions, emergency department visits, for respiratory and cardiovascular effects. Other studies, however, have not found such effects (EPA, 2009). Concentrations of ultrafine particles can vary geographically, and it is not clear how well central site monitors may capture actual exposures.

EPA staff has presented conclusions on causal determination of several health effects of ultrafine PM based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the table below.

[Additional discussion on the sources and health effects of ultrafine particles can be found in Chapter 9 of the 2012 AQMP.](#)

CARBON MONOXIDE

The high affinity of carbon monoxide (CO) to bond with oxygen-carrying proteins (hemoglobin and myoglobin) results in reduced oxygen supply in the bloodstream of exposed individuals. The reduced oxygen supply is responsible for the toxic effects of CO which are typically manifested in the oxygen-sensitive organ systems. The effects have been studied in controlled laboratory environments involving exposure of humans and animals to CO, as well as in population-based studies of ambient CO exposure effects. People with deficient blood supply to the heart (ischemic heart disease) are known to be susceptible to the effects of CO. Protection of this group is the basis of the existing National Ambient Air Quality Standards for CO at 35 ppm for one hour and 9 ppm averaged over eight hours. The health effects of ambient CO have been recently reviewed (U.S. EPA, 2000, 2010).

Inhaled CO has no known direct toxic effect on lungs but rather exerts its effects by interfering with oxygen transport through the formation of carboxyhemoglobin (COHb, a chemical complex of CO and hemoglobin). Exposure to CO is often evaluated in terms of COHb levels in blood measured as percentage of total hemoglobin bound to CO. COHb levels in non-smokers range between 0.3 and 0.7% and 5 to 10% in smokers. COHb levels in excess of 1.5% in a significant proportion of urban non-smoking populations can be considered as evidence of widespread exposure to environmental CO.

Under controlled laboratory conditions, healthy subjects exposed to CO sufficient to result in 5% COHb levels exhibited reduced duration of maximal exercise performance and consumption of oxygen. Studies involving subjects with coronary artery disease who engaged in exercise during CO exposures have shown that COHb levels as low as 2.4% can lead to earlier onset of electrocardiograph changes indicative of deficiency of oxygen supply to the heart. Other effects include an earlier onset of chest pain, an increase in the duration of chest pain, and a decrease in oxygen consumption.

Findings of epidemiologic studies have observed associations between ambient CO concentration and emergency department visits and hospital admissions for ischemic heart disease and other cardiovascular diseases.

Animal studies associated with long-term exposure to CO resulting in COHb levels that are equivalent to those observed in smokers have shown indication of reduction in birth weight and impaired neurobehavior in the offspring of exposed animals.

This page contains no comments

Epidemiological studies conducted in Southern California have indicated an association with CO exposure during pregnancy to increases in pre-term births. (Ritz, 2000). However, the results were not consistent in different areas studied. The increase in the pre-term births was also associated with PM10 levels. Another study found increased risks for cardiac related birth defects with carbon monoxide exposure in the second month of pregnancy (Ritz, 2002). Toxicological studies in laboratory animals with higher than ambient levels of CO have also reported decrements in birth weight and prenatal growth.

EPA staff has presented conclusions on causal determination of the health effects of carbon monoxide based on a recent review of the available scientific studies (EPA, 2010). These are depicted in the table below.

NITROGEN DIOXIDE

The U.S. EPA has recently reviewed the health effects of nitrogen dioxide (U.S. EPA, 2008a). Evidence for low-level nitrogen dioxide (NO₂) exposure effects is derived from laboratory studies of asthmatics and from epidemiological studies. Additional supportive evidence is derived from animal studies.

Epidemiological studies using the presence of an unvented gas stove as a surrogate for indoor NO₂ exposures suggest an increased incidence of respiratory infections or symptoms in children.

Recent studies related to outdoor exposure have found health effects associated with ambient NO₂ levels, including respiratory symptoms, respiratory illness, decreased lung function, increased emergency room visits for asthma, and cardiopulmonary mortality. However, since NO₂ exposure generally occurs in the presence of other pollutants, such as particulate matter, these studies are often unable to determine the specific role of NO₂ in causing effects.

The Children's Health Study in Southern California found associations of air pollution, including NO₂, PM₁₀, and PM_{2.5}, with respiratory symptoms in asthmatics (McConnell, 1999). Particles and NO₂ were correlated, and effects of individual pollutants could not be discerned. A subsequent analysis indicated a stronger role for NO₂ (McConnell, 2002).

Ambient levels of NO₂ were also associated with a decrease in lung function growth in a group of children followed for eight years. In addition to NO₂, the decreased growth was also associated with particulate matter and airborne acids. The study authors postulated that these may be a measure of a package of pollutants from traffic sources. (Gauderman, 2004).

Results from controlled exposure studies of asthmatics demonstrate an increase in the tendency of airways to contract in response to a chemical stimulus (bronchial reactivity). Effects were observed with exposures from 0.1 to 0.3 ppm NO₂ for periods ranging from 30 minutes to 3 hours. A similar response is reported in some studies with healthy subjects at higher levels of exposure (1.5 - 2.0 ppm). Mixed results have been reported when people with chronic obstructive lung disease are exposed to low levels of NO₂.

Short-term controlled studies of animals exposed to NO₂ over a period of several hours indicate cellular changes associated with allergic and inflammatory response and interference with detoxification processes in the liver. In some animal studies

This page contains no comments

the severity of the lung structural damage observed after relatively high levels of short-term ozone exposure is observed to increase when animals are exposed to a combination of ozone and NO₂.

In animals, longer-term (3-6 months) repeated exposures at 0.25 ppm appear to decrease one of the essential cell-types (T-cells) of the immune system. Non-specific changes in cells involved in maintaining immune functions (cytotoxic T-cells and natural killer cells) have been observed in humans after repeated exposure (4-6 days) to >0.6 ppm of NO₂ (20 min. - 2 hours). All these changes collectively support the observation reported both in population and animal studies of increased susceptibility to infections, as a result of NO₂ exposure.

The U.S. EPA recently adopted a new short-term standard of 100 ppb (0.1 ppm) averaged over 1 hour. The standard was designed to protect against increases in airway reactivity in individuals with asthma observed in controlled exposure studies, as well as respiratory symptoms observed in epidemiological studies.

SULFUR DIOXIDE

Controlled laboratory studies involving human volunteers have clearly identified asthmatics as the most sensitive group to the effects of ambient sulfur dioxide (SO₂) exposures. Healthy subjects have failed to demonstrate any short-term respiratory functional changes at exposure levels up to 1.0 ppm over 1-3 hours.

In exercising asthmatics, brief exposure (5-10 minutes) to SO₂ at levels between 0.2-0.6 ppm can result in significant alteration of lung function, such as increases in airway resistance and decreases in breathing capacity. In some, the exposure can result in severe symptoms necessitating the use of medication for relief. The response to SO₂ inhalation is observable within 2 minutes of exposure, increases further with continuing exposure up to 5 minutes then remains relatively steady as exposure continues. SO₂ exposure is generally not associated with any delayed reactions or repetitive asthmatic attacks.

In epidemiologic studies, associations of SO₂ levels with increases in respiratory symptoms, increases in emergency department visits and hospital admissions for respiratory-related causes have been reported.

The U.S. EPA has recently revised the SO₂ air quality standard. The previous 24-hour standard was rescinded and replaced with a new 1-hour standard at 75 ppb (0.075 ppm) to protect against high short-term exposures.

This page contains no comments

Animal studies have shown that despite SO₂ being a respiratory irritant, it does not cause substantial acute or chronic toxicity in animals exposed at ambient concentrations. However, relatively high exposures (10 ppm of SO₂ for 72 hours) in mice can lead to tissue damage, fluid accumulation and sloughing of respiratory lining. Sensitization to allergies is observable in guinea pigs repeatedly exposed to high levels (72 ppm) of SO₂. This effect needs further evaluation in clinical and population studies to identify any chronic exposure impact on both asthmatic incidence and attacks in a population.

Some epidemiological studies indicate that the mortality and morbidity effects associated with the fine fraction of particles show a similar association with ambient SO₂ levels. In these studies, efforts to separate the effects of SO₂ from fine particles have not been successful. Thus, it is not clear whether the two pollutants act synergistically, or whether being generated from similar combustion sources, they represent the same pollution index for the observed effects.

SULFATES

Based on a level determined necessary to protect the most sensitive individuals, the California Air Resources Board (CARB) in 1976 adopted a standard of 25 µg/m³ (24-hour average) for sulfates. There is no federal air quality standard for sulfates.

In recent years, a vast majority of effects (mortality and morbidity) associated with fine particles (PM_{2.5}) and sulfur dioxide have shown a similar association with ambient sulfate levels in some population studies. The efforts to fully separate the effects of sulfates from other coexisting pollutants have not been successful. This may be due to the fact that these pollutants covary under ambient conditions, having been emitted from common sources; and the effects observed may be due to the combination of pollutants, rather than a single pollutant.

A clinical study involving exposure of human subjects to sulfuric acid aerosol indicated that adolescent asthmatics may be a susceptible population subgroup with some changes in lung function observed with exposures below 100 µg/m³. In general, however, laboratory exposures of human volunteers to sulfates at or near ambient levels have not found significant changes in lung function.

Results from animal studies involving exposures to sulfuric acid aerosol, ammonium bisulfate and ammonium sulfate indicate that acidic particles (former two) are more toxic than non-acidic particles (latter). In addition, the severity or magnitude of both

mortality and morbidity effects is relatively higher in population studies of the eastern United States and Canada where sulfate concentrations are higher than for those observed in the western United States. Mixed results have been reported from studies which attempted to ascertain the role of acidity in determining the observed toxicity.

LEAD

The U.S. EPA has recently reviewed the health effects of ambient lead exposures in conjunction with a review of the NAAQS for lead. (U.S. EPA 2006b; U.S. EPA 2007b). The following summary is taken from these reviews.

There are a number of potential public health effects at low level exposures. The health implications are generally indexed by blood lead levels, which are related to lead exposures both from inhalation as well as from ingestion. As identified by EPA, effects include impacts on population IQ, as well as heart disease and kidney disease. The array of health effects includes the following.

- Heme biosynthesis and related functions;
- Neurological development and function;
- Reproduction and physical development;
- Kidney function;
- Cardiovascular function
- Immune function

Children appear to be sensitive to the neurological toxicity of lead, with effects observed at blood lead concentration ranges of 5 – 10 µg/dL, or possibly lower. No clear threshold has yet been established for such effects.

According to the EPA review, the most important effects observed are neurotoxic effects in children and cardiovascular effects in adults. The effects in children include impacts on intellectual attainment and school performance.

EPA has recently revised the NAAQS for lead to a level of 0.15 µg/m³ averaged over a 3 month period to protect against lead toxicity. The following two charts, taken from the U.S. EPA review, depict the health effects of lead in relation to blood levels.

TOXIC AIR CONTAMINANTS

Toxic air contaminants are pollutants for which there generally are no ambient air quality standards. Under California's Air Toxics Program, CARB staff and Office of Environmental Health Hazard Assessment (OEHHA) assess the health effects of substances that may pose a risk of adverse health effects. These effects are usually an increased risk for cancer or adverse birth outcome. After review by the state Scientific Review Panel, CARB holds a public hearing on whether to formally list substances that may pose a significant risk to public health as a Toxic Air Contaminant.

CARB and OEHHA also establish potency factors for air toxics that are carcinogenic. The potency factors can be used to estimate the additional cancer risk from ambient levels of toxics. This estimate represents the chance of contracting cancer in an individual over a lifetime exposure to a given level of an air toxic and is usually expressed in terms of additional cancer cases per million people exposed.

The District conducted studies on the ambient concentrations and estimated the potential health risks from air toxics (SCAQMD, 2008). In the latest study, a two year monitoring program was undertaken at 10 sites throughout the SCAB over the time period 2004-2006. Over 30 substances were measured, and annual average levels were calculated. The results showed that the overall risk for excess cancer from a 70-year lifetime exposure to the levels of air toxics calculated as the average level at the 10 sites was about 1,200 in a million. The largest contributor to this risk was diesel ~~exhaust~~particulate matter, accounting for about 84% of the air toxics risk. A breakdown of the major contributors to the air toxics risk is shown in ~~FIGURE 1-2~~FIGURE I-4.

[While the California Air Resources Board listed Diesel Particulate Matter as a Toxic Air Contaminant in 1989, the International Agency for Research on Cancer, an arm of the World Health Organization, recently convened an international panel of scientists to review the published literature regarding the carcinogenicity of diesel combustion emissions. The panel concluded that Diesel Exhaust is a substance that causes cancer in humans \(Benbrahim-Tallaa, 2012\).](#)

FIGURE I-42

Major Pollutants Contributing to Air Toxics Cancer Risk in the South Coast Air Basin

For non-cancer health effects, OEHHA has developed acute and chronic Reference Exposure Levels (RELs). RELs are concentrations in the air below which adverse health effects are not likely to occur. Acute RELs refer to short-term exposures, generally of one-hour duration. Chronic RELs refer to long-term exposures of several years. The ratio of ambient concentration to the appropriate REL can be used to calculate a Hazard Index. A Hazard Index of less than one would not be expected to result in adverse effects. The measured levels from the most recent study were below the applicable Reference Exposure Levels.

The key air toxics contributing to risk from mobile and stationary sources are listed in TABLE I-9.

This page contains no comments

TABLE I-9

Key Toxic Air Contaminants in the SCAB

MOBILE SOURCES	STATIONARY SOURCES
Acetaldehyde	Hexavalent Chromium
Benzene	Methylene Chloride
1,3 Butadiene	Nickel
Diesel Exhaust Particulate Matter	Perchloroethylene
Formaldehyde	Trichloroethylene

CONCLUSION

A large body of scientific evidence shows that the adverse impacts of air pollution in human and animal health are clear. A considerable number of population-based and laboratory studies have established a link between [air pollution and](#) increased morbidity and, in some instances, earlier mortality ~~and air pollution~~.

[As the scientific methods for the study of air pollution health effects has progressed over the past decades, adverse effects have been shown to occur at lower levels of exposure. For some pollutants, no clear thresholds for effects have been demonstrated. The new findings have, in turn, led to the revision and lowering of National Ambient Air Quality Standards which, in the judgment of the Administrator of the U.S. EPA, are necessary to protect public health. The figures below are meant to convey some of the historical context to recent revisions to the NAAQS for ozone and for particulate matter.](#)

COMMENTS RECEIVED ON DRAFT APPENDIX I FROM SCAQMD ADVISORY COUNCIL

Section 40471 of the California Health and Safety Code calls for the periodic preparation of a report on the health impacts of particulate matter air pollution in the South Coast Air Basin as part of the Air Quality Management Plan (AQMP) revisions. The report is to be submitted to the Advisory Council for review and comment.

The correspondence requesting comments from the Advisory Council and a copy of their comments received through October 5, 2012, follow.

Subject: Review of Health Effects - 2012 AQMP Draft Appendix I

Greetings to all,

I want to thank all of you for agreeing to participate on the AQMD's Advisory Council, and provide an update to our schedule.

As you know, Section 40471 of the California Health and Safety Code calls for the periodic preparation of a report on the health impacts of particulate matter air pollution in the South Coast Air Basin as part of the Air Quality Management Plan (AQMP) revisions. The report is to be submitted to the Advisory Council for review and comment.

We have prepared a draft of the report on PM2.5, which also includes other air pollutant health impacts, as a draft Appendix I to the 2012 AQMP. The draft Appendix I is attached for your review.

We have scheduled a meeting of the Advisory Council to provide comments to District staff. The details are below.

Date: Wednesday, July 11, 2012

Time: 2:00 p.m.-4:00 p.m.

Place: SCAQMD Conference Room CC-8

Please send any written comments you might have to me by July 11, 2012. Electronic format is preferred. All comments received will be attached to the Appendix when it is released in final form.

The Advisory Council is subject to the California open meetings regulations. Please do not copy other Advisory Council members regarding your comments. There will be opportunity for discussion at the meeting on July 11. The Advisory Council Roster is attached for your information.

Thanks again, and please let me know if I can provide any additional information.

Jean Ospital

Dear Dr. Ospital:

Comments on Appendix I: Health Effects Draft 2012 Air Quality Management Plan

Thank you for the opportunity to represent Los Angeles County Sanitation Districts and Supervisor Antonovich in submitting these brief comments on Appendix I of the 2012 Draft Air Quality Management Plan. As you well know, the AQMP presents varying degrees of significant impacts on all the residents of the air basin, and we recognize the staff's considerable efforts to address many of those in the AQMP as specifically as possible and applaud your efforts. We have the following comments on Appendix I and the health aspects draft 2012 AQMP.

1. Consider implementing the most beneficial control measures healthwise-speaking first. While there is the obligatory ranking of control measures with respect to cost effectiveness, another permutation on this might be showing the reduction in population exposure per control measure, if such a calculation can be made. Implementing the most beneficial measures healthwise first might also garner more popular support for the plan.
2. We raised a concern as to the focus of air toxics measures in the 2007 AQMP and are not certain we ever got a response and will take this opportunity to raise it again. On Page I-25 of the 2012 Appendix I, the basinwide cancer risk is reported to be 1200 in a million, largely the impact of Diesel particulate matter and other mobile source emissions. We also look again at Dr. Thomas Mack's 2004 work Cancers in the Urban Development¹, a detailed study "atlas" of three quarters of a million cancer types reported to the Cancer Surveillance Program at USC by mostly L.A. County doctors between 1972 and 1998. With the exception of high-risk tracts around the 405, 605, 105, and 710 freeways and some areas between the two ports (we will return to this) the L.A. County rates for nose and throat, all types of lung and bronchus carcinomas, papillary

¹ Cancers in the Urban Environment *Patterns of Malignant Disease in Los Angeles County and Its Neighborhoods*; Thomas Mack, Dept. of Preventive Medicine, Keck School of Medicine, Norris Comprehensive Cancer Center, University of Southern California; Elsevier Academic Press, 2004.

carcinoma of the thyroid, squamous bladder carcinoma, diffuse mixed B-cell non-Hogkin lymphoma were similar to the national rate while prostate carcinoma, brain malignancies, small cell carcinoma of the lung and bronchus, adenocarcinoma of the lung and bronchus were slightly lower than the national rate. In the last paragraph on Page 7 of the 645 page tome, in a section entitled *Environmental and Other Causes of Cancer* the author states, "...no local increase in cancer due to pollution has yet been clearly identified in the United States. Even such highly publicized sites of pollution as the Love Canal, Three Mile Island and those popularized in the movies *Erin Brockovich* and *A Civil Action* did not produce clear evidence of a cancer excess, although each of these examples of irresponsible industrial contamination represented a clear potential danger to local residents and may have produced other medical problems." In the very last sentence of that same book on Page 645, Dr. Mack also states, "As of this writing, no evidence of a malignancy caused by a strictly environmental carcinogen has yet been confirmed."

Several types of cancers unfortunately seem more prevalent around certain freeways and between the ports and these are worthy of more study. We believe the AQMP should focus on acute and chronic effects of non-carcinogenic air pollution as a priority, while the localized impacts around freeways and ports is further studied for their carcinogenic health effects.

3. We believe that some analysis of indoor air quality and the PM2.5 attainment plan is appropriate at this time. A significant portion of human exposure to PM2.5 occurs indoors where people spend ~85-90% of their time.²

We thank you for this opportunity to comment.

Very truly yours,

Grace Robinson Chan

I'll see you at the meeting tomorrow. Attached are some comments.

best regards-afif

Comments on the “Draft 2012 AQMP Appendix I-Health Effects”

From Afif El-Hasan, MD, Member-Environmental Justice Committee, AQMD

The 2012 AQMP Draft Report on Health Effects summarized the deleterious effects of a number of airborne pollutants. I would like to make the following comments:

Lower income populations tend to live in closer proximity to freeways, large volume transportation corridors or other sources of man-made air pollution. Other factors compounding the issue include reduced use of air conditioning (more open windows) and less use of auto transportation (more walking in polluted areas and using bikes/buses). This population also has less access to routine medical care, inhaled anti-inflammatory medication for chronic lung disease, and antibiotics for infection. These environmental and socioeconomic factors must be taken into account in future population studies on the effects of air pollution.

Obesity must be addressed in these studies. Decreased activity due to poor outside air quality, lung disease, asthma, and lack of access to healthier (more expensive) food are all contributors to obesity. In turn, obesity increases the prevalence of asthma, lung disease, cardiovascular disease and cancer. Physical activity then becomes further decreased which leads to further health issues. Fat cells can also store lipid soluble chemicals that are absorbed from the environment. This may possibly contribute to the body’s deterioration with chronic exposure to pollutants.

Pregnancy is another unique and serious issue. Pregnancy is associated with reduced lung function at a time when the mother’s lungs and cardiovascular system are supporting both the mother and the child. At the same time, the fetus is vulnerable to chemical exposure at a critical time in development. The human toll to the family of a baby with health problems and the cost to society of a premature infant or an infant with birth defects makes protection of the pregnant women a priority from a public health standpoint.

Studies have suggested a decrease in mental function associated with exposure to air pollution. This has been documented in adults with chronic exposure to high levels of air pollution, and in children born and raised in these areas. When establishing values for safe levels of pollution in the air, risks to cognitive function must be addressed. This is especially important for children who may attend schools or use parks that are in close proximity to freeways and other transportation corridors.

Subject: Comments on Appendix I Draft 2012 Air Quality Management Plan

Dear Dr. Ospital:

I appreciate the opportunity to represent the Home Rule Advisory Group (HRAG) in submitting comments on the draft report on PM_{2.5}, and other air pollutant health impacts, as they are set forth in Appendix I of the 2012 Draft Air Quality Management Plan (AQMP). Speaking on behalf of the HRAG, we understand that the AQMP promises to have significant impacts on all who are participating in the process and applaud the time and effort required to produce a thorough and feasible plan.

Following are my comments:

In the draft, considerable effort has gone into explaining the adverse health effects associated with exposure to air pollutants and toxic air contaminants and linking it with increases in illness (morbidity) and increases in death rates (mortality). On Page I-25, for example, the report states that the cancer risk throughout the South Coast Air Basin (SCAB) is 1200 in a million and largely attributable to diesel exhaust from mobile sources, accounting for as much as 84% of the air toxics risk. This is confirmed by the chart (Figure 2) on Page I-26, showing "*Major pollutants contributing to Air Toxics Cancer Risks in the South Coast Air Basin,*" and Table 9, on Page I-26: "*Key Toxic Air Contaminants in the SCAB.*"

While stationary sources and mobile sources contribute to the overall cancer risk, clearly, the latter is the major contributor and should warrant the greatest and most immediate attention from a regulatory, as well as a health effects perspective. It has been discouraging, from our participation in the AQMP Advisory Group meetings, to learn that suggested strategies for reducing diesel exhaust from mobile sources seem to be more voluntary than prescriptive and don't appear to have the same degree of urgency as those for stationary sources.

Telephone: (714) 778-0763 • Fax: (714) 778-0763

Website: <http://www.calsmallbusinessalliance.org>

We also noticed that a number of reviews, analyses and studies on the effects of air pollution, ozone, and particulate matter are cited throughout the report. Some of this research was done on a national and international level, and some was done in specific cities throughout the United States. One study which is specific to California, and involved a cohort of individuals from 11 California counties, was conducted by Dr. James E. Enstrom, and represents a contrarian perspective of the PM_{2.5} and mortality relationship. Little coverage of the study, and the significance of the findings, is given in the report. Other relevant scientific data which can be found in research by Dr. Robert Phalen's book: "*The Particulate Air Pollution Controversy*" would be a useful and instructive addition to the final version of this report. One other body of research which has been completely overlooked or disregarded in this report is "*Cancers in the Urban Environment*," by Dr. Thomas M. Mack.

This research appears to be extremely relevant because it is focused on patterns of malignant disease in Los Angeles County and its neighborhoods. In his book, Dr. Mack discusses many cases involving nonrandom, geographic variations, thus indicating that factors other than chance determine the pattern of community incidence. Among the factors known to be responsible for individual malignancies are personal experiences other than occupational exposures. Some of these are habits, recreational preferences, past reproductive and medical events, and genetic inheritance.

In at least six instances in his book the geographic distribution of high risk of disease was clearly nonrandom, but did not conform to the pattern that would have been predicted by available knowledge. The malignancies in question included oropharyngeal carcinoma, small cell carcinoma and adenocarcinoma of the lung, papillary carcinoma of the thyroid, squamous carcinoma of the bladder, and diffuse mixed B-cell non-Hodgkin lymphoma. According to Dr. Mack, the true explanation for none of these patterns is currently known, although educated guesses provide tentative hypotheses that are currently still to be evaluated. As a final statement in his book, Dr. Mack states that "*as of this writing, no evidence of a malignancy caused by a strictly environmental carcinogen has yet been confirmed.*"

In December 2006, when commenting on the 2007 AQMP, I raised a concern about the methodology used by a district consultant when attempting to quantify the health effects from improvements in levels of PM_{2.5} and ozone and assigning economic values to those same health effects for that AQMP. Our comments were made out of concern for the environment, as well as for the health and welfare of the workforce, our families, and the general public. Another reason for expressing my concern and commenting on this aspect of the 2007 AQMP was over the alarming and ever increasing cost of compliance with the rules that are ultimately promulgated after every AQMP. Just as the cost of health care continues to rise, so does the cost of compliance.

We were encouraged to read on Page I-13 of the report that the district acknowledges that more research is needed to better assess the relative effects of fine (PM_{2.5}) and coarse (PM_{10-2.5}) fractions of particulate matter on mortality. It is common knowledge that the district and much if not all of the business community differs over the methodology used to measure the costs and

benefits associated with certain emissions and/or risk reduction strategies. We hope that these differences can be quickly and amicably resolved.

As a way of emphasizing the importance of realistically measuring costs and benefits for control strategies, I would like to mention that at the time the 2007 AQMP was being drafted the unemployment rate in the Los Angeles County was 4.7%. The 2007 Budget Act signed by then Governor Schwarzenegger included the largest reserve of any budget act in the state's history. Today, while the state of our air quality continues to improve the state of our economy and the availability of jobs has worsened. If the goal of the AQMP is to improve air quality, reduce the adverse health impacts of particulate matter and exposure to toxic air contaminants, it is essential that the Plan represents the needs of all stakeholders. For the business community this means that control measures must be more than just feasible, they must be reasonable, acceptable to industry, and cost effective, as measured by a standard or standards which are suitable to business.

Finally, when reading the last sentence on Page I-3: "*Another long-term study of a national cohort found that long-term exposures to ozone were associated with respiratory-related causes of mortality, **but not cardiovascular causes, when PM2.5 exposure were also included in the analysis,***" we believe there is a conflict with a statement made on Page I-10, halfway down the page beginning with the sentence: "*The major types of effects associated with particulate matter include:*

- *Increased mortality*
- *Exacerbation of respiratory disease **and of cardiovascular disease** as evidenced by increases in:*
 - *Respiratory symptoms*
 - *Hospital admissions and emergency room visits*
 - *Physician office visits*
 - *School absences*
 - *Work loss days*
- *Effects on lung function*
- *Changes in lung morphology*

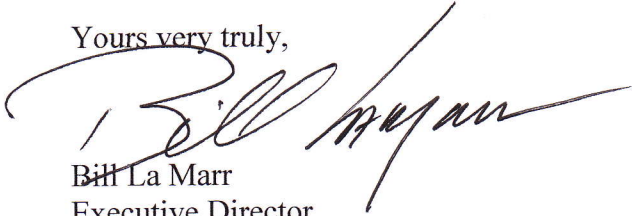

Legitimate scientific research - regardless of the point of view - should be part of the collaborative process between the district and relevant stakeholders, if we are to create a better consensus on how to improve air quality as required by existing law while simultaneously improving the region's economy.

Jean Ospital, Dr. P.H.
Health Effects Officer
South Coast Air Quality Management District

**Comments on Appendix I Draft
2012 Air Quality Management Plan**

In closing, I want to express my sincere appreciation for inviting me to serve on the AQMP Advisory Group and on the AQMD Advisory Council, and thank you for the opportunity to comment on this important Appendix to the 2012 AQMP.

Yours very truly,

Subject: Great meeting today!

Jean,

At our meeting today, I promised to send you two things tonight. Here you go:

- Latest MSAT list
 - Reference:
http://www.fhwa.dot.gov/environment/air_quality/air_toxics/policy_and_guidance/100109guidmem.pdf
 - From the document:
“EPA identified seven compounds with significant contributions from mobile sources that are among the national and regional-scale cancer risk drivers from their 1999 National Air Toxics Assessment (NATA) (<http://www.epa.gov/ttn/atw/nata1999/>). These are *acrolein, benzene, 1,3-butadiene, diesel particulate matter plus diesel exhaust organic gases (diesel PM), formaldehyde, naphthalene, and polycyclic organic matter.*”
- EPA figure on progression of new standards
 - I’m still checking my citations for the presentation I remember. I will have to send it later.

I thought that the discussion at the meeting today was very thought provoking. As I mentioned, I thought that the draft Appendix I did a nice job describing and summarizing the latest pertinent health studies (by pollutant).

Regards,

Julia

Dear Dr. Ospital,

I attach the AQMP health effects appendix with a few comments embedded in the text. In general, I think this is a good summary drawing on the key studies and reviews conducted as the foundation for regulatory decisions by EPA staff and CARB.

Although there is a review of toxicity of ultrafine particles, there is no mention of the strong emerging epidemiological evidence that near-roadway exposures cause asthma and ischemic heart disease. Ultrafine particles are a leading candidate for the causal component of the near-roadway mixture. I know you have administrative constraints based on the current regulatory framework and the evidence base, and the current lack of a standard covering UF particles. However, if ultrafine particles are to be reviewed, the near-roadway literature may deserve some mention. Dr. Nino Kunzli, a world expert on the health effects of air pollution, recently published an editorial (I believe it was in the European Respiratory Journal) calling for regulation of ultrafine PM fraction.

Hope this is useful. Will there be a full AQMP that we will be asked to review later or is the extent of our commitment/obligation in this regard?

As I indicated to you earlier, it's unlikely I'll be able to join you on the 11th, but I'd be happy to review any follow-up documents or comment on any discussion items that correspond to my area of expertise.

Sincerely,

Rob McConnell MD
Professor of Preventive Medicine.

Summary of Comments on 2012 AQMP Appendix I Draft 06-05-2012.pdf

Page: 11

The major subgroups of the population considered to be at increased risk from ozone exposure are outdoor exercising individuals, including children, and people with preexisting respiratory disease(s) such as asthma. The data base identifying the former group as being at increased risk to ozone exposure is much stronger and more quantitative than that for the latter group, probably because of a larger number of studies conducted with healthy individuals. The adverse effects reported with short-term ozone exposure are greater with increased activity because activity increases the breathing rate and the volume of air reaching the lungs, resulting in an increased amount of ozone reaching the lungs. Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher ventilation rate than adults.

A number of adverse health effects associated with ambient ozone levels have been identified from laboratory and epidemiological studies (EPA, 1996; 2006, 2011; ATS, 1996). These include increased respiratory symptoms, damage to cells of the respiratory tract, decrease in lung function, increased susceptibility to respiratory infection, and increased risk of hospitalization.

Increases in ozone levels are associated with elevated absences from school. The Children's Health Study, conducted by researchers at the University of Southern California, followed a cohort of children that live in 12 communities in Southern California with differing levels of air pollution for several years. A publication from this study reported that school absences in fourth graders for respiratory illnesses were associated with ambient ozone levels. An increase of 20 ppb ozone was associated with an 83% increase in illness-related absence rates (Gilliland, 2001).

The number of hospital admissions and emergency room visits for all respiratory causes (infections, respiratory failure, chronic bronchitis, etc.) including asthma shows a consistent increase as ambient ozone levels increase in a community. These excess hospital admissions and emergency room visits are observed when hourly ozone concentrations are as low as 0.06 to 0.10 ppm.

Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).

Multicity studies of short-term ozone exposures (days) and mortality have also examined regional differences. Evidence was provided that there were generally higher ozone-mortality risk estimates in northeastern U.S. cities, with the southwest and urban mid-west cities showing lower or no associations (Smith, 2009; Bell, 2008). Another long-term study of a national cohort found that long-term exposures to ozone were associated with respiratory-related causes of mortality, but not

Author: rmcconne Subject: Sticky Note Date: 7/10/2012 10:54:29 AM

Not mutually exclusive. I think the exercising asthmatic children are one of the more studied at risk groups. Exercise in non-asthma causing new onset depends largely on our study, which has gotten a lot of attention because design was strong.

For a given mass concentration, ultrafine particles have much higher numbers and surface area compared to larger particles. Particles can act as carriers for other adsorbed agents, such as trace metals and organic compounds; and the larger surface area may transport more of such toxic agents than larger particles.

Smaller particles can also be inhaled deep into the lungs. As much as 50% of 0.02 µm diameter particles are estimated to be deposited in the alveolar region of the lung. There is complex nature of the relation between deposition and particle size. The ultrafine particles generally have higher fractional deposition in the alveolar region. However, for the smaller nucleation mode (particles less than 0.01 µm size) the deposition in the alveolar region declines, but increases in the extrathoracic region.

Exposures of laboratory animals to ultrafine particles have found cardiovascular and respiratory effects. Mice exposed to concentrated near roadway ultrafine particles showed larger early atherosclerotic lesions than mice exposed to PM2.5 or filtered air (Ary 2008). In a mouse allergy model, exposures to concentrated ultrafine particles resulted in a greater response to antigen challenge to ovalbumin (Li, 2010), indicating that vehicular traffic exposure could exacerbate allergic inflammation in already-sensitized animals.

Controlled exposures of human volunteers to ultrafine particles either laboratory generated or as products of combustion, such as diesel exhaust containing particles, have found physiological changes related to vascular effects. Mills, 2011, for example found exposure to diesel exhaust particulate attenuated both acetylcholine and sodium-nitroprusside -induced vasorelaxation.

There are no long-term studies of human population exposure to ultrafine particles, as there is a lack of a monitoring network in the U.S. There have been several cross sectional epidemiological studies of ultrafine particles, mainly from Europe. Some of these studies found effects on hospital admissions, emergency department visits, for respiratory and cardiovascular effects. Other studies, however, have not found such effects (EPA, 2009). Concentrations of ultrafine particles can vary geographically, and it is not clear how well central site monitors may capture actual exposures.

EPA staff has presented conclusions on causal determination of several health effects of ultrafine PM based on a recent review of the available scientific studies (EPA, 2009). These are depicted in the table below.

spelled Araujo
- Author: rmconne Subject: Sticky Note Date: 7/10/2012 10:54:29 AM
I think most have been time series studies rather than cross sectional, but you might check to be sure.

The Children's Health Study in Southern California found associations of air pollution, including NO₂, PM10, and PM2.5, with respiratory symptoms in asthmatics (McConnell, 1999). Particles and NO₂ were correlated, and effects of individual pollutants could not be discerned. A subsequent analysis indicated a stronger role for NO₂ (McConnell, 2002).

Ambient levels of NO₂ were also associated with a decrease in lung function growth in a group of children followed for eight years. In addition to NO₂, the decreased growth was also associated with particulate matter and airborne acids. The study authors postulated that these may be a measure of a package of pollutants from traffic sources. (Gauderman, 2004).

Results from controlled exposure studies of asthmatics demonstrate an increase in the tendency of airways to contract in response to a chemical stimulus (bronchial reactivity). Effects were observed with exposures from 0.1 to 0.3 ppm NO₂ for periods ranging from 30 minutes to 3 hours. A similar response is reported in some studies with healthy subjects at higher levels of exposure (1.5 - 2.0 ppm). Mixed results have been reported when people with chronic obstructive lung disease are exposed to low levels of NO₂.

Short-term controlled studies of animals exposed to NO₂ over a period of several hours indicate cellular changes associated with allergic and inflammatory response and interference with detoxification processes in the liver. In some animal studies the severity of the lung structural damage observed after relatively high levels of short-term ozone exposure is observed to increase when animals are exposed to a combination of ozone and NO₂.

In animals, longer-term (3-6 months) repeated exposures at 0.25 ppm appear to decrease one of the essential cell-types (T-cells) of the immune system. Non-specific changes in cells involved in maintaining immune functions (cytotoxic T-cells and natural killer cells) have been observed in humans after repeated exposure (4-6 days) to >0.6 ppm of NO₂ (20 min. - 2 hours). All these changes collectively support the observation reported both in population and animal studies of increased susceptibility to infections, as a result of NO₂ exposure.

The U.S. EPA recently adopted a new short-term standard of 100 ppb (0.1 ppm) averaged over 1 hour. The standard was designed to protect against increases in airway reactivity in individuals with asthma observed in controlled exposure studies, as well as respiratory symptoms observed in epidemiological studies.

SULFUR DIOXIDE

Controlled laboratory studies involving human volunteers have clearly identified asthmatics as the most sensitive group to the effects of ambient sulfur dioxide (SO₂) exposures. Healthy subjects have failed to demonstrate any short-term respiratory functional changes at exposure levels up to 1.0 ppm over 1-3 hours.

Subject: RE: Advisory Council meeting at 2:00 p.m. on July 11, 2012 @ SCAQMD in CC-8 re: Review of Health Effects-2012 AQMP Draft Appendix I
Attachments: June 2012 IARC.pdf

Jean .. Nice work and addition for the AQMP. My two suggestions focus on the PM section.

First, while PM is a criteria pollutant and part of NAAQS, the introduction should mention that it is legally a Toxic Air Contaminant California and words along CARB's introductory language for diesel PM might be appropriate.

Background on Diesel Health Effects

(<http://www.arb.ca.gov/research/diesel/diesel-health.htm>)

Diesel engines emit a complex mixture of air pollutants, composed of gaseous and solid material. The visible emissions in diesel exhaust are known as particulate matter or PM. In 1998, California identified diesel exhaust particulate matter (PM) as a [toxic air contaminant](#) based on its potential to cause cancer, premature death, and other health problems. Diesel engines also contribute to California's fine particulate matter (PM2.5) air quality problems. Those most vulnerable are children whose lungs are still developing and the elderly who may have other serious health problems. Based on year 2006-2008 emissions in California, diesel PM contributes each year to approximately 2,000 premature deaths, with an uncertainty range of 1,500 to 2,400.

Second, while their report came out after your report, it would be valuable to add the recent finding of IRAC: " as of June 12, 2012 " the International Agency for Research on Cancer (IARC), which is part of the World Health Organization (WHO), today classified diesel engine exhaust as carcinogenic to humans (Group 1), based on sufficient evidence that exposure is associated with an increased risk for lung cancer." The press release is attached ..

Respectfully submitted, Wayne Miller, PhD

IARC: DIESEL ENGINE EXHAUST CARCINOGENIC

Lyon, France, June 12, 2012 -- After a week-long meeting of international experts, the International Agency for Research on Cancer (IARC), which is part of the World Health Organization (WHO), today classified diesel engine exhaust as **carcinogenic to humans (Group 1)**, based on sufficient evidence that exposure is associated with an increased risk for lung cancer.

Background

In 1988, IARC classified diesel exhaust as *probably carcinogenic to humans (Group 2A)*. An Advisory Group which reviews and recommends future priorities for the IARC Monographs Program had recommended diesel exhaust as a high priority for re-evaluation since 1998.

There has been mounting concern about the cancer-causing potential of diesel exhaust, particularly based on findings in epidemiological studies of workers exposed in various settings. This was re-emphasized by the publication in March 2012 of the results of a large US National Cancer Institute/National Institute for Occupational Safety and Health study of occupational exposure to such emissions in underground miners, which showed an increased risk of death from lung cancer in exposed workers (1).

Evaluation

The scientific evidence was reviewed thoroughly by the Working Group and overall it was concluded that there was *sufficient evidence* in humans for the carcinogenicity of diesel exhaust. The Working Group found that diesel exhaust is a cause of lung cancer (*sufficient evidence*) and also noted a positive association (*limited evidence*) with an increased risk of bladder cancer (Group 1).

The Working Group concluded that gasoline exhaust was possibly carcinogenic to humans (Group 2B), a finding unchanged from the previous evaluation in 1989.

Public health

Large populations are exposed to diesel exhaust in everyday life, whether through their occupation or through the ambient air. People are exposed not only to motor vehicle exhausts but also to exhausts from other diesel engines, including from other modes of transport (e.g. diesel trains and ships) and from power generators.

Given the Working Group's rigorous, independent assessment of the science, governments and other decision-makers have a valuable evidence-base on which to consider environmental standards for diesel exhaust emissions and to continue to work with the engine and fuel manufacturers towards those goals.

Increasing environmental concerns over the past two decades have resulted in regulatory action in North America, Europe and elsewhere with successively tighter emission standards for both diesel and gasoline engines. There is a strong interplay between standards and technology – standards drive technology and new technology enables more stringent standards. For diesel engines, this required changes in the fuel such as marked decreases in sulfur content, changes in engine design to burn diesel fuel more efficiently and reductions in emissions through exhaust control technology.

However, while the amount of particulates and chemicals are reduced with these changes, it is not yet clear how the quantitative and qualitative changes may translate into altered health effects; research into

IARC: Diesel engines exhaust carcinogenic

this question is needed. In addition, existing fuels and vehicles without these modifications will take many years to be replaced, particularly in less developed countries, where regulatory measures are currently also less stringent. It is notable that many parts of the developing world lack regulatory standards, and data on the occurrence and impact of diesel exhaust are limited.

Conclusions

Dr Christopher Portier, Chairman of the IARC working Group, stated that “The scientific evidence was compelling and the Working Group’s conclusion was unanimous: diesel engine exhaust causes lung cancer in humans.” Dr Portier continued: “Given the additional health impacts from diesel particulates, exposure to this mixture of chemicals should be reduced worldwide.”(2)

Dr Kurt Straif, Head of the IARC Monographs Program, indicated that “The main studies that led to this conclusion were in highly exposed workers. However, we have learned from other carcinogens, such as radon, that initial studies showing a risk in heavily exposed occupational groups were followed by positive findings for the general population. Therefore actions to reduce exposures should encompass workers and the general population.”

Dr Christopher Wild, Director, IARC, said that “while IARC’s remit is to establish the evidence-base for regulatory decisions at national and international level, today’s conclusion sends a strong signal that public health action is warranted. This emphasis is needed globally, including among the more vulnerable populations in developing countries where new technology and protective measures may otherwise take many years to be adopted.”

Summary evaluation

The summary of the evaluation will appear in [The Lancet Oncology](#) as an online publication ahead of print on June 15, 2012.

About IARC

The International Agency for Research on Cancer (IARC) is part of the World Health Organization. Its mission is to coordinate and conduct research on the causes of human cancer, the mechanisms of carcinogenesis, and to develop scientific strategies for cancer control. The Agency is involved in both epidemiological and laboratory research and disseminates scientific information through publications, meetings, courses, and fellowships.

IARC: Diesel engines exhaust carcinogenic

Annexes

Evaluation groups - Definitions

Group 1: The agent is carcinogenic to humans.

This category is used when there is *sufficient evidence of carcinogenicity* in humans. Exceptionally, an agent may be placed in this category when evidence of carcinogenicity in humans is less than *sufficient* but there is *sufficient evidence of carcinogenicity* in experimental animals and strong evidence in exposed humans that the agent acts through a relevant mechanism of carcinogenicity.

Group 2.

This category includes agents for which, at one extreme, the degree of evidence of carcinogenicity in humans is almost *sufficient*, as well as those for which, at the other extreme, there are no human data but for which there is evidence of carcinogenicity in experimental animals. Agents are assigned to either Group 2A (*probably carcinogenic to humans*) or Group 2B (*possibly carcinogenic to humans*) on the basis of epidemiological and experimental evidence of carcinogenicity and mechanistic and other relevant data. The terms *probably carcinogenic* and *possibly carcinogenic* have no quantitative significance and are used simply as descriptors of different levels of evidence of human carcinogenicity, with *probably carcinogenic* signifying a higher level of evidence than *possibly carcinogenic*.

- **Group 2A: The agent is probably carcinogenic to humans.**
This category is used when there is *limited evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals. In some cases, an agent may be classified in this category when there is *inadequate evidence of carcinogenicity* in humans and *sufficient evidence of carcinogenicity* in experimental animals and strong evidence that the carcinogenesis is mediated by a mechanism that also operates in humans. Exceptionally, an agent may be classified in this category solely on the basis of *limited evidence of carcinogenicity* in humans. An agent may be assigned to this category if it clearly belongs, based on mechanistic considerations, to a class of agents for which one or more members have been classified in Group 1 or Group 2A.
- **Group 2B: The agent is possibly carcinogenic to humans.**
This category is used for agents for which there is *limited evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals. It may also be used when there is *inadequate evidence of carcinogenicity* in humans but there is *sufficient evidence of carcinogenicity* in experimental animals. In some instances, an agent for which there is *inadequate evidence of carcinogenicity* in humans and less than *sufficient evidence of carcinogenicity* in experimental animals together with supporting evidence from mechanistic and other relevant data may be placed in this group. An agent may be classified in this category solely on the basis of strong evidence from mechanistic and other relevant data.

Group 3: The agent is not classifiable as to its carcinogenicity to humans.

This category is used most commonly for agents for which the evidence of carcinogenicity is *inadequate* in humans and *inadequate* or *limited* in experimental animals.

Exceptionally, agents for which the evidence of carcinogenicity is *inadequate* in humans but *sufficient* in experimental animals may be placed in this category when there is strong evidence that the mechanism of carcinogenicity in experimental animals does not operate in humans.

Agents that do not fall into any other group are also placed in this category.

An evaluation in Group 3 is not a determination of non-carcinogenicity or overall safety. It often means that further research is needed, especially when exposures are widespread or the cancer data are consistent with differing interpretations.

IARC: Diesel engines exhaust carcinogenic

Group 4: The agent is *probably not carcinogenic to humans*.

This category is used for agents for which there is *evidence suggesting lack of carcinogenicity* in humans and in experimental animals. In some instances, agents for which there is *inadequate evidence of carcinogenicity* in humans but *evidence suggesting lack of carcinogenicity* in experimental animals, consistently and strongly supported by a broad range of mechanistic and other relevant data, may be classified in this group.

Evidence for studies in humans - Definition

As shown previously, the evidence relevant to carcinogenicity is evaluated using standard terms. For studies in humans, evidence is defined into one of the following categories:

Sufficient evidence of carcinogenicity: The Working Group considers that a causal relationship has been established between exposure to the agent and human cancer. That is, a positive relationship has been observed between the exposure and cancer in studies in which chance, bias and confounding could be ruled out with reasonable confidence. A statement that there is *sufficient evidence* is followed by a separate sentence that identifies the target organ(s) or tissue(s) where an increased risk of cancer was observed in humans. Identification of a specific target organ or tissue does not preclude the possibility that the agent may cause cancer at other sites.

Limited evidence of carcinogenicity: A positive association has been observed between exposure to the agent and cancer for which a causal interpretation is considered by the Working Group to be credible, but chance, bias or confounding could not be ruled out with reasonable confidence.

Inadequate evidence of carcinogenicity: The available studies are of insufficient quality, consistency or statistical power to permit a conclusion regarding the presence or absence of a causal association between exposure and cancer, or no data on cancer in humans are available.

Evidence suggesting lack of carcinogenicity: There are several adequate studies covering the full range of levels of exposure that humans are known to encounter, which are mutually consistent in not showing a positive association between exposure to the agent and any studied cancer at any observed level of exposure. The results from these studies alone or combined should have narrow confidence intervals with an upper limit close to the null value (e.g. a relative risk of 1.0). Bias and confounding should be ruled out with reasonable confidence, and the studies should have an adequate length of follow-up. A conclusion of *evidence suggesting lack of carcinogenicity* is inevitably limited to the cancer sites, conditions and levels of exposure, and length of observation covered by the available studies. In addition, the possibility of a very small risk at the levels of exposure studied can never be excluded.

In some instances, the above categories may be used to classify the degree of evidence related to carcinogenicity in specific organs or tissues.

To: Jean Ospital
Subject: Appendix I: comments and articles

Jean:

Per our conversation during this afternoon's meeting, I am enclosing the mentioned articles:

1) Two studies provide new evidence that prenatal exposure to PAHs, at levels commonly encountered in New York City (and other urban areas), is associated with obesity in childhood (Rundle et al., 2012) and may adversely affect child behavior (anxiety, depression and attention problems; Perera et al., 2012).

Rundle et al. Association of Childhood Obesity With Maternal Exposure to Ambient Air Polycyclic Aromatic Hydrocarbons During Pregnancy. *Am J Epidemiol.* 2012 Jun 1;175(11):1163-72.

Perera et al. Prenatal Polycyclic Aromatic Hydrocarbon (PAH) Exposure and Child Behavior at Age 6-7 Years. *Environ Health Perspect.* 2012 Jun;120(6):921-6.

2) According to a recent investigation by Loma Linda University scientists (Spencer-Hwang et al., 2011), for kidney transplant recipients, ambient ozone levels potentially are associated with higher risk of fatal CHD. For each 10-ppb increase in O₃, risk of fatal coronary heart disease increased by 34% (95% confidence interval, 3%-76%) in models adjusted for sex, race, age, year of transplant, primary cause of kidney failure, months of pre-transplant dialysis, and PM₁₀. Please note that the publication of this article was accompanied by an invited editorial (see attached pdf: "Laden editorial") on the same issue of the *American Journal of Kidney Diseases* by Francine Laden (Harvard School of Public Health) and Wolfgang Winkelmayr (Stanford University School of Medicine). While numerous studies exist on the effects of air pollution on health-related outcomes in the general population or certain subpopulations, this is the first study in patients with kidney disease. As pointed out by Laden, the overarching question is whether kidney transplant recipients (and possibly other organ recipients) should be considered a susceptible subpopulation in the context of the Clean Air Act. These patients experience states of increased inflammation and oxidative stress, which may make enhance their susceptibility to air pollution. In addition, transplant patients receive long-term immunosuppressive medication. Immunosuppression per se may increase subsequent health risks among these patients.

Spencer-Hwang et al. Ambient air pollutants and risk of fatal coronary heart disease among kidney transplant recipients. *Am J Kidney Dis.* 2011 Oct;58(4):608-16.

Subject: RE: The Advisory Council re: AQMP's Appendix I: comments and articles--Articles from Dr. Soret

To all: I have read the articles that were attached from Marilyn Traynor, and I feel it is important to comment on the PAH issue. There appears to be some belief that PAHs are the etiologic agents associated with increased health risk. However, the true etiologic agents are either epoxides, radical cations, or quinones, that is, products of metabolism or atmospheric chemistry. We have published research demonstrating that naphthalene and phenanthrene decreases as one goes east in the LA Basin whereas the levels of quinones increases as one travels from Santa Monica/Long Beach to Riverside.

The quinones are highly reactive and likely the key agents in the toxicity of PAHs. PAHs are surrogates, but there are important issues about the levels of PAHs in relation to PAH quinones. The research on PAHs is well meaning, but there needs to be a better understanding of the chemistry that results in toxicity. This is quite important. Our research at the Long Beach Railyard showed the highest PAHs, but the inflammatory markers were off the charts in San Bernadino. It makes a difference whether the key agents are properly understood. See Trevor Penning et al, Chemical Research in Toxicology, volume 12(1), 1999 and the myriad of papers that followed to the present. I hope this is of interest. The key in all this is that the primary etiologic agents from fossil fuels are prooxidant (ROS) pathways or binding with electrophilic agents. PAHs themselves require bioactivation or atmospheric chemistry to act toxicologically.

For each 10-ppb increase in O₃, risk of fatal coronary heart disease increased by 34% (95% confidence interval, 3%-76%) in models adjusted for sex, race, age, year of transplant, primary cause of kidney failure, months of pre-transplant dialysis, and PM₁₀. Please note that the publication of this article was accompanied by an invited editorial (see attached pdf: "Laden editorial") on the same issue of the *American Journal of Kidney Diseases* by Francine Laden (Harvard School of Public Health) and Wolfgang Winkelmayr (Stanford University School of Medicine). While numerous studies exist on the effects of air pollution on health-related outcomes in the general population or certain subpopulations, this is the first study in patients with kidney disease. As pointed out by Laden, the overarching question is whether kidney transplant recipients (and possibly other organ recipients) should be considered a susceptible subpopulation in the context of the Clean Air Act. These patients experience states of increased inflammation and oxidative stress, which may make enhance their susceptibility to air pollution. In addition, transplant patients receive long-term immunosuppressive medication. Immunosuppression per se may increase subsequent health risks among these patients.

Spencer-Hwang et al. Ambient air pollutants and risk of fatal coronary heart disease among kidney transplant recipients. *Am J Kidney Dis.* 2011 Oct;58(4):608-16.

Best.

Subject: AQMP Appendix I comments
Date: Friday, August 31, 2012 12:33:28 PM

Hello Jean,

Thank you for the opportunity to participate in the SCAQMD Advisory Council with focus on health effects of PM10. I believe your summary of Health Effects of Air Pollution included as Appendix I of the Draft 2012 AQMP is a thorough and comprehensive update on the latest published scientific research.

The discussion at our Advisory Council meeting on July 11, 2012 was excellent. After a review of the Draft published in July, I am confident that you included our substantive comments within the scope of purpose for Appendix I. As new and ongoing research is conducted, it clarifies the mechanisms of the health effects and drives the regulatory standard review process.

It is exciting progress to have the Multiple Air Toxics Exposure Study IV include a year of ultrafine particulate monitoring at ten stations as well as near sources. For personal reasons, it would be rewarding to have the MATES from 1987 included in your references!

I look forward to reviewing your Draft Final in early September.

Sincerely,
Emily Nelson, D.Env.

Subject: FW: synthesis paper

Jean: Please use the attached as my contribution to the AQMP. One paper reflects Particle Center work up to 2009 and the second paper represents work to the present and it is in press. The two papers reflect the overview of the Particle Center efforts and are comprehensive in nature. These papers are the most advanced documents on the topic of airborne particulate matter including ultrafines. Note that the papers represent my thinking as I am an author on both and was very actively involved in their preparation. You will see references to our work in the papers. The authors in the second paper (most recent) include two distinguished epidemiologists, Jonathan Samet and Ralph Delfino. As you know Ralph is a member of our Center and his work has been funded by AQMD. These papers represent the most advanced work in the field. You should use the papers as my comments since I am an author and they reflect my knowledge base.

Rob McConnell should review the epidemiology that is directly pertinent to issues in California including work by Burt Brunekreef on the mortality issues. I am not an epidemiologist and Rob would be the more appropriate person, since he can discuss the work of Jerrett, Enstrom, and Brunekreef. In addition AQMD is currently funding Dr. Art Cho on mechanistic issues relating to particles and vapors in relation to inflammation. This funded proposal reflects our mechanistic considerations.

The two EHP papers should be read and considered carefully as they represent the state of the art. The 2012 paper is in press and should not be quoted until I give the go ahead. Get back to me with questions.
John

NOTE: The first paper referenced above follows. The second paper is in press and is not included at this time. The reference follows:

OBJECTIVE: The U.S. Environmental Protection Agency funded five academic centers in 1999 to address the uncertainties in exposure, toxicity, and health effects of airborne particulate matter (PM) identified in the “Research Priorities for Airborne Particulate Matter” of the National Research Council (NRC). The centers were structured to promote interdisciplinary approaches to address research priorities of the NRC. In this report, we present selected accomplishments from the first 6 years of the PM Centers, with a focus on the advantages afforded by the interdisciplinary, center-based research approach. The review highlights advances in the area of ultrafine particles and traffic-related health effects as well as cardiovascular and respiratory effects, mechanisms, susceptibility, and PM exposure and characterization issues.

DATA SOURCES AND SYNTHESIS: The collective publications of the centers served as the data source. To provide a concise synthesis of overall findings, authors representing each of the five centers identified a limited number of topic areas that serve to illustrate the key accomplishments of the PM Centers program, and a consensus statement was developed.

CONCLUSIONS: The PM Centers program has effectively applied interdisciplinary research approaches to advance PM science.

KEY WORDS: acute effects, biological mechanisms, chronic effects, criteria pollutants, dosimetry, exposure assessment, morbidity, mortality, particulate matter. *Environ Health Perspect* 117:167–174 (2009). doi:10.1289/ehp.11543 available via <http://dx.doi.org/> [Online 15 September 2008]

The U.S. Environmental Protection Agency (EPA) funded five academic centers in 1999 to address the uncertainties in exposure, toxicity and health effects of airborne particulate matter (PM) identified in the “Research Priorities for Airborne Particulate Matter” of the National Research Council (NRC 1998). Centers were established at Harvard University (Boston, MA), New York University (New York, NY), University of Rochester (Rochester, NY), University of Washington (Seattle, WA), University of California (Irvine, CA), University of California (Los Angeles, CA), and University of Southern California (Los Angeles, CA). All centers were structured to promote interdisciplinary approaches to address the research priorities of the NRC. A midterm report of PM Center findings was published previously (Lippmann et al. 2003). This report highlights selected accomplishments from the first 6 years of the PM Centers, with a focus on the advantages of interdisciplinary, center-based research. A more detailed summary of research findings and bibliography may be found in supplemental material available from the U.S. EPA PM Centers website (U.S. EPA 2008).

PM Exposure Research Highlights

Characterization of ambient PM. The PM Centers worked to characterize ambient PM and the substantial variation of concentration

and composition with source, region, seasonal and diurnal patterns, and size fraction. Examples of these findings follow. In the eastern United States, PM_{2.5} (PM with aerodynamic diameter < 2.5 μm) composition varies seasonally, with relatively more sulfate from long-range transport in the winter, and nitrate in the summer. Substantial spatial variability in PM components and copollutants was observed (Maciejczyk and Chen 2005). In the Pacific Northwest, organic carbon (OC) derived from wood burning is a major contributor to fine particle mass (Larson et al. 2006). PM₁₀ (PM < 10 μm in aerodynamic diameter) collected in Southern California derives largely from road dust and soil and contains significant quantities of metals, whereas PM_{2.5} from the same locations contains primarily nitrates, OC, and elemental carbon (EC). Ultrafine PM (UFP; PM < 0.1 μm in aerodynamic diameter) is especially high in OC (Sardar et al. 2005). Semivolatile components of PM have received increased attention in recent investigations, especially with regard to combustion-derived UFP in which a significant fraction of emissions by mass can consist of semivolatile material that has condensed onto a nonvolatile, primarily carbon core (Kuhn et al. 2005a; Robinson et al. 2007). Atmospheric processes generate UFP in regions of the Los Angeles, California, air basin that receive advected pollutant air masses (Fine et al. 2004; Singh et al.

2006). The role of atmospheric chemistry in formation of UFP is important: photo-oxidation of diesel emissions rapidly generates organic PM (Ntziachristos et al. 2007).

Source apportionment. Research on sources emphasized mobile sources/traffic during the first 6 years of the PM Centers (see below). A workshop was held by the PM Centers to compare different methods for source apportionment of PM. The outcomes of different analytical methods found good agreement across different investigators and methods in apportioning sources of PM_{2.5} mass in two U.S. cities: Phoenix, Arizona, and Washington, D.C. (Hopke et al. 2006; Thurston et al. 2005). Center research also included identification of tracer compounds for use in identifying sources of ambient particles (Fine et al. 2004).

Personal exposure. A significant body of data on personal exposure resulted from field studies of the PM Centers, including longitudinal studies conducted in different airsheds, populations, and housing. Extensive intrapersonal and interpersonal variability in the ratio of personal to ambient exposure measures was observed in some studies (Liu et al. 2003), but taken collectively the data establish that ambient air concentrations at central site monitors can yield valid estimates of average personal exposure for population-based epidemiologic studies (Sarnat et al. 2000, 2002). The location of central site monitors, extent of PM penetration into indoor environments, personal activities, and the influence of

indoor PM sources can affect personal/ambient exposure ratios (Larson et al. 2004; Sarnat et al. 2006). The effects of these factors differ with PM size and composition; for example, freeway-derived UFP in the 70- to 100-nm range penetrated indoors to a greater extent than 10- to 20-nm PM (Zhu et al. 2005). The relationship of ambient criteria pollutant concentrations to ambient and personal PM_{2.5} was explored. Ambient criteria pollutant levels were better predictors of personal PM_{2.5} than they were of personal exposure to the gaseous species themselves, suggesting that the criteria pollutants may be useful as surrogates of PM_{2.5} exposure, but are unlikely to act as confounders in epidemiologic studies (Sarnat et al. 2005). In a study of ambient UFP, hourly and 24-hr number concentrations were not significantly associated with concentrations of gaseous copollutants (Sardar et al. 2004).

PM Health Effects and Mechanisms of Injury Highlights

During the effort of the U.S. EPA to establish a national ambient air quality standard for fine particles, considerable questions about the biological plausibility of epidemiologic findings on hospitalization and mortality from cardiopulmonary effects arose. As a result the NRC committee recommended research into the mechanisms of injury that underlie PM health effects, especially daily mortality. Developments in defining toxicologic

mechanisms and intermediate clinical conditions that may explain the observed cardiovascular mortality are one of the highest impact areas of the scientific contributions of the PM Centers, in particular by addressing PM size-specific research, for example, ultrafine, fine, and coarse PM.

PM effects on the cardiovascular system. The PM Centers convened a workshop to discuss potential mechanisms of PM-associated cardiovascular effects and to identify fruitful research approaches [Frampton et al. 2009 (in press; Utell et al. 2002)] (Figure 1). During the first 6 years, center investigators have contributed to several review papers on cardiovascular responses to inhaled UFP and PM_{2.5} (Brook et al. 2004; Delfino et al. 2005; Godleski 2006; Mar et al. 2006; Pope and Dockery 2006). New statistical methodology was developed and applied to strengthen the interpretation of acute mortality studies (Coull et al. 2001; Janes et al. 2005; Schwartz and Coull 2003; Zanobetti et al. 2000, 2001; Zeka and Schwartz 2004). Epidemiologic studies that focused on specific cardiovascular outcomes, such as myocardial infarction (Peters et al. 2001, 2004; Zanobetti and Schwartz 2005) or cause-specific mortality (Franklin et al. 2007; Miller et al. 2007; Pope et al. 2002; Zeka et al. 2005) produced hypotheses for testing in laboratory animal research and human clinical studies. Toxicologists have contributed by identifying cellular and biomolecular mechanisms involved in the cardiovascular

effects that result from acute and long-term exposures to ambient PM (Araujo et al. 2008; Corey et al. 2006; Lippmann et al. 2005a, 2006; Sun et al. 2005). Most recently, toxicologic studies (Ghelfi et al. 2008) have shown that increases in reactive oxygen species (ROS) in the heart associated with inhalation of concentrated ambient particles (CAPs) may be abrogated by blocking neural receptors in the lung (Figure 2).

Investigations in the PM Centers and elsewhere supported the hypothesis that inflammatory responses contribute to cardiovascular toxicity. Possible mechanisms were proposed. Pulmonary inflammation could release ROS, cytokines, and chemokines from the lung to the systemic circulation (Frampton et al. 2006b). Vascular inflammatory markers were associated with PM_{2.5} exposure in a subchronic mouse study (Sun et al. 2005). Gong et al. (2007), which demonstrated that both diesel extract and oxidized lipid components synergistically affect the expression profile of several gene modules related to vascular inflammatory processes. Evidence for an increase in C-reactive protein and a shift to a procoagulatory state of the blood was seen in coronary artery disease patients exposed to various size fractions of PM (Rückerl et al. 2006). Temporal and other parameters differed with the specific air pollution mixture in this study, which limited interpretation. Pope et al. (2004) concluded that fine particulate air pollution is a risk for cause-specific cardiovascular disease mortality via inflammation, accelerated atherosclerosis, and altered autonomic function. Zeka et al. (2006) reached similar conclusions. Their epidemiologic study supports the hypothesis that particles can induce cardiovascular disease through inflammatory pathways and suggests greater toxicity of traffic-related particles.

Autonomic function effects manifested as alterations in heart rate and heart rate variability (HRV) have been associated with PM_{2.5} exposure. Decreased HRV was associated with

Figure 1. Mechanistic pathways for PM cardiovascular effects. Abbreviations: ET, endothelin; MI, myocardial infarction; NO, nitric oxide; TF, tissue factor. Modified from Frampton et al. 2009 (in press) with permission from Wolters Kluwer.

Figure 2. Capsazepine (CPZ) aerosolization prevents oxidative stress and damage in the heart of rats exposed to CAPs. Adult Sprague-Dawley rats received aerosols containing either 500 μM CPZ or saline for 20 min immediately prior to exposure to CAPs. PM_{2.5} exposure in panel studies of elderly subjects (Adar et al. 2007; Henneberger et al. 2005; Schwartz et al. 2005a). No associations with altered heart rate or HRV were seen in Seattle during the winter woodburning season (Mar et al. 2005b; Sullivan et al. 2005). A population-based study that drew on an established cohort (the Normative Aging Study) confirmed the association between decreased HRV and PM_{2.5} seen in other studies; history of ischemic heart disease, hypertension, and diabetes modified the effects of PM_{2.5} (Park et al. 2005). Cardiac arrhythmias and vascular changes such as endothelial cell responses and alterations in blood pressure are other important clinical signs of cardiovascular toxicity that have been identified in both humans and animals exposed to PM (Frampton et al. 2006b; Gong et al. 2004; Nadziejko et al. 2002).

Atherosclerosis is emerging as an important toxic end point of PM_{2.5} exposure. Atherosclerosis findings may be related to reports of myocardial infarction associated with PM_{2.5} in epidemiologic studies (Peters et al. 2004; Zanobetti and Schwartz 2005). The Peters study relates traffic exposures and myocardial infarction. Atherosclerotic lesions in a susceptible mouse model were enhanced by PM_{2.5} exposure in a number of reports (Araujo et al. 2008; Chen and Hwang 2005; Chen and Nadziejko 2005; Lippmann et al. 2005b; Sun et al. 2005). Araujo et al. (2008) compared the proatherogenic effects of ambient UFP with PM_{2.5} in apolipoprotein E-deficient mice. UFP-exposed mice exhibited significantly larger atherosclerotic lesions than mice exposed to PM_{2.5} or filtered air (Figure 3).

Respiratory effects of PM exposure. PM Centers research has added to a wide body of literature investigating toxicologic mechanisms and effects of PM in the respiratory system. Overall, the issue of respiratory effects and PM exposure has been reviewed recently with reference to work produced by the PM Centers as well as others (Boothe and Shendell 2008; Salam et al. 2008). Salam focuses on asthma, whereas the Boothe and Shendell paper addresses some other end points in addition to respiratory effects. Results from clinical and panel studies in asthmatic and elderly subjects, as well as experimental studies in animals and *in vitro* cellular systems with relevance to respiratory tissues were reported. The discovery that UFP deposition is increased in asthmatic subjects during exercise has important implications for defining populations at greater risk of PM-related effects (Chalupa et al. 2004; Daigle et al. 2003). Adjuvant effects of ambient PM in promoting allergic airways responses occurred in a sensitized mouse model (Kleinman et al. 2005). Acute exposures to ambient PM in Seattle were associated with increased inflammation in asthmatic subjects, as measured by exhaled nitric

oxide (Jansen et al. 2005; Koenig et al. 2005; Mar et al. 2005a). Respiratory effects in children were also a focus. Increased risk of infant hospitalization for bronchiolitis was significantly associated with subchronic and chronic exposures to PM in Los Angeles (Karr et al. 2007), where exposures in the month prior to hospitalization (subchronic) and mean lifetime exposure (chronic) referenced to the case diagnosis date were assessed on the basis of data derived from the California Air Resources Board. Epidemiologic studies that linked the PM Centers and the Children's Health Study (CHS) contributed findings that identify infants and children as important populations of concern for respiratory effects of PM (Gauderman et al. 2004, 2005, 2007; Molitor et al. 2007; Trenga et al. 2006). These studies demonstrate that exposure to PM_{2.5} and other air pollutants were associated with reduced lung function growth in children and provided evidence for compromised lung function. The CHS/PM Center studies identified traffic as a risk factor (Gauderman et al. 2004, 2005, 2007; McConnell et al. 2006).

Identification of new target tissues. UFP of carbon-13 were detected in the olfactory bulbs of rats after inhalation exposure (Oberdörster et al. 2004), suggesting that the central nervous system is a potentially important toxicologic target of PM_{2.5} (Figure 4). In support of this significant result, studies of mice chronically exposed to ambient PM_{2.5} documented loss of brain neurons (Veronesi et al. 2005) and changes in gene expression in the brain consistent with inflammatory effects (Gunnison and Chen 2005). In another study, proinflammatory cytokines were increased in brains of mice exposed to concentrated PM_{2.5} compared with those of control animals (Campbell et al. 2005).

Chemical mechanisms of PM toxicity. To better identify the most toxic PM components and sources, the PM Centers have pursued experimental linkages between toxicologic properties and specific physical/chemical characteristics of particles including size, surface area, and PM components such as transition metals, endotoxin, and organics including reactive organic compounds. Multiple chemical and biological mechanisms by which PM can induce toxic effects in a variety of target cell types have been proposed (Frampton 2006; Yang et al. 2008). Oxidative stress, a common effect of toxicant exposure, is a change in the redox environment of the cell (Schafer and Buettner 2001) through changes in the ratios of concentrations of oxidized to reduced cellular antioxidants. Oxidative stress occurs by increasing intracellular ROS or by depleting glutathione (GSH). GSH is the predominant antioxidant in cells and plays important roles in protecting against oxidative and electrophile stress (Rahman and MacNee 2000). A number

of PM Center studies during the first 6 years contributed to what is now a strong evidentiary basis for oxidative damage as a general toxicologic mechanism of PM injury (Delfino et al. 2005; Ghelfi et al. 2008; González-Flecha 2004; Gurgueira et al. 2002; Li et al. 2003a, 2003b; Rhoden et al. 2004, 2005; Tao et al. 2003; Xia et al. 2006). There is widespread agreement throughout the PM Centers that oxidative stress may be a mechanism of major importance for cardiorespiratory effects.

Studies of reactive chemical components of ambient PM samples reported that particles possess intrinsic chemical reactivity

Figure 3. UFP is the most proatherogenic fraction. Atherosclerotic lesions were quantitatively analyzed in serial aortic root sections and stained with oil red O. Lesional area was scored as square micrometers per section and averaged ≥ 25 sections per animal. Group averages are indicated by straight horizontal bars. One mouse exposed to filtered air (FA) was an obvious outlier in its group and was removed from the atherosclerotic lesion analysis. However, its inclusion did not modify the overall significance. Mice exposed to FA are represented by white circles ($n = 14$), fine particles (FP) by blue circles ($n = 16$), and UFPs by black circles ($n = 15$). Reproduced from Araujo et al. (2008) with permission from Wolters Kluwer.

Figure 4. Time course of ¹³C tissue concentrations in lung, olfactory bulb, cerebellum, and cerebrum of rats after a 6-hr inhalation exposure to ultrafine (36 nm count median diameter) elemental ¹³C particles ($n = 3$ rats per time point). Adapted from Oberdörster et al. (2004) with permission from Taylor and Francis. * $p < 0.05$ (ANOVA).

that may play an important role in toxicity (Cho et al. 2005; Venkatchari et al. 2005). Covalent modification of biological molecules by reactive electrophilic compounds, particularly organics, and ROS production are two key chemical mechanisms by which PM can disrupt intracellular biochemistry, ultimately altering gene expression and subcellular organelle function in target cells. Center investigators demonstrated covalent binding of a cellular enzyme by electrophilic agents, including organic compounds, present in ambient PM (Rodriguez et al. 2005; Samet et al. 1999) and reported that PM can directly inhibit the activity of enzymes involved in oxidative stress response in a cell-free assay (Hatzis et al. 2006). There is accumulating evidence that transition metals such as copper, vanadium, chromium, nickel, cobalt, and iron, as well as aromatic and polar organic substances, play a role in ROS production. An important role of metals may be alteration of signal transduction pathways involving oxidative stress (Samet et al. 2003). Assays that can screen for both oxidative and covalent binding properties of PM are of interest for comparing the toxicologic potential of PM from different sources, locations of interest, season, and other parameters of interest (Borm et al. 2007).

Life shortening associated with exposure to PM. In analyses at the Harvard Center in which daily deaths in 10 European cities were investigated by examining all-cause, respiratory, and cardiovascular deaths for all ages and stratifying by age groups, it was found that the effect of air pollution is not limited to advancing mortality by a few weeks, but that effects persist for over a month after exposure. The short-term mortality effect size estimate for PM₁₀ doubles when longer-term effects for all mortality and cardiovascular mortality are considered and becomes five times higher for respiratory mortality (Zanobetti et al. 2003). Reduction of ambient air pollution levels was associated with reduced total, cardiovascular, and lung cancer mortality in the Harvard Six Cities Cohort (Laden et al. 2006). Long-term exposure was associated with excess lung cancer in cohort studies of Pope et al. (2002), Laden et al. (2006), and Pope and Dockery (2006).

Susceptibility factors and populations of concern for PM-induced health effects. When the PM Centers research was initiated, epidemiologic studies had indicated that the elderly and people with cardiovascular or chronic lung disease were at greater risk for morbidity and mortality associated with acute PM exposure. The PM Centers explored the basis for this susceptibility and also produced research findings that expand the spectrum of populations of concern. Support for the epidemiologic observations that elderly and chronic obstructive pulmonary disease patients have higher rates of hospitalization and mortality

associated with acute PM exposure has come from human clinical studies showing that elderly people experience greater effects of PM on HRV and blood parameters (Park et al. 2005; Pope and Dockery 2006; Schwartz et al. 2005a, 2005b). Further support for the elderly as a population of concern comes from studies of geriatric laboratory animals (Elder et al. 2004a, 2004b).

A study of PM-related daily mortality found greater effects in diabetic subjects (Zeka et al. 2006). The increase in mortality in diabetics may be related to increased susceptibility to the cardiovascular effects of PM exposure, as indicated by greater rate of hospitalization for heart disease (Zanobetti and Schwartz 2002), sensitivity to changes in HRV (Park et al. 2005), and altered vasomotor function (O'Neill et al. 2005) in diabetic subjects. It is possible that these patients may be more susceptible to inflammatory effects of PM, which in turn affect vascular tissues (O'Neill et al. 2007). In contrast, recent results from the Women's Health Initiative suggest that diabetics in this cohort were not at increased risk (Miller et al. 2007). More work on this subject is needed, and controlled human exposures in diabetic studies have been initiated by the PM Centers (Frampton et al. 2006a). Schwartz et al. (2005b) reported an association between presence or absence of the allele for glutathione-S-transferase M1 and the high frequency component of HRV. Genetic susceptibility is an area in which the PM Centers are currently increasing research focus.

Advances in Critical Interdisciplinary Research Areas

Interdisciplinary research has been a hallmark of the PM Centers since their inception. Two subject areas that were exemplary in terms of bringing together multiple investigative perspectives were investigations of UFP and mobile sources.

Ultrafine particles: unique in composition and toxicity. Center-based research allowed a major effort to characterize size distributions, chemical speciation, and the effect of atmospheric processes of UFP to be integrated with toxicologic research (Donaldson and Stone 2003). UFP in urban airsheds are largely derived from fresh combustion sources, although secondary formation of UFP from atmospheric photochemical processes is also an important source (Sioutas et al. 2005). UFP freshly generated by combustion are short-lived and subsequently grow to form aggregates. UFP dominate particle number concentration in ambient PM samples while contributing little to PM mass concentrations. In part because of a complex fractal structure (Friedlander and Xiong 2000), UFP possess much greater surface area per unit mass than larger ambient particles. The large surface

area, in turn, allows greater per-mass concentrations of adsorbed or condensed toxic air pollutants (oxidant gases, organic compounds, transition metals) to collect on UFP (Sioutas et al. 2005). Studies on ambient and model particles have concluded that the large specific surface area of UFP may be a key component in their toxicology (Oberdörster 2001).

The PM Centers produced an integrated body of exposure and toxicologic studies on ambient and model UFP as well as studies of controlled human exposures. Dosimetry work showed that UFP will have significant accumulation in the lung (Kreyling et al. 2006). In addition, UFP of varying composition can cross cellular membranes by diffusion (Geiser et al. 2005) and gain access to vulnerable targets within cells. The potential for translocation from the site of lung deposition into systemic circulation, although rates have been low with test particles (Kreyling et al. 2002), could have major mechanistic implications (Elder and Oberdörster 2006). Electron microscopy indicated subcellular penetration and mitochondrial damage by UFP in *in vivo* studies and, to a lesser extent, by fine particles (Li et al. 2003b). Disruption of mitochondrial functions may play an important role in PM-mediated health effects (Xia et al. 2007).

In a study of size-segregated concentrated ambient PM samples, the ability of PM to catalyze ROS generation, an initial step in the induction of oxidative stress, was greatest in the UFP fraction (Cho et al. 2005). Li et al. (2003a) summarized contrasting features of coarse, fine, and ultrafine particles from Southern California, including relevant chemical and biological parameters. The toxicologic findings correlated with PM OC and polycyclic aromatic hydrocarbon (PAH) composition, suggesting a role of organic agents in generating redox activity (Table 1).

The PM Centers conducted controlled human exposure studies with UFP. Results from these studies were limited, because of small group sizes and because these exposures are necessarily brief and conducted at low concentrations compared with the background PM exposures that may be experienced by urban study subjects. In the first set of studies, short-term exposures were conducted with 10–50 µg/m³ carbon UFP generated in the laboratory. Alterations in blood cell adhesion molecules and in a marker of vascular perfusion suggest that UFP exposure may produce subtle changes in pulmonary vasoconstriction (Frampton 2007; Pietropaoli et al. 2004). A small but statistically significant reduction in arterial oxygen saturation and some evidence for reduced HRV were found, although the small study size limited interpretation (Gong et al. 2008). An expanded focus on UFP in epidemiologic studies is needed but has been limited to date by the challenges of assessing exposure to UFP.

Traffic: mobile sources are highly relevant to the public health impacts of PM. The center-based research context was particularly useful in advancing the science on mobile sources of PM, the focus of an extensive international research effort. Numerous investigations of the physical and chemical attributes of PM collected alongside freeways and in roadway tunnels were performed. The results have yielded data on size distribution, number and mass concentrations, chemical speciation, emissions factors, volatility, penetration indoors, and the impact of atmospheric processes on roadway PM (Biswas et al. 2007; Fine et al. 2004; Geller et al. 2006; Kuhn et al. 2005b, 2005c; Phuleria et al. 2007; Sardar et al. 2005; Zhu et al. 2005). Detailed spatial profiles of UFP concentration at varying distances from freeways were generated (Zhu et al. 2002a, 2002b). Concentrations of UFP drop exponentially with distance from the center of the freeway, reaching upwind levels at approximately 300 meters. The size distribution of UFP also changed markedly with distance reflective of coagulation and other atmospheric particle processes. Winter particle number concentrations are greater than summer, indicating formation of UFP from vapor condensation. Exposure to motor vehicle exhaust emissions during commuting may constitute a substantial fraction of daily personal PM exposure, especially to UFP (Sioutas et al. 2005; Zhu et al. 2007).

Toxicologic studies of traffic-derived aerosols studied by PM Centers included *in vitro* findings that implicate PM collected in freeway microenvironments in the production of reactive chemical species, stimulation of proinflammatory effects, and altered gene expression in cellular test systems. UFP fraction, carbonaceous content, and an organic tracer for vehicles were linked with toxicologic activity of PM in a variety of assays (Cho et al. 2005; Li et al. 2003a, 2003b). Several studies of laboratory animals exposed to PM on or near busy roadways have identified cardiovascular and allergic airways effects (Elder et al. 2004b, 2007; Kleinman et al. 2005). Evidence that traffic-derived air pollution affects humans has expanded significantly during the first 6 years of PM Centers funding, implicating mobile source in respiratory effects in children (Gauderman et al. 2004, 2005, 2007; McConnell et al. 2006), cardiovascular effects (Riediker et al. 2004) including myocardial infarction (Peters et al. 2004; Tonne et al. 2007), and low birth weight (Wilhelm and Ritz 2003). Toxicologic studies are needed to follow up the epidemiologic findings of effects on the fetus. In a reanalysis of data from the Harvard Six Cities study of daily mortality and PM, source apportionment approaches identified the mobile source factor as most strongly associated with increased daily mortality (Laden et al. 2000).

Policy Implications of PM Centers Research

Research findings from the PM Centers have had a significant influence on science policy, most directly in terms of the science that underlies the National Ambient Air Quality Standards (NAAQS) for PM. The findings of morbidity and mortality that form the scientific basis for the short-term and annual PM NAAQS were strengthened through epidemiologic and statistical research. Mechanistic investigations and studies of preclinical markers established biological plausibility for observed relationships between ambient air PM and observed acute mortality. In personal exposure studies, validation of the use of central site ambient concentrations provided crucial support to the interpretation of epidemiologic results.

The PM NAAQS are based on mass concentration. The state of the science suggests that no single parameter, whether mass, size fraction, surface area, or a particular chemical component, is responsible for all the diverse mechanisms and toxicologic end points that have been associated with PM, and a more sophisticated approach to standards will be needed. Based on findings from the PM Centers and others, the potential efficacy of number and component based standards should be assessed. As more data become available to link specific PM emissions sources, chemical composition, and physical characteristics with quantitative measures of toxicity, the question of source-specific control strategies to maximize public health protection also needs to be considered.

The increasing level of evidence that UFP are toxic but may not be controlled well by existing regulatory approaches raises other policy issues including mitigation of the risk of health effects associated with housing, schools, parks, and other heavily populated public facilities located near heavily traveled roadways, busy seaports, and other combustion sources that are the major urban sources of exposure to UFP. There are potential environmental justice concerns associated with transportation-derived combustion, as it is often areas of lower socioeconomic status that are most affected by proximity to these sources.

Looking Forward: Research Priorities and Current Directions

As the PM Centers program moved forward into the second phase, the original guiding research priorities were reevaluated, and new priorities have emerged. Several areas of investigation identified during the development of the 1997 PM NAAQS are still of critical relevance today, but the scientific questions being asked have been refined. Some research topics being pursued in the current round of PM Centers are described below.

Particle source characterization and PM components as factors in PM toxicity. The PM Centers current research agenda includes detailed studies of the physical and chemical attributes of ambient PM associated with specific sources. The current science indicates that multiple mechanisms of injury, in backgrounds modified by host susceptibility factors, can be activated by a variety of PM components and characteristics. To address the complexity associated with assessing the health effects associated with specific PM components, the current PM Centers research agenda compares toxicologic properties of PM by source type in addition to compositional attributes. Mobile sources continue to be a priority focus, and there is a need to better understand the fate of fossil fuel combustion emissions from a variety of mobile and stationary sources, including airports, seaports, and other sources as well as roadways. Building upon the productive body of work on mobile source PM in the first 6 years of PM Center work, the current PM Centers include human panel and clinical studies and toxicologic studies in laboratory animals and *in vitro* systems that test hypotheses about the effects of mobile source PM exposures. Source apportionment efforts are ongoing as well, to build on previous work that found mobile sources are dominant contributors to urban UFP loads. *In vitro* studies will pay particular attention to UFP, organic compounds, and transition metals. UFP formed from nucleation of ambient air vapors are a new focus, as they may be especially toxic.

Dosimetry and toxicokinetics. Research at the PM Centers is addressing particle deposition, uptake, distribution, and fate, including

Table 1. Contrasting features of coarse, fine, and ultrafine particles.

Parameters	Coarse PM ₁₀	Fine PM ₁₀	Ultrafine PM ₁₀
Size (µm)	2.5–10	2.5–0.15	< 0.15
OC content	+	++	+++
EC content	+	++	+++
Metals (% of total elements)	+++	++	+
PAH content	+	+	+++
Redox activity (DTT assay)	+	++	+++
HO-1 induction	+	++	+++
GSH depletion	+	+++	+++
Mitochondrial damage	None	Some	Extensive

Data from Li et al. (2003a).

the effects of developmental stage on disposition of PM. Cell culture systems with gene expression and proteomics methods are being used for studies of metabolic and genetic responses that will be useful for toxicokinetics. Studies of the dosimetry and toxicokinetics associated with UFP are especially important, given previous PM Centers findings that these particles distribute into systemic circulation and secondary target organs such as the CNS, and can enter cells and subcellular organelles.

Mechanisms. All the current PM Centers have a strong focus on continuing to develop understanding of the toxic mechanisms that underlie clinically and epidemiologically defined adverse health effects of PM. Mechanisms being pursued include reactive chemical species that cause cellular oxidative stress responses. In the first 6 years, studies of oxidative damage associated with PM were performed using diverse chemical species, cell culture experiments, and laboratory animal studies. Evolving from that work, the current PM Centers studies are looking at markers of oxidative stress processes in humans and a range of clinical and preclinical biomarkers. The list of gene products that can be used as indicators of PM exposure or toxicity in various cell types has expanded. Mechanistic hypotheses are being tested in panel and other epidemiologic studies.

Susceptibility. Susceptibility is a major theme, drawing on the work from the earlier center and noncenter investigators showing that individuals with pulmonary and cardiac health conditions, elderly, children, diabetics, and others may be more susceptible to the adverse effects of PM exposure than the general population. The PM Centers are looking at early life exposures to PM in animal models, performing panel studies of elderly subjects or subjects with compromised health status, using a large established cohort to identify how risk factors for PM-related health outcomes may be modified by individual factors such as medication use, diet, and genotype. Compromised animal models are a key theme of current research into susceptibility. PM exposure studies on ApoE^{-/-} mice (an atherosclerosis-prone model), hypertensive rats, and diabetic rats are all planned or underway.

Conclusions

In 1998, a committee of the NRC published the first of a four-volume report titled "Research Priorities for Airborne Particulate Matter" that identified the 10 highest-priority targets for PM research (NRC 1998). Within the research portfolio of the PM Centers, the priority areas have been addressed. A subsequent NRC report (2001) emphasized that these research priorities require multidisciplinary approaches. Recognizing that progress in understanding the health effects consequent

to air pollution exposure requires talents from highly divergent fields, we believe that the PM Centers effectively promote interdisciplinary cross-fertilization. The next 5 years of this program will bring the experience and results of the first centers to fruition in new, focused studies that we hope will be instrumental in addressing the difficult scientific and public health policy problems that arise from ubiquitous particulate air pollution.

CORRECTION

In the title of the manuscript originally published online, the date range in the title was incorrect. It has been corrected here.

Jonathan M. Samet, MD, MS
Professor and Flora L. Thornton Chair
Director, USC Institute of Global Health

September 25, 2012

Jean Ospital, MPH, PhD
Health Effects Officer
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

Dear Jean,

As you requested, I attach comments concerning the Health Effects Appendix of the District's draft Air Quality Management Plan. Please do not hesitate to contact me if you have questions with regard to these comments.

Yours sincerely,

Jonathan M. Samet, MD, MS
Professor and Flora L. Thornton Chair
Department of Preventive Medicine
Director, USC Institute for Global Health

Review: Health Effects Appendix
South Coast Air Quality Management District
Jonathan M. Samet, MD, MS

General Comments:

This relatively brief document provides an overview of the health effects of various air pollutants, giving emphasis to pollution by airborne particulate matter. The document also covers other “criteria pollutants” as well as ultrafine particulate matter and toxic air contaminants. This range of topics is appropriate to the development of an Air Quality Management Plan.

As presented, the document represents a summary, and an apparent updating of an earlier report. It is necessarily selective in its coverage and relies to an extent on the review documents prepared by the US Environmental Protection Agency for the “criteria” pollutants. I have the following general comments:

- Preparation of reviews of the health effects of air pollution is a daunting task, given the extensive data available and its continuing and rapid accrual. The South Coast Air Quality Management District is not well positioned to prepare a comprehensive and up-to-date review. Consequently, there are deficiencies of this review related to its scope and timeliness. The basis for the document’s development is provided in the last paragraph on page I-2. While the statement is clear, the methods are not fully transparent. In particular, several older reviews are mentioned, along with more recent documents from the US Environmental Protection Agency and several prepared by the California EPA. I suggest that more careful attention be given to describing the basis for this review and to consideration of its methodology. For example, given the complexity and scope of the literature, the developers of the review might rely solely on summary documents or to also summarize documents and research published based on studies in California. In the present version, I could not readily identify why particular studies were included.
- I understand that the South Coast Air Quality Management District is required to provide a review in support of its air quality management plan. As stated, the California Health and Safety Code Section 40471(b) requires the preparation of report on “the health impacts of particulate matter in the South Coast Air Basin (SCAB) in conjunction with the preparation of the Air Quality Management Plan revisions.” This document does not directly address the health impacts, if some quantification of burden is implicit in the requirement. The identification of health effects and selected of examples of risks from the literature represents a starting point in estimating the health impact. As noted in my next comment, the review might have establishing the relevance of the broad body of evidence to the South Coast Air Quality Management District as one objective.

- There is an extensive literature on airborne particulate matter and health, as well as on the risks of various other air pollutants. One question that might be reasonably addressed in this report is the generalizability of findings from this broad literature to California. Here, a careful review of studies in California might be of benefit. Additionally, considerations might be given to the mixture of pollutants in the South Coast Air Basin to support conclusions about the generalizability of findings.
- The document needs further editing in part to improve clarity and in part to bring in some of the most recent and relevant references. Additionally, if the most recent US EPA documents are to be used as the basis of the report, some updating is needed.

Specific comments:

See attached.

INTRODUCTION

This document presents a summary of scientific findings on the health effects of ambient air pollutants. The California Health and Safety Code Section 40471(b) requires that the South Coast Air Quality Management District prepare a report on the health impacts of particulate matter in the South Coast Air Basin (SCAB) in conjunction with the preparation of the Air Quality Management Plan revisions. This document, which was prepared to satisfy that requirement, also includes the effects of the other major pollutants.

HEALTH EFFECTS OF AIR POLLUTION

Ambient air pollution is a major public health concern. Excess deaths and increases in illnesses associated with high air pollution levels have been documented in several episodes as early as 1930 in Meuse Valley, Belgium; 1948 in Donora, Pennsylvania; and 1952 in London. Although levels of pollutants that occurred during these acute episodes are now unlikely in the United States, ambient air pollution continues to be linked to increases in illness, (morbidity) and increases in death rates (mortality).

The adverse health effects associated with air pollution are diverse and include:

- ^{Premature} ~~Increased~~ mortality
- Increased health care utilization (hospitalization, physician and emergency room visits)
- Increased respiratory illness (symptoms, infections, and asthma exacerbation) ^{and other morbidity}
- Decreased lung function (breathing capacity)
- Lung inflammation
- Potential immunological changes
- Increased airway reactivity to a known ~~chemical~~ ^{pharmacological agent} exposure - a method used in laboratories to evaluate the tendency of airways to have an increased possibility of developing an asthmatic response
- A decreased tolerance for exercise.

The list needs to include cardiovascular effects.

Biomarkers??

The evidence linking these effects to air pollutants is derived from population-based observational and field studies (epidemiological) as well as controlled laboratory studies involving human subjects and animals. There have been an increasing number of studies focusing on the mechanisms (that is, on learning how specific organs, cell types, and biochemicals are involved in the human body's response to air pollution) and specific pollutants responsible for individual effects. Yet the underlying biological pathways for these effects are not always clearly understood.

Although individuals inhale pollutants as a mixture under ambient conditions, the regulatory framework and the control measures developed are ~~mostly~~ pollutant-specific. This is appropriate, in that different pollutants usually differ in their sources, their times and places of occurrence, the kinds of health effects they may cause, and their overall levels of health risk. Different pollutants, from the same or different sources, may sometimes act together to harm health more than they would acting separately. Nevertheless, as a practical matter, health scientists, as well as regulatory officials, usually must deal with one pollutant at a time in determining health effects and in adopting air quality standards. To meet the air quality standards, comprehensive plans are developed such as the Air Quality Management Plan (AQMP), and to minimize toxic exposure a local air toxics control plan is also prepared. These plans examine multiple pollutants, cumulative impacts, and transport issues related to attaining healthful air quality. A brief overview of the effects observed and attributed to various air pollutants is presented in this document.

For six major outdoor pollutants covered under Sections 108 + 109 of the CAA

This summary is drawn substantially from reviews presented previously (SCAQMD, 1996, 2003, 2007), and from reviews on the effects of air pollution by the American Thoracic Society (ATS, 1996), the U.S. EPA reviews for ozone (U.S. EPA, 2006), Carbon Monoxide (U.S. EPA, 2010), and Particulate Matter (U.S. EPA, 2004, 2009), from a published review of the health effects of air pollution (Brunekreef and Holgate, 2002), and from reviews prepared by the California EPA Office of the Environmental Health Hazard Assessment for Particulate Matter (Cal EPA, 2002) and for Ozone (Cal EPA, 2005). Additional materials are from EPA's current review of the ozone standard and health effects (EPA, 2011). More detailed citations and discussions on air pollution health effects can be found in these references.¹

and ongoing

¹ Most of the studies referred to in this appendix are cited in the above sources. Only more recent specific references will be cited in this summary.

OZONE

Ozone is a highly reactive compound, and is a strong oxidizing agent. When ozone comes into contact with the respiratory tract, it can react with tissues and cause damage in the airways. Since it is a gas, it can penetrate into the gas exchange region of the deep lung.

The EPA primary standard for ozone, adopted in 2008, is 0.075 ppm averaged over eight hours. The California Air Resources Board (CARB) has established standards of 0.09 ppm averaged over one hour and at 0.070 ppm averaged over eight hours.

*see latest
ESA to
update* { The major subgroups of the population considered to be at increased risk from ozone exposure are outdoor exercising individuals, including children, and people with preexisting respiratory disease(s) such as asthma. The data base identifying the former group as being at increased risk to ozone exposure is much stronger and more quantitative than that for the latter group, probably because of a larger number of studies conducted with healthy individuals. The adverse effects reported with short-term ozone exposure are greater with increased activity because activity increases the breathing rate and the volume of air reaching the lungs, resulting in an increased amount of ozone reaching the lungs. Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher ventilation rate than adults.

A number of adverse health effects associated with ambient ozone levels have been identified from laboratory and epidemiological studies (EPA, 1996; 2006, 2011; ATS, 1996). These include increased respiratory symptoms, damage to cells of the respiratory tract, decrease in lung function, increased susceptibility to respiratory infection, and increased risk of hospitalization. *mortality?*

Increases in ozone levels are associated with elevated absences from school. The Children's Health Study, conducted by researchers at the University of Southern California, followed a cohort of children that live in 12 communities in Southern California with differing levels of air pollution for several years. A publication from this study reported that school absences in fourth graders for respiratory illnesses were associated with ambient ozone levels. An increase of 20 ppb ozone was associated with an 83% increase in illness-related absence rates (Gilliland, 2001). *positively*

The number of hospital admissions and emergency room visits for all respiratory causes (infections, respiratory failure, chronic bronchitis, etc.) including asthma

shows a consistent increase as ambient ozone levels increase in a community. These excess hospital admissions and emergency room visits are observed when hourly ozone concentrations are as low as 0.06 to 0.10 ppm.

Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).

Multicity studies of short-term ozone exposures (days) and mortality have also examined regional differences. Evidence was provided that there were generally higher ozone-mortality risk estimates in northeastern U.S. cities, with the southwest and urban mid-west cities showing lower or no associations (Smith, 2009; Bell, 2008). Another long-term study of a national cohort found that long-term exposures to ozone were associated with respiratory-related causes of mortality, but not cardiovascular-related causes, when PM_{2.5} exposure were also included in the analysis.

at risk?

Several population-based studies suggest that asthmatics are more adversely affected by ambient ozone levels, as evidenced by increased hospitalizations and emergency room visits. Laboratory studies have attempted to compare the degree of lung function change seen in age and gender-matched healthy individuals versus asthmatics and those with chronic obstructive pulmonary disease. While the degree of change evidenced did not differ significantly, that finding may not accurately reflect the true impact of exposure on these respiration-compromised individuals. Since the respiration-compromised group may have lower lung function to begin with, the same degree of change may represent a substantially greater adverse effect overall.

→ There are two issues: 1) Is asthma adversely affected by ozone? and 2) Is the lung function response to ozone different in asthmatics and non-asthmatics

Another publication from the Children's Health Study focused on children and outdoor exercise. In communities with high ozone concentrations, the relative risk of developing asthma in children playing three or more sports was found to be over three times higher than in children playing no sports (McConnell, 2002). These findings indicate that new cases of asthma in children are associated with heavy exercise in communities with high levels of ozone. While it has long been known that air pollution can exacerbate symptoms in individuals with respiratory disease, this is among the first studies that indicate ozone exposure may be causally linked to asthma onset.

associated with episodic and chronic exposure effects may not exhibit similar adaptation. That is, internal damage to the respiratory system may continue with repeated ozone exposures, even if externally observable effects (chest symptoms and reduced lung function) disappear.

In a laboratory, exposure of human subjects to low levels of ozone causes reversible decrease in lung function as assessed by various measures such as respiratory volumes, airway resistance and reactivity, irritative cough and chest discomfort. Lung function changes have been observed with ozone exposure as low as 0.06 to 0.12 ppm for 6-8 hours under moderate exercising conditions. Similar lung volume changes have also been observed in adults and children under ambient exposure conditions (0.10 - 0.15 ppm). The responses reported are indicative of decreased breathing capacity and are reversible. *update with Kim study?*

The results of several studies where human volunteers were exposed to ozone for 6.6 hours at levels between 0.04 and 0.12 ppm were recently summarized (Brown, 2008). As shown in the figure below, there is an increasing response on lung function with increasing exposure levels in moderately exercising subjects.

FIGURE I-1

Comparison of mean ozone-induced decrements in lung function following 6.6 hours of ozone exposure (from Brown, 2008)

In addition to controlled laboratory conditions, studies of individuals exercising outdoors, including children attending summer camp, have shown associations of reduced lung function with ozone exposure. There were wide ranges in responses among individuals.

Results of epidemiology studies support the relationship between ozone exposure and respiratory effects. Several, but not all, studies have found associations of short-term ozone levels and hospital admissions and emergency department admissions for respiratory-related conditions (EPA, 2011).

In laboratory studies, cellular and biochemical ^{changes} associated with respiratory tract inflammation have also been consistently ~~reported~~ ^{found} in the airway lining after low level exposure to ozone. These changes include an increase in specific cell types and in the concentration of biochemical mediators of inflammation and injury such as cytokines and fibronectin. Indications of lung injury and inflammatory changes have been observed in healthy adults exposed to ozone in the range of 0.06 to 0.10 ppm.

The susceptibility to ozone observed under ambient conditions could be due to the combination of pollutants that coexist in the atmosphere or ozone may actually sensitize these subgroups to the effects of other pollutants.

Some animal studies show results that indicate possible chronic effects including functional and structural changes of the lung. These changes indicate that repeated inflammation associated with ozone exposure over a lifetime may result in sufficient damage to respiratory tissue such that individuals later in life may experience a reduced quality of life in terms of respiratory function and activity level achievable. An autopsy study involving Los Angeles County residents provided supportive evidence of lung tissue damage (structural changes) attributable to air pollution.

A study of birth outcomes in southern California found an increased risk for birth defects in the aortic and pulmonary arteries associated with ozone exposure in the second month of pregnancy (Ritz et al., 2002). This ^{was} is the first study linking ambient air pollutants to birth defects in humans. Studies conducted since mostly focusing on cardiac and oral cleft defects have found mixed results, with some showing associations, but others did not. ~~Confirmation by further studies is needed.~~

In summary, adverse effects associated with ozone exposures have been well documented, although the specific causal mechanism is still somewhat unclear.

Need to acknowledge the mechanistic work.

PARTICULATE MATTER

Airborne particulates are a complex group of pollutants that vary in source, size and composition, depending on location and time. The components include nitrates, sulfates, elemental carbon, organic carbon compounds, acid aerosols, trace metals, and material from the earth's crust. Substances of biological origin, such as pollen and spores, may also be present.

Until several years ago, the health effects of particulates were focused on those sized 10 μm (micrometers) aerodynamic diameter and smaller. These can be inhaled through the upper airways and deposited in the lower airways and gas exchange tissues in the lung. These particles are referred to as PM₁₀. EPA initially promulgated ambient air quality standards for PM₁₀ of 150 $\mu\text{g}/\text{m}^3$ averaged over a 24-hour period, and 50 $\mu\text{g}/\text{m}^3$ for an annual average. EPA has since rescinded the annual PM₁₀ standard, but kept the 24-hour standard.

In recent years additional focus has been placed on particles having an aerodynamic diameter of 2.5 μm or less (PM_{2.5}). A greater fraction of particles in this size range can penetrate and deposit deep in the lungs. The EPA (recently) lowered the air quality standards for PM_{2.5} to 35 $\mu\text{g}/\text{m}^3$ for a 24-hour average and reaffirmed 15 $\mu\text{g}/\text{m}^3$ for an annual average standard. There was considerable controversy and debate surrounding the review of particulate matter health effects and the consideration of ambient air quality standards (Kaiser, 1997; Vedal, 1997) when the EPA promulgated the initial PM_{2.5} standards in 1997.

Since that time, numerous studies have been published, and some of the key studies were closely scrutinized and analyses repeated. The result is that there are now substantial data confirming the adverse health effects of PM_{2.5} exposures.

There are also differences in the composition and sources of particles in the different size ranges that may have implications for health effects. The particles larger than 2.5 μm (often referred to as the coarse fraction) are mostly produced by mechanical processes. These include automobile tire wear, industrial processes such as cutting and grinding, and resuspension of particles from the ground or road surfaces by wind and human activities.

In contrast, particles smaller than 2.5 μm are mostly derived from combustion sources, such as automobiles, trucks, and other vehicle exhaust, as well as from stationary combustion sources. The particles are either directly emitted or are formed

in the atmosphere from gases that are emitted. Components from material in the earth's crust, such as dust, are also present, with the amount varying in different locations.

Attention to another range of very small particles has been increasing over the last few years. These are generally referred to as "ultrafine" particles, with diameters of 0.1 μm or less. These particles are mainly from fresh emissions of combustion sources, but are also formed in the atmosphere from photochemical reactions. Ultrafine particles have relatively short half lives (minutes to hours) and rapidly grow through condensation and coagulation process into larger particles within the PM_{2.5} size range. These particles are garnering interest since laboratory studies indicate that their toxicity may be higher on a mass basis than larger particles, and there is evidence that these small particles can translocate from the lung to the blood and to other organs of the body.

There have been several reviews of the health effects of ambient particulate matter (ATS, 1996; Brunekreef, 2002; U.S. EPA, 2004; U.S. EPA, 2009). In addition, the California Air Resources Board (CARB) and the Office of Environmental Health and Hazard Assessment (OEHHA) have reviewed the adequacy of the California Air Quality Standards for Particulate Matter (Cal EPA, 2002).

The major types of effects associated with particulate matter include:

- Increased mortality
- Exacerbation of respiratory disease and of cardiovascular disease as evidenced by increases in:
 - Respiratory symptoms
 - Hospital admissions and emergency room visits
 - Physician office visits
 - School absences
 - Work loss days
- Effects on lung function
- Changes in lung morphology

Not mentioned on page 1-1

The current federal and California standards are listed below:

TABLE I-4

Ambient Air Quality Standards for Particulate Matter

STANDARD	FEDERAL	CALIFORNIA
PM10 24-Hour average	150 $\mu\text{g}/\text{m}^3$	50 $\mu\text{g}/\text{m}^3$
PM10 Annual Average	--	20 $\mu\text{g}/\text{m}^3$
PM 2.5 24-Hour Average	35 $\mu\text{g}/\text{m}^3$	--
PM 2.5 Annual Average	15 $\mu\text{g}/\text{m}^3$	12 $\mu\text{g}/\text{m}^3$

Short-Term Exposure Effects

Epidemiological studies have provided evidence for most of the effects listed above. An association between increased daily or several-day-average concentrations of PM10 and excess mortality and morbidity is consistently reported from studies involving communities across the U.S. as well as in Europe, Asia, and South America. A review and analysis of epidemiological literature for acute adverse effects was undertaken by Dockery and Pope to estimate these effects as percent increase in mortality associated with each incremental increase of PM10 by 10 $\mu\text{g}/\text{m}^3$. The estimates are presented in Table I-5. It appears that individuals who are elderly or have preexistent lung or heart disease are more susceptible than others to the adverse effects of PM10.

Many recent studies have confirmed that excess mortality and morbidity are associated with particulate matter levels. Estimates of mortality effects from these studies range from 0.3 to 1.7% increase for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 levels. The National Morbidity, Mortality, and Air Pollution Study (NMMAPS), a study of 20 of the largest U.S. cities, determined a combined risk estimate of about a 0.5% increase in total mortality for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 (Samet, 2000a). This study also analyzed the effects of gaseous co-pollutants. The results indicated that the association of PM10 and mortality were not confounded by the presence of the gaseous pollutants. When the gaseous pollutants were included in the analyses, the significance of the PM10 estimates remained. The PM10 effects were reduced somewhat when O₃ was also considered and tended to be variably decreased when NO₂, CO, and SO₂ were added to the analysis. These results argue that the effects are likely due to the particulate exposures; they cannot readily be explained by coexisting weather stresses or other pollutants.

Never reports available.

Not flawed, but not appropriate set in its defaults.

An expansion of the NMMAPS study to 90 U.S. Cities also reported association with PM10 levels and mortality (Samet 2000b). It was discovered that this study was one that used a flawed statistical software package. The investigators have reanalyzed the data using corrected settings for the software (Dominici, 2002a, Dominici 2002b). When the estimates for the 90 cities in the study were recalculated, the estimate changed from 0.41% increase in mortality for a 10 $\mu\text{g}/\text{m}^3$ increase in PM10 to a 0.27% increase. There remained a strong positive association between acute exposure to PM10 and mortality. Thus while the quantitative estimate was reduced, the major findings of the study did not change.

TABLE I-5

Combined Effect Estimates of Daily Mean Particulate Pollution

% CHANGE IN HEALTH INDICATOR PER EACH 10 $\mu\text{g}/\text{m}^3$ INCREASE IN PM10	
Increase in Daily Mortality	
Total deaths	1.0
Respiratory deaths	3.4
Cardiovascular deaths	1.4
Increase in Hospital Usage (all respiratory diagnoses)	
Admissions	1.4
Emergency department visits	0.9
Exacerbation of Asthma	
Asthmatic attacks	3.0
Bronchodilator use	12.2
Emergency department visits*	3.4
Hospital admissions	1.9
Increase in Respiratory Symptom Reports	
Lower respiratory	3.0
Upper respiratory	0.7
Cough	2.5
Decrease in Lung Function	
Forced expiratory volume	0.15

severe effects, larger numbers experience milder effects, which may relate either to the coarse or to the fine fraction of airborne particulate matter.

In the NMMAPS study, hospital admissions for those 65 years or older were assessed in 14 cities. Hospital admissions for these individuals showed an increase of 6% for cardiovascular diseases and a 10% increase for respiratory disease admissions, per 50 $\mu\text{g}/\text{m}^3$ increase in PM10. The excess risk for cardiovascular disease ranges from 3-10% per 50 $\mu\text{g}/\text{m}^3$ PM10 and from 4-10% per 25 $\mu\text{g}/\text{m}^3$ PM2.5 or PM10-2.5.

Similarly, school absences, lost workdays and restricted activity days have also been used in some studies as indirect indicators of acute respiratory conditions. The results are suggestive of both immediate and delayed impact on these parameters following elevated particulate matter exposures. These observations are consistent with the hypothesis that increased susceptibility to infection follows particulate matter exposures.

Some studies have reported that short-term particulate matter exposure is associated with changes in lung function (lung capacity and breathing volume); upper respiratory symptoms (hoarseness and sore throat); and lower respiratory symptoms (increased sputum, chest pain and wheeze). The severity of these effects is widely varied and is dependent on the population studied, such as adults or children with and without asthma. Sensitive individuals, such as those with asthma or pre-existing respiratory disease, may have increased or aggravated symptoms associated with short-term particulate matter exposures. Several studies have followed the number of medical visits associated with pollutant exposures. A range of increases from 3% to 42% for medical visits for respiratory illnesses was found corresponding to a 50 $\mu\text{g}/\text{m}^3$ change in PM10. A limited number of studies also looked at levels of PM2.5 or PM10-2.5. The findings suggest that both the fine and coarse fractions may have associations with some respiratory symptoms.

The biological mechanisms by which particulate matter can produce health effects are being investigated in laboratory studies. Inflammatory responses in the respiratory system in humans and animals exposed to concentrated ambient particles have been measured. These include effects such as increases in neutrophils in the lungs. Other changes reported include increased release of cytokines and interleukins, chemicals released as part of the inflammatory process. The effects of particulate matter may be mediated in part through the production of reactive oxygen species during the inflammatory process. (Recent reviews discuss mechanistic studies in more detail (Brunekreef, 2002; Brook, 2004)).

↳ no longer recent!

Long-Term Exposure Effects

While most studies have evaluated the acute effects, some studies specifically focused on evaluating the effects of chronic exposure to PM10 and PM2.5. Studies have analyzed the mortality of adults living in different U.S. cities. After adjusting for important risk factors, taken as a whole these studies found a positive association of deaths and exposure to particulate matter. A similar association was observable in both total number of deaths and deaths due to specific causes. The largest effects were observed from cardiovascular causes and ischemic heart disease. A shortening of lifespan was also reported in these studies.

→ there are other recent studies not included

Since the initial promulgation by EPA of the National Ambient Air Quality Standards for PM2.5, controversy has remained over the association of mortality and exposures to PM2.5. Thus an expanded discussion of these studies is presented below.

Significant associations for PM2.5 for both total mortality and cardiorespiratory mortality were reported in a study following a national cohort recruited by the American Cancer Society for a Cancer Prevention Study over several years. A re-analysis of the data from this study confirmed the initial finding (Krewski, 2000). In this study, mortality rates and PM2.5 levels were analyzed for 51 metropolitan areas of the U.S. Average levels from monitors in each area were used to estimate exposures. At these levels of aggregation, regional differences in the association of PM2.5 and mortality were noted, with higher associations in the Northeast, and lower or non-significant associations in the West.

The Harvard Six Cities Study evaluated several size ranges of particulate matter and reported significant associations with PM15, PM2.5, sulfates, and non-sulfate particles, but not with coarse particles (PM15 – PM2.5). An extension of the Harvard Six Cities Cohort confirmed the association of mortality with PM2.5 levels (Laden, 2006). These studies provide evidence that the fine particles, as measured by PM2.5, may be more strongly associated with mortality effects from long-term particulate matter exposures than are coarse compounds. An update to this study covering a follow-up over the years 1974 to 2009 (Lepeule, 2012) was recently published. Findings indicated a linear relationship of PM2.5 levels and mortality from all causes, cardiovascular causes, and from lung cancer. According to the authors, the PM2.5 levels decreased over time, but no evidence of a threshold for these effects was found.

methods (Jerrett, 2005) and another applied land use regression techniques (Krewski, 2009) to estimate exposures to the study individuals. Significant associations of PM_{2.5} with mortality from all causes and cardiopulmonary disease were reported, with the magnitude of risks being up to three times higher than those from the national studies of the American Cancer Society cohort. This provides evidence that using methods to provide more detailed exposure estimates can result in stronger associations of PM_{2.5} and mortality.

Two recent reports have been released looking at air pollution and health effects in California. One study (Lipsett, 2011) followed school teachers recruited in 1995, and followed through 2005. Pollutant exposures at the subject residence were estimated using data from ambient monitors, and extrapolated using a distance weighted method. The authors reported significant association of PM_{2.5} levels and mortality from ischemic heart disease, but no associations were found with all cause, cardiovascular, or respiratory disease.

The second study (Jerrett, 2011) followed individuals in the Los Angeles area from the American Cancer Society cohort recruited starting in 1982, with follow up to 2000. Pollutant levels at subject residences were estimated using several methods. All but one of the methods found no association of all-cause mortality with PM_{2.5} levels. All exposure estimation methods were reported to have found significant associations with ischemic heart disease mortality, however. The authors noted that mortality rates differ in urban areas compared to non-urban areas, and so included a variable for this in a land use regression model to estimate effects on mortality. When the authors applied the land use regression model including an urban indicator to estimate exposures, all-cause mortality, mortality from cardiovascular disease, and mortality from ischemic heart disease were all significantly associated with PM_{2.5} levels.

Other studies report evidence indicating that particulate matter exposure early in pregnancy may be associated with lowered birth weights (Bobak, 1999). Studies from the U.S., the Czech Republic and Mexico City have reported that neonatal and early postnatal exposure to particulate matter may lead to increased infant mortality. A more recent study in Southern California found increased risks for infant deaths associated with exposures to particulates and other pollutants (Ritz, 2006). These results suggest that infants may be a subgroup affected by particulate matter exposures.

ULTRAFINE PARTICLES

As noted above, numerous studies have found association of particulate matter levels with adverse effects, including mortality, hospital admissions, and respiratory disease symptoms. The vast majority of these studies used particle mass of PM10 or PM2.5 as the measure of exposure. Some researchers have postulated, however, that ultrafine particles may be responsible for some of the observed associations of particulate matter and health outcomes (Oberdorster, et al, 1995; Seaton, et al, 1995).

Ultrafine particles are generally classified of 0.1 μm and small diameter.

Several potential mechanisms have been brought forward to suggest that the ultrafine portion may be important in determining the toxicity of ambient particulates, some of which are discussed below.

For a given mass concentration, ultrafine particles have much higher numbers and surface area compared to larger particles. Particles can act as carriers for other adsorbed agents, such as trace metals and organic compounds; and the larger surface area may transport more of such toxic agents than larger particles.

Smaller particles can also be inhaled deep into the lungs. As much as 50% of 0.02 μm diameter particles are estimated to be deposited in the alveolar region of the lung. There is complex nature of the relation between deposition and particle size. The ultrafine particles generally have higher fractional deposition in the alveolar region. However, for the smaller nucleation mode (particles less than 0.01 μm size) the deposition in the alveolar region declines, but increases in the extrathoracic region.

Exposures of laboratory animals to ultrafine particles have found cardiovascular and respiratory effects. Mice exposed to concentrated near roadway ultrafine particles showed larger early atherosclerotic lesions than mice exposed to PM2.5 or filtered air (Arujo, 2008). In a mouse allergy model, exposures to concentrated ultrafine particles resulted in a greater response to antigen challenge to ovalbumin (Li, 2010), indicating that vehicular traffic exposure could exacerbate allergic inflammation in already-sensitized animals.

Controlled exposures of human volunteers to ultrafine particles either laboratory generated or as products of combustion, such as diesel exhaust containing particles, have found physiological changes related to vascular effects. Mills, 2011, for example found exposure to diesel exhaust particulate attenuated both acetylcholine and sodium-nitroprusside -induced vasorelaxation.

NITROGEN DIOXIDE

The U.S. EPA has recently reviewed the health effects of nitrogen dioxide (U.S. EPA, 2008a). Evidence for low-level nitrogen dioxide (NO₂) exposure effects is derived from laboratory studies of asthmatics and from epidemiological studies. Additional supportive evidence is derived from animal studies.

Epidemiological studies using the presence of an unvented gas stove as a surrogate for indoor NO₂ exposures suggest an increased incidence of respiratory infections or symptoms in children. *Some studies, evidence mixed.*

Recent studies related to outdoor exposure have found health effects associated with ambient NO₂ levels, including respiratory symptoms, respiratory illness, decreased lung function, increased emergency room visits for asthma, and cardiopulmonary mortality. However, since NO₂ exposure generally occurs in the presence of other pollutants, such as particulate matter, these studies are often unable to determine the specific role of NO₂ in causing effects.

The Children's Health Study in Southern California found associations of air pollution, including NO₂, PM₁₀, and PM_{2.5}, with respiratory symptoms in asthmatics (McConnell, 1999). Particles and NO₂ were correlated, and effects of individual pollutants could not be discerned. A subsequent analysis indicated a stronger role for NO₂ (McConnell, 2002).

Ambient levels of NO₂ were also associated with a decrease in lung function growth in a group of children followed for eight years. In addition to NO₂, the decreased growth was also associated with particulate matter and airborne acids. The study authors postulated that ^{is} these ^{result} may be a ^{measure} of a package of pollutants from traffic sources. (Gauderman, 2004). *effect*

Results from controlled exposure studies of asthmatics demonstrate an increase in the tendency of airways to contract in response to a chemical stimulus (bronchial reactivity). Effects were observed with exposures from 0.1 to 0.3 ppm NO₂ for periods ranging from 30 minutes to 3 hours. A similar response is reported in some studies with healthy subjects at higher levels of exposure (1.5 - 2.0 ppm). Mixed results have been reported when people with chronic obstructive lung disease are exposed to low levels of NO₂.

Short-term controlled studies of animals exposed to NO₂ over a period of several hours indicate cellular changes associated with allergic and inflammatory response and interference with detoxification processes in the liver. In some animal studies

a number of these studies have looked at consequences of inhaled allergens

the severity of the lung structural damage observed after relatively high levels of short-term ozone exposure is observed to increase when animals are exposed to a combination of ozone and NO₂.

In animals, longer-term (3-6 months) repeated exposures at 0.25 ppm appear to decrease one of the essential cell-types (T-cells) of the immune system. Non-specific changes in cells involved in maintaining immune functions (cytotoxic T-cells and natural killer cells) have been observed in humans after repeated exposure (4-6 days) to >0.6 ppm of NO₂ (20 min. - 2 hours). All these changes collectively support the observation reported both in population and animal studies of increased susceptibility to infections, as a result of NO₂ exposure.

The U.S. EPA recently adopted a new short-term standard of 100 ppb (0.1 ppm) averaged over 1 hour. The standard was designed to protect against increases in airway reactivity in individuals with asthma observed in controlled exposure studies, as well as respiratory symptoms observed in epidemiological studies.

SULFUR DIOXIDE

Controlled laboratory studies involving human volunteers have clearly identified asthmatics as ~~the most~~ sensitive group to the effects of ambient sulfur dioxide (SO₂) exposures. Healthy subjects have failed to demonstrate any short-term respiratory functional changes at exposure levels up to 1.0 ppm over 1-3 hours.

a very
NOT proven to be "most" sensitive

In exercising asthmatics, brief exposure (5-10 minutes) to SO₂ at levels between 0.2-0.6 ppm can result in significant alteration of lung function, such as increases in airway resistance and decreases in breathing capacity. In some, the exposure can result in severe symptoms necessitating the use of medication for relief. The response to SO₂ inhalation is observable within 2 minutes of exposure, increases further with continuing exposure up to 5 minutes then remains relatively steady as exposure continues. SO₂ exposure is generally not associated with any delayed reactions or repetitive asthmatic attacks.

In epidemiologic studies, associations of SO₂ levels with increases in respiratory symptoms, increases in emergency department visits and hospital admissions for respiratory-related causes have been reported.

The U.S. EPA has recently revised the SO₂ air quality standard. The previous 24-hour standard was rescinded and replaced with a new 1-hour standard at 75 ppb (0.075 ppm) to protect against high short-term exposures.

Dr. Jean Ospital
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

Dear Dr. Ospital:

I have completed my review of Appendix I. The comments follow.

General Comments:

The health literature in the Appendix provides valid support for the CA air quality standards. I do agree with Dr. McConnell who suggested in his comments the utility of expanding the section on epidemiological evidence showing that near roadway exposures are associated with asthma and ischemic heart disease.

With regard to air toxics it might be useful to recognize that emissions from modern diesel engines and retrofitted older diesels are quantitatively and perhaps qualitatively different from that of the older unmodified diesels which are still part of the fleet but of diminishing numbers. There is a gap in our knowledge at this time as to whether health impacts are indeed reduced (as one would expect) and better information on how long it would take to phase out unmodified diesels would be useful for future projections.

I noted a comment from Bill La Marr (California Small Business Assoc) regarding a possible conflict on I-3 and I-10. Note that I-3 deals with cardiovascular mortality studies whereas I-10 speaks to exacerbation of cardiovascular disease (i.e. morbidity) not mortality, so there is no conflict.

I also read Dr. Enstrom's comments. I considered the contention that there is "NO relationship in California between PM and total mortality". First, total mortality might not be the most useful metric to use since the most sensitive individuals include those with respiratory and cardiovascular disease. I think that Dr. Jarrett's paper using land use regression to provide improved exposure metrics demonstrate significant health effects.

I have several specific comments which are tabulated below. I also have some additional editorial suggestions that I will send by mail rather than transcribe them here.

Pg	Comment
I-2 Para 2	<p>Although individuals inhale pollutants as a mixture under ambient conditions, the regulatory framework and the control measures developed are mostly pollutant-specific. This is appropriate, in that different pollutants usually differ in their sources, their times and places of occurrence, the kinds of health effects they may cause, and their overall levels of health risk. Different pollutants, from the same or different sources, may sometimes act together to harm health more than they would acting separately. Nevertheless, <u>evidence for more than additive effects have not been strong and</u>, as a practical matter, health scientists, as well as regulatory officials, usually must deal with one pollutant at a time in determining health effects and in adopting air quality standards. To meet the air quality standards, comprehensive plans are developed such as the Air Quality Management Plan (AQMP), and to minimize toxic exposure a local air toxics control plan is also prepared. These plans examine multiple pollutants, cumulative impacts, and transport issues related to attaining healthful air quality. A brief overview of the effects observed and attributed to various air pollutants is presented in this document.</p>
I-3 Para3	<p>Children may be a particularly vulnerable population to air pollution effects because they spend more time outdoors, are generally more active, and have a higher <u>specific</u> ventilation rate than adults (<u>i.e. after normalization for body mass</u>).</p>
I-3 Para 5	<p>Increases in ozone levels are associated with elevated <u>increased numbers of</u> absences from school.</p>
I-4 Para 2	<p>Numerous recent studies have found positive associations between increases in ozone levels and excess risk of mortality. These associations <u>are strongest during warmer months but overall</u> persist even when other variables including season and levels of particulate matter are accounted for. This indicates that ozone mortality effects may be independent of other pollutants (Bell, 2004).</p>
I-4 Para 4	<p>Since the respiration-compromised group may have lower lung function to begin with, the same total degree of change may represent a substantially greater <u>relative</u> adverse effect overall.</p>
I-4 Para 5	<p>Another publication from the Children's Health Study focused on children and outdoor exercise. In <u>California</u> communities with high ozone concentrations, the relative risk of developing asthma in children</p>

	<p>playing three or more sports was found to be over three times higher than in children playing no sports (McConnell, 2002). These findings indicate that new cases of asthma in children are associated with <u>their performance of</u> heavy exercise in communities with high levels of ozone. While it has long been known that air pollution can exacerbate <u>or trigger</u> symptoms in individuals with <u>preexisting</u> respiratory disease, this is among the first studies that indicate ozone exposure may be causally linked to asthma onset.</p>
I-5 Table I-1 Row 1, Col 2	<p>exposure, <u>decreased temperature</u>, and other environmental factors resulting in increased summertime hospital admissions and emergency department visits for respiratory causes (<u>NOTE: while cold air can trigger asthma, this is confusing in the face of increased effects during warmer weather</u>)</p> <p>Exacerbation of respiratory symptoms (e.g., cough, chest pain) in individuals with preexisting disease (e.g., asthma) with low ambient</p>
I-5 Table I-1 Row 2, Col 2	<p><u>NOTE: include reference to the latest Kim paper that shows effects at 0.06ppm Kim, C. S., N. E. Alexis, et al. (2011). "Lung function and inflammatory responses in healthy young adults exposed to 0.06 ppm ozone for 6.6 hours." American Journal of Respiratory and Critical Care Medicine 183(9): 1215-1221.</u></p> <p><u>RATIONALE: Exposure to ozone causes a decrease in spirometric lung function and an increase in airway inflammation in healthy young adults at concentrations as low as 0.08 ppm, close to the National Ambient Air Quality Standard for ground level ozone. OBJECTIVES: To test whether airway effects occur below the current ozone standard and if they are more pronounced in potentially susceptible individuals, such as those deficient in the antioxidant gene glutathione S-transferase mu 1 (GSTM1). METHODS: Pulmonary function and subjective symptoms were measured in 59 healthy young adults (19-35 yr) immediately before and after exposure to 0.0 (clean air, CA) and 0.06 ppm ozone for 6.6 hours in a chamber while undergoing intermittent moderate exercise. The polymorphonuclear neutrophil (PMN) influx was measured in 24 subjects 16 to 18 hours postexposure. MEASUREMENTS AND MAIN RESULTS: Subjects experienced a significantly greater (P = 0.008) change in FEV(1) (+/- SE) immediately after exposure to 0.06 ppm ozone compared with CA (-1.71 +/- 0.50% vs. -0.002 +/- 0.46%). The decrement in FVC was also greater (P = 0.02) after ozone versus CA (-2.32 +/- 0.41% vs. -1.13 +/- 0.34%). Similarly, changes in %PMN were greater after ozone (54.0 +/- 4.6%) than CA (38.3 +/- 3.7%) exposure (P < 0.001). Symptom scores were not different between ozone versus CA. There were no significant differences in changes in FEV(1), FVC, and %PMN between subjects with GSTM1-positive and GSTM1-null genotypes. CONCLUSIONS: Exposure of healthy young adults to 0.06 ppm ozone for 6.6 hours causes a significant decrement of FEV(1) and an increase in neutrophilic inflammation in the airways. GSTM1 genotype alone appears to have no significant role in modifying the effects.</u></p>
I-6 Fig I-1	<u>Add data point from Kim (2011) O3 vs CA (-1.71 +/- 0.50% vs. -0.002 +/- 0.46%)</u>
I-7 Para 1	<u>One could note in Figure I-1 that, not surprisingly, the results of studies</u>

	<p><u>conducted using subjects residing in California (Adams, et. al.) are consistent with measurements made with residents of other states (e.g. Kim et al., 2011)</u></p> <p>In addition to controlled laboratory conditions, studies of individuals exercising outdoors, including children attending summer camp, have shown associations of reduced lung function with ozone exposure. There were wide ranges in responses among individuals.</p>
I-7 Para 2	<p>In laboratory studies, cellular and biochemical changes associated with respiratory tract inflammation have also been consistently reported in the airway lining after low level exposure to ozone. These changes include an increase in specific cell types and in the concentration of biochemical mediators of inflammation and injury such as <u>eytokines Interleukin-1, Tumor Necrosis Factor α</u> and fibronectin.</p>
I-7 Para 4	<p><u>There may be interactions between ozone and other ambient pollutants.</u> The susceptibility to ozone observed under ambient conditions could be <u>modified</u> due to the combination of pollutants that coexist in the atmosphere, or ozone <u>may actually might</u> sensitize these subgroups to the effects of other pollutants.</p>
I-7 Para 5	<p>Some animal studies show results that indicate possible chronic effects including functional and structural changes of the lung. These changes indicate that repeated inflammation associated with ozone exposure over a lifetime may result in <u>suffieient-cumulative</u> damage to respiratory tissue such that individuals later in life may experience a reduced quality of life in terms of respiratory function and activity level achievable.</p>
I-7 Para 7	<p>In summary, adverse effects associated with ozone exposures have been well documented. <u>–Although the specific causal-mechanisms of action are not fully identified-is still somewhat unclearthere is a strong likelihood that oxidation of key enzymes and proteins and inflammatory responses play important roles.</u></p>
I-8 Para 1	<p><u>NOTE: It might be useful to add the following:</u> <u>On the basis of the most recent evaluations of ozone health effects the CASAC has recommended to the USEPA Administrator that the NAAQS be reduced and recommended a range in which 0.070 ppm would be the upper limit, i.e. moving the national standard to be consistant with the CA standard.</u></p>
I-9 P 3-4	<p>In recent years additional focus has been placed on particles having an aerodynamic diameter of 2.5 μm or less (PM2.5). A greater <u>f</u>raction of particles in this size range can penetrate and deposit deep in the lungs. The EPA recently lowered the air quality standards for PM2.5 to 35 $\mu\text{g}/\text{m}^3$ for a 24-hour average and reaffirmed 15 $\mu\text{g}/\text{m}^3$ for an annual average standard.</p> <p>There was considerable controversy and debate surrounding the review</p>

	<p>of particulate matter health effects and the consideration of ambient air quality standards (Kaiser, 1997; Vedal, 1997) when the EPA promulgated the initial PM_{2.5} standards in 1997. Since that time, numerous studies have been published, and some of the key studies were closely scrutinized and analyses repeated<u>the data were reanalyzed by additional investigators</u>. The result is that there are now substantial data<u>analyses confirming</u> confirmed the <u>significant findings of</u> adverse health effects of PM_{2.5} exposures <u>and some additional studies demonstrated adverse effects at ambient concentrations at or below the current NAAQS</u>.</p>
I-10 P 1	<p>in the atmosphere from gases<u>by condensation of vapors</u> that are emitted <u>or by chemical or photochemical reactions with other contaminants in the air</u>.</p>
I-10 P 2	<p>These particles are garnering interest since <u>a limited number of epidemiological and several</u> laboratory studies indicate that their toxicity may be higher on a mass basis than larger particles, and there is evidence that these small particles, <u>or toxic components carried on their surface</u>, can translocate from the lung to the blood and to other organs of the body.</p>
I-10 P 4	<p>The major types of effects associated with particulate matter include<u>are shown in Table I-4</u>. California did not set a separate 24-hr average PM_{2.5} standard; the 35 µg/m³ NAAQS applies.</p>
I-11 Table I-4	<p><u>COMMENT: Insert NAAQS for 24 hr PM_{2.5} in brackets? Indicate in a footnote if the forms of the standard are not the same.</u></p>
I-11 P2 L7	<p><u>Was the mortality CV, Resp. total, all of the above??</u></p>
I-11 P2	<p><u>There are statistical associations between PM₁₀ and several of the gaseous co-pollutants and therefore the association of PM₁₀ and health</u> effects were reduced somewhat when O₃ was also considered and tended to be variably decreased when NO₂, CO, and SO₂ were added to the analysis. <u>However, in many studies there are significant independent associations of PM and health effects</u> These results argue<u>thus supporting the contention</u> that the effects are likely due to the particulate exposures; they cannot readily be explained by coexisting weather stresses or other pollutants.</p>
I-13	<p><u>COMMENT: It gets confusing when the basis changes from 10 µg/m³ to 25 µg/m³ or other metrics.</u> <u>There should be a reference for the Mexico City and Chile studies.</u></p>
I-13 P3	<p>The relative importance of both PM_{2.5} and PM_{10-2.5} may vary in different regions depending on the relative concentrations and components, which can also vary by season. <u>A major knowledge gap is the relative paucity of direct measurements of PM_{2.5-10}. Most estimates are made by subtracting PM_{2.5} from PM₁₀ measured at co-located samplers, a process that is subject to large errors that are</u></p>

	<u>inherent in the subtracting of one relatively large number from another.</u> More research is needed to better assess the relative effects of fine (PM2.5)
I-14 P3	These observations are consistent with the hypothesis that increased susceptibility to infection follows particulate matter exposures, <u>which is consistent with mechanistic studies that show that PM exposures suppress the innate immune system.</u>
I-14 P 4	The findings suggest that both the fine and coarse fractions may have associations with some respiratory symptoms, <u>consistent with mechanistic studies that both coarse and fine PM suppress innate immune functions.</u>
I-15 P4	<u>COMMENT: This might also be a reflection that mortality in general is lower in the western states – perhaps analogous to the “healthy worker” effect seen in occupational studies. However effects are seen more clearly when analyses are focused on susceptible groups and when more personal metrics of exposure are used as shown by Jerrit et al.</u>
I-16 P4	<u>COMMENT: Pollutant levels dropped dramatically from 83-02. The impact of pollution on mortality would have dropped as well. When looking at a changing independent variable it may be more appropriate to look at the changes in mortality vs the changes in pollution over the entire period rather than arbitrary slices.</u>
I-18 P1 L4	<u>...couple OF cohort...</u>
I-18 P2	<u>...fetuses and infants may be subgroups...</u>
I-21 P2 L4	<u>Araujo,2008</u>
I-26 P6 L3	...have been reported. <u>Coupled with the human clinical studies, these data suggest that SO2 can trigger asthmatic episodes in individuals with pre-existing asthma.</u>
I-26 P7	...to protect against high short term exposure <u>accute asthma attacks in sensitive individuals.</u>

Sincerely,

Michael T. Kleinman

Summary of Attached Pages:

- 1) Enstrom Criticism of Draft 2012 AQMD AQMP Appendix I Health Effects makes the primary points that a) overwhelming epidemiologic evidence indicates particulate matter is not killing Californians; b) since 2001 AQMD has not prepared reports on “the health impacts of particulate matter in the South Coast Air Basin” in accord with California Health and Safety Code (CHSC) Section 40471 (b); c) the AQMD Advisory Council failed to properly peer review AQMP Appendix I Health Effects; and d) AQMD must hold a Governing Board Hearing on AQMP Appendix I Health Effects before the 2012 AQMP is finalized.
- 2) Enstrom Op-Ed for The Desert Sun on particulate matter in the Coachella Valley, which was scheduled to be published on April 4, 2012 but which has never been published, makes a strong case that a) particulate matter is not currently harming Coachella Valley residents and b) there will be no health risk from particulate matter after the Sentinal Power Plant is operational.
- 3) Figure 21 from 2000 Health Effects Institute Reanalysis Report by Krewski, Jerrett, et al., shows clear and large variation in PM_{2.5} mortality risk across the US, with low risk in California
- 4) Enstrom Table 1 summary of the epidemiologic evidence shows NO relationship between PM_{2.5} and total mortality in California.
- 5) Enstrom Table 2 summary of the epidemiologic evidence shows NO relationship between PM₁₀ and total mortality in California; also, US EPA summary of PM NAAQS indicates revocation of the annual PM₁₀ standard in 2006 due to lack of long-term health effects.
- 6) NCHS US map shows 2009 age-adjusted total death rate by state, with California third lowest; also, California county data shows that the death rate in the South Coast Air Basin is lower than the death rate in every state except Hawaii.

Criticism of Draft 2012 South Coast Air Quality Management District Air Quality Management Plan Appendix I Health Effects

The Southern California Air Quality Management District (AQMD) has released its Draft 2012 Air Quality Management Plan (AQMP) (<http://www.aqmd.gov/aqmp/2012aqmp/index.htm>). This plan proposes aggressive and costly emission control measures, such as, increased use of zero emission vehicles and severe restrictions on wood-burning fireplaces, in order to reduce air pollution in the South Coast Air Basin (SCAB). This air basin includes about 17 million residents in Orange County and the urban portions of Los Angeles, Riverside, and San Bernardino Counties. The primary goal of the AQMP is to bring the SCAB into compliance with the US Environmental Protection Agency (EPA) National Ambient Air Quality Standards (NAAQS) for criteria pollutants, such as, particulate matter (PM2.5 and PM10) and ozone. These standards are based on the nationwide health effects of these pollutants (<http://www.epa.gov/air/criteria.html>).

However, the AQMP needs to address the health effects of air pollution in the SCAB. In particular, California Health and Safety Code (CHSC) Section 40471 (b) specifically states “On or before December 31, 2001, and every three years thereafter, as part of the preparation of the air quality management plan revisions, the south coast district board, in conjunction with a public health organization or agency, shall prepare a report on the health impacts of particulate matter air pollution in the South Coast Air Basin. The south coast district board shall submit its report to the advisory council appointed pursuant to Section 40428 for review and comment. The advisory council shall undertake peer review concerning the report prior to its finalization and public release. The south coast district board shall hold public hearings concerning the report and the peer review, and shall append to the report any additional material or information that results from the peer review and public hearings.” (<http://www.leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=40001-41000&file=40460-40471>).

As best I can determine, AQMD never prepared a “report on the health impacts of particulate matter air pollution in the South Coast Air Basin” at the end of 2001, 2004, 2007, or 2010. The only “health impacts” reports that I can find are Appendix I “Health Effects” of the 2003 AQMP, 2007 AQMP, and Draft 2012 AQMP. However these reports do not specifically address “the health impacts of particulate matter air pollution in the South Coast Air Basin.” Indeed, the 2003 AQMP Appendix I states “The purpose of this appendix is to provide an overview of air pollution health effects, rather than to provide estimates of health risk from current ambient levels of pollutants in specific areas of the SCAB.” (http://www.aqmd.gov/aqmp/docs/2003AQMP_AppI.pdf).

Failure to comply with CHSC Section 40471 (b) is a serious matter because the local health effects of PM provide the primary public health justification for the entire AQMP. Overwhelming epidemiologic evidence now indicates that there is NO relationship in California between PM and total mortality (also known as "premature deaths"), as I explained in the June 4, 2012 Orange County Register (<http://www.ocregister.com/articles/air-357230-california-pollution.html>).

This null relationship in California has been known since 2000, but the specific null evidence is only partially presented in the Draft 2012 AQMP and was entirely omitted from the earlier AQMPs. For instance, each AQMP Appendix I cites the 2000 Health Effects Institute Special Report "Reanalysis of the Harvard Six Cities Study and the American Cancer Society Study of Particulate Air Pollution and Mortality," a major report relied upon by EPA and AQMD. However, only the nationwide PM2.5 mortality risk results in this report are cited in the AQMP, whereas Figures 5 and 21 show substantial geographic variation in PM2.5 mortality risk across the US, with Los Angeles ranking fifth lowest among 49 cities (<http://www.scientificintegrityinstitute.org/HEIFigure5093010.pdf>).

In total, ten separate analyses of five major California cohorts have found no relationship between PM2.5 and total mortality. Indeed, detailed analyses of two of these cohorts, funded by AQMD and completed in 2011, have found no relationship between any criteria pollutant and total mortality in California (www.scientificintegrityinstitute.org/Enstrom081512.pdf). Keep in mind, total mortality is the primary health impact that justifies the NAAQS. However, these national standards are not based on health effects or mortality in California or the SCAB. In 2009 the SCAB had an age-adjusted total death rate lower than the death rate in every state in the continental US (<http://www.scientificintegrityinstitute.org/NCHSRR070811.pdf>).

The 16 members of the 2012 AQMD Advisory Council were asked on June 7, 2012 to review and comment on Appendix I, particularly regarding the "health impacts of particulate matter air pollution in the South Coast Air Basin," and to attend a July 11, 2012 meeting at AQMD regarding Appendix I. Only 7 members submitted any written comments. The three members with the most relevant scientific expertise on PM did not address the "health impacts of particulate matter air pollution in the South Coast Air Basin". UCLA Professor John R. Froines did not submit any written comments; USC Professor Rob S. McConnell did not submit any comments on PM health effects; and LLU Professor Samuel Soret failed to reveal the null PM findings from AHSMOG in the December 2011 LLU Dr. P.H. dissertation of Lie Hong Chen (http://books.google.com/books/about/Coronary_Heart_Disease_Mortality_and_Lon.html?id=pA8ltwAACAJ).

Dr. Soret served on the committee for Dr. Chen's highly relevant dissertation, CORONARY HEART DISEASE MORTALITY AND LONG-TERM EXPOSURE TO AMBIENT PARTICULATE AIR POLLUTANTS IN ELDERLY NONSMOKING CALIFORNIA RESIDENTS. The Abstract states "The purpose of this study is to assess the effect of long-term concentrations of ambient PM on risks of all causes The health effects of long-term ambient air pollution have been studied with up to 30 years of follow-up in the AHSMOG cohort, a cohort of 6,338 nonsmoking white California adults."

Before the Draft 2012 AQMP is finalized and approved, AQMD must hold a public hearing on the health impacts of air pollution in the SCAB, in accordance with CHSC Section 40471 (b). If the hearing confirms the overwhelmingly null evidence cited above, then the AQMP should not propose emission control measures necessary to comply with NAAQS that are not appropriate for California or the SCAB. Instead, AQMD should request a waiver from compliance with the NAAQS using the special waiver status granted to California in Section 209 of the Clean Air Act (<http://www.epa.gov/otaq/cafr.htm>).

Subject: RE: Proposed Op-Ed on Particulate Matter Health Effects in CV

Dr. Engstrom, here's the edited version. I did minimal editing, just a few tweaks to match AP style. I replaced $\mu\text{g}/\text{m}^3$ with "micrograms per cubic meter." Please let me know if that's acceptable.

Also, I took your website references out of the body of the column and put them in a breakout (below) to make it more readable.

It will be in Wednesday's edition. Thanks for the contribution.

The Desert Sun has recently published a special report and an editorial on the Sentinel power plant that is under construction by Competitive Power Ventures. Substantial concern has been expressed about the impact of the particulate matter (PM) pollution that will be generated by the plant. I would like to provide my perspective on the PM levels associated with the plant and the health effects associated with PM. PM consists of "inhalable coarse particles" (PM10) and "fine particles" (PM2.5).

Based on the April 15, 2010, California Energy Commission air quality assessment for the Sentinel plant, Table 13 indicates that the maximum annual background PM10 level in the Coachella Valley will be increased from 54.9 microgram per cubic meter to 55.33 during plant operation. This represents a "worse case (maximum)" increase of only 0.8 percent. Based on the South Coast Air Quality Management District (AQMD) Final 2007 Air Quality Management Plan, the maximum annual average PM10 level in the Coachella Valley (Salton Sea Air Basin) is only 45.7 micrograms per cubic meter.

All these levels are quite similar to the U.S. EPA's 1987-2006 annual standard for PM10 of 50 micrograms per cubic meter. However, this standard was revoked in 2006 due to "inadequate" evidence of long-term health effects of PM10, as summarized in the 2004 and 2009 EPA Integrated Science Assessment for Particulate Matter.

The Desert Sun claim that "the Sentinel plant would increase the (PM10) level to 277 percent above the state standard" is highly misleading because it is based on the California Energy Commission's Table 13 comparison of 55.33 micrograms per cubic meter with the California annual standard for PM10 of 20. But this state standard was established by the California Air Resources Board in 2002 and does not reflect the extensive null evidence on PM10 health effects that has been published since 2002.

In January 2007, the Air Resources Board and AQMD approved \$1,034,358 in funding, half from each agency, for two major epidemiologic studies on the relationship between PM (PM10 and PM2.5) and death in California. The study based on the American Cancer Society cohort was conducted by UC Berkeley professor Michael Jerrett and 13 other investigators.

The study based on the California Teachers Study cohort was conducted by Michael Lipsett of the California Department of Public Health and nine other investigators. A primary purpose of these studies was to produce new California evidence "to assist with the review of ambient air quality standards."

The results of these two studies were published in 2011 and they both found no relationship between PM and total mortality in California. The Jerrett Study found that total mortality during 1982-2000

among about 75,000 California adults was not related to either PM10 or PM2.5 in eight of nine models tested. The Lipsett Study found that total mortality during 2000-2005 among about 75,000 female

California teachers was not related to either PM10 or PM2.5.

The studies found some unexplained evidence of increased cardiovascular disease risk and decreased cancer risk, but there was no overall increased risk of death. These null results agree with the overwhelmingly null results for California that have been published since 2000, which include my 2005 results.

Thus, based on all the evidence described above, there is no health risk associated with PM in the Coachella Valley or in California as a whole and there will be no health risk from PM after the Sentinal power plant is operational. However, since AQMD and others have a different perspective and since The Desert Sun stated that "Robust debate on this issue is needed," I propose that an open forum be organized so that AQMD Executive Officer Barry Wallerstein and I can debate our different views on the health effects of PM in the Coachella Valley. Hopefully, our debate will help resolve the PM health effects issue.

James E. Enstrom is on the research faculty at the UCLA School of Public Health and has been conducting epidemiologic research there since 1973. Email him at jenstrom@ucla.edu

FOLLOWING THE SCIENCE: How National Ambient Air Quality Standards (NAAQS) for Particulate Matter (PM) Have Changed Over Time (<http://www.epa.gov/pm/agriculture.html>)

- EPA has regulated particle pollution since 1971. Our standards have evolved over time, as science has taught us more about how exposure to particles affects health and welfare.
- The 1971 standards, for example, set levels for all particles in the air, known as “total suspended particulate.” This covered all sizes of airborne particles, including dirt and other larger particles.
- In 1987, EPA changed the standards to focus on those particles 10 micrometers in diameter and smaller, because particles larger than that don’t generally get past the nose into the respiratory system. The Agency set both daily and annual PM10 standards at that time.
- In 1997, based on an expanding body of scientific evidence linking fine particles (PM2.5) to serious health effects, EPA added both daily and annual standards for fine particles.
- The Agency revised those standards in 2006, tightening the daily standard. That same year, **EPA revoked the annual standard for PM10, because there was insufficient evidence linking long-term exposure to inhalable coarse particle pollution to health problems.** EPA retained the daily PM10 standard – at 150 micrograms per cubic meter, the same level since 1987.

Do death rates vary by state?

States experience different risks of mortality. Hawaii has the lowest age-adjusted death rate (619.8 deaths per 100,000 population) of all the states, 16.4 percent lower than the average rate for the United States (741.0). West Virginia had the highest state age-adjusted death rate in 2009, 28.2 percent higher than the average U.S. rate.

In general, states in the Southeast region have higher rates than those in other regions of the country. Louisiana, for example, is typical of the region and has an age-adjusted death rate of 887.5 deaths per 100,000 population (3). States in other regions of the country, such as Illinois in the Midwest (743.0 deaths per 100,000 population) and Oregon in the West (733.1 deaths per 100,000 population), have rates that are more comparable with the average U.S. rate (3) (Figure 4).

Figure 4. Age-adjusted death rates, by state and the District of Columbia: United States, preliminary 2009

SOURCE: CDC/NCHS, National Vital Statistics System, Mortality.

Ratio of 2009 Age-Adjusted Total Death Rates (deaths/100,000)

California / U.S.	$652.2 / 741.1 = 0.88 = 88\%$
'South Coast Air Basin' (4 Counties) / U.S.	$650.8 / 741.1 = 0.88 = 88\%$
Los Angeles County / U.S.	$637.3 / 741.1 = 0.86 = 86\%$
Orange County / U.S.	$570.9 / 741.1 = 0.77 = 77\%$

jenstrom@ucla.edu
(310) 825-2048

September 20, 2012

- 1) In spite of my repeated submissions to AQMD since 2008 of overwhelming evidence of no mortality impacts, including the evidence in my August 30, 2012 Criticism of the Draft 2012 AQMP (<http://scientificintegrityinstitute.org/AQMP083012.pdf>), the September 7, 2012 Revised Draft AQMP Appendix I Health Effects continues to seriously misrepresent and exaggerate the mortality impacts of criteria pollutants, like particulate matter, in the South Coast Air Basin (<http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/AppI.pdf>).
- 2) Since 2000, overwhelming epidemiologic evidence that fine particulate matter is not killing Californians has been published by 26 accomplished doctoral level scientists (Ph.D. or M.D.), including myself. Since 2008, extensive written and/or verbal comments by 16 doctoral level critics, including myself, have been submitted to US EPA, CARB, and/or AQMD and these comments strongly criticize the way the California-specific evidence has been characterized by the three regulatory agencies. The names of the scientists and critics are listed on the next page.
- 3) The 2012 AQMP (<http://www.aqmd.gov/aqmp/2012aqmp/index.htm>) does not comply with California Health and Safety Code (CHSC) Section 40471 (b): “On or before December 31, 2001, and every three years thereafter, as part of the preparation of the air quality management plan revisions, the south coast district board, in conjunction with a public health organization or agency, shall prepare a report on the health impacts of particulate matter air pollution in the South Coast Air Basin. The south coast district board shall submit its report to the advisory council appointed pursuant to Section 40428 for review and comment. The advisory council shall undertake peer review concerning the report prior to its finalization and public release. The south coast district board shall hold public hearings concerning the report and the peer review, and shall append to the report any additional material or information that results from the peer review and public hearings.” (<http://www.leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=40001-41000&file=40460-40471>).
- 4) Before the 2012 AQMP is finalized and approved, the AQMD Governing Board must hold a public hearing on “the report and the peer review” regarding “the health impacts of particulate matter air pollution in the South Coast Air Basin,” as required by CHSC Section 40471 (b).

Members of the South Coast Air Quality Management District Board of Directors:

The recently released draft for Air Quality Management by the Southern California Air Quality Management District (AQMD) proposes very significant regulatory changes for more than 15 million residents of the area, however the South Coast AQMD proposes these changes without benefit of the prescribed triennial Air quality management plan revisions announcements. In conjunction with an effort to elicit public comments. Draft 2012 is, like so many drafts before, the product of a black box project at the South Coast AQMD, the precautionary principle and acceptance of science that has been effectively challenged in public in the past 4 years.

That is not according to Federal or State Clean Air Act law or the intent of environmental compliance provisions.

The Air Quality Management Plan (AQMP) (<http://www.aqmd.gov/aqmp/2012aqmp/index.htm>) proposes aggressive and draconian provisions that would have major impacts on the residents of the South Coast Basin Area.

I have included previous submissions to CARB on air regulations that were the product of the 2008-2010 activities and proposals and public comments made by prominent experts opposed to the new CARB air pollution measures. The South Coast Air Management Plan process should include close review and evaluations of those public comments that criticize and conflict with the studies relied on by the District planners.

The economic impact of the Management plan will kill or harm business, industry, transportation, and agricultural activity for now good reason, since air pollution is not killing anyone in South Coast. The proposed AQM Plan will cause hardship and shorten lives for the residents of the area in addition to depressing the economy with the well-known effect that can be expected, higher unemployment, stress and hardship, resulting in shortened life expectancies and misery—all for AQMD chasing a phantom menace—small particle pollution, that by evidence of the studies, causes no harm or deaths.

AQMP also should follow the law, that specifically states at Section 40471 of the Health and Safety Code “On or before December 31, 2001, and every three years thereafter, as part of the

preparation of the air quality management plan revisions, the south coast district board, in conjunction with a public health organization or agency, shall prepare a report on the health impacts of particulate matter air pollution in the South Coast Air Basin. The south coast district board shall submit its report to the advisory council appointed pursuant to Section 40428 for review and comment. The advisory council shall undertake peer review concerning the report prior to its finalization and public release. The south coast district board shall hold public hearings concerning the report and the peer review, and shall append to the report any additional material or information that results from the peer review and public hearings.”
(<http://www.leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=40001-41000&file=40460-40471>).

The district has failed to comply. Therefore they should correct their failure and stand down from pursuing the Plan proposed until the review and hearing process is complete.

For 4 years 2008-2012, the California Air Resources Board (CARB) has attempted to push through air pollution/small particle control regulations that the CARB claimed were based on evidence of human health effects that included deaths from small particles.

Here are the links, which include my previous submissions protesting the inadequacy of the human health effects science relied on by CARB.

Criticism of June 9, 2011 Draft and October 28, 2011 Final Jarrett Report on PM2.5 Deaths in CA

October 28, 2011 Compilation of All Criticism since June 9, 2011 of Jarrett Report on CA PM2.5 Deaths

(<http://www.scientificintegrityinstitute.org/JarrettCriticism102811.pdf>)

Careful review of the submissions above by previous commenters would justify a stand down from the proposed AQMP outlined by the South Coast MD. Research shows that current ambient air pollution in California is not harmful and doesn't justify aggressive new AQMP plans.

Reputable scientists repeatedly raised important issues and Michael Jarrett's joke of a research project based on his selection of the "conurbation" model data, confirms that the CARB claims of thousands of lives saved by air regs is a house of cards built by CARB on small particle research data dredges to find poorly defined "premature deaths" supposed associated with poorly defined small particle pollution. Such uncertainties certainly cannot justify the extreme elements of the South Coast AMP.

The CARB never was able to properly dispel the objections raised in 2008-2010, and in February of 2010 lost the major face to face debate in a knockout when Dr. Michael Jarrett's project came a cropper and Dr. Jarrett admitted he couldn't find any current air pollution health effects.

Then Dr. Jarrett went back to his computer tricks and decided to redo his research with modeling that is risible, then 9 models showed no effect but one of his ten models finally gave him the results that allowed him to do what CARB asked—support their position that small particles are killers.

Dr. Jarrett's co-authors, an impressive array of fellow travelers in the small particle hunting research community, never excused or explained the decision to rely on the "conurbation" model as more reliable than the 9 models that showed no effect. Although conurbation sounds exotic, it is the game played by researchers called torturing the data, and in this case Dr. Jarrett found a way to dice and chop the geography of California to find populations that had the "associations" of air pollution and deaths he was looking for.

That is called the outcome based research fallacy and is fueled by the fact that Jarrett and his coauthors knew who funded their research, an agency that had a stake in promoting the public perception that small particles are killers.

South Coast Air Management District should comply with California Health and Safety Code Section 40471 (b) and schedule a Hearing for a full vetting of the small particle research issues before implementing the proposed AQMP and then act reasonably and discard the Plan.

There are no impact studies for the past decade, and the AQMD has no reports on health impacts

on record for 2001 through 2010 when there should have been at least 3 reports filed, and at one point an AQMD report said, ignoring its responsibility in reporting, “The purpose of this appendix is to provide an overview of air pollution health effects, rather than to provide estimates of health risk from current ambient levels of pollutants in specific areas of the SCAB.” (http://www.aqmd.gov/aqmp/docs/2003AQMP_AppI.pdf).

The health effects studies are the foundation for any management plan and have been discarded in favor of aggressive regulatory proposals based on the precautionary principle or good intentions, but not on the science demanded in the Clean Air Act and its corresponding California Statutes. The research presented to the CARB and the public comments provided make a strong case for no effect from current ambient air pollution. No death effect, no measurable health effect from the criteria air pollutants.

Please consider the comments from 2008 on the proposed CARB Tran report, the submissions made for the debate in February of 2010, and the comments by experts on the final version of the Jerrett study that asserted the “conurbation” model justified the CARB pursuit of new and aggressive small particle regulations.

Many studies have found no PM 2.5 health effect and yet the CARB and the South Coast Management district continue to press forward to the detriment of the California economy. California cohorts have found no relationship between PM2.5 and total mortality. Indeed, detailed analyses of two of these cohorts funded by AQMD and completed in 2011, have found no relationship between any criteria pollutant and total mortality in California (www.scientificintegrityinstitute.org/Enstrom081512.pdf).

The CARB and US EPA human health effects research on small particles and other criteria pollutants have been depended on the questionable methodology of data dredging for “premature deaths. The problem is defining premature deaths, and the studies in fact do not count premature deaths as in a medical investigation, but the noise of variation in death rates. That is an opportunity for irresponsible data torturing to find air pollution and daily variation in death rates to call “premature deaths” that are not. The premature deaths projected by researchers, the USEPA and CARB to thousands in the state or nation are projections of deaths that area more than the daily average, not premature deaths of individuals who have been assessed for confounders and found to die short of life expectancy.

The research is unreliable, and misleading, and projections of hundreds of thousands of lives saved is deceitful nonsense. There are no deaths from small particles, the research is deceptive desk top death certificate data dredging that harvests the noise from day to day death rate variations and calls it signal, then projects the “correlations” the population to make impressive scare numbers of “premature deaths.”

These data dredged mortalities are the primary health impact used to justify the NAAQS. So the number is the product of data torturing and deception but even if the AQMD accepts the unreliable counting and methodology, the national standards are not based on health effects or mortality in California or the SCAB. In 2009 the SCAB had an age-adjusted total death rate lower than the death rate in every state in the continental US. (<http://www.scientificintegrityinstitute.org/NCHSRR070811.pdf>).

The AQMD is obligated to evaluate the reliability of the research and another consideration is the already mentioned Krewski map that shows no California air pollution effects. That alone should give California policy makers pause before initiating another aggressive regulatory regime.

A good faith effort to review the human health effects science should convince the SC AMD policy makers to reconsider the proposed aggressive Management Plan.

Cordially,

John Dale Dunn MD JD

October 11, 2012

- 1) In spite of my extensive and repeated criticism of the scientific and public health basis for the 2012 AQMD Air Quality Management Plan (AQMP), including my September 28, 2012 American Statistical Association JSM Proceedings Paper "Particulate Matter is Not Killing Californians" (<http://www.scientificintegrityinstitute.org/ASA092812.pdf>), the October 9, 2012 Revised Draft AQMP Appendix I Health Effects Version 2 continues to seriously misrepresent and exaggerate the health impacts of particulate matter in the South Coast Air Basin (SCAB) (<http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/AppI-v2.pdf>).
- 2) Since 2000, overwhelming epidemiologic evidence that fine particulate matter is not killing Californians has been published by 26 accomplished doctoral level scientists (Ph.D. or M.D.), including myself. Since 2008, extensive written and/or verbal comments by 16 doctoral level critics, including myself, have been submitted to US EPA, CARB, and/or AQMD and these comments strongly criticize the way the California-specific evidence has been characterized by the three regulatory agencies. This evidence has not been properly recognized or used by AQMD in its assessment of the health impacts of particulate matter in the SCAB since 2000.
- 3) Since 2001 the Appendix I Health Effects for the AQMP has never complied with various clearly written provisions of California Health and Safety Code (CHSC) Section 40471 (b) (<http://www.leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=40001-41000&file=40460-40471>). In particular, Appendix I does not focus on "the health impacts of particulate matter air pollution in the South Coast Air Basin;" Appendix I has not been prepared "in conjunction with a public health organization or agency;" the AQMD Advisory Council did not "undertake peer review concerning the report," using a standard definition of peer review; the AQMD Governing Board has not complied with the requirement to "hold public hearings concerning the report and the peer review."
- 4) Before the 2012 AQMP is finalized and approved, the AQMD must be required to comply with all provisions of CHSC Section 40471 (b). In particular, the AQMD Governing Board must hold at least one public hearing that focuses on "the report and the peer review" regarding "the health impacts of particulate matter air pollution in the South Coast Air Basin."

Keywords: epidemiology ; particulate matter ; mortality ; causality ; statistics ; California

Abstract: There is now overwhelming epidemiologic evidence that particulate matter (PM), both fine particulate matter (PM_{2.5}) and coarse particulate matter (PM₁₀), is not related to total mortality in California. I will examine all the long-term PM epidemiologic cohort studies in California, and discuss the ways the findings from these studies have been used and/or ignored. I will discuss the limitations of these studies: lack of access to key databases; the ecological fallacy; failure to consider other pollutants; failure to satisfy causality criteria; and failure to consider other competing health risks. Also, ethical issues underlying much of PM_{2.5} epidemiology will be discussed. I will make a strong case that PM_{2.5} is not killing Californians and that there is not a scientific or public health basis for the many of the existing and proposed regulations designed to reduce PM levels in California. Finally, I will make the case that PM health effects and regulations must be put into perspective with other factors that influence health in California, given the low age-adjusted total death rate in this state.

Abstract

There is now overwhelming epidemiologic evidence that particulate matter (PM), both fine particulate matter (PM_{2.5}) and course particulate matter (PM₁₀), is not related to total mortality in California. I will examine all the long-term PM epidemiologic cohort studies in California, and discuss the ways the findings from these studies have been used and/or ignored. I will discuss the limitations of these studies: lack of access to key databases; the ecological fallacy; failure to consider other pollutants; failure to satisfy causality criteria; and failure to consider other competing health risks. Also, ethical issues underlying much of PM_{2.5} epidemiology will be discussed. I will make a strong case that PM_{2.5} is not killing Californians and that there is not a scientific or public health basis for the many of the existing and proposed regulations designed to reduce PM levels in California. Finally, I will make the case that PM health effects and regulations must be put into perspective with other factors that influence health in California, given the low age-adjusted total death rate in this state.

Key Words: epidemiology, particulate matter, mortality, causality, statistics, California

1. Background

1.1 Relationship of PM_{2.5} Epidemiology to EPA, CARB, and AQMD

This paper focuses on particulate matter (PM) epidemiology in California. PM consists of fine particulates (PM_{2.5}), defined to have particle size <2.5 μm in diameter, and course particulates (PM₁₀), defined to have a particle size <10 μm in diameter. PM_{2.5} is generated mainly by combustion processes, such as, forest fires, agricultural dust, industrial combustion, and diesel engines. PM_{2.5} epidemiology played a major role in the US Environmental Protection Agency (EPA) establishment of the 1997 National Ambient Air Quality Standard (NAAQS) for PM_{2.5} (<http://www.epa.gov/air/criteria.html>). EPA has recently proposed to lower the annual NAAQS for PM_{2.5} from the current level of 15 μg/m³ to 12-13 μg/m³

(<http://www.epa.gov/pm/actions.html>). The PM2.5 regulations established since 1997 have had multi-billion dollar economic impacts in the United States and California and have been highly contested (<http://science.house.gov/press-release/harris-and-brown-question-administration%E2%80%99s-environmental-cost-benefit-analyses>).

PM2.5 epidemiology has also been used by the California Air Resources Board (CARB) to establish the draconian Truck and Bus Regulation to reduce PM emissions from diesel vehicles in California (<http://www.arb.ca.gov/msprog/onrdiesel/onrdiesel.htm>). During the past five years, I have challenged the scientific and public health justifications for these regulations ([http://www.arb.ca.gov/lists/gmbond2011/2-enstrom letter to coal cornez re suspend carb diesel regs 121311.pdf](http://www.arb.ca.gov/lists/gmbond2011/2-enstrom%20letter%20to%20coal%20cornez%20re%20suspend%20carb%20diesel%20regs%20121311.pdf)).

PM2.5 epidemiology is also being used by the Southern California Air Quality Management District (AQMD) in the development of the 2012 Air Quality Management Plan (AQMP) (<http://www.aqmd.gov/aqmp/2012aqmp/index.htm>). The AQMP proposes aggressive and costly emission control measures in order to reduce existing PM and ozone levels in the South Coast Air Basin (SCAB). This air basin includes about 17 million residents in Orange County and the urban portions of Los Angeles, Riverside, and San Bernardino Counties. The primary goal of the AQMP is to bring the SCAB into compliance with the NAAQS for criteria pollutants, primarily, PM2.5 and ozone.

An elevated relative risk ($RR > 1.00$) in an epidemiologic cohort study, i.e., increase in total (all cause) mortality risk for a $10 \mu\text{g}/\text{m}^3$ increase in PM2.5 level, is interpreted by EPA, CARB, and AQMD as evidence that PM2.5 “causes” “premature deaths.” Because EPA assigns a lifetime monetary value of about \$7-9 million to each “premature death,” the health benefits of preventing these deaths exceed the compliance costs of the regulations that are designed to reduce PM2.5 levels and PM2.5-related “premature deaths.” Without PM2.5-related “premature deaths” the PM2.5 regulations are not justified on a cost-benefit basis.

During the past two decades there has been extensive criticism of PM2.5 epidemiology and its use for regulation of PM by EPA, CARB, and AQMD. Five major reasons for doubting a “causal” relationship between PM2.5 and “premature deaths” are: 1) the relative risk of death due to PM2.5 is small ($RR \sim 1.10$), varies by time and place, and shows no consistent dose-response relationship; 2) confounding variables, including other pollutants, often reduce the PM2.5 effect to zero ($RR \sim 1.00$); 3) the ecological fallacy applies to all PM2.5 epidemiology because PM2.5 measurements made at selected monitoring stations are imputed to individuals living near these stations; 4) the chemical composition of PM2.5 varies greatly across the US; and 5) the major PM2.5 epidemiologic findings that have been used to establish regulations are based on secret data maintained by the American Cancer Society and Harvard University (Krewski 2000), that is not accessible for independent reanalysis.

1.2 Major Lectures on PM2.5 and Mortality in California by Enstrom

The above epidemiologic issues are too complex to fully address in this paper. Additional relevant information can be found in the following major lectures that I have given since 2010, often in conjunction with other experts on this subject:

February 26, 2010 CARB Symposium "Estimating Premature Deaths from Long-term Exposure to PM2.5, with Enstrom talk "Critique of CARB Diesel Science, 1998-2010" (http://www.arb.ca.gov/research/health/pm-mort/pm-mort-ws_02-26-10.htm) (<http://www.arb.ca.gov/research/health/pm-mort/enstrom.pdf>)

November 28, 2011 UCLA Institute of the Environment Enstrom Seminar "Does Fine Particulate Matter Kill Californians? An Epidemiologic and Regulatory Controversy" (<http://www.environment.ucla.edu/calendar/showevent.asp?eventid=667>) and (http://www.arb.ca.gov/lists/gmbond2011/3-ioes_seminar_does_particulate_matter_kill_californians_enstrom_112811.pdf)

April 24, 2012 Dose-Response 2012 Conference Enstrom Lecture "Pseudoscientific Aspects of Fine Particulate Matter Epidemiology, 1993-2012" (http://dose-response.org/conference/2012/pdf/Enstrom_Dose_Response_Fine_Part particulate.pdf)

August 1, 2012 American Statistical Association Joint Statistical Meeting Session "Are Fine Particulates Killing Californians?" with title talk by Enstrom (<http://www.amstat.org/meetings/jsm/2012/onlineprogram/ActivityDetails.cfm?SessionID=207510>) and (<http://www.scientificintegrityinstitute.org/ASA080112.pdf>)

2. PM2.5 and Total Mortality in California

2.1 California-specific Epidemiologic Results Summarized

Table 1 summarizes ten separate analyses of five major California cohorts that have found no relationship between PM2.5 and total mortality. References to these analyses are cited in the table and listed at the end of this paper and additional details are provided at this link (<http://www.scientificintegrityinstitute.org/Enstrom081512.pdf>). Included in Table 1 is an analysis limited to the Los Angeles area (Jerrett 2005). Table 2 summarizes five separate analyses of three of the major California cohorts. These analyses have found no relationship between PM10 and total mortality. There are no statewide cohort analyses that show a positive relationship between PM (PM2.5 and PM10) and total mortality in California. Indeed, three of these analyses (Jerrett 2011, Lipsett 2011, Ostro 2011), funded by CARB and AQMD, found no relationship between any criteria pollutant and total mortality in California.

The first published evidence of no PM2.5 mortality risk in California is contained in the July 2000 Health Effects Institute (HEI) Reanalysis Report (Krewski 2000). Figure 21, a U.S. map of "Fine Particulates and Mortality Risk," indicates no excess mortality risk in California. Figure 5 provides further evidence of the geographic variation in PM2.5 mortality risk, with Fresno (city #3) ranking second lowest in risk among 49 cities and Los Angeles (city #39) ranking fifth lowest in risk (<http://www.scientificintegrityinstitute.org/HEIFigure5093010.pdf>). Figure 1 below reproduces Figure 21 and Figure 5 with a city number assigned to each data point. The null California PM2.5 mortality risk findings in Figure 21 were confirmed in the August 31, 2010 letter from Krewski to HEI (Krewski 2010).

2.2 Misrepresentation of PM2.5 and Mortality in California by CARB

My December 15, 2005 *Inhalation Toxicology* paper, "Fine Particulate Air Pollution and Total Mortality Among Elderly Californians, 1973–2002" (Enstrom 2005), found no relationship between PM2.5 and mortality in California during 1983-2002. This is the first, largest, and most detailed peer reviewed journal publication that focuses on the relationship between PM2.5 and total mortality in California. Enstrom 2005 appeared just after the November 2005 *Epidemiology* paper "Spatial Analysis of Air Pollution and Mortality in Los Angeles" (Jerrett 2005), which found an unusually large relative risk between PM2.5 and mortality in the Los Angeles basin during 1982-2000. The finding is in direct contrast to the low absolute PM2.5 mortality risk for Los Angeles found in Figure 21. These conflicting findings need to be resolved with further analysis.

Enstrom 2005 was submitted to CARB health effects scientist Linda Smith on January 9, 2006 (http://www.arb.ca.gov/planning/gmerp/declplan/gmerp_comments/enstrom.pdf). The March 23, 2006 CARB meeting PPT presentation "Stronger Relationship Between Particulate Matter (PM) and Premature Death" gave extensive details on Jerrett 2005 and cited several other positive national studies, including Krewski 2000, Pope 2002, and Laden 2006 (<http://www.arb.ca.gov/research/health/healthup/march06.pdf>). However, it made no mention of Enstrom 2005, which was published one month after Jerrett 2005 and one month before a major Harvard Six Cities Study analysis (Laden 2006) appeared online. On August 21, 2006 CARB scientists Richard Bode, Linda Smith, and Hien T. Tran conducted a "Public Workshop on Updating the Methodology for Estimating Premature Death Associated with PM2.5 Exposures" and gave a PPT presentation (<http://www.arb.ca.gov/research/health/pm-mort/ws-slides.pdf>). The PPT presentation for this Workshop specifically shows Jerrett 2005 and Laden 2006, but not Enstrom 2005, as "New studies emerged since 2002." These PPT presentations show a pattern of omission of null findings like Enstrom 2005.

Additional misrepresentation of PM2.5 mortality risk in California was contained in the Draft and Final versions of the 2008 CARB Staff Report by Hien T. Tran "Methodology for Estimating Premature Deaths Associated with Long-term Exposure to Fine Airborne Particulate Matter in California." The October 24, 2008 Final Report states that PM2.5 contributes to 18,000 annual premature deaths in California, with 3,500 of these deaths due to diesel PM. These estimates of premature deaths provided the primary public health justification for new on-road diesel vehicle regulations approved and implemented by CARB. However, the premature death claims in this report are now entirely contradicted by the null findings presented in Table 1. My December 10, 2008 CARB comments exposed major flaws in this report (http://www.arb.ca.gov/lists/truckbus08/897-carb_enstrom_comments_on_statewide_truck_regulations_121008.pdf). The CARB misrepresentations of PM2.5 mortality risk in California continue up to the present, as explained in my talks and submissions cited above.

2.3 Failure to Properly Review Particulate Matter Health Impacts by AQMD

As an essential part of its currently ongoing preparation of the 2012 AQMP, the AQMD is required to address the health effects of air pollution in the SCAB. Indeed, California Health and Safety Code (CHSC) Section 40471 (b) specifically states "On or before December 31, 2001, and every three years thereafter, as part of the preparation of the air quality management plan revisions, the south coast district board, in conjunction with a public health organization or agency, shall prepare a report on the health impacts of

particulate matter air pollution in the South Coast Air Basin. The south coast district board shall submit its report to the advisory council appointed pursuant to Section 40428 for review and comment. The advisory council shall undertake peer review concerning the report prior to its finalization and public release. The south coast district board shall hold public hearings concerning the report and the peer review, and shall append to the report any additional material or information that results from the peer review and public hearings.” (<http://www.leginfo.ca.gov/cgi-bin/displaycode?section=hsc&group=40001-41000&file=40460-40471>).

However, based on available information, AQMD has never prepared a “report on the health impacts of particulate matter air pollution in the South Coast Air Basin” at the end of 2001, 2004, 2007, or 2010. The only “health impacts” reports are Appendix I “Health Effects” of the 2003 AQMP, 2007 AQMP, and Draft 2012 AQMP. However these reports do not specifically address PM health impacts in the SCAB. Indeed, the 2003 AQMP Appendix I states “The purpose of this appendix is to provide an overview of air pollution health effects, rather than to provide estimates of health risk from current ambient levels of pollutants in specific areas of the SCAB.” (http://www.aqmd.gov/aqmp/docs/2003AQMP_AppI.pdf).

Failure to comply with CHSC Section 40471 (b) is a serious matter because the local health effects of PM provide the primary public health justification for the entire AQMP. As shown in Tables 1 and 2, there is now overwhelming epidemiologic evidence that there is NO relationship in California between PM and total mortality (also known as “premature deaths”). However, the 2003 AQMP Appendix I (https://aqmd.gov/aqmp/docs/2003AQMP_AppI.pdf, page I-14), 2007 AQMP Appendix I (https://aqmd.gov/aqmp/07aqmp/aqmp/Appendix_I.pdf, page I-14), 2012 Draft AQMP Appendix I (<http://www.aqmd.gov/aqmp/2012aqmp/draft/Appendices/AppxI.pdf>, page I-18), and 2012 Revised Draft AQMP Appendix I (<http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/AppI.pdf>, page I-19) all make incorrect statements regarding the evidence in California and the SCAB.

All four Health Effects appendices have been authored by AQMD Health Effects Officer Jean Ospital (http://www.aqmd.gov/bios/ms_ospital_jean.html). These documents come to exactly the same conclusion regarding PM mortality risk: “Despite data gaps, the extensive body of epidemiological studies has both qualitative and quantitative consistency suggestive of causality. A considerable body of evidence from these studies suggests that ambient particulate matter, alone or in combination with other coexisting pollutants, is associated with significant increases in mortality and morbidity in a community. In summary, the scientific literature indicates that an increased risk of mortality and morbidity is associated with particulate matter at ambient levels. The evidence for particulate matter effects is mostly derived from population studies with supportive evidence from clinical and animal studies.”

The null PM_{2.5} - mortality relationship in California has been known since 2000, but the specific null evidence is only partially presented in the Draft 2012 AQMP and was entirely omitted from the earlier AQMPs. For instance, each AQMP Appendix I cites Krewski 2000. However, only the nationwide PM_{2.5} mortality risk results in this report are cited, not the California-specific results in Figure 21. The 2007 AQMP Appendix review cites Jerrett 2005, Laden 2006, and the Pope 2006 review, which contains two references to Enstrom 2005, but Enstrom 2005 itself is not mentioned. Enstrom 2005 is mentioned briefly in the Draft 2012 Appendix I, but not assigned any major significance.

The overwhelmingly null evidence in Figures 1 and 2 is not fully or properly described in either the Draft or Revised Draft 2012 Appendix I. I pointed out major deficiencies in my April 21, 2011 CARB comments (http://www.arb.ca.gov/lists/sip2011/3-carb_enstrom_comments_on_sip_for_pm2.5_042711.pdf). Since August 2008 I have also had repeated direct communications with Ospital, including an April 4, 2012 email message requesting that null evidence be included in the 2012 AQMP Appendix I (<http://www.scientificintegrityinstitute.org/Ospital040412.pdf>).

The health impacts of PM in the SCAB are still not addressed in the September 7, 2012 Revised 2012 Draft AQMP Appendix I (<http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/AppI.pdf>). Furthermore, this version makes an incorrect assessment of the California-specific evidence by uncritically relying on the June 2012 US EPA Regulatory Impact Analysis (RIA) (US EPA 2012). The RIA looked at California-specific studies regarding PM_{2.5} and mortality published in the scientific literature. Appendix I states "The EPA analysis concluded 'most of the cohort studies conducted in California report central effect estimates similar to the (nation-wide) all-cause mortality risk estimate we applied from Krewski et al. (2009) and Laden et al. (2006) albeit with wider confidence intervals. A couple cohort studies conducted in California indicate higher risks than the risk estimates we applied.' Thus in EPA's judgment the California related studies provided estimates of mortality consistent with or higher than those from the national studies."

However, there are clear errors in virtually every California-specific RR in EPA RIA Table 5.B-10. The McDonnell 2000 ratio, RR (males) = 1.09 (0.98–1.24), should be RR (both sexes) ~ 1.00 (0.95–1.05), based on inclusion of an approximated RR for females. The partially adjusted Jerrett 2005 ratio, RR = 1.15 (1.03–1.29), should be the fully adjusted value, RR = 1.11 (0.99–1.25). The Enstrom 2005 ratio for 1973-1982, RR = 1.04 (1.01–1.07), should be the ratio for the entire follow-up period (1973-2002), RR = 1.01 (0.99–1.03). The Krewski 2009 ratio, RR = 1.42 (1.26–1.27), is obviously invalid and should be replaced by the Krewski 2010 ratio, RR = 0.968 (0.916–1.022), which is the ratio for all California subjects in Krewski 2009. The implausibly high Ostro 2010 ratio, RR = 1.84 (1.66–2.05), is invalid and has been replaced by the new Ostro 2011 ratio, RR = 1.06 (0.96–1.16). The corrected ratios are all consistent with RR = 1.00 and DO NOT support the EPA RIA claim that California-specific results are consistent with national results. Ospital uncritically accepted the EPA RIA and did not mention a single one of the EPA errors cited above.

The July 11, 2012 AQMP Advisory Council meeting did not result in proper peer review of Draft 2012 Appendix I. The three Advisory Council members with the most expertise on PM mortality studies and PM health effects epidemiology are John R. Froines, Ph.D., Samuel Soret, Ph.D., and Rob S. McConnell, M.D. They have not done peer review of Appendix I regarding "the health impacts of particulate matter air pollution in the South Coast Air Basin," as specified in CHSC Section 40471 (b). Also, there is evidence that they are not objective peer reviewers regarding PM health effects.

UCLA Professor John R. Froines has engaged in inappropriate activism regarding PM science based on the information contained in the following documents:

- 1) June 30, 2009 letter and attachments from Norman R. Brown to UCLA officials (http://www.calcontrk.org/CARBdocs/Delta_UCLA_Letter_063009.pdf);
- 2) February 20, 2011 Bakersfield Californian column by Lois Henry

(<http://www.bakersfieldcalifornian.com/columnists/lois-henry/x1902890284/Politics-air-rules-make-for-a-smelly-situation>), and 3) April 15, 2012 Bakersfield Californian column by Lois Henry (<http://www.bakersfieldcalifornian.com/health/x1322083219/The-ex-radical-who-heads-air-boards-key-panel>).

Loma Linda University (LLU) Professor Samuel Soret has not responded to my August 23, 2012 and September 14, 2012 email messages regarding his peer review of the AQMP Appendix I (<http://www.scientificintegrityinstitute.org/Soret091412.pdf>). His July 11, 2012 email message to AQMD did not mention the highly relevant December 2010 paper that he co-authored and apparently submitted to *Epidemiology* "The Mortality & Long-Term Exposure to AP in Elderly CA Adventists" (Chen 2010). Also, he has not properly described the overwhelmingly null relationship between PM and total mortality in the 35-year LLU Adventist Health Study of Air Pollution (AHSMOG) project (<http://www.llu.edu/public-health/health/ahsmog.page>).

USC Professor Rob S. McConnell has not responded to my August 25, 2012 and September 17, 2012 email messages regarding his incomplete July 9, 2012 peer review of AQMP Appendix I, which did not discuss PM in the SCAB (<http://www.scientificintegrityinstitute.org/McConnell091712.pdf>).

I submitted comments to AQMD regarding AQMP Appendix I on August 30, 2012 (<http://www.scientificintegrityinstitute.org/AQMP083012.pdf>) and on September 20, 2012 (<http://www.scientificintegrityinstitute.org/AQMP092012.pdf>).

These comments emphasize the need for AQMD to comply with all provisions of CHSC Section 40471 (b) before finalizing the 2012 AQMP. It is particularly important that the AQMD Governing Board conduct a hearing on the health impacts of PM in the SCAB. This hearing will allow scientists with diverse views to directly present evidence to the Board Members. This hearing could have a profound impact on the emission control measures that are approved in the 2012 AQMP.

Conclusions

There is now overwhelming epidemiologic evidence that PM (PM_{2.5} and PM₁₀) is not killing Californians. This evidence must be fully examined and recognized by EPA, CARB, and AQMD before there are any further regulations to reduce PM levels in California, particularly in the SCAB. In addition, there needs to be a full reassessment of the current PM regulations to be sure that they are based on the actual health effects evidence in California. AQMD should not be required to comply with NAAQS that are not appropriate for California or the SCAB. Instead, AQMD should request a waiver from compliance with the NAAQS using the special waiver status granted to California in Section 209 of the Clean Air Act (<http://www.epa.gov/otaq/cafr.htm>). Finally, PM health effects and regulations must be put into perspective with other factors that influence health in California. Keep in mind the findings in Figure 2, which show that, based on the 2009 age-adjusted total death rate by state, California had the third lowest rate. Furthermore, the SCAB had a total death rate that was lower than the rate for every state except Hawaii (<http://www.scientificintegrityinstitute.org/NCHSRR070811.pdf>).

Table 1. Epidemiologic Cohort Studies of PM_{2.5} and Total Mortality in California

Driven Away * USA - Ports' clean air program shuts down some truckers.

Randy Thomas Trucking is preparing to close his business, he's unable to purchase new trucks to comply with port regulations taking effect in January

Reprinted from October 12, 2009 Los Angeles Business Journal article by FRANCISCO VARA-ORTA

<http://labusinessjournal.com/accounts/login/?next=/news/2009/oct/12/driven-away/>

<http://los-angeles-business-journal.vlex.com/vid/driven-ports-clean-air-shuts-truckers-69119761>

Randy Thomas has spent the last four decades proudly running his South Los Angeles trucking firm, which services the ports of Los Angeles and Long Beach... As the ports ballooned to become the largest trade complex in the country, Thomas' business grew from one truck he drove to a thriving little firm with 15 drivers. He put his three children through college – the first generation in his family to go. He was starting to look forward to retiring. He planned to leave his business to his family... Instead, the 60-year-old owner of Randy Thomas Trucking is preparing to close his business about Christmas. The reason: He's unable to purchase new trucks to comply with port regulations taking effect in January... In all, about 900 trucking companies shuttle cargo containers in and out of the two ports. Hundreds of them, like Thomas' company, are in danger of slipping out of existence in the next few months. Following them are thousands of truckers who own their own rigs and contract with small companies like Thomas'... The recession-driven downturn in trade has pushed them to the precipice, but many believe what's shoving them over the edge is the Clean Trucks Program, which falls hardest on small operators... The program seeks to eliminate old polluting trucks from the ports. The program in October 2008 banned trucks made before 1989. But on Jan. 1, a more stringent ban extends to all trucks made before 1994 and those that have an engine made before 2004... It's unclear how many trucks will be sidelined as a result, but the number is a big one. The ports earlier estimated that as many as 12,000 trucks would fall into that criteria, but last week the L.A. port estimated 4,000 to 6,000 trucks would be banned Jan. 1... A new diesel truck costs about \$100,000, while retrofitting a truck with a new engine costs about \$10,000 to \$15,000. Many small trucking firms, already scraping by on low margins, paying off existing trucks and whacked by the downturn in business at the ports, say it's not worth it to load up on debt to stay in the industry... (End of Road: Randy Thomas will cut the ignition on his trucking firm in December)

October 11, 2012

Peer Review is an indispensable component of reliable science. Indeed the Rules governing the SCAQMD Air Quality Reports recognize that science without proper Peer Review is second-rate at best, and not a valid basis for important policy decisions.

However, in preparing its required 2012 Report on the Health Effects of particulate matter (PM) air pollution in the Southern Coast Air Basin, SCAQMD reveals a fundamental misunderstanding of the nature of a Peer Review. Every branch of science relies on *impartial* critiques of all its results, before they can be accepted. Scientific Peer Review is therefore the *opposite* of "Self-Review". It must be done by scientific peers who are clearly *independent* of the authors of all the work under consideration. In fact it is essential that some, or most, of the reviewers (or 'Referees' as they are typically called) be selected specifically for their rivalry, disagreements, or competition with the authors. This is necessary because in the marketplace of scientific ideas there is always more than one point of view, a fact which is very dangerous to forget. The essence of scientific Peer Review is a thorough search for all possible problems or limitations with the research being reviewed. It is precisely the job of a Peer Reviewer to attempt to pick apart every aspect of the work, which will result in its revision and improvement. Reliable science is completely dependent on this correction mechanism. A scientific research report can only be accepted after it has weathered all available criticisms.

Unfortunately, all of the "Reviews" that have been obtained for Appendix I, particularly on the long-term Health Effects of PM_{2.5}, are either "Self-Reviews"--by authors and co-authors of the studies used by Appendix I (more accurately called 'editing')--or "Friends Reviews" (ie, by close colleagues and collaborators, known to share the same views as those authors). Self-Reviews may be of some use to 'clean up' a report, so long as it is clearly understood that they are *in no way a substitute* for actual Peer Review. Fortunately there is no shortage of fully qualified Peer Reviewers who are unambiguously independent of the views advanced in Appendix I. Proper scientific Peer Review, and the rules in 40471(b) which mandate it, now require input from this large, hitherto excluded, group of health scientists.

Supplemental submission on the AQMP

Members of the Board of South Coast Air Management District,

I write to supplement my previous submission showing that there is no reliable evidence that human health effects in California and specifically in the South Coast District justify the proposed Management Plan.

I must reemphasize that I also believe that the South Coast District is not in compliance with the CA statutes that require a review of human health effects science on a regular basis and particularly when a new Management Plan is promulgated.

It is my understanding that before the Draft 2012 AQMP is finalized and approved, AQMD must hold a public hearing on the health impacts of air pollution in the SCAB, in accordance with CHSC Section 40471 (b).

If the hearing is held, in compliance with statute, I am convinced that the policy makers and board will find overwhelming the lack of evidence to justify any proposed plan, particularly the aggressive plan as proposed by AQMD staff.

The AQMP should not propose emission control measures necessary to comply with NAAQS that are not appropriate for California or the SCAB. Instead, AQMD should request a waiver from compliance with the NAAQS using the special waiver status granted to California in Section 209 of the Clean Air Act (<http://www.epa.gov/otaq/cafr.htm>).

To reiterate, and reemphasize, in January of 2007, the Air Resources Board and AQMD approved funding for two studies on the human health effects relationship to particle air pollution and the studies by Lipsett, and by Jarrett and others showed no human health effect, no association or relationship between PM and total mortality in California. The Jarrett Study found that total mortality during 1982-2000 among about 75,000 California adults was not related to either PM10 or PM2.5 in eight of nine models tested. He tortured the data to get one model to show an association, the model he called the conurbation model, which was nothing more than slicing the geographical pieces to find a small increase in deaths associated with Air Pollution. I have made fun of such nonsense and data dredging in my first submission. The Lipsett Study found that total mortality during 2000-2005 among about 75,000 female

California teachers was not related to either PM10 or PM2.5. The studies found some unexplained evidence of increased cardiovascular disease risk and decreased cancer risk, but there was no overall increased risk of death but in these studies there is no effort made to avoid the problem of noise in the small ranges of association. However that is the problem with epidemiology funded by government—the researchers know there will be no funds in the

future for a study that fails to find what the government entity wants to justify a new regulatory regime.

These null results by Lipsett and Jarrett agree with the overwhelmingly null results for California that have been published since 2000, which include the study by Enstrom on 50,000 Californians. They also are coherent with the Krewski map mentioned before that shows a null California association of deaths and small particle pollution.

Thus, based on all the evidence described in my first submission and in this supplemental submission, I assert there is no health risk associated with PM in the South Coast regions, including the Coachella Valley. There is no evidence of death association in California as a whole and there will be no health risk from PM that would justify concern about the Sentinal power plant.

I urge that the AQMD Board and Staff review carefully review the evidence and consider the negative economic effects from draconian air management regulatory proposals. It is time to focus on the welfare of the public and the California economy is critical to people's well-being.

No human health effects research would justify more damage to the economy of the South Coast region or California as a whole.

Cordially,

News at HSPH

Prevailing Winds

A decades-long fight to bring clean air standards in line with environmental health science offers lessons for today.

Doug Dockery

On a raw January day in Washington, DC, [Douglas Dockery](#) climbed Capitol Hill on his way to testify to Congress about the Harvard School of Public Health study he'd been running. He would have preferred to be anywhere else. It jarred Dockery—today, chair of the [Department of Environmental Health](#)—to confront people wearing white lab coats, holding signs that read, “Harvard, release the data!” Employed by an industry-backed group called Citizens for a Sound Economy, the protesters pressed on passersby fliers claiming that Harvard was hiding “secret” data. Their message was aimed directly at Dockery.

The year was 1997, and Dockery had arrived in Washington to tell Congress that because it had promised study participants confidentiality, Harvard couldn't share the raw data from its federally funded Six Cities study. The landmark research—one of the single most influential public health studies ever conducted—examined over 14 to 16 years the health effects of air pollution on more than 8,000 adults and 14,000 children in six U.S. cities. During that time, HSPH scientists published more than 100 peer-reviewed papers detailing their findings.

The blockbuster paper came in 1993, when Dockery's team described what he now calls amazing results. Residents of Steubenville, Ohio—the city with the dirtiest air—were 26 percent more likely to die prematurely than were citizens of Portage, Wisconsin, the city with the cleanest air. The primary culprit: fine particulates, up to hundreds of times narrower than a human hair, which were associated with increased incidence of lung cancer and cardiopulmonary disease. “The effects of air pollution were about two years' reduction in life expectancy,” Dockery says. “It was much, much higher than we had expected.” To Dockery and his colleagues, the results were conclusive evidence that soot produced by fossil fuel combustion kills.

That evidence was also enough for the U.S. Environmental Protection Agency (EPA), which in 1997 used the science, along with many other studies, as the foundation for the first-ever Clean Air Act regulations on particulate matter smaller than 2.5 microns in diameter. The EPA claimed the new PM2.5 rules would prevent 15,000 premature deaths annually and produce other huge benefits, among them preventing 250,000 incidences of aggravated asthma, 60,000 cases of bronchitis, and 9,000 hospital admissions every year.

But meeting the new standards would be far from simple or cheap. Manufacturing, power, steel, auto and other industries spent untold millions trying to disprove the science, discredit the EPA, and defeat the new regulations. The New York Times dubbed the clash “the environmental fight of the decade.” It embroiled the Six Cities study in a years-long controversy—one that holds lessons for public health professionals

working on issues critical in this year's election cycle, from new Clean Air Act rules and oil drilling to natural gas fracking and the ubiquitous pesticides and chemicals in our food, homes, and bodies.

A Deadly Cloud

Why Six Cities Matters Today

The clash between industry, politics, and science over the Six Cities study remains relevant today. Consider just a small sampling of contemporary public health controversies:

Global Warming:

A U.S. federal appeals court in June agreed with the EPA that auto and power plant emissions endanger the public health. Opponents had filed more than 60 lawsuits to block the EPA from regulating greenhouse gas emissions. As Matthew Wald of *The New York Times* wrote, "The judges unanimously dismissed arguments from industry that the science of global warming was not well supported and that the agency had based its judgment on unreliable studies."

Natural Gas Fracking:

Public health studies show the hydrofracturing, or fracking, process of drilling fouls the air and water and may contribute to earthquakes. Industry advocates question the certainty of that science and say the country needs cheap, "clean" fuel.

Mining and Cancer:

The Mining Awareness Resource Group, a mining-industry-funded organization, spent years going to the courts and to Congress for assistance in accessing data from, and delaying publication of, a study showing that miners exposed to diesel exhaust underground were at high risk of developing lung cancer. Twenty years after the study was launched, the Journal of the National Cancer Institute finally published the results.

Ever since a toxic black cloud dubbed the "Great Smog"—made up primarily of coal-burning emissions and diesel exhaust—hovered over London in 1952 and killed more than 4,000 people within days, environmental scientists had worried about the mysterious ingredients composing industrial haze. In the U.S., that concern intensified in 1973 following the Arab oil embargo, when power plants were expected to substitute cheap, high-sulfur coal for expensive oil. What could the nasty emissions from dirtier fuel do to people?

HSPH's Ben Ferris, a legendary public health professor who died in 1996, and Frank Speizer, professor of environmental science, proposed to find out: They would sample the air quality in six Eastern cities with varying degrees of pollution while simultaneously monitoring the health of thousands of those cities' residents. Among their team were the wiry, intense Jack Spengler, now the Akira Yamaguchi Professor of Environmental Health and Human Habitation, who built personal air quality monitoring equipment that participants wore; and the tall, reserved Dockery, who traveled from city to city, setting up air pollution monitors in residents' homes. Jim Ware, professor of biostatistics, joined the team in 1979. Later, Joel Schwartz, professor of environmental epidemiology, would join the team and become one of its most prolific authors.

Their goal was simple: to identify links between illness and death rates and air pollution levels. They sampled the air for toxic emissions, including sulfur dioxide and particulate matter, a brew of acids, metals, petroleum byproducts, diesel soot, and other potentially harmful substances that readily deposit deep in the lungs.

In the mid-1970s, no one had yet conducted a comprehensive study of particulates' effects on human health. Dockery and his colleagues expected to learn that the true threat of industrial haze would stem from sulfur dioxide. But it was the fine particles that were the biggest dangers (although the study did not show how these particles created illness, a missing link critics would highlight). Another surprise: indoor air pollution was more harmful than outdoor toxins, setting the stage for years of important research.

Today, because of Six Cities, it is conventional wisdom that particulate matter contributes significantly to a wide variety of illnesses across the spectrum of life, from asthma and bronchitis to sudden infant death syndrome and lung cancer.

Industry Responds

Public health considerations aside, the new standards forced dramatic changes on industry. The *New York Times* reported that old Midwestern power plants would have to install expensive pollution control equipment; states would need to invest in mass transit and other initiatives designed to reduce auto pollution; and factories that burned mountains of coal would have to switch to cleaner-burning fuels. How much those changes would cost depended upon who was doing the estimating: industry spokesmen said the bill would reach into the hundreds of billions of dollars. The EPA put the final tab at \$6 to \$8 billion. As the debate grew more contentious, many experts—including Philip H. Abelson, former editor of *Science* magazine—pushed the EPA to delay regulations until the science was more certain. Abelson maintained that the makeup of particulate matter differed greatly from place to place. In an editorial, he queried, “How can the EPA minimize the effects of particulates if it does not know what they are or which, if any, have deleterious physiological effects?”

Others, like fellow HSPH faculty member John D. Graham, professor of policy and decision sciences at HSPH, were also critical of the EPA, arguing that the Clean Air Act's legal framework for rule making does not allow the agency to consider costs, just health outcomes. Graham had pioneered the study of risk analysis at HSPH, having founded and, from 1990 to 2001, directed the [Harvard Center for Risk Analysis](#). From 2001 to 2006, he led the White House's Office of Information and Regulatory Affairs, making him what the Natural Resources Defense Council called “the second most powerful environmental official in the nation after George W. Bush.” Today, he serves as Dean of Indiana University's School of Public and Environmental Affairs.

Over the years, Graham testified at many congressional hearings that there should be an opportunity for cost/benefit analysis during EPA rule making. “One of my key arguments is that practical people are going to do it anyway,” he says. “We shouldn't make them do it behind closed doors. That's not good, because their arguments are then not open to public scrutiny.”

The Battle Lines Harden

James Ware

Citizens for a Sound Economy blanketed the country with ads designed to influence public opinion. The group, which the Washington Post called the “pro-industry alliance at the center of an extraordinary, multimillion-dollar campaign to turn back EPA regulations for smog and soot,” attracted grassroots supporters by contending the new rules would force bans on such American icons as backyard barbecues, farm tractors, and wood stoves.

In addition, critics from industry, members of Congress, and some governors demanded that Harvard release the raw data. “We declined,” says [James H. Ware](#), then HSPH acting dean and now Frederick Mosteller Professor of Biostatistics. The team had promised participants that their personal data would never be released. When Harvard refused, critics accused the researchers of conspiracy and pressured Congress to hold hearings. “The issue is the quality of the science,” said National Association of Manufacturers spokesman Richard Siebert. “In order for people to ascertain the science they need to understand the background data ... What are they hiding?”

“It was a painful time,” says Dockery. “You’d get up in the morning and look in the paper and there you’d be again.”

Still, the scientists held their ground. “We knew that if we released the data, it would be endless aggravation and defending against attacks,” says Ware. “To have a hostile group combing through your data looking for anything to attack you about was not something any of us relished.” Furthermore, [Frank Speizer](#) told Dockery, to release the raw data would be to allow “biased groups” to manipulate it and to set a precedent that “will undermine future research by academic institutions.”

EPA under siege

"Uncertain Science" Claim

When public health and industry collide, foes of regulation often claim that epidemiology is an uncertain science, says Sheila Jasanoff, Pforzheimer Professor of Science and Technology Studies at Harvard Kennedy School of Government. “The most favored method is to ‘deconstruct’ agency scientific claims, on grounds of methodological inadequacy,” she says. “The problem is that public health research often operates in zones of ignorance and uncertainty; it is relatively easy to find, or at least claim to find, ‘problems in the science.’”

The inherent uncertainty of emerging science leads to fiery rhetoric on both sides—which is unfortunate, Jasanoff adds. “The constant debates about ‘good science’ and repeated charges of overregulation undermine trust in government and hinder a mature understanding of how to live prudently in complex industrial societies that will never be risk-free and where full scientific certainty on many issues will likely take very long to achieve.”

Even today, the Six Cities debates linger. John Graham applauded HSPH’s decision to give its data to the nonpartisan organization Health Effects Institute for analysis. But 15 years later, he remains frustrated that Harvard didn’t share the original data earlier. “These findings are still utilized around the world,” Graham says. “They sit as a foundation for multibillion-dollar decisions in China, Brazil, and elsewhere. I would still like to see the data be made publicly available. It’s the basic principle of transparency in science.”

But the EPA, too, was under siege—from lobbyists and from Congress, which demanded the agency produce so-called “secret data” on which the new rules rested. In February 1997, EPA bowed to the pressure and urged Harvard to do so. As a compromise, the team came up with the idea of asking an independent scientific panel to audit the researchers’ findings. They gave a warehouse full of data to the Cambridge, Massachusetts-based Health Effects Institute (HEI), which was funded by both the automotive industry and the EPA.

It took HEI three years to reanalyze the data—an agonizing period of limbo for the scientists. But it was worth the wait. In 2000, HEI scientists confirmed the original Six Cities findings. It was a huge win for the School.

In 1997, while HEI was auditing the data, President Bill Clinton approved the new Clean Air Act’s PM2.5 regulations and tightened ozone standards. In 1999, Alabama Republican Senator Richard Shelby, still simmering about Harvard’s “hidden” data, inserted a single sentence into a 4,000-page budget bill that would change everything for future researchers. The still-controversial Shelby Amendment calls for those university scientists working on federally funded projects to share their data with anyone who requests it via the Freedom of Information Act.

When the issue of sharing primary data first arose, critics like HSPH’s Frank Speizer feared such a rule would dampen future research by dissuading potential participants whose confidentiality could no longer be protected. Today, the issue is so fraught that, even within HSPH, scientists find themselves on opposing sides. Doug Dockery calls the Shelby Amendment “a direct assault on research conducted by universities,” because privately funded studies aren’t subject to the same rules. In contrast, Jim Ware says, “As a matter of principle, the Shelby Amendment is right: When the federal government pays for research ... that research ought to be made available for scrutiny by others and for debate and examination.”

The Long View

Today, Dockery looks out his 13th-floor window across the Charles River at the Cambridge skyline, a view that, decades earlier, had often been obscured by urban haze. “I can see a long way,” he says. “That’s gratifying.”

Over the last 30 years, air quality nationwide has improved dramatically, due to Clean Air Act rules based in part on Six Cities research. In 2009, Dockery and colleagues Arden Pope (now at Brigham Young University) and Majid Ezzati (now at Imperial College London) demonstrated that from 1980 to 2000, reductions in exposure to fine particulate matter had increased average American life spans by 1.6 years. “That’s huge,” Dockery says. “If you got rid of all cancers, the net effect on average life expectancy would be two years.”

The Clean Air Act and the policies triggered by HSPH’s Six Cities study are classic examples of how public health should work: good science shapes public policy, and policy, in turn, saves people’s lives.

A Steel Backbone

Jack Spengler

On a crowded shelf in his office, Dockery keeps two six-inch-thick binders of correspondence and media clippings from the Six Cities fight. Buried in them are memories—many painful—but also lessons for today’s public health professionals.

For Dockery, two stand out. First, “Solid, quality science does stand up over time.” Second: “How you present the information—how you translate the data—is extremely important.”

He believes the PM2.5 standards survived because, for the first time, the science made it possible to calculate the costs and finger the sources of air-pollution-related disease.

“We provided the basis for quantifying how many hospital visits, how many asthma attacks, how many COPD [chronic obstructive pulmonary disease] cases, how many heart attacks, and how many deaths were associated with these air pollutants,” he says. “It completely changed the discussion. When you actually

used those numbers, suddenly the cost/benefit analysis became very clear—and suddenly, the benefits were found to far outweigh the cost of controls.”

Years later, Office of Management and Budget (OMB) analysis confirmed Dockery’s claims: in a 2011 report, the OMB stated, “Of [EPA’s] 20 air rules, the rule with the highest estimated benefits is the Clean Air Fine Particle Implementation Rule, with benefits estimated at a minimum of \$19 billion per year. While the benefits of this rule far exceed the costs, the cost estimate for the Clean Air Fine Particle Implementation Rule is also the highest at \$7.3 billion per year.”

Although not everyone agrees with OMB’s assessment or even with the legitimacy of assigning a price tag to health outcomes (what is the monetary value of a human life saved?), many believe such data are more important than ever. The industry lobby has gained strength in the 15 years since the Six Cities brouhaha. In 2011, a hearing before the Republican-led House of Representatives subcommittee on new Clean Air Act rules was entitled, “Lights Out: How EPA Regulations Threaten Affordable Power and Job Creation.”

Challenges in Today’s Politics

The Debate Goes On

The controversy over standards for fine particulate matter air pollution continues today. In June 2012, a federal court order forced the EPA to propose new, tighter standards; the agency settled on reducing the allowed annual level from 15 micrograms per cubic meter to a range between 13 and 12.

But a 2011 report by the American Lung Association, Clean Air Task Force, and Earthjustice claims that this reduction doesn’t go far enough. Their analysis, which cites Six Cities findings, argues that at those levels, a maximum of 15,000 premature deaths would be averted annually. The coalition argues that the EPA should adopt a more stringent annual limit of 11 micrograms per cubic meter, which its analysis shows would prevent nearly 36,000 premature deaths yearly.

The EPA is expected to issue final standards in December 2012.

Seen through a 2012 lens, it may be surprising that the Six Cities imbroglio wasn’t a strictly partisan fight. Unlike today, earlier environmental battles didn’t erupt along party lines. It was President Richard Nixon who established the EPA in 1970, setting the stage for a string of Republican environmental accomplishments, including the first major reauthorization of the Clean Air Act in 1990 under George H. W. Bush. “When you look at the record,” says Dockery, “the Republican administrations have been better for environmental controls than the Democratic administrations.”

Dockery believes today’s political environment is actually far more difficult for science than it was in 1997. “Before, there was the cry that we wanted the best science for defining the regulation,” he says. Now, he adds, referring to debates like those over global warming and certain childhood vaccinations, “What we’re seeing is a total rejection of science as the basis for making regulatory decisions.”

HSPH’s [John Spengler](#) has become convinced that scientists studying today’s environmental problems need both new communication skills and a steel backbone. “You really have to know you’ve got the personality to do this,” he says. “If you choose a public health career and you believe in it, and if you have an urgent public health message that needs to be delivered, this is part of the territory.”

To Spengler, that means public health educators have a new job to do: teaching scientists how to lead and how to deliver their messages to policymakers. “We teach people to be statisticians, epidemiologists, lab analysts, exposure scientists,” he says. “But we must also equip them for the big fights.”

Elaine Appleton Grant is assistant director of development communications and marketing at HSPH and a former public radio reporter.

2012aqmpcomments@aqmd.gov

Dear Board Members:

I am writing to convey my emphatic support a 2012 Air Quality Management Plan (AQMP) Appendix I Health Effects that focuses on “the health impacts of particulate matter air pollution in the South Coast Air Basin,” in accord with California Health and Safety Code Section 40471(b). In addition, I urge you to hold a Board hearing on the health impacts report and its peer review, in accord with this Code Section.

In particular, please address the September 25 public comments of Jonathan M. Samet, M.D., and the August 30 and September 20 public comments of James E. Enstrom, Ph.D. I have been a cancer epidemiologist for over 30 years, and I have been aware of the important research of these outstanding epidemiologists during this entire period. In addition, I have personally worked with Dr. Enstrom on environmental epidemiology issues. You need to take their criticism of Appendix I very seriously.

My own examination of the PM_{2.5} epidemiologic findings of Dr. Samet, Dr. Enstrom, and two dozen other highly qualified scientists, convincingly shows that there is no relationship between PM_{2.5} and total mortality in California and that the current US EPA National Ambient Air Quality Standard (NAAQS) for PM_{2.5} is not applicable to California or the South Coast Air Basin (SCAB). Therefore, the AQMP should request a waiver from this NAAQS, rather than proposing stricter emission controls.

In conclusion, the final 2012 AQMP must be based on the actual health impacts of particulate matter in the SCAB. Otherwise, I believe that it can be vigorously challenged on scientific, economic, and legal grounds. I am following this issue from New York because the PM_{2.5} NAAQS has national epidemiologic and regulatory significance and because the exaggeration of PM_{2.5} risks fits the pattern of examples described in my 2008 book “Hyping Health Risks.”

Thank you for your attention to my comments.

Sincerely yours,

Geoffrey C. Kabat, Ph.D.

SUMMARY

SUMMARY

This appendix contains a detailed summary of the air quality in 2011 and the prior year trends for the South Coast Air Basin (Basin) and the Coachella Valley portion of Salton Sea Air Basin (SSAB), under the jurisdiction of the South Coast Air Quality Management District (District). The Basin includes Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties. In 2011, the District measured concentrations of air pollutants at 35 routine air monitoring stations in Southern California's Los Angeles, Orange, Riverside and San Bernardino counties, including two stations in the Coachella Valley. In addition, six source-specific lead (Pb) monitors were operated in 2011, near potential Pb emission sources.

Chapter 1 of this appendix presents descriptions of the air quality setting for the District's jurisdiction, including the relevant boundaries, weather factors and emissions for both the Basin and the Coachella Valley. It also briefly describes the properties and health effects of each criteria pollutant and the state and federal ambient air quality standards, along with revisions to the standards, both adopted and currently proposed. Criteria pollutants are those which have associated health-based National Ambient Air Quality Standards (NAAQS). Chapters 2 and 3 present summaries of current air quality for each of the criteria pollutants in the Basin and the Coachella Valley, respectively. These chapters include comparisons of the current concentrations compared to the state and federal standards, along with spatial, seasonal, and diurnal variations. Air quality statistics and trends presented in this Appendix provide information on the recent history and current status and progress toward attainment of the NAAQS and state standards, providing a baseline for planning toward future attainment.

Ozone (O₃) and fine particulate matter (PM_{2.5}) are the main pollutants for which the U.S. EPA has designated the Basin as nonattainment. The Coachella Valley is also a nonattainment area for ozone and PM₁₀, but PM_{2.5} concentrations remain below the federal standards. PM_{2.5} concentrations in the Basin have improved considerably, with 2010 and 2011 the cleanest years on record for the area. However, the Basin had the highest number of days exceeding the federal ozone standard of any urban area nationwide in 2011.

The Los Angeles County portion of the Basin is also currently nonattainment for the recently lowered federal lead standard, due to source-specific monitoring near a stationary Pb source, as required under the new U.S. EPA regulation. The remaining ambient Pb monitoring measurements throughout the Basin are below the current Pb

NAAQS. Pb air quality and attainment has been addressed separately in the 2012 Lead SIP for Los Angeles County submitted to U.S. EPA in June 2012.

While the new federal 1-hour standard concentration level was exceeded on one day for nitrogen dioxide (NO₂) in 2011, it should be noted that this does not include nonattainment. The Basin has not been designated as nonattainment of the NAAQS, since the Basin has not exceeded the design value¹ form of the revised NO₂ standard (98th percentile concentration, averaged over 3 years).

Both the Basin and the Coachella Valley are currently listed as PM10 nonattainment areas by U.S. EPA, based on the current 24-hour PM10 NAAQS. However, all exceedances of the federal 24-hour PM10 NAAQS in recent years have been flagged in the U.S. EPA Air Quality System (AQS) database for exclusion based on the U.S. EPA Exceptional Events Regulation (due to high wind events and Independence Day fireworks displays). The District has requested that U.S. EPA consider redesignate both areas to attainment status. State and federal standards for carbon monoxide (CO), sulfur dioxide (SO₂), and sulfate (SO₄²⁻) were not exceeded in the District.

¹ A design value is a statistic that describes the air quality status of a given area relative to the level and form of the National Ambient Air Quality Standards (NAAQS). For most criteria pollutants, the design value is a 3-year average and takes into account the form of the short-term standard (e.g., 98th percentile, fourth high value, etc.)

Summary of Criteria Pollutants and Air Quality Standards

AIR QUALITY SETTING

District Jurisdiction and Boundaries

California's first local air pollution control agency, the Los Angeles County Air Pollution Control District (LAAPCD), was formed in 1947, and APCDs were formed in Orange, Riverside, and San Bernardino Counties soon afterward. These four agencies combined in 1976 to form the Southern California APCD, which was later replaced by the South Coast Air Quality Management District, the Mojave Desert AQMD, (which covers the Mojave Desert Air Basin except for the portion within the South Coast Air District in the eastern portion of Riverside County), and the Antelope Valley APCD (which covers portions of Los Angeles County not within the South Coast Air Basin).

The South Coast Air Quality Management District (District) was established by state legislation effective February 1, 1977, and was assigned jurisdiction over air quality in the South Coast Air Basin (Basin). The Basin includes all of Orange County and the non-desert areas of Los Angeles, Riverside, and San Bernardino Counties. The District is also responsible for air quality in the Riverside County portion of the Salton Sea Air Basin (SSAB), which is primarily the Coachella Valley. The region encompassed by the District is shown in Figure 1-1.

FIGURE 1-1
South Coast Air Quality Management District and Surrounding Jurisdictions

The Basin has an area of 6,800 square miles with a population of approximately 16 million people in 2011. The Los Angeles urban area (the nation's second largest), the Anaheim-Fullerton urban area, and the Riverside-San Bernardino urban area lie within the Basin's boundaries. About two-thirds of the Basin's population lives within Los Angeles County. The 2011 population in the Riverside county portion of the SSAB portion under the jurisdiction of the District was approximately 450,000. The District also has the jurisdiction over a small portion of the MDAB in Eastern Riverside County (see Figure 1-1). The area is sparsely populated desert and contains a portion of Joshua Tree National Park. Table 1-1 summarizes the historic, current and future projections of the population of the Basin and the Coachella Valley.

TABLE 1-1
Historic Population and Projections for South Coast Air Basin and Coachella Valley

Area	1980	1990	2000	2010	2020	2030
South Coast Air Basin	10,500,000	13,022,000	14,681,000	15,759,412	16,901,492	18,129,690
Coachella Valley	139,000	267,000	320,892	439,357	558,321	710,430

The SSAB and the Mojave Desert Air Basin (MDAB) have a combined area of approximately 32,200 square miles. The two Basins include the desert portions of Los Angeles, Riverside, and San Bernardino Counties, as well as Imperial County and part of Kern County.

In 2011, the District maintained a network of 33 regular air monitoring stations² in the Basin and two in the Coachella Valley area. In addition, six monitors measure source-specific lead near emissions sources. Figure 1-2 shows the locations of the ambient air monitoring stations along with the District boundaries. PM_{2.5} monitoring has been significantly increased throughout the District in recent years, using both Federal Reference Method (FRM) filter measurements and continuous measurements for real-time data. Table A-1 and Figure A-1 in the Attachment to Appendix II also show the District's current ambient air monitoring network.

² Not all criteria pollutants are measured at every station.

FIGURE 1-2

South Coast Air Quality Management District Ambient Air Monitoring Stations in 2011

Weather Factors

The climate of the District varies considerably between the coastal zone, inland valleys, mountain areas and deserts. Most of the Basin is relatively arid, with very little rainfall and abundant sunshine during the summer months. It has light winds and poor vertical mixing compared to other large urban areas in the U.S. The combination of poor air dispersion and abundant sunshine provides conditions especially favorable to the formation of photochemical smog and the trapping of particulates and other pollutants. The Basin is bounded to the north and east by mountains with maximum elevations exceeding 10,000 feet. The unfavorable combination of meteorology, topography, and emissions from the nation's second largest urban area results in the Basin having some of the worst air quality in the U.S.

The prevailing daytime sea breeze tends to transport pollutants and precursor emissions from coastal areas into the Basin's inland valleys, and from there, still further inland into neighboring areas of the SSAB, as well as the MDAB. Concentrations of primary pollutants (those emitted directly into the air) are typically highest close to the sources which emit them. However, secondary pollutants (those formed in the air by chemical reactions, such as ozone and the majority of PM_{2.5}) reach maximum concentrations some distance downwind of the sources that emit the precursors, due to the fact that the

polluted air mass is moved inland by the prevailing winds many miles to areas where maximum concentrations are reached.

Emissions

The quantity of each of the major pollutants emitted into the atmosphere of the Basin in 2008 is shown in Figure 1-3 (in thousands of Tons per Day). The year 2008 emissions are the base year emissions used for the Draft Final 2012 AQMP. In that year, the Basin's annual average daily emissions were approximately 2880 tons of CO, 593 tons of volatile organic compounds (VOC), 754 tons of oxides of nitrogen (NO_x), 54 tons of oxides of sulfur oxides (SO_x), 170 tons of PM10, and 80 tons of PM2.5. Figure 1-4 shows the amount of each of the major pollutants emitted into the atmosphere in the Coachella Valley (in Tons per Day). These are much lower than those emitted in the Basin, by a factor of 10 to over 350, depending on the pollutant. The difference in local emissions between these two areas and the prevailing wind flows illustrate the importance of pollutant transport to the Coachella Valley's air quality.

Additional PM10 and PM2.5 material forms through chemical reactions of gaseous precursor emissions. Most emissions vary relatively little by season, but there are large seasonal differences in the atmospheric concentrations of pollutants due to seasonal variations in the weather. VOCs and NO_x are precursors of ozone, and they also react to form nitrates and solid organic compounds, which are a significant fraction of the ambient particulate matter. SO₂ reacts to form sulfates which are also significant contributors to the Basin's PM10 and PM2.5 levels. In addition to the particulates formed by the reaction of gaseous precursors, there is directly emitted PM10 and PM2.5, most of which is attributed to fugitive dust sources such as re-entrained road dust, construction activities, farming operations and wind-blown dust but also includes other directly-emitted substances such as diesel particulate. Details of the 2008 base year and future-year projected emissions inventories are contained in Chapter 3 and Appendix III.

FIGURE 1-3
2008 South Coast Air Basin Average Daily Emissions (Thousand Tons per Day)

FIGURE 1-4
2008 Coachella Valley Average Daily Emissions (Tons per Day)

AMBIENT AIR QUALITY STANDARDS

Both the federal government and the State of California have adopted ambient air quality standards, which define the concentration below which long-term or short-term exposure to a pollutant is not expected to cause adverse effects to public health and welfare. The criteria pollutants, those that have health-based standards, are: ozone (O₃), carbon monoxide (CO), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), coarse and fine particulate matter (PM₁₀ and PM_{2.5}, respectively), lead (Pb), and sulfate (SO₄²⁻, California only). California also has a welfare-based standard for visibly-reducing particles. In 2011, the District monitored ambient air quality for criteria pollutants at 35 routine monitoring sites throughout the Basin and in the neighboring Coachella Valley in the Riverside county portion of the Salton Sea Air Basin (SSAB), plus six additional source-specific lead monitors.

For several National Ambient Air Quality Standards (NAAQS), there are both primary and secondary standards. Primary standards provide public health protection, including protecting the health of "sensitive" populations such as asthmatics, children, and the elderly. Secondary standards provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. This document focuses on the primary federal standards. The federal and state primary standards are summarized in Table 1-2, along with a brief summary of health effects. Further discussion of the health effects of air pollutants is presented in Chapter 2 and more detailed health information is presented in Appendix I.

TABLE 1-2
Current Primary Ambient Air Quality Standards and Health Effects

Air Pollutant	State Standard	Federal Standard (NAAQS)	Relevant Health and Welfare Effects [#]
	Concentration, Averaging Time	Concentration, Averaging Time	
Ozone (O₃)	0.09 ppm, 1-Hour 0.070 ppm, 8-Hour	0.075 ppm, 8-Hour (2008) 0.08 ppm 8-Hour (1997)	(a) Pulmonary function decrements and localized lung edema in humans and animals; (b) Risk to public health implied by alterations in pulmonary morphology and host defense in animals; (c) Increased mortality risk; (d) Risk to public health implied by altered connective tissue metabolism and altered pulmonary morphology in animals after long-term exposures and pulmonary function decrements in chronically exposed humans; (e) <u>Vegetation damage</u> ; (f) <u>Property damage</u>
Carbon Monoxide (CO)	20 ppm, 1-Hour 9.0 ppm, 8-Hour	35 ppm, 1-Hour 9 ppm, 8-Hour	(a) Aggravation of angina pectoris and other aspects of coronary heart disease; (b) Decreased exercise tolerance in persons with peripheral vascular disease and lung disease; (c) Impairment of central nervous system functions; (d) Possible increased risk to fetuses
Nitrogen Dioxide (NO₂)	0.18 ppm, 1-Hour 0.030 ppm, Annual	100 ppb, 1-Hour 0.053 ppm, Annual	(a) Potential to aggravate chronic respiratory disease and respiratory symptoms in sensitive groups; (b) Risk to public health implied by pulmonary and extra-pulmonary biochemical and cellular changes and pulmonary structural changes; (c) <u>Contribution to atmospheric discoloration</u>
Sulfur Dioxide (SO₂)	0.25 ppm, 1-Hour 0.04 ppm, 24-Hour	75 ppb, 1-Hour	Bronchoconstriction accompanied by symptoms which may include wheezing, shortness of breath, and chest tightness during exercise or physical activity in persons with asthma
Suspended Particulate Matter (PM₁₀)	50 µg/m ³ , 24-Hour 20 µg/m ³ , Annual	150 µg/m ³ , 24-Hour	(a) Exacerbation of symptoms in sensitive patients with respiratory or cardiovascular disease; (b) Declines in pulmonary function growth in children; (c) Increased risk of premature death
Suspended Particulate Matter (PM_{2.5})	12.0 µg/m ³ , Annual	35 µg/m ³ , 24-Hour 15.0 µg/m ³ , Annual	
Sulfates-PM₁₀ (SO₄²⁻)	25 µg/m ³ , 24-Hour	N/A	(a) Decrease in lung function; (b) Aggravation of asthmatic symptoms; (c) Aggravation of cardio-pulmonary disease; (d) <u>Vegetation damage</u> ; (e) <u>Degradation of visibility</u> ; (f) <u>Property damage</u>
Lead (Pb)	1.5 µg/m ³ , 30-day	0.15 µg/m ³ , 3-month rolling	(a) Learning disabilities; (b) Impairment of blood formation and nerve conduction
Visibility-Reducing Particles	In sufficient amount such that the extinction coefficient is greater than 0.23 inverse kilometers at relative humidity less than 70 percent, 8-hour average (10am - 6pm)	N/A	<u>Visibility impairment</u> on days when relative humidity is less than 70 percent

ppm – parts per million by volume

ppb – parts per billion by volume

State standards are “not-to-exceed” values; Federal standards follow the design value form of the NAAQS

[#] More detailed health effect information can be found in the 2012 AQMP Appendix I or the U.S. EPA NAAQS documentation at <http://www.epa.gov/ttn/naaqs/>

Design Values

Air quality statistics can be presented in terms of the maximum concentrations measured at monitoring stations or in air basins, as well as for the number of days exceeding state or federal standards. These are instructive in regard to trends and the effectiveness of control programs. However, it should be noted that an exceedance of the concentration *level* of a federal standard does not necessarily lead to a violation of the NAAQS or that lead to a nonattainment designation. The form of the standard as defined by the federal NAAQS regulations must also be considered. For 24-hour PM_{2.5}, the *form* of the standard is the 98th percentile measurement of all the 24-hour PM_{2.5} samples at each station. For 8-hour O₃, the 4th highest measured 8-hour average concentration is used for each station. For NAAQS attainment/nonattainment decisions, the most recent 3 years of data are considered, along with the form of the standard, and are typically averaged to calculate a *Design Value* for each station. The overall design value for an air basin is the highest design value of all the stations in that basin. U.S. EPA also allows certain data to be flagged and not considered for NAAQS attainment status, when that data is influenced by exceptional events, such as high winds, wildfires, volcanoes, or some cultural events (Independence Day fireworks) that meet strict criteria. Table 1-3 shows the design value requirements utilizing the form of the federal standards for the federal criteria pollutants.

TABLE 1-3
Primary National Ambient Air Quality Standards (NAAQS) and Design Value Requirements

Pollutant	Averaging Time	Standard Level	Design Values and Form of Standards*
Ozone (O ₃)	1-Hour** (1979)	0.12 ppm	Not to be exceeded more than once per year averaged over 3 years
	8-Hour (1997)	0.08 ppm	Annual fourth highest 8-hour average concentration, averaged over 3 years
	8-Hour (2008)	0.075 ppm	Annual fourth highest 8-hour average concentration, averaged over 3 years
Carbon Monoxide (CO)	1-Hour	35 ppm	Not to be exceeded more than once a year
	8-Hour	9 ppm	
Nitrogen Dioxide (NO ₂)	1-Hour	100 ppb	Three-year average of the annual 98 th percentile of the daily maximum 1-hour average concentrations (rounded)
	Annual	0.053 ppm	Annual average concentration, averaged over 3 years
Sulfur Dioxide (SO ₂)	1-Hour	75 ppb	99 th percentile of 1-hour daily maximum concentrations, averaged over 3 years
	24-Hour [#]	0.14 ppm	Not to be exceeded more than once per year
	Annual [#]	0.03 ppm	Annual arithmetic average
Particulate Matter (PM ₁₀)	24-Hour	150 µg/m ³	Not to be exceeded more than once per year averaged over 3 years
	Annual**	50 µg/m ³	Annual average concentration, averaged over 3 years
Particulate Matter (PM _{2.5})	24-Hour	35 µg/m ³	Three-year average of the annual 98 th percentile of daily 24-hour concentration
	Annual	15.0 µg/m ³	Annual average concentration, averaged over 3 years
Lead (Pb)	3-Month Rolling ^{###}	0.15 µg/m ³	Highest rolling 3-month average of the three years

* Standard is attained when the design value (form of concentration listed) is equal to or less than the NAAQS; for pollutants with the design values based on “exceedances” (1-hour O₃, 24-hour PM₁₀, CO, and 24-hour SO₂), the NAAQS is attained when the concentration associated with the design value is less than or equal to the standard:

- For 1-hour O₃ and 24-hour PM₁₀, the standard is attained when the 4th highest daily concentrations of the 3-year period is less than or equal to the standard
- For CO and 24-hour SO₂, the standard is attained when the 2nd highest daily concentration of the most recent year is equal to or less than the standard

** Standard has been revoked. For 1979 1-hour O₃, nonattainment areas have some continuing obligations under the former 1979 standard. For 8-hour O₃, the standard has been lowered from (0.08 ppm to 0.075 ppm), but the 1997 O₃ standard and most related implementation requirements remain in place until further action by U.S. EPA

Annual and 24-hour SO₂ NAAQS will be revoked one year from attainment designations for the new (2010) 1-hour SO₂ standard

3-month rolling Pb averages of the first year (of the three year period) include November and December monthly averages of the prior year. The 3-month average is based on the average of “monthly” averages

Summary of Criteria Pollutants and Air Quality Standards

Ambient air quality standards are periodically reviewed by U.S. EPA and state agencies to incorporate the findings from the most current research available on the effects of pollutants. Alert and advisory levels for advising the public about unhealthful air quality are also recommended. The section below summarizes the pollutant properties and health information, along with the air quality standards, including the recently revised or newly established standards and recently proposed revisions of the particulate NAAQS. Further discussion of the health effects of air pollutants is presented in Chapter 2 and more detailed health effects information is presented in Appendix I.

Particulate Matter Properties

Particulate matter (PM) air pollution is a complex mixture of small particles and liquid droplets, made up of a number of components, including acids and salts (such as nitrates and sulfates), organic chemicals, metals, and soil or dust particles. Particles originate from a variety of anthropogenic mobile and stationary sources and from natural sources. These particles can be emitted directly or formed in the atmosphere by transformations of gaseous emissions, such as sulfur oxides (SO_x), nitrogen oxides (NO_x), ammonia (NH₃) and volatile organic compounds (VOC). Examples of secondary particle formation include: 1) conversion of SO_x and NO_x to acid droplets or vapor that further react with ammonia to form ammonium sulfate and ammonium nitrate; and 2) reactions involving gaseous VOC, yielding organic compounds that condense on existing particles to form secondary organic aerosol (SOA) particles.

The size of particles is directly linked to their potential for causing health problems. Particles that are 10 micrometers (µm) in diameter or smaller (PM₁₀) are of more concern than larger particles because those are the particles that generally pass through the throat and nose and enter the lungs. (A µm is 1/1000th of a millimeter; there are 25,400 micrometers in an inch.) Once inhaled, these particles can affect the heart and lungs and cause serious health effects. PM air pollution is typically grouped into two overlapping categories:

- *Inhalable coarse particles* (PM₁₀), such as those found near roadways and dusty industries, are smaller than 10 µm in diameter. PM₁₀ includes all PM_{2.5} particles;

- *Fine particles* (PM2.5), such as those found in smoke and haze, are 2.5 μm in diameter and smaller. These particles can be directly emitted from combustion sources, such as from diesel exhaust (soot) or forest fire smoke, or they can form when gases emitted from power plants, industries and motor vehicles react in the air. PM2.5 is a subset of PM10 particles.

PM10 Properties

Respirable particles (particulate matter less than about 10 micrometers in diameter) can accumulate in the respiratory system and aggravate health problems such as asthma, bronchitis, and other lung diseases. Children, the elderly, exercising adults, and those suffering from asthma are especially vulnerable to PM10.

PM10 particles are both directly emitted and formed chemically in the atmosphere from diverse emission sources. Major sources of PM10 include re-suspended road dust or soil entrained into the atmosphere by wind or activities such as construction and agriculture. These are mainly the coarser particles, in the PM10-PM2.5 coarse fraction range (often referred to as PM-Coarse, i.e., particles in the size range between 2.5 μm and 10 μm). Other components of PM10 form in the atmosphere (secondary PM10) from gaseous precursor emissions. These are mostly the smaller particles, mainly in the PM2.5 size range.

PM2.5 Properties

PM2.5, also known as fine particles, are the finer sized particles less than 2.5 μm in diameter, small enough to penetrate the defenses of the human respiratory system and lodge in the deepest recesses of the lung, causing potential adverse health impacts. The health effects include increased risks of heart attacks and strokes, aggravated asthma, acute bronchitis and chronic respiratory problems such as shortness of breath and painful breathing (in children, the elderly and sensitive people), and premature deaths (mainly in the elderly due to weaker immune systems). Sources of PM2.5 include diesel-powered vehicles such as buses and trucks, fuel combustion from automobiles, power plants, industrial processes, and wood burning.

In the Basin, much of the PM10 fraction is actually PM2.5 and smaller in size than 2.5 μm , a situation which has major implications for both health and atmospheric visibility. Reducing PM2.5 concentrations will therefore not only reduce the threat to the health of the Basin's population, but will also improve visibility in this region.

Total Suspended Particulate (TSP) Properties

Total suspended particulate (TSP) is the name applied to the complex mixture of particles suspended in the atmosphere, with no strict differentiation for particle size. TSP is collected on a glass fiber filter by means of a high volume sampler. Samples are collected for a 24-hour period every sixth day, and then returned to the District laboratory to be weighed for mass and chemically analyzed to determine the concentrations of sulfate, nitrate, and lead. The federal and state standards for lead are based on the analysis of TSP samples. In 2011, TSP samples were collected by the District at 14 sites. In addition, the District measured TSP lead at several source-specific sites in the vicinity of facilities known to emit lead, in order to comply with recent federal requirements to monitor those sources. The lead measurements throughout the Basin are detailed further at the end of this Chapter. Other than the specific health effects of lead, the fine fraction of TSP has greater effects on health and visibility than the coarse fraction. Of greatest concern to public health are the particles small enough to be inhaled into the lungs (PM₁₀) and especially the smaller fine particles that are inhaled more deeply into the lungs (PM_{2.5}). As a result the federal standard for TSP mass has been replaced with the PM₁₀ and PM_{2.5} standards.

Particulate Matter (PM) Air Quality Standards

PM₁₀ Air Quality Standards

In 1987, U.S. EPA adopted PM₁₀ standards, replacing the earlier TSP standard. The District began PM₁₀ monitoring in late 1984. U.S. EPA promulgated both a short-term 24-hour average standard (150 µg/m³)³ and an annual standard (50 µg/m³). Over the years, the forms and levels of the federal PM₁₀ standards were reviewed by U.S. EPA. Changes to the federal standards for PM₁₀ became effective on December 17, 2006. U.S. EPA first proposed to revise the 24-hour PM₁₀ standard by establishing a new indicator for coarse particles (particles generally between 2.5 and 10 µm in diameter, PM_{10-2.5}), to include PM_{10-2.5} that is mainly generated by resuspended dust from high-density traffic on paved roads, industrial sources, and construction sources; but specifically excluding PM_{10-2.5} that is generated by rural windblown dust and soils and by agricultural and mining sources. U.S. EPA proposed to set the PM_{10-2.5} standard at a level of 70 µg/m³. However, the coarse particle standard was not included as part of the final regulation which retained the 24-hour PM₁₀ standard (150 µg/m³). U.S. EPA also revoked the annual PM₁₀ standard due to a cited lack of evidence of adverse health

³ µg/m³ = micrograms per cubic meter

effects linked to long-term exposure to coarse particles, beyond that already protected against by the PM_{2.5} annual standard. As part of the revision to the ambient air monitoring regulations in 2006, PM_{10-2.5} monitoring was required at National Core (NCore) multi-pollutant monitoring stations by January 1, 2011. Currently, the District measures PM_{10-2.5} at two NCore PM monitoring sites in the Basin (Central Los Angeles and Riverside-Rubidoux). In the most recent review of the PM standards completed in June of 2012, U.S. EPA did not propose changes to the PM₁₀ standard.

PM_{2.5} Air Quality Standards

In 1997, U.S. EPA adopted new federal air quality standards for the subset of fine particulate matter, PM_{2.5}, to complement existing PM₁₀ standards that target the full range of inhalable particulate matter. The District began monitoring PM_{2.5} concentrations in 1999. Federal annual and 24-hour standards and a state annual standard for PM_{2.5} were established. In 2006, U.S. EPA significantly lowered the level of the 24-hour PM_{2.5} standard, from 65 $\mu\text{g}/\text{m}^3$ to 35 $\mu\text{g}/\text{m}^3$, while retaining the level of the annual PM_{2.5} standard at 15 $\mu\text{g}/\text{m}^3$.

In the 2006 PM NAAQS review, U.S. EPA determined that individuals with pre-existing heart and lung diseases, older adults, and children are at greater risk from the effects associated with fine PM exposures. Based on the results of the previous studies and an extensive new body of scientific evidence that links the negative health impacts of PM_{2.5} exposure on these and possibly additional sensitive subpopulations (e.g., fetuses (unborn babies), newborns, and genetically susceptible populations) at lower levels than previously understood, U.S. EPA has proposed to strengthen the annual PM_{2.5} standard. On June 14, 2012 U.S. EPA proposed a lower annual standard with a concentration range between 12 and 13 $\mu\text{g}/\text{m}^3$. The current 24-hour standard of 35 $\mu\text{g}/\text{m}^3$ is proposed to remain unchanged. In addition, U.S. EPA proposed a requirement for near-roadway PM_{2.5} monitoring in urban areas. They also proposed adjustments to the Air Quality Index (AQI), which is used to report current and forecasted pollutant levels, to be consistent with the current 24-hour and new proposed annual PM_{2.5} standards. Final action on the proposed PM_{2.5} standard is anticipated by December 14, 2012.

For the 3-year (2009-2011) PM_{2.5} annual design value (the 3-year average of the annual PM_{2.5} averages), the Basin exceeded the current federal annual PM_{2.5} standard at only one location, (in Northwestern Riverside County at Mira Loma). Lowering the annual standard concentration to 13 or 12 $\mu\text{g}/\text{m}^3$ would have resulted in 6 to 10 additional stations exceeding the annual standard level in 2011. Figure 1-5 shows the effect of the

proposed annual PM2.5 standard on the Basin’s attainment status, based on the 2009-2011 annual PM2.5 design values.

Recently, ultrafine particles (UFP; diameter less than 0.1 µm) have received particular attention due to their ability to penetrate deep into the human respiratory tract, cross into the blood stream and other organs, and to cause adverse health effects in humans. However, UFPs are not currently regulated by the U.S. EPA (see Chapter 9 of the 2012 AQMP for additional details). Table 1-4 summarizes the history of the PM NAAQS to date.

FIGURE 1-5

Annual PM2.5 3-Year (2009-2011) Design Values by Station Compared to Current and Proposed Federal Standards

TABLE 1-4
Summary of National Ambient Air Quality Standards (NAAQS) for Particulate Matter, 1971-
Present (with Proposed)

Year of Final Rule	Indicator	Averaging Time	Level ($\mu\text{g}/\text{m}^3$)
1971	TSP - Total Suspended Particles ($\leq 25\text{-}45 \mu\text{m}$)	24-hour	260
		Annual	75
1987	PM10	24-hour	150
		Annual	50
1997	PM2.5	24-hour	65
		Annual	15
	PM10	24-hour	150
		Annual	50
2006	PM2.5	24-hour	35
		Annual	15
	PM10	24-hour*	150
		Annual	(revoked)
2012 (proposed)	PM2.5	24-hour	35
		Annual	12-13**
	PM10	24-hour	150

* In the 1997 revision of the 24-hour PM10 standard, the form of the standard was revised to 99th percentile, averaged over 3 years. When the 1997 standards were vacated, the form of 1987 standards remained in place (not to be exceeded more than once per year averaged over 3 years).

** A lower PM2.5 annual standard was proposed by U.S. EPA on June 14, 2012, with comments solicited on a concentration range from 12 to 13 $\mu\text{g}/\text{m}^3$

Ozone Properties

The Basin's unique air pollution problem was first recognized in the 1940's. The Los Angeles urban area smog was worse than other areas. Early research showed that ozone was being formed in the Basin's atmosphere from VOCs and NO_x being emitted into the air in the presence of steady sunshine and trapped laterally by the mountainous terrain and vertically by strong low-altitude temperature inversions that act as a lid to vertical

mixing of air. Regular monitoring of total oxidants was begun by the Los Angeles Air Pollution Control District (LAAPCD) in the 1950's, and annual maximum 1-hour ozone concentrations in excess of 0.60 ppm (600 ppb) were recorded at that time.

Ozone (O₃), a colorless gas with a sharp odor at very high concentrations, is a highly reactive form of oxygen. High ozone concentrations exist naturally high above the earth in the stratosphere. Some mixing of stratospheric ozone downward to the earth's surface does occur; however, the extent of ozone transport from aloft is limited. At the earth's surface in sites remote from urban areas, ozone concentrations are normally very low (0.03-0.05 ppm).

In urban areas, ozone is formed by a complicated series of chemical and photochemical reactions between VOCs, NO_x, and the oxygen in the air. A decrease in ozone precursors may or may not result in a linear decrease in ozone. Ozone concentrations are dependent not only on overall precursor levels, but also on the ratio of the concentrations of VOCs to NO_x, the reactivity of the specific VOCs present, the spatial and temporal distribution of emissions, the level of solar radiation, and other weather factors.

While ozone is beneficial in the stratosphere because it blocks skin-cancer-causing ultraviolet radiation, it is a highly reactive oxidant. It is this reactivity which accounts for its damaging effects on materials, plants, and human health at the earth's surface.

The propensity of ozone to react with organic materials causes it to be damaging to living cells, and ambient ozone concentrations in the Basin are frequently sufficient to cause adverse health effects. Ozone enters the human body primarily through the respiratory tract and causes respiratory irritation and discomfort, makes breathing more difficult during exercise, and reduces the respiratory system's ability to remove inhaled particles and fight infection. People with respiratory diseases, children, the elderly, and people who exercise heavily are more susceptible to the effects of ozone.

Plants are sensitive to ozone at concentrations well below the health-based standards and ozone is responsible for significant crop damage and damage to forests and other ecosystems.

Ozone Air Quality Standards

Studies have shown that even relatively low concentrations of ozone, if lasting for several hours, can significantly reduce lung function in normal healthy people. Effective September 16, 1997, the U.S. Environmental Protection Agency (U.S. EPA) adopted an

8-hour average federal ozone standard with a level of 0.08 ppm (not to exceed), intending to replace the 1-hour standard that was adopted in 1979 (0.12 ppm, not to exceed). This 8-hour ozone standard was more stringent than the 1-hour standard (0.12 ppm) and provided greater protection to public health. The 8-hour standard is intended to help protect people who spend a significant amount of time working or playing outdoors, a group that is particularly vulnerable to the effects of ozone. (Due to the monitoring and reporting requirements of the older ozone standards, a level of 0.085 ppm or 85 ppb is required to exceed the 1997 8-hour standard and 0.125 ppm or 125 ppb is required to exceed the 1979 1-hour standard.)

The U.S. EPA eventually revoked the 1979 federal 1-hour ozone standard, effective June 15, 2005. However, the South Coast Air Basin and the former Southeast Desert Modified Air Quality Management Area (which included the Coachella Valley) had not attained the 1-hour federal ozone standard by the attainment date and have some continuing obligations under the former standard.

The 8-hour standard was subsequently lowered from 0.08 to 0.075 ppm (75 ppb, not to exceed, i.e., 76 ppb exceeds), effective May 27, 2008. However, nonattainment areas of the 1997 8-hour ozone standard still have some continuing obligations to demonstrate attainment of that standard by the applicable attainment date. In 2010, U.S. EPA proposed to lower the 8-hour ozone standard again and solicited comments on a proposed standard between 0.060 and 0.070 ppm. U.S. EPA did not take final action on a lower ozone standard and the NAAQS currently remains at the 0.075 ppm, as established in 2008. Potential new ozone standards are under review with proposed regulations expected by 2014. Statistics presented in this Appendix refer to both the current (2008) 8-hour standard and the former 1997 8-hour and 1979 1-hour standards for purposes of historical comparison and assessment of progress towards attainment of those standards.

The State of California Air Resources Board (CARB), established a new 8-hour average state ozone standard (0.070 ppm), effective May 17, 2006. The earlier state 1-hour ozone standard (0.09 ppm) also continues to remain in effect. Comparisons of the current (2008) and 1997 8-hour ozone standards, along with the former 1-hour ozone standard, for the Basin and the Coachella Valley can be found in Chapters 2 and 7.

While the 1-hour ozone episode levels and the related health warnings still exist, they are essentially replaced by the more protective health warnings associated with the current NAAQS. The 1-hour O₃ episode warning levels include the state Health Advisory (0.15 ppm), Stage 1 (0.20 ppm), Stage 2 (0.35 ppm) and Stage 3 (0.50 ppm). Only the lowest

of these 1-hour episode thresholds, the state Health Advisory, was exceeded in 2011. The last 1-hour O₃ Stage 1 episode occurred in 2003. The last Stage 2 episode occurred in 1988, and the last Stage 3 episode occurred in 1974.

CO Properties

Carbon monoxide (CO) is a colorless, odorless, relatively inert gas. It is a trace constituent in the unpolluted troposphere, and is produced by both natural processes and human activities. In remote areas far from human habitation, carbon monoxide occurs in air at an average background concentration of 0.04 ppm, primarily as a result of natural processes such as forest fires and the oxidation of methane. Global atmospheric mixing of CO from urban and industrial sources creates higher background concentrations (up to 0.20 ppm) near urban areas. The major source of CO in urban areas is incomplete combustion of carbon-containing fuels, mainly gasoline. In 2000, 98 percent of the CO emitted into the Basin's atmosphere was from mobile sources. Consequently, CO concentrations are generally highest in the vicinity of major concentrations of vehicular traffic. CO concentrations have continued to decrease due to reformulated fuels and more efficient combustion in newer vehicles.

As a primary pollutant, carbon monoxide is directly emitted into the air, and not formed in the atmosphere by chemical reaction of precursors as is the case with ozone and other secondary pollutants. Ambient concentrations of CO in the Basin exhibit large spatial and temporal variations, due to variations in the rate and locations at which CO is emitted, and in the meteorological conditions that govern transport and dilution. Unlike ozone, CO tends to reach high concentrations in the fall and winter months. The highest concentrations frequently occur on weekdays at times consistent with rush hour traffic and late at night during the coolest, most atmospherically stable portion of the day.

When carbon monoxide is inhaled in sufficient concentration, it can displace oxygen and bind with the hemoglobin in the blood, reducing the capacity of the blood to carry oxygen. Individuals most at risk from the effects of CO include heart patients, fetuses (unborn babies), smokers, and people who exercise heavily. Normal healthy individuals are affected at higher concentrations, which may cause impairment of manual dexterity, vision, learning ability, and performance of work. The results of studies concerning the combined effects of CO and other pollutants in animals have shown a synergistic adverse effect after exposure to CO and ozone.

CO Air Quality Standards

The state and federal CO standards have been reviewed recently, with no changes recommended. The CO standards are based on both short-term (1-hour; 35 ppm federal and 20 ppm state) and longer-term (8-hour; 9 ppm federal and 9.0 ppm state) exposures.

NO₂ Properties

Nitrogen dioxide (NO₂) is a reddish-brown gas with a bleach-like odor. Nitric oxide (NO) is a colorless gas, formed from nitrogen (N₂) and oxygen (O₂) in air under conditions of high temperature and pressure which are generally present during combustion of fuels; NO reacts with the oxygen in air to give NO₂. NO₂ is largely responsible for the brownish tinge of polluted urban air. The two gases, NO and NO₂, are referred to collectively as oxides of nitrogen (NO_x). In the presence of sunlight, NO₂ reacts to produce nitric oxide and an oxygen atom. The oxygen atom can react further to produce ozone, via a complex series of chemical reactions involving hydrocarbons (VOCs). NO₂ may also react to produce nitric acid (HNO₃) which reacts further to produce nitrates, which are a component of PM.

NO₂ is a respiratory irritant and reduces resistance to respiratory infection. Children and people with respiratory disease are most susceptible to its effects.

Nitrogen Dioxide Standards

U.S. EPA has established a new primary NO₂ 1-hour standard to supplement the existing annual standard, at a level of 100 ppb (based on the 3-year average of the annual 98th percentile of 1-hour daily maximum concentrations for each station). U.S. EPA has also established new requirements for the NO₂ monitoring network in large metropolitan areas that will include monitors at locations within 50 meters of major roadways. This near-source monitoring requirement is in addition to the ambient monitoring requirements to measure the area-wide NO₂ concentrations that occur more broadly across communities. This rule became effective on April 12, 2010. The 1971 annual NO₂ federal standard (0.053 ppm) remains in effect. Effective March 20, 2008, the California Air Resources Board (CARB) revised the state NO₂ 1-hour state standard from 0.25 ppm to 0.18 ppm, and established a new annual state standard of 0.030 ppm.

SO₂ Properties

Sulfur dioxide (SO₂) is a colorless gas with a sharp odor. It reacts in the air to form sulfuric acid (H₂SO₄), which contributes to acid deposition, and sulfates, which is a

component of PM10 and PM2.5. Most of the SO₂ emitted into the atmosphere is produced by the burning of sulfur-containing fuels.

At sufficiently high concentrations, sulfur dioxide affects breathing and the defenses of the lungs, and it can aggravate respiratory and cardiovascular diseases. Asthmatics and people with chronic lung disease or cardiovascular disease are most sensitive to its effects. Sulfur dioxide also causes plant damage, damage to materials, and acidification of lakes and streams.

Sulfur Dioxide Standards

U.S. EPA established a new 1-hour SO₂ standard at a level of 75 ppb, based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations and has revoked both the 24-hour and annual primary SO₂ standards, effective June 2, 2010.

Sulfate Properties

Sulfates are chemical compounds which contain the sulfate ion (SO₄²⁻) and are part of the mixture of solid materials which make up PM2.5, PM10 and TSP. Most of the sulfates in the atmosphere are produced by oxidation of sulfur dioxide. Oxidation of sulfur dioxide yields sulfur trioxide (SO₃) which reacts with water to produce sulfuric acid (H₂SO₄), which contributes to acid deposition. The reaction of sulfuric acid with basic substances such as ammonia yields sulfates, a component of PM.

Lead (Pb) Properties

Lead in the atmosphere is present as a mixture of a number of lead compounds. Leaded gasoline and lead smelters had historically been the main Basin sources of lead emitted into the air. Due to the phasing out of leaded gasoline, there has been a dramatic reduction in atmospheric lead in the Basin over the past three decades.

Lead Standards

The national standard for Lead (Pb) was revised on October 15, 2008 from a quarterly average of 1.5 µg/m³ to a rolling 3-month average of 0.15 µg/m³, with a maximum (not-to-be-exceeded) form, evaluated over a 3-year period (36 months). The current indicator of Pb in total suspended particles (Pb-TSP) was retained. The revision became effective on January 12, 2009.

U.S. EPA has also enhanced the Pb monitoring requirements in its 2008 NAAQS revisions, requiring air monitoring near Pb sources with potential 3-month average Pb concentration exceeding the revised standard of $0.15 \mu\text{g}/\text{m}^3$. Pb monitoring is required in large urban areas with monitors located to measure Pb concentrations in areas impacted by resuspended dust from roadways, nearby industrial sources identified as significant Pb sources, hazardous waste sites, construction and demolition projects, or other fugitive dust sources of Pb. Following a petition in 2009, U.S. EPA revised the monitoring requirements, lowering the emission threshold at which monitoring is required for both source-oriented and large urban area-based non-source oriented monitoring. The monitoring revision became effective in January 2011. In 2011, the District's Pb monitoring network included 10 regular monitoring sites and an additional five source-specific sites, one of which exceeded the revised Pb standard (at a lead source in the City of Vernon, Los Angeles County). A separate Pb SIP addressing the 2008 Pb standard was submitted to U.S. EPA in June 2012.

Chapters 2 and 3 contain summaries of air quality in the South Coast Air Basin (Basin), and the Riverside County (Coachella Valley) portion of the Salton Sea Air Basin (SSAB), respectively. For ozone, PM10, and PM2.5, the pollutants for which the Basin is still designated as nonattainment of the federal standards, maps are presented which show the geographical air quality variability. Detailed air quality statistics for each of the District's monitoring locations in the Basin and SSAB are contained in the Attachment to this report, for the years 1995 through 2011. Please refer to Appendix II from the 2003 AQMP for the 1976-1989 prior-year statistics and to Appendix II from the 2007 AQMP for 1990-2005 data.

AIR QUALITY IN THE SOUTH COAST AIR BASIN

Violations of Standards

In the South Coast Air Basin (Basin), the maximum pollutant concentrations measured at District monitoring stations in 2011 exceeded the levels of the federal and state standards for ozone (O₃), PM_{2.5}, nitrogen dioxide (NO₂), and lead (Pb). In the year 2011, a total of 125 days exceeded the levels of the current short-term (24-hour average or less) federal standards for 8-hour O₃, 1-hour NO₂, or 24-hour PM_{2.5} at one or more Basin locations. As discussed below, the NO₂ reading did not cause a “violation” of the standard. The more stringent state 8-hour O₃ or 24-hour PM₁₀ standards were exceeded on 137 days (based on the FRM filter data for PM₁₀, which is not sampled every day). While the Basin exceeded the state annual and 24-hour PM₁₀ standards, it did not exceed the 24-hour federal standard. The federal and state annual PM_{2.5} standards were exceeded in the Basin in 2011, with only one station exceeding the federal standard. While the state PM₁₀ annual standard was exceeded, the revoked federal annual PM₁₀ standard was not. The other criteria pollutants, sulfur dioxide (SO₂), carbon monoxide (CO), and sulfate (SO₄²⁻) did not exceed federal or state standards. Figure 2-1 shows the Basin maximum pollutant concentrations for 2011, as a percentage of the federal and state standards.

* High lead concentrations recorded at monitoring sites adjacent to sources known to emit lead

FIGURE 2-1

2011 South Coast Air Basin Maximum Pollutant Concentrations
(as Percent of State and Federal Standards)

Design Values and NAAQS Attainment Status

As shown above, the Basin exceeded the pollutant concentration levels defined by the National Ambient Air Quality Standards (NAAQS) for ozone, PM_{2.5}, NO₂, and Pb. However, attainment of the NAAQS is measured with the three-year design values that take into account the form of the federal standards and multi-year averages, as detailed previously in Table 1-3. The exceedances of the NO₂ standard level on one day in 2011 at two stations did not constitute a violation of the NAAQS or affect the Basin’s NO₂ designation. The Basin did not exceed the federal standard for PM₁₀ in 2011, or any year since 2008; the exceedances in 2007 and 2008 were flagged in the U.S. EPA AQS database to request exclusion from attainment consideration under the U.S. EPA Exceptional Events Rule. Figure 2-2 shows the federal ozone and PM design value status for the Basin, along with the Coachella Valley, for the 2009-2011 3-year period. The current U.S. EPA NAAQS attainment designations for the Basin are presented in Table 2-1.

FIGURE 2-2
South Coast Air Basin and Coachella Valley 3-Year (2009-2011) Design Values
(Percentage of Federal Standards, by Criteria Pollutant)

TABLE 2-1
National Ambient Air Quality Standards (NAAQS) Attainment Status
South Coast Air Basin

Criteria Pollutant	Averaging Time	Designation ^{a)}	Attainment Date ^{b)}
1979 1-Hour Ozone^{c)}	1-Hour (0.12 ppm)	Nonattainment (Extreme)	11/15/2010 (not attained)
1997 8-Hour Ozone^{d)}	8-Hour (0.08 ppm)	Nonattainment (Extreme)	6/15/2024
2008 8-Hour Ozone	8-Hour (0.075 ppm)	Nonattainment (Extreme)	12/31/2032
CO	1-Hour (35 ppm) 8-Hour (9 ppm)	Attainment (Maintenance)	6/11/2007 (attained)
NO₂^{e)}	1-Hour (100 ppb)	Unclassifiable/Attainment	N/A
	Annual (0.053 ppm)	Attainment (Maintenance)	9/22/1998
SO₂^{f)}	1-Hour (75 ppb)	Designations Pending	N/A
	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	3/19/1979 (attained)
PM₁₀	24-hour (150 µg/m ³)	Nonattainment (Serious) ^{g)}	12/31/2006 (redesignation request submitted) ^{g)}
PM_{2.5}	24-Hour (35 µg/m ³)	Nonattainment	12/14/2014 ^{h)}
	Annual (15.0 µg/m ³)	Nonattainment	4/5/2015
Lead (Pb)	3-Months Rolling (0.15 µg/m ³)	Nonattainment (Partial) ⁱ⁾	12/31/2015

- a) U.S. EPA often only designates Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable
- b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration
- c) 1979 1-hour O₃ standard (0.12 ppm) was revoked, effective June 15, 2005 ; however, the Basin did not attain this standard based on 2008-2010 data and has continuing obligations under the former standard
- d) 1997 8-hour standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the 1997 O₃ standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA
- e) New NO₂ 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO₂ standard retained
- f) The 1971 annual and 24-hour SO₂ standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO₂ 1-hour standard. Area designations are expected in 2013, with the Basin likely designated Unclassifiable /Attainment
- g) Annual PM₁₀ standard was revoked, effective December 18, 2006; redesignation request to attainment of the 24-hour PM₁₀ standard is pending with U.S. EPA
- h) Attainment deadline for the 2006 24-Hour PM_{2.5} NAAQS is December 14, 2014
- i) Pb partial nonattainment designation – Los Angeles County portion of the Basin only

Air Quality Compared to Other U.S. Metropolitan Areas

Despite significant improvement, the Basin still has some of the worst air quality in the nation in terms of the number of days per year exceeding the federal standards. In 2011, the U.S. location with the highest number of days over the federal 8-hour average ozone standard was located in the Basin (Central San Bernardino Mountains-Crestline, 84 days). The Basin exceeded the 24-hour average PM_{2.5} standard on multiple days, but the 98th percentile PM_{2.5} concentration (which is used to compare with the federal PM_{2.5} standard) exceeded the standard at one location only in Northwestern Riverside County (Mira Loma). The Basin did not exceed the federal 24-hour average and annual PM₁₀ standards in 2011.

Figures 2-3 and 2-4 show maximum pollutant concentrations in 2011 for the Basin compared to other urban areas in the U.S. and California, respectively. Maximum concentrations in all of these areas exceeded the 2008 federal 8-hour average O₃ standard. The annual PM_{2.5} standard was exceeded in the South Coast Air Basin and in one other California air basin (San Joaquin Valley). The 24-hour PM_{2.5} standard, however, was exceeded in a few of the other large U.S. urban areas and in many California air basins. The 24-hour PM₁₀ standard was exceeded in one of the U.S. urban areas shown (Phoenix), although potential flagging of exceptional events may affect the treatment of that data. It is important to note that maximum pollutant concentrations do not necessarily indicate potential NAAQS violations and subsequent nonattainment designations, as the design values that are used for attainment status are based on the form of the standard.

FIGURE 2-3
 2011 South Coast Air Basin Air Quality Compared to Other U.S. Urban Areas
 (Maximum Pollutant Concentrations as Percentages of the Corresponding Federal Standards)

FIGURE 2-4

2011 South Coast Air Basin Air Quality Compared to Other California Air Basins (Maximum Pollutant Concentrations as Percentages of the Corresponding Federal Standards)

NO₂ concentrations exceeded the recently established 1-hour standard in the Basin and Phoenix (on one day each). Denver, Colorado (not shown in Figure 2-3), was the only other U.S. urban area exceeding the NO₂ standard in 2011. SO₂ concentrations were below the recently established 1-hour federal standard in the Basin and all of the urban areas shown in Figures 2-3 and 2-4. However, the SO₂ standard was exceeded in other U.S. areas, with the highest concentrations recorded in Hawaii, due to volcanic emissions. The CO standards were not exceeded in the U.S. in 2011.

In 2011, the Central San Bernardino Mountains area in the Basin recorded the highest maximum 1-hour and 8-hour average ozone concentrations in the nation (0.160 and 0.136 ppm, respectively). The highest 8-hour average concentration was more than one and a half times the federal standard level. In 2011, seven out of ten stations with the highest maximum 8-hour average ozone concentrations in the nation were located in the Basin⁴. The South Coast Air Basin also exceeded the 8-hour ozone standard on more

⁴ The 10 highest measured O₃ concentrations in 2011 included 7 Basin stations: Central San Bernardino Mountains (Crestline), East San Bernardino Valley (Redlands), Central San Bernardino Valley (Fontana and San Bernardino), Santa Clarita Valley (Santa Clarita), Northwest San Bernardino Valley (Upland), and Metropolitan Riverside (Rubidoux).

days (106) than most other urban areas in the country in 2011, with only California's San Joaquin Valley exceeding on more days (109).

Air Quality Trends

There have been significant improvements in the Basin's air quality over the years since measurements began, with PM_{2.5} showing the most dramatic improvement in recent years. Figure 2-5 shows the trend (1990-2011) of *basin-days*⁵ exceeding the federal standards for ozone and particulates, as a percentage of days with monitoring data. Figure 2-6 shows the trend of maximum pollutant concentrations in the Basin for the past two decades, as percentages of the corresponding federal standards. Note that this is based on maximum concentrations and that actual attainment of the standards is based on the design value. The pollutant-specific sections of this chapter contain additional trends by pollutant.

FIGURE 2-5

Trend of Basin-Days Exceeding Federal Standards, 1990-2011

⁵ A "basin-day" is recorded if one or more locations in the air basin exceeded the level of the standard. Multiple locations exceeding on the same day count as a single basin-day.

FIGURE 2-6
Trends of South Coast Air Basin Maximum Pollutant Concentrations
(Percentages of Federal Standards)

Spatial and Temporal Variability

Air quality in the Basin varies widely by season and by area. The highest pollutant concentrations were all recorded in, or downwind of, the densely populated areas of the Basin. The number of days exceeding the current (2008) 8-hour federal ozone standard (0.075 ppm⁶, or 75 ppb⁷, not to exceed) varied widely by location, from zero to 84 days. Exceedances were fewest along the coast, increasing in the inland valleys to a maximum in the Basin's Central San Bernardino Mountains. The District station in the Central San Bernardino Mountains area (Crestline-Lake Gregory) exceeded the 2008 federal 8-hour average ozone standard most frequently (84 days).

Ozone concentrations tend to be higher on weekends than on weekdays, although this difference is less distinct in recent years. The time of day with highest average ozone concentrations is in the early to middle afternoon, although the inland areas of the Basin will peak later in the afternoon on the higher days. Day-of-week and time-of-day PM2.5 concentrations vary considerably by location but, overall for 2009-2011, weekday

⁶ ppm = parts per million, by volume

⁷ ppb = parts per billion, by volume; 1 ppm = 1000 ppb

PM_{2.5} concentrations were slightly higher on Fridays and daily peaks occur in the morning, after the period of heaviest traffic.

The Basin's air quality concentrations and the occurrence of exceedances vary with season due to seasonal differences in the weather, sunlight for photochemical reactions, and to a lesser extent, seasonal variations in emissions. High ozone concentrations are generally recorded during the May to October "smog season" and exceedances of the federal and state standards are most frequent in July and August. Particulate matter (PM₁₀ and PM_{2.5}) levels do not have as clear of a pattern as ozone, and high concentrations may be recorded throughout the year. However, high PM₁₀ and PM_{2.5} concentrations are typically recorded during late fall and winter months. Figure 2-7 shows the number of Basin-wide days per month when the most stringent of the state or federal standards were exceeded in the Basin in 2011. Additional spatial and temporal analyses are presented in the pollutant-specific sections that follow.

* The term Basin-days represents the number of days a standard was exceeded by at least one monitoring station in the Basin

FIGURE 2-7
Number of Basin-Days per Month Exceeding the Most Stringent State
or Federal Standards in 2011

POLLUTANT-SPECIFIC AIR QUALITY DISCUSSION

Particulate Matter (PM)

PM10 and PM2.5 concentrations are monitored throughout the District by samples collected on quartz or teflon filters in samplers with size selective inlets, known as Federal Reference Methods (FRM). Some stations also have continuous monitors, using either Beta Attenuation Monitor (BAM) or Tapered Element Oscillating Microbalance (TEOM) instrumentation. This data is available in real-time and is used for air quality forecasting and public reporting of current conditions. Where the continuous BAM or TEOM PM10 monitors have been certified by U.S. EPA to be Federal Equivalent Methods (FEM), the continuous PM10 data is averaged for the 24-hour period (midnight to midnight) and used for comparison to the standards on days when a valid FRM filter measurement was not collected. For PM2.5, there are significant differences between the FEM and FRM results that have been recognized by national assessments of the technologies. The District measures FRM PM2.5 on a daily basis at the critical stations in the Basin, and does not use the FEM PM2.5 data to compare to the NAAQS. This issue is being explicitly addressed in U.S. EPA's new proposed PM2.5 NAAQS, and future use of FEM data will be consistent with the final federal requirements. In 2011, the District measured PM10 and PM2.5 concentrations at 26 and 20 locations, respectively, including two locations in the Coachella Valley for both. Figures 2-8 and 2-9 show the PM2.5 and PM10 monitoring sites, respectively, in the District's jurisdiction.

FIGURE 2-8
South Coast Air Quality Management District PM2.5 Air Monitoring

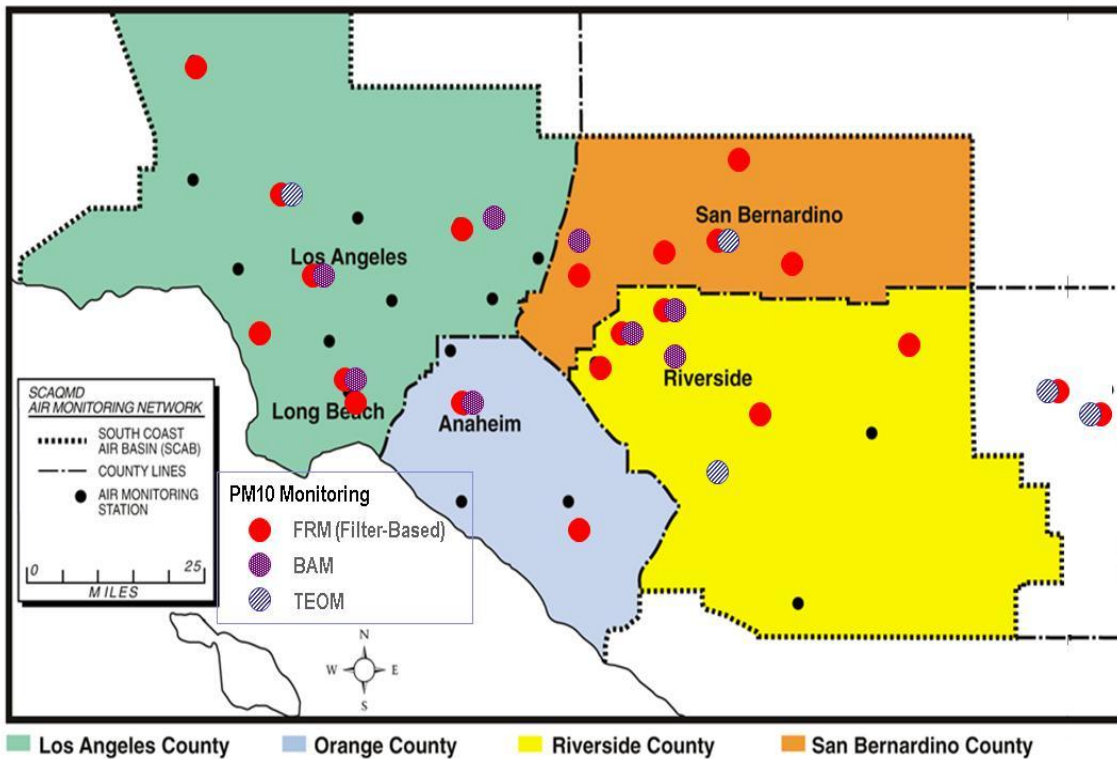

FIGURE 2-9
South Coast Air Quality Management District PM10 Monitoring

PM2.5 Air Quality

The District began routine monitoring of PM2.5 regularly in 1999 and the number of PM2.5 monitoring stations has increased in recent years. In 2011, the District monitored PM2.5 concentrations at 25 routine sampling locations (including 2 in the Coachella Valley), 22 with Federal Reference Method (FRM) filter samplers and 3 with Federal Equivalent Method (FEM) continuous monitors (shown in Figure 2-8). The FRM PM2.5 measurements, based on samplers with size-selective inlets using teflon filters, are collected for a 24-hour period every 3 days at most locations, except for seven stations that historically have higher concentrations where daily FRM samples are collected. One station in the Big Bear Lake area has a 24-hour sample collected every 6 days.

All PM2.5 data from sites in the District's network using FRM samplers are suitable for comparison to PM2.5 NAAQS for attainment purposes. The PM2.5 network also includes continuous FEM and non-FEM Beta Attenuation Monitors (BAM) throughout the District's jurisdiction. At the sites where both 24 hour FRM PM2.5 samplers and FEM PM2.5 continuous analyzers are deployed together, the 24 hour FRM PM2.5 sampler remains the primary analyzer used for attainment purposes. On many days, there is poor comparability of the FEM PM2.5 monitors and the FRM method. Therefore, the continuous hourly measurements that are available in real time are used primarily for forecasting and public notification of PM2.5 air pollution levels.

The highest 24-hour PM2.5 measurement recorded in 2011 in the Basin (94.6 $\mu\text{g}/\text{m}^3$ on July 5 at East San Gabriel Valley at Azusa) was flagged in the U.S. EPA Air Quality System (AQS) database for exclusion under the U.S. EPA Exceptional Event Rule, due to Independence Day fireworks displays. With this data included, the 2009-2011 24-hour design value for Azusa would exceed the federal standard level in 2011 and the 3-year design value. With that exceptional event flagged (pending further documentation and U.S. EPA concurrence), the only station with a 24-hour design value exceeding the 24-hour federal standard is in Metropolitan Riverside County (Mira Loma). The daily FRM sampler at Mira Loma exceeded the 24-hour federal standard on 8 days in 2011. The annual and 24-hour design values for the former Basin maximum station in Metropolitan Riverside County (Riverside-Rubidoux) are currently below the federal standards, based on the 2009-2011 data.

The federal 24-hour PM2.5 standard concentration level was exceeded at 75 percent of the locations monitored in the District in 2011. With the one exceptional event day flagged, the Basin's next-highest 24-hour average (65.0 $\mu\text{g}/\text{m}^3$) occurred in the Central San Bernardino Valley (City of San Bernardino) and was 183 percent of the federal 24-

hour PM_{2.5} standard. However, that location did not exceed the 98th percentile design value form of the standard in 2011, nor the 2009-2011 3-year design value.

In 2011, the federal annual average PM_{2.5} standard was exceeded at one location (Metropolitan Riverside at Mira Loma). The maximum annual average recorded there (15.3 µg/m³) was 101 percent of the federal standard and 126 percent of the state standard. The maximum 24-hour and annual average PM_{2.5} concentrations in 2011 are summarized by county in Tables 2-2 and 2-3, respectively, along with comparisons to the federal and state standards. Tables A-9 to A-12 in the Attachment to this appendix show the annual arithmetic mean, percentage of sampling days over the 24-hour federal standard, maximum 24-hour average concentrations, and 98th percentile 24-hour concentrations for the years 1999-2011 at all monitoring stations.

TABLE 2-2
2011 Maximum 24-hour Average PM_{2.5} Concentrations by Basin and County

Basin/County	Maximum 24-Hr Average [#] (µg/m ³)	Percent of Federal Standard* (35 µg/m ³)	Area
South Coast Air Basin			
Los Angeles**	49.5	139	East San Gabriel Valley
Orange	39.2	110	Central Orange County
Riverside	60.8	171	Metropolitan Riverside County
San Bernardino	65.0	183	Central San Bernardino Valley
Salton Sea Air Basin			
Riverside***	35.4	99.7	Coachella Valley

Based on FRM data

* Although maximum 24-hour concentrations exceed the standard, the 98th percentile form of the 2009-2011 design value only exceeded the standard at one station in Metropolitan Riverside County

** One higher concentration that was recorded due to “Independence Day” firework activities has been flagged for exclusion from NAAQS comparison in accordance with the U.S. EPA Exceptional Events Regulation; with this data included, the 2009-2011 design value for East San Gabriel Valley would also exceed the federal standard

*** While this concentration of 35.4 µg/m³ is near the level of the standard, it is technically not exceeding the standard (35.5 µg/m³ exceeds); this concentration was associated with a high wind exceptional event

TABLE 2-3
2011 Maximum Annual Average PM_{2.5} Concentrations by Basin and County

Basin/County	Annual Average* (µg/m ³)	Percent of Federal Standard (15 µg/m ³)	Percent of State Standard (12 µg/m ³)	Area
South Coast Air Basin				
Los Angeles	13.2	87	109	Central Los Angeles
Orange	11.0	73	90	Central Orange County
Riverside	15.3	101	126	Metropolitan Riverside County
San Bernardino	13.2	87	109	Southwest San Bernardino Valley
Salton Sea Air Basin				
Riverside	7.2	48	60	Coachella Valley

* Based on FRM data

PM_{2.5} Spatial Variation

Figure 2-10 shows the 2011 annual average arithmetic mean PM_{2.5} concentrations mapped throughout the Basin. Like PM₁₀, PM_{2.5} annual concentrations were higher in the inland valley areas of Metropolitan Riverside County. Figure 2-11 shows the 2011 24-hour PM_{2.5} concentrations, using the 98th percentile form of the standard, mapped throughout the Basin. As is seen with the annual average, the 98th percentile concentration only exceeds the 24-hour federal standard in the Metropolitan Riverside County area (Mira Loma). A larger area is just below the NAAQS, with concentrations in the 30 to 35 µg/m³ range, from the eastern San Fernando Valley and Central Los Angeles in the western Basin through the urban areas of Riverside and San Bernardino.

The higher PM_{2.5} concentrations in the Basin are mainly due to the secondary formation of smaller particulates resulting from mobile, stationary and area source emissions of gases (NO_x, SO_x, NH₄, VOC) that are converted to particulate matter in the atmosphere. In contrast to PM₁₀, PM_{2.5} concentrations were low in the Coachella Valley area of SSAB. While PM₁₀ concentrations are normally higher in the desert areas due to windblown and fugitive dust emissions, PM_{2.5} is relatively low in the desert due to fewer combustion-related emissions sources.

FIGURE 2-10

 (24-hour PM_{2.5} NAAQS = 35 $\mu\text{g}/\text{m}^3$)

PM2.5 Trends

Figure 2-12 shows the Basin 3-year design values (plotted by end year) for the current 24-hour and annual PM2.5 standards, for the period from 2001 through 2011. This illustrates the significant progress toward attainment of the standards in the last ten years.

FIGURE 2-12
South Coast Air Basin PM2.5 Design Value Trends, 2001-2011

PM2.5 Temporal Variation

Seasonal and day-of-week variations in PM2.5 concentrations are complex and location dependant, and may vary from year to year depending on meteorological conditions, the presence of large wildfires, and other factors. Previous analyses showed that the highest PM2.5 concentrations tend to occur in the fall, of most years. That held true in 2011. Figure 2-13 shows the Basin-wide monthly averaged PM2.5 concentrations, by month for the year 2011. In that year, the monthly PM2.5 averages were highest in October, followed closely by December. The somewhat lower multi-station averages in November 2011 likely resulted from an above-normal number of offshore wind days in that month that generally provided good dispersion and brought cleaner air from the deserts into the Basin.

FIGURE 2-13

2011 PM2.5 Variation of Basin-wide FRM Monthly Average Concentration

Figure 2-14 shows an analysis of day-of-week variation in Basin-wide PM2.5 daily concentrations averaged for the three most recent years (2009-2011). This shows that Fridays have slightly higher average PM2.5, possibly due to increased traffic and/or build up of pollution over multiple week-days. Saturdays and Thursdays follow, but the average difference from the lowest day (Monday) to the highest (Friday) is only 3.2 µg/m³.

FIGURE 2-14

PM2.5 Basin-wide Day-of-Week Variation of 24-hour Average FRM PM2.5 Concentrations, 2009-2011

Figure 2-15 shows average PM2.5 concentration by hour of the day for the period 2009-2011, based on the hourly BAM sampler data. The diurnal plots are for the Basin maximum PM2.5 monitor (Metropolitan Riverside at Mira Loma), Central Los Angeles (Downtown), Central Orange County (Anaheim), and the average of several sites throughout the Basin. In general, PM2.5 concentrations peak around 8 a.m. (Pacific Standard Time), with the morning traffic. They decrease in the early afternoon, then peak in the evening due to secondary aerosol formation following evening traffic, and late at night when the lower nighttime temperature inversion traps the pollutants in a shallower layer near the surface.

**FIGURE 2-15**

Diurnal Variation of Hourly FEM PM_{2.5}, Averaged by Time of Day (2009-2011)

PM_{2.5} Speciation

PM_{2.5} speciation sampling to determine the chemical components of PM_{2.5} is also a part of the District's PM_{2.5} measurement program. Currently, PM_{2.5} speciation samplers are deployed at four representative locations in each of the Basin's counties (Anaheim, Fontana, Los Angeles and Rubidoux). Analysis of the filters from the ambient network Speciation Air Sampling System (SASS) samplers are conducted at the District's laboratory. Figure 2-16 shows the trends of the annual concentration of six PM_{2.5} component species: Elemental Carbon (EC), Organic Carbon (Organics), Sulfate (SO₄), Nitrate (NO₃), Ammonium (NH₄), and Crustal Elements (soils). Most of the components show a downward trend in recent years. Figure 2-17 shows the composition from the speciation sampler at the Riverside-Rubidoux station, comparing the 2010 annual average to the 2010 peak 24-hour average sampled at this location. This is the closest PM_{2.5} speciation station to the Basin maximum PM_{2.5} station (Riverside-Mira Loma) and it was the Basin maximum location before monitoring began at Mira Loma. On the high day, the nitrate becomes a larger fraction of the mass compared to the annual average, indicating the importance of secondary atmospheric processes to the PM_{2.5} composition in Riverside County.

(Riverside-Rubidoux SASS Speciation Sampler)

PM10 Air Quality

In 2011, the District measured PM10 concentrations at 23 locations throughout the Basin and two locations in the Salton Sea Air Basin (Coachella Valley), as shown in Figure 2-9. Size-selective inlet (SSI) manual high volume FRM samplers are operated at 19 sites in the Basin and two sites in the Coachella Valley to meet the requirements for PM10 Federal Reference Method (FRM) sampling. All of these FRM monitors operate on a one-in-six-day schedule, with the exception of two that operate on a one-in-three-day schedule (Riverside-Rubidoux in the Basin and Indio in the Coachella Valley).

PM10 continuous analyzers, including Beta Attenuation Monitor (BAM) and Tapered Element Oscillating Microbalance (TEOM), are operated at 13 sampling sites, including four that are not collocated with FRM samplers. Real-time monitors, for the most part, are clustered in the higher concentration areas. At locations where both FRM samplers and PM10 continuous analyzers are deployed together, the data is generally combined for attainment purposes, with the FRM data considered the primary data source.

The highest annual PM10 concentrations were recorded in and around the metropolitan Riverside County area and further inland in the San Bernardino Valley areas. The

federal 24-hour standard ($150 \mu\text{g}/\text{m}^3$) was not exceeded at any of the locations monitored in 2011, although Riverside County came close with a 24-hour concentration of $152 \mu\text{g}/\text{m}^3$ (98 percent of the federal 24-hour standard; the concentration must reach $155 \mu\text{g}/\text{m}^3$ to exceed the NAAQS). The revoked annual average PM10 federal standard ($50 \mu\text{g}/\text{m}^3$) was also not exceeded in the Basin in 2011.

The more stringent state annual ($20 \mu\text{g}/\text{m}^3$) and 24-hour ($50 \mu\text{g}/\text{m}^3$) PM10 standards were exceeded in more than two-thirds of the areas monitored. The state 24-hour standard was also exceeded most frequently in the Basin's inland valleys, centered on Metropolitan Riverside County. Maximum 24-hour and annual average PM10 concentrations in 2011 are shown in Tables 2-4 and 2-5. For each routine District ambient air monitoring station, the annual arithmetic mean, percent of sampling days exceeding state and federal standards, and maximum 24-hour average concentrations are shown in Tables A-6 to A-8 in the Attachment for the years 1995-2011. Please refer to Appendix II from the 2003 AQMP for the 1976-1989 prior-year statistics and to Appendix II from the 2007 AQMP for 1990-2005 data.

TABLE 2-4
2011 Maximum 24-hour Average PM10 Concentrations by Basin and County

Basin/County	Maximum 24-Hr Average* ($\mu\text{g}/\text{m}^3$)	Percent of Federal Standard ($150 \mu\text{g}/\text{m}^3$)#	Percent of State Standard ($50 \mu\text{g}/\text{m}^3$)	Area
South Coast Air Basin				
Los Angeles	119	77	233	Central Los Angeles
Orange	79	51	155	Central Orange County
Riverside	152	98	298	Metropolitan Riverside County
San Bernardino	127	82	249	Central San Bernardino Valley
Salton Sea Air Basin**				
Riverside	120	77	235	Coachella Valley

* Based on the FRM and FEM data

** Higher concentrations were recorded for high wind events in the Coachella Valley which have been flagged for exclusion from NAAQS comparison in accordance with the U.S. EPA Exceptional Events Rule

A level of $155 \mu\text{g}/\text{m}^3$ is needed to exceed the federal standard, thus percentages are based on $155 \mu\text{g}/\text{m}^3$

** The federal annual PM10 standard was revoked in 2006

PM10 Spatial Variation

Figure 2-18 shows the contour map of the annual average (arithmetic mean) PM10 concentrations distribution in the Basin in 2011. The areas with the highest annual average PM10 concentrations were located in the Metropolitan Riverside County area. The maximum annual average recorded ($41.4 \mu\text{g}/\text{m}^3$) was 81 percent of the former federal annual PM10 standard.

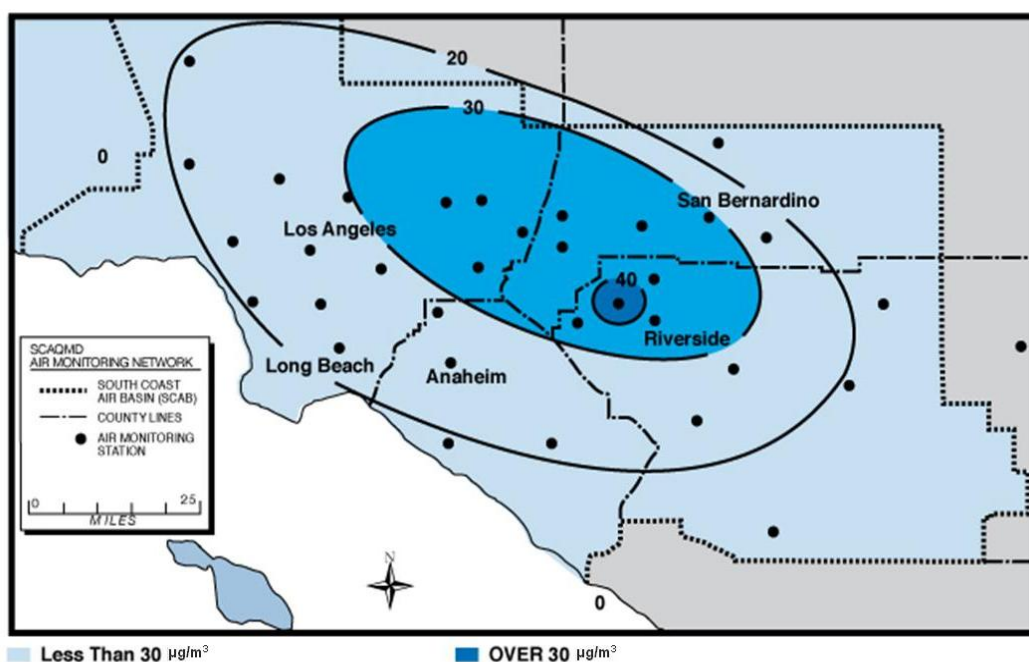

FIGURE 2-18
Annual Arithmetic Mean PM10 Particulate Matter ($\mu\text{g}/\text{m}^3$) in 2011

PM10 Trends

Figure 2-19 shows the trend for the period between 2000 and 2011 of the design value form of the 24-hour federal PM10 standards for the Basin (i.e., the fourth highest 24-hour average PM10 concentration in three years). It also shows the trend for the design value form of the revoked annual federal PM10 standard, that is, the 3-year average of the annual arithmetic mean concentrations. Since 2005, the Basin has remained below the design value form of the federal PM10 standard (150 $\mu\text{g}/\text{m}^3$). The District has petitioned U.S. EPA to consider redesignation of the Basin to attainment for the PM10 standard. The most recent year, 2011, was also remained below the revoked federal annual PM10 standard (50 $\mu\text{g}/\text{m}^3$).

FIGURE 2-19

PM10 Particulate Matter Design Value Trend
 (2000 through 2011 data, 3-Year Average of Annual Arithmetic Mean and 4th Highest 24-Hour
 PM10 Concentration in 3 Years, $\mu\text{g}/\text{m}^3$)

PM10 Temporal Variation

Exceedances of the 24-hour PM10 federal standard in the Basin have become rare in recent years. In fact, the only exceedances in the Basin for several years have been associated with exceptional events, such as high wind natural events or cultural events (Independence Day fireworks). As a consequence, variations in exceedances of the state

standard are considered here for the seasonal and day-of-week patterns in the Basin, using the FRM and FEM PM10 measurements combined.

Previous analyses of seasonal variations in PM10 show that the monthly average PM10 concentrations and the monthly average number of days exceeding the state standard tend to peak in summer and fall in the inland valley area of the Basin where PM10 concentrations are highest. However, in the South Coastal Los Angeles County area (Long Beach), monthly average PM10 concentrations and the average number of days exceeding the state standard were highest in the late fall and winter months.

Figure 2-20 shows the number of days in each month exceeding the state standard at one or more Basin locations over the period 2009-2011. Overall, the greatest number of exceedances of the state standard occurred in the summer months. Due to the higher number of exceedances in the inland valleys, the pattern for the Basin is more similar to those for individual sites in the inland valley areas. Figure 2-21 shows the monthly exceedances for stations in two areas, Metropolitan Riverside County (Riverside-Rubidoux) and South Coastal Los Angeles County (Long Beach). As was found in the previous analyses, the number of days exceeding state standards are more frequent in the summer and fall months in the inland valley areas, but higher in the late fall and winter months in the coastal areas. Most of the coastal high values occur at that time due to windblown dust from the strong, offshore Santa Ana winds that occur in the fall and winter.

FIGURE 2-20

Basin-Days Exceeding the State PM10 Standard ($50 \mu\text{g}/\text{m}^3$) by Month, 2009-2011

FIGURE 2-21

Number of Station Days Exceeding State PM10 Standard ($50 \mu\text{g}/\text{m}^3$) by Month, 2009-2011

Figure 2-22 shows the total number of days exceeding the state standard by day of week in the Basin and at selected sites in each county, for the period 2009-2011. The highest numbers of PM10 state standard exceedances occur on Thursday and Friday, possibly due to vehicle traffic, especially truck traffic, on those days and more construction activities than the weekend. Stations in the western Basin showed significant improvement on the weekends. On Sundays, the number of exceedances was lowest across the Basin, on average.

FIGURE 2-22

PM10 Day-of-Week Variation, 2009-2011

(Number of Days Exceeding State the Standard ($50 \mu\text{g}/\text{m}^3$) by Day of Week, for Basin and Individual Stations)

Figure 2-23 shows average PM10 concentrations for each hour of the day for the period 2009-2011 for the entire Basin and for select monitoring stations in the Basin, based on the hourly BAM and TEOM data. On average, PM10 concentrations show a peak around near 0900 to 1100 PST in the morning, just after the heaviest morning traffic rush-hour traffic.

FIGURE 2-23
 PM10 Diurnal Variation, 2011
 (Annual Averaged FEM Hourly PM10 Concentrations, by Hour of the Day)

Ozone

Current Ozone Air Quality

In 2011, the District monitored ozone concentrations at 27 locations in the Basin and two in the Coachella Valley portion of the SSAB. All counties of the Basin and the Coachella Valley exceeded the current (2008) 8-hour ozone standard (0.075 ppm) in 2011. That standard was exceeded on 106 days, Basin-wide. All counties in the Basin, except Orange County, exceeded the 1997 8-hour ozone standard (0.08 ppm). The highest 8-hour average (0.136 ppm) in 2011 occurred in the Central San Bernardino

Mountains (Crestline) and was 180 percent of the 2008 8-hour ozone standard and 160 percent of the 1997 standard.

The revoked 1979 federal 1-hour ozone standard was exceeded on 16 days in the Basin, with all counties exceeding, except Orange County. The maximum 1-hour concentration (0.160 ppm) also occurred in the Central San Bernardino Mountains (Crestline) and was 128 percent of the 1979 1-hour standard.

The more stringent California state standards were exceeded almost everywhere in the Basin, except for a few coastal stations, with the greatest number of exceedances occurring in the Central San Bernardino Mountains (Crestline) and adjacent valleys. The California state 1-hour (0.09 ppm) and 8-hour (0.070 ppm) standards were exceeded on 90 days and 125 days, respectively. The highest 1-hour average and 8-hour average ozone concentrations recorded in 2011 (0.160 ppm and 0.136 ppm) were 176 percent and 192 percent of the state standards, respectively.

In 2011, all stations measured 1-hour ozone well below the Stage 1 episode level (0.20 ppm, 1-hour). Except for one day in 2003, the stage 1 episode level has not been exceeded in the Basin since 1998. There have been no exceedances of the Stage 2 episode level (1-hour average ozone \geq 0.35 ppm) since 1988 and the Stage 3 episode level (1-hour average ozone \geq to 0.50 ppm) has not been exceeded since 1974. The maximum concentrations measured in the Basin in 2011 exceeded the California 1-hour ozone Health Advisory level (0.15 ppm) at two stations on one day (July 2), with 1-hour concentrations of 0.160 ppm (Central San Bernardino Mountains – Crestline) and 0.151 ppm (East San Bernardino Valley - Redlands).

Tables 2-6 and 2-7 show the maximum 1-hour and 8-hour O₃ concentrations by air basin and county, along with the percentages over the federal and state standards. Tables A-2 through A-5 in the Attachment show the number of days exceeding the federal 8-hour and 1-hour ozone standards, as well as the 4th high 8-hour average and maximum 1-hour concentrations, at all routine District air quality monitoring stations, for the period 1995-2011. Please refer to Appendix II from the 2003 AQMP for the 1976-1989 prior-year statistics and to Appendix II from the 2007 AQMP for 1990-2005 data.

TABLE 2-6

2011 Maximum 1-Hour Average Ozone Concentrations by Basin and County

Basin/County	Maximum 1-Hr Average (ppm)	Percent of Federal Standard (0.12 ppm)	Percent of State Standard (0.09 ppm)	Area
South Coast Air Basin

San Bernardino	0.136	180	192	Central San Bernardino Mountains
Salton Sea Air Basin				
Riverside	0.098	130	138	Coachella Valley

Ozone Spatial Variation

The number of days exceeding federal standards for ozone in the Basin varies widely by area. Figures 2-24 and 2-25 map the number of days in 2011 exceeding the current 8-hour and former 1-hour ozone federal standards in different areas of the Basin in 2011. The former 1-hour federal standard was not exceeded in areas along or near the coast in the Counties of Los Angeles and Orange, due in large part to the prevailing sea breeze which transports emissions inland before high ozone concentrations can be reached. The standard was exceeded most frequently in the Central San Bernardino Mountains. Ozone exceedances also extended through San Bernardino and Riverside County valleys in the eastern Basin, as well as the northeast and northwest portions of Los Angeles

County in the foothill and valley areas. The number of exceedances of the 8-hour federal ozone standard was also lowest at the coastal areas, increasing towards the Riverside and San Bernardino valleys and the adjacent mountain areas. The Central San Bernardino Mountains area recorded the greatest number of exceedances of the 1-hour and 8-hour federal standards (8 days and 84 days, respectively) and 8-hour state standard (103 days). While the Coachella Valley did not exceed the former 1-hour ozone standard in 2011, the current 8-hour federal standard was exceeded on 54 days.

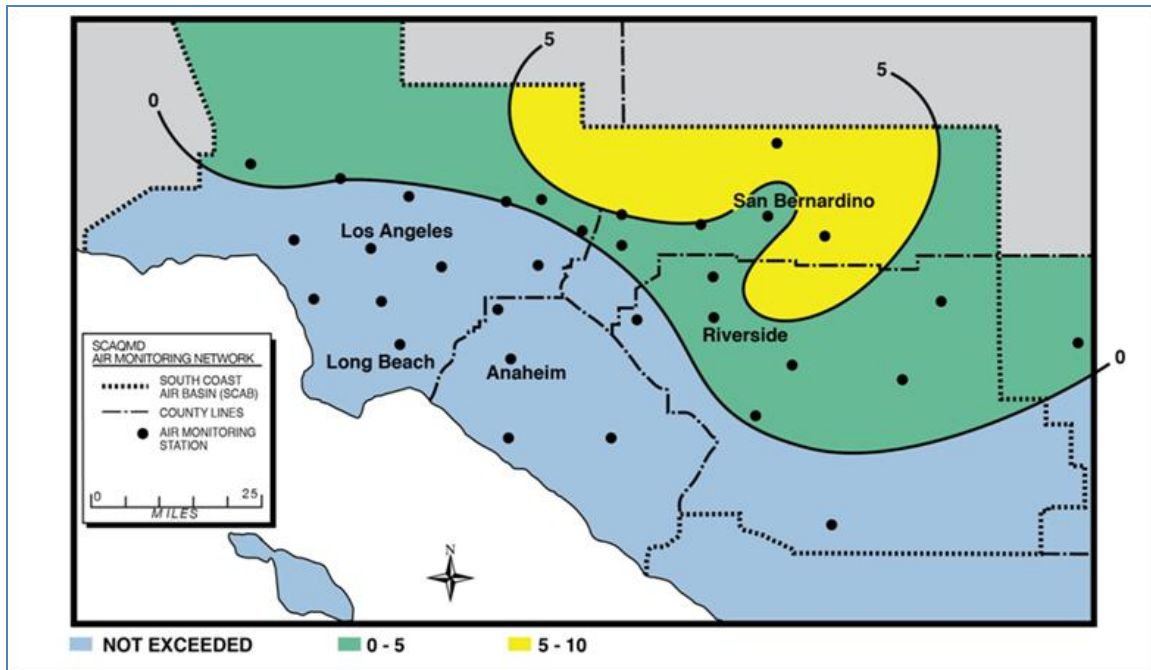

FIGURE 2-24

Number of Days in 2011 Exceeding the 1979 1-Hour Ozone Federal Standard
(1-hour average Ozone standard > 0.12 ppm)

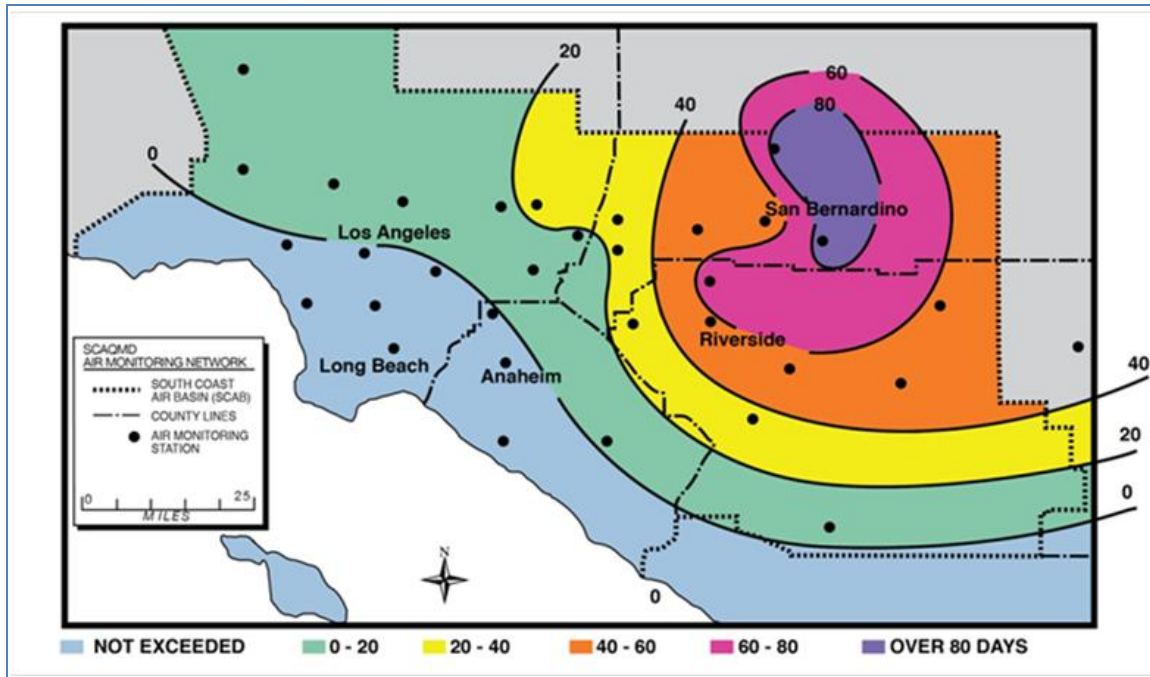

FIGURE 2-25

Number of Days in 2011 Exceeding the Current (2008) Federal 8-Hour Ozone Standard (8-hour average Ozone standard > 0.075 ppm)

Ozone Trends

The rate of ozone air quality improvement has been dramatic since the concerted effort to manage air quality in the Basin began in the 1970s. Significant improvements were seen throughout the 1990s. While the rate of improvement in ozone has slowed somewhat in the past decade, the overall trend, as well as the expectation for the future, is continuing gradual improvement. Figure 2-26 shows the Basin-wide trend (1990-2011) of number of days exceeding the 2008 and 1997 8-hour ozone standards and the former (1979) 1-hour ozone standard, along with the trend of Basin maximum 8-hour averaged ozone concentrations. Figure 2-27 shows the trend (1990-2011) of the 8-hour and 1-hour ozone 3-year design values for the Basin.

FIGURE 2-26

Trend of Annual Basin Days Exceeding Federal 8-Hour and 1-hour Ozone Standards (left axis) and Peak Concentrations (red line, right axis) (South Coast Air Basin; by year, 1990-2011)

FIGURE 2-27

South Coast Air Basin Ozone Design Value Trends, 1990-2011 (1 ppb = 0.001 ppm)

Ozone Temporal Variation

Because photochemical reactions require sunlight to proceed, ozone formation is favored by strong solar radiation. Solar radiation is more intense and of longer duration in summer than in winter and summertime temperature inversions are stronger and more persistent. This causes ozone concentrations to be higher in summer than in winter. Peak ozone concentrations generally occur near the middle of the day during the period May through September.

Figure 2-28 shows the number of days per month that one or more monitoring stations exceeded the most recent (2008) federal 8-hour ozone standard level for the years 2000, 2005 and 2011. Most exceedances occur in July and August, with most days exceeding the federal standard in those months. Up until the late 1980's it was common to have days exceeding the federal ozone standard as early as February and as late as November. By the late 1990's there were no exceedances in the months of November through February. There have been relatively few exceedances in March or October in more recent years. The frequency of exceedances in the spring (April-June) has continued to decline in recent years.

FIGURE 2-28

Monthly Distribution of Basin Days Exceeding the (2008) Federal 8-hour Ozone Standard (South Coast Air Basin, for Years 2000, 2005 and 2011)

Since the mid-1970s, it has been documented that ozone concentrations in the Basin are higher on weekends than on weekdays, in spite of the fact that ozone precursors are lower on weekends than on weekdays. Similar effects have been observed in some other metropolitan areas in the nation such as San Francisco, Washington D.C., Philadelphia, and New York. This “weekend effect” was quite pronounced in previous years in the Basin. CARB has sponsored several research projects to study the causes of elevated ozone levels on weekends in the Basin. Changes in daily patterns that impact the quantity and temporal loading of emissions have been suggested as strongly contributing to these observations. Carryover of matured precursors from weekdays to weekends is also suggested as a contributing factor. It is generally expected that this difference will decrease as ozone precursor emissions continue to decline.

In 2005, more exceeding station-days⁸ in the Basin occurred on either Saturdays or Sundays than any one weekday by more than a factor of two. The number of exceedances was slightly higher on Sundays than Saturdays. Figure 2-29 shows the number of station-days exceeding the federal 8-hour ozone standard for each day of the week in the Basin for the year 2011. In 2011, the weekends were still higher than the weekdays, with Sundays having the most exceedances, but by a much smaller margin than in earlier analyses. Averaged ozone concentrations by day-of-week also show a pattern similar to the average number of exceedances, with weekends somewhat higher than weekdays.

⁸ The term *station-days* represents the total number of days the standard was exceeded at individual monitoring stations summed for all stations in the Basin.

FIGURE 2-29
8-Hour Ozone Day-of-Week Variation, 2011
(Basin Station-Days Exceeding the 2008 Federal Ozone Standard)

Because time and sunlight are required for precursor organic gases and nitrogen oxides to react to form ozone, peak ozone concentrations usually occur from afternoon to early evening. By this time, the prevailing sea breeze has moved the polluted air mass miles inland from the major sources of precursor emissions. Ozone concentrations in the Basin are typically low during early morning hours, increasing rapidly after sunrise and peaking in the afternoon. However, peak concentrations occur earlier in the day for coastal areas and later in the day for locations further downwind.

Figure 2-30 illustrates the average of the smog season (May-October) 1-hour ozone concentrations for each hour of the day (shown in Pacific Standard Time), by station, for the year 2011. The average peak occurs near noon at the coastal stations (LAX) and most stations in the Basin reach their peak by the 2 p.m. The far inland stations at Central San Bernardino Valley (San Bernardino) and Central San Bernardino Mountains (Crestline, where the highest concentrations have been measured in recent years) peak near 3 or 4 p.m., but the ozone at Crestline decreases at a slower rate in the evening, leading to higher 8-hour ozone values. On the worst smog days, this station can remain relatively high through the night.

FIGURE 2-30

Diurnal Variation of Basin May-October 2011 Averaged Hourly Ozone Concentrations

Carbon Monoxide (CO)

CO Air Quality

The District currently monitors carbon monoxide air quality at 25 of its 34 air monitoring stations, including one station in the Coachella Valley. The highest CO concentrations are found in coastal and central Los Angeles County. The highest 8-hour average CO concentration in 2011 (4.7 ppm) was recorded in South Central Los Angeles county and was 49 percent of the federal 8-hour standard (9 ppm) and 52 percent of the state 8-hour standard (9.0 ppm). In recent years, the Basin has measured the lowest concentrations since carbon monoxide monitoring began in this region, several decades ago. The highest 1-hour average concentration in 2011 (6 ppm) was 17 percent of the federal 1-hour standard (35 ppm) and 29 percent of the state 1-hour standard (20 ppm). Concentrations in the less urbanized areas of the Basin and in the SSAB were well below the standards.

Carbon monoxide has continued to remain below the federal standards at all locations monitored since 2003. U.S. EPA redesignated the Basin to attainment of the federal CO

standards, effective June 11, 2007. The highest concentrations are typically recorded in Los Angeles County, in the area of South Central Los Angeles. There have also been no exceedances of the Stage 1 episode (federal alert) level (8-hour average CO greater than or equal to 15 ppm) since 1997. Table 2-8 shows the 2011 maximum 8-hour and 1-hour average carbon monoxide concentrations by Basin and county. The annual maximum 8-hour CO concentrations at all District air monitoring stations are shown in Table A-13 in the Attachment, for the period 1995-2011.

TABLE 2-8

2011 Maximum 8-Hour and 1-Hour CO Concentrations by Basin and County

Basin/County	Maximum 8-Hr Average (ppm)	Percent of Federal Standard (9 ppm)	Maximum 1-Hr Average (ppm)	Percent of Federal Standard (35 ppm)	Area
South Coast Air Basin					
Los Angeles	4.7	49	6.0	17	South Central L.A. County
Orange	2.2	23	3.4	10	North Coastal Orange County
Riverside	1.9	20	2.7	8	Metropolitan Riverside County
San Bernardino	1.7	18	1.8	5	Central San Bernardino Valley
Salton Sea Air Basin					
Riverside	0.6	6	3.0	8	Coachella Valley

Nitrogen Dioxide (NO₂)

NO₂ Air Quality

In 2011, the District monitored NO₂ concentrations at 25 locations, including one in the Coachella Valley. For the newly-promulgated 1-hour NO₂ standard, the Basin had not exceeded the federal annual standard for NO₂ (0.053 ppm or 53 ppb) since 1991, when the Los Angeles County portion of the Basin recorded the last exceedance of the standard in any U.S. county. The level of the recently established 1-hour average NO₂ federal standard (100 ppb), however, was exceeded on one day in 2011. The state NO₂ standards were not exceeded in the Basin.

The maximum 1-hour and annual average NO₂ concentrations for 2011 are shown in Table 2-9, by basin and county. The Basin maximum annual average NO₂ concentration (24.6 ppb, recorded in the Pomona/Walnut Valley area) was 46 percent of the federal annual NO₂ standard and 82 percent of the state annual standard (0.030 ppm or 30 ppb). The maximum 1-hour average NO₂ concentration in the Basin (109.6 ppb, in Central Los Angeles County) was 109 percent of the new federal standard (100 ppb) and 61 percent

of the state standard (180 ppb). Concentrations in the downwind Coachella Valley areas were much lower than in the Basin.

The exceedances of the federal 1-hour NO₂ standard in 2011 occurred on the same day at two stations in Los Angeles County (Central Los Angeles and Long Beach). When considering the 98th percentile form of the federal standard or the 3-year design value, the Basin did not exceed the NAAQS and attainment status is not affected. Although the Basin is in attainment of the state and federal standards, NO₂ is still a concern since it is a precursor to both ozone and particulate matter. Further control of oxides of nitrogen will be required to attain the ozone and particulate standards.

The annual averages and annual maximum 1-hour average concentrations for each monitoring station in the District for the years 1995-2011 are shown in Tables A-14 and A-15, respectively, in the Attachment.

TABLE 2-9
2011 Maximum 1-Hour and Annual Average NO₂ Concentrations by Basin and County

Basin/County	Maximum 1-Hour Average (ppb)	Percent of Federal Standard (100 ppb)	Maximum Annual Average (ppb)	Percent of Federal Standard (53 ppb)	Area
South Coast Air Basin					
Los Angeles	109.6*	109	24.6	46	Central Los Angeles County; Pomona/Walnut Valley
Orange	73.8	73	16.8	31	North Orange County
Riverside	63.3	63	16.9	32	Metropolitan Riverside County
San Bernardino	76.4	76	21.1	39	Central San Bernardino Valley
Salton Sea Air Basin					
Riverside	44.7	44	8.0	15	Coachella Valley

* Although the maximum 1-hour concentrations exceeded the standard, the 98th percentile form of the design value did not exceed the NAAQS

Sulfur Dioxide (SO₂)

SO₂ Air Quality

In 2011, sulfur dioxide was measured at seven Basin locations. Based on the review of the SO₂ standards, U.S. EPA has established the 1-hour SO₂ standard to protect the public health against short-term exposure. The level of the standard is now set at 75 ppb 1-hour average, revoking the existing annual (0.03 ppm) and 24-hour (0.14 ppm) federal standards, effective August 2, 2010. No violations have occurred of the current federal

1-hour standards, the former federal annual or 24-hour standards, or the state standards (0.25 ppm, 1-hour or 0.04 ppm, 24-hour). The annual and 24-hour federal standards were last exceeded in the 1960's and the state standards were last exceeded in 1990.

The maximum 1-hour average SO₂ concentrations recorded in the District in 2011 are shown in Table 2-10. The highest 1-hour average SO₂ concentration (51.2 ppb in Metropolitan Riverside County) was 68 percent of the federal 24-hour standard. While SO₂ concentrations in the Basin no longer exceed standards, SO₂ is a precursor of sulfate, which is a component of PM10 and PM2.5. The highest 24-hour average SO₂, measured in the South Coastal Los Angeles County area, near the Ports of Los Angeles and Long Beach was 0.013 ppm, 32 percent of the state standard. Annual maximum 1-hour average SO₂ concentrations for each air monitoring station for the years 1995-2011 are shown in Table A-16 in the Attachment.

TABLE 2-10

2011 Maximum 1-Hour Average SO₂ Concentrations by Basin and County

Salton Sea Air Basin			
Riverside	N.D.		Coachella Valley

N.D. = No Data. Historical measurements and lack of emissions sources indicate concentrations are well below standards.

Sulfate (SO₄²⁻)

Sulfate Air Quality

In 2011, sulfate concentrations were measured at 21 Basin locations and one in the Coachella Valley. The current form of the state standard (25 µg/m³) is based on sulfate from PM10 (24-hour average); there is no federal sulfate standard. In 2011, the state PM10-sulfate standard was not exceeded anywhere in the Basin and this standard has not been exceeded in the Basin or the Coachella Valley in many years. Maximum concentrations by air basin and county are shown in Table 2-11. The maximum sulfate concentration (12.6 µg/m³) recorded in the District was 50 percent of the state standard.

The maximum 24-hour average concentrations at each District air monitoring station for the years 1995-2011 are shown in Table A-17 in the Attachment.

TABLE 2-11

2011 Maximum 24-Hour Average Sulfate (PM10) Concentrations by Basin and County

Riverside	5.7	23	Coachella Valley

Lead (Pb)

Current Lead Air Quality

In 2011 lead concentrations were measured at ten Basin urban ambient air monitoring stations and five source-specific stations near major Pb emissions sources. Except for the source-specific monitoring that is now required under the new NAAQS, there have been no violations of the lead standards at the District's regular ambient air monitoring stations since 1982, primarily as a direct result of the removal of Pb from gasoline. However, monitoring at two stations immediately adjacent to stationary sources of Pb have recorded exceedances of the standards in localized areas of the Basin in more recent years.

U.S. EPA designated the Los Angeles County portion of the Basin (excluding the high desert areas, and San Clemente and Santa Catalina Islands) as nonattainment for the recently revised (2008) federal Pb standard ($0.15 \mu\text{g}/\text{m}^3$, rolling 3-month average), due to the source-specific monitoring under the new federal regulation. This designation was based on two source-specific monitors in the Los Angeles County Cities of Vernon and Industry exceeding the new standard in the 2007-2009 period of data used by U.S. EPA. For the most recent 2009-2011 design value data period, only one of these stations (Vernon) still exceeded the Pb standard, with a maximum 3-month rolling average of $0.67 \mu\text{g}/\text{m}^3$ that was measured in 2009 (432 percent of the federal standard). In 2011, the maximum rolling 3-month average at the Vernon site was $0.46 \mu\text{g}/\text{m}^3$ (297 percent of

the federal standard). A separate PB SIP addressing the 2008 lead standard in the Basin was submitted to U.S. EPA in June 2012.

The remainder of the Basin, other than the one source specific monitor in the Los Angeles County nonattainment area, is currently attaining the new Pb standard, including both ambient and source-specific monitoring. The old (1978) Pb standard ($1.5 \mu\text{g}/\text{m}^3$, as a quarterly average) remained in effect until one year after the area was designated for the 2008 standard, for areas in attainment of the 1978 standard. While the entire Basin has remained in attainment of the 1978 lead standard, U.S. EPA's current Pb designations for the new standard became effective on December 31, 2010 so the old standard is now fully superseded by the 2008 revised NAAQS. Nonetheless, the revoked (1978) federal lead standard ($1.5 \mu\text{g}/\text{m}^3$, as a quarterly average) and the state Pb standard ($1.5 \mu\text{g}/\text{m}^3$, as a 30-day average) were not exceeded in the District's ambient network in 2011. The highest 30-day average in 2011 at the source-specific monitor at Vernon was $0.45 \mu\text{g}/\text{m}^3$ (30 percent of the state standard). The highest 30-day average for an ambient Pb monitor was $0.02 \mu\text{g}/\text{m}^3$ (less than 2 percent of the state standard).

Table 2-12 shows the maximum 3-month rolling average Pb concentrations recorded in 2011, for each county in the Basin. The state standard maximum monthly average and federal standards maximum quarterly and 3-month rolling average lead concentrations at each District air monitoring site for the years 1995-2011 are given in Tables A-18 to A-20 in the Attachment.

TABLE 2-12
2011 Maximum 3-Month Rolling Pb Concentrations by Basin and County

N.D. = No Data. Historical measurements indicate concentrations are well below standards.

CHAPTER 3

AIR QUALITY IN THE RIVERSIDE COUNTY PORTION OF THE SALTON SEA AIR BASIN (COACHELLA VALLEY)

Air Quality in the SSAB, Riverside County (Coachella Valley)

Fine Particulate Matter (PM_{2.5})

Particulate Matter (PM₁₀)

Ozone (O₃)

Carbon Monoxide (CO)

Nitrogen Dioxide (NO₂)

Sulfur Dioxide (SO₂)

Sulfate (SO₄²⁻)

Lead (Pb)

AIR QUALITY IN THE SSAB, RIVERSIDE COUNTY (COACHELLA VALLEY)

In 2011, the District monitored air quality at two routine locations in the Riverside county portion of the Salton Sea Desert Air Basin (SSAB), both in the Coachella Valley. Figure 3-1 shows a map of the area and topography. One monitoring station (Palm Springs) is located immediately downwind of the densely populated South Coast Air Basin (Basin). The second station (Indio) is located further downwind in the Coachella Valley.

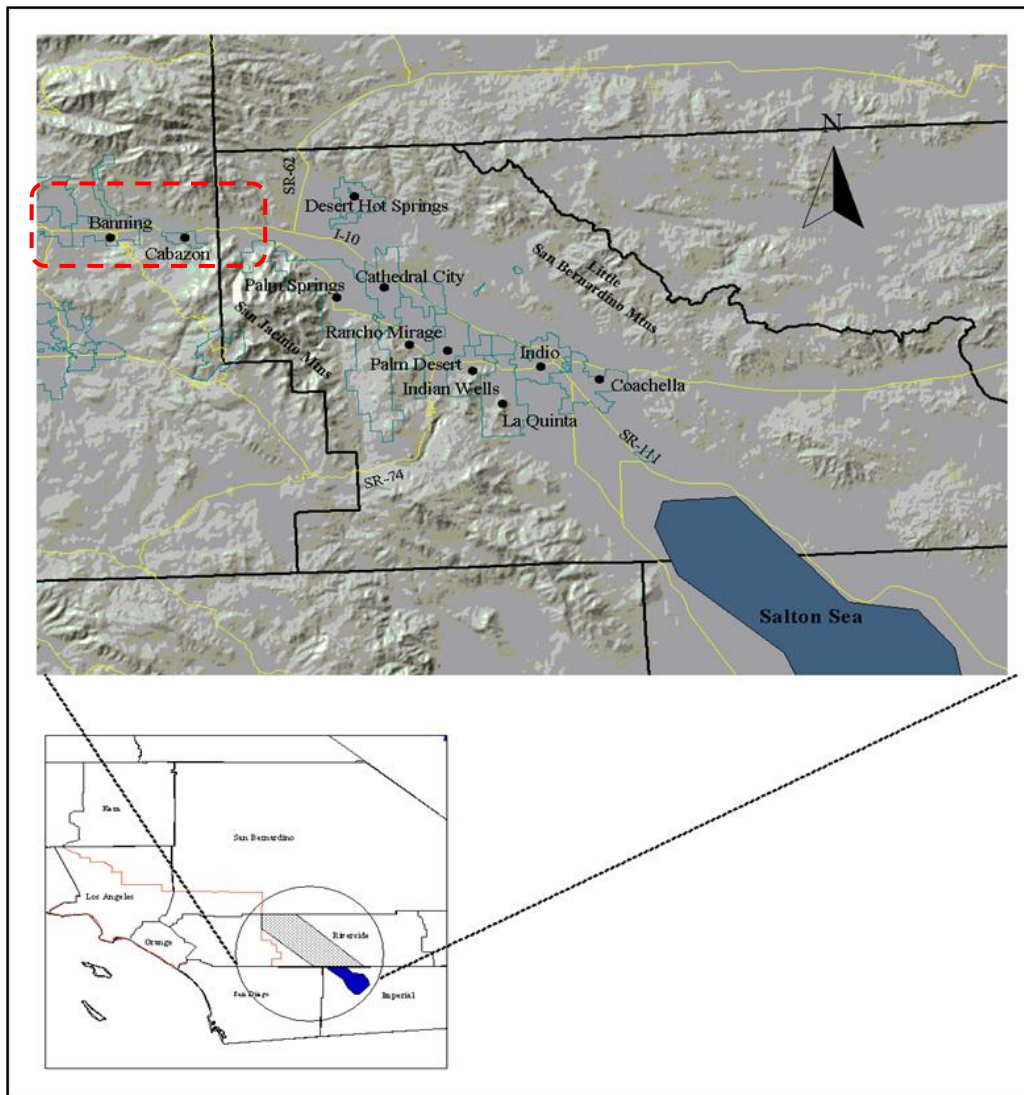

FIGURE 3-1
Location and Topography of the Coachella Valley
(Dashed red box indicates the San Geronimo Pass; District Coachella Valley air monitoring stations are located at Palm Springs and Indio)

Federal and state standards for PM_{2.5}, carbon monoxide (CO), and nitrogen dioxide (NO₂) were not exceeded in the Coachella Valley in 2011, nor was the state standard for Sulfate (SO₄²⁻, from PM₁₀). However, the Coachella Valley exceeded state and federal standards for ozone (O₃) and PM₁₀. The most current (2008) federal 8-hour O₃ standard was exceeded on 54 days in this area in 2011.

The two days in 2011 that exceeded the 24-hour PM₁₀ National Ambient Air Quality Standards (NAAQS) were flagged by the District for consideration under the U.S. EPA Exceptional Events Rule⁹, due to high-wind natural events (windblown dust from thunderstorm outflows). With those days flagged, the Coachella Valley did not violate the 24-hour PM₁₀ NAAQS.

The maximum concentrations measured at the District’s Coachella Valley air monitoring stations in 2011 are shown in Figure 3-2, as percentages of the state and federal standards. Figure 3-3 shows the Coachella Valley 3-year (2009-2011) design values, as percentages of the current and revoked federal standards.

FIGURE 3-2
Coachella Valley 2011 Maximum Pollutant Concentrations
as Percent of State and Federal Standards

⁹The U.S. EPA Exceptional Events Rule, *Treatment of Data Influence by Exceptional Events*, became effective May 21, 2007. The previous U.S. EPA *Natural Events Policy* for Particulate Matter was issued on May 30, 1996. Under the Exceptional Events Rule, U.S. EPA allows certain data to be flagged in the U.S. EPA Air Quality System (AQS) database and not considered for NAAQS attainment status when that data is influenced by exceptional events, such as high winds, wildfires, volcanoes, or some cultural events (Independence Day fireworks) that meet strict requirements.

FIGURE 3-3

Coachella Valley 3-Year (2009-2011) Design Values as Percent of Federal Standards

The current NAAQS, as attainment designations for the Coachella Valley are presented in Table 3-1. Coachella Valley station data is also included, along with the Basin stations, in the tables by pollutant for the years 1995-2011, in the Attachment to this Appendix.

TABLE 3-1
National Ambient Air Quality Standards (NAAQS) Attainment Status
Coachella Valley Portion of the Salton Sea Air Basin

Criteria Pollutant	Averaging Time	Designation ^{a)}	Attainment Date ^{b)}
1979 1-Hour Ozone^{c)}	1-Hour (0.12 ppm)	Nonattainment (Severe-17)	11/15/2007 (not timely attained ^{c)})
1997 8-Hour Ozone^{d)}	8-Hour (0.08 ppm)	Nonattainment (Severe-15)	6/15/2019
2008 8-Hour Ozone	8-Hour (0.075 ppm)	Nonattainment (Severe-15)	12/31/2027
CO	1-Hour (35 ppm) 8-Hour (9 ppm)	Unclassifiable/Attainment	N/A
NO₂^{e)}	1-Hour (100 ppb)	Unclassifiable/Attainment	N/A
	Annual (0.053 ppm)	Unclassifiable/Attainment	N/A
SO₂^{f)}	1-Hour (75 ppb)	Designations Pending	N/A
	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	N/A
PM10	24-hour (150 µg/m ³)	Nonattainment (Serious) ^{g)}	12/31/2006 (redesignation request submitted)
PM2.5	24-Hour (35 µg/m ³) Annual (15.0 µg/m ³)	Unclassifiable/Attainment	N/A
Lead (Pb)	3-Months Rolling (0.15 µg/m ³)	Unclassifiable/Attainment	N/A

- a) U.S. EPA often only designates Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable
- b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration
- c) 1-hour O₃ standard (0.13 ppm) was revoked, effective June 15, 2005; the Southeast Desert Modified Air Quality Management Area, including the Coachella Valley, did not attain this standard based on 2005-2007 data and has some continuing obligations under the former standard (latest 2009-2011 data shows attainment)
- d) 1997 8-hour O₃ standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the 1997 O₃ standard and most related implementation rules remain in place until the 1997 standard is revoked by U.S. EPA
- e) New NO₂ 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO₂ standard retained
- f) The 1971 annual and 24-hour SO₂ standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO₂ 1-hour standard. Area designations expected in 2012, with SSAB likely designated Unclassifiable /Attainment
- g) Annual PM10 standard was revoked, effective December 18, 2006; redesignation request to Attainment of the 24-hour PM10 standard is pending with U.S. EPA

Fine Particulate Matter (PM2.5)

PM2.5 has been measured in Coachella Valley since 1999 when the District began PM2.5 monitoring, using filter-based Federal Reference Method (FRM) samplers on a 1-in-3-day schedule. PM2.5 has remained relatively low compared to the South Coast Air Basin due to fewer combustion-related emissions sources and also the increased vertical mixing and horizontal dispersion in the desert area. In 2011, federal PM2.5 standards (35 $\mu\text{g}/\text{m}^3$, 24-hour average; 15.0 $\mu\text{g}/\text{m}^3$, annual average) were not exceeded at either of the two Riverside County SSAB air monitoring sites. The Coachella Valley maximum 24-hour average and annual average concentrations recorded in 2011 (35.4 $\mu\text{g}/\text{m}^3$ and 7.2 $\mu\text{g}/\text{m}^3$) were, respectively, 99.7 percent and 48 percent of the federal 24-hour and annual standards.

While not exceeding the 24-hour federal standard, the relatively high 24-hour concentration of 35.4 $\mu\text{g}/\text{m}^3$ was unusual for the Coachella Valley and occurred at Indio on one of the exceptional event days that had extremely high PM10 due to windblown dust from thunderstorm activity. The second high 24-hour PM2.5 average for the Coachella Valley was 26.3 $\mu\text{g}/\text{m}^3$ (74 percent of the federal standard), at Palm Springs. When looking at the 3-year design values (2009-2011) that considers the form of the federal standard, the Coachella Valley PM2.5 24-hour design value is 15.0 $\mu\text{g}/\text{m}^3$ (42 percent of the short-term standard) and the PM2.5 annual design value is 7.3 $\mu\text{g}/\text{m}^3$ (48 percent of the annual standard).

The annual PM2.5 state standard (12.0 $\mu\text{g}/\text{m}^3$) was not exceeded in the Coachella Valley, with the maximum annual average of 7.2 $\mu\text{g}/\text{m}^3$ (at Palm Springs) at 60 percent of the standard. This suggests that the Coachella Valley will also be in attainment of the upcoming revision to the federal annual PM2.5 standard, which has been proposed within a range from 12.0 to 13.0 $\mu\text{g}/\text{m}^3$. The Coachella Valley was between 55 and 60 percent of the proposed new PM2.5 annual standard for the year 2011. Figure 3-4 shows the trend of the annual average PM2.5 and PM10 concentrations in the Coachella Valley for the station showing the highest PM10 measurements from 1990 through 2011. Tables A-9 to A-12 in the Attachment to this appendix show the annual arithmetic mean, percentage of sampling days over the 24-hour federal standard, maximum 24-hour average concentrations, and 98th percentile 24-hour concentrations for the years 1999-2011 for all monitoring stations, including the two in the Coachella Valley.

FIGURE 3-4

Coachella Valley Trend of Annual Average PM2.5 and PM10, 1990-2011

Particulate Matter (PM10)

Although exceedances of the ozone standard in the Coachella Valley area are due primarily to the transport of ozone from the densely populated areas of the Basin upwind, the same cannot be said for PM10 exceedances. PM10 exceedances in the Coachella Valley are primarily due to locally generated sources of fugitive dust (e.g., natural wind-blown sources, construction and agricultural activities, and re-entrained dust from paved road travel) and not as a result of secondary particulates generated from precursor gaseous emissions. PM10 is the only pollutant which has sometimes reached higher concentrations in the SSAB than in the Basin.

The Coachella Valley is subject to frequent high winds which generate wind-blown sand and dust, especially from disturbed soil and natural desert blowsand¹⁰. Air forced

¹⁰ The blowsand process is a natural sand migration caused by the action of winds on the vast areas of sand in the Coachella Valley. The sand is supplied by weather erosion of the surrounding mountains and foothills. Although the sand migration is somewhat disrupted by urban growth in the Valley, the overall region of blowsand activity encompasses approximately 130 square miles, extending from near Cabazon in the San Geronio Pass to near Indio.

through the San Gorgonio Pass (also referred to as Banning Pass) creates strong northwesterly winds along the centerline of the Coachella Valley. This forcing is often related to the marine air mass and westerly onshore (sea-breeze) flows in the South Coast Air Basin pushing through the Pass. At other times, storm systems with frontal passages create strong winds through the Pass and along the Valley. Hourly averaged winds measured near Cathedral City, in the Whitewater River Wash near the centerline of the Valley, exceeded 25 mph for at least one hour on approximately one third of the days between 2005 and 2009.

High PM₁₀ concentrations in the Coachella Valley can also be caused by desert dust and sand entrained by downdraft outflows from the thunderstorms activity that is common in the southwestern U.S. deserts in the summer. On some of the high days, transport of wind-generated dust and sand occurs with relatively light winds in the Coachella Valley, when deeply entrained dust from desert thunderstorm outflows travels to the Coachella Valley from the desert areas of southeastern California, Arizona, Nevada, or northern Mexico. All days in recent years that exceeded the 24-hour federal PM₁₀ standard at Indio or Palm Springs would not have exceeded except for the contribution of windblown dust and sand due to strong winds in the upwind source area (high-wind natural events).

PM₁₀ is measured daily at both Indio and Palm Springs by supplementing the primary 1-in-3-day Federal Reference Method (FRM) filter sampling at Indio and the 1-in-6-day FRM at Palm Springs with secondary continuous hourly Federal Equivalent Method (FEM) measurements at both stations.

In 2011, two high-wind exceptional events occurred in the Coachella Valley that caused high 24-hour PM₁₀ concentrations (397 and 344 $\mu\text{g}/\text{m}^3$, at Palm Springs and Indio, respectively on July 3; 375; and 265 $\mu\text{g}/\text{m}^3$ at Indio and Palm Springs, respectively on August 28). The high PM₁₀ concentrations measured on these days were due to strong outflows from thunderstorms over Arizona and northern Mexico that deeply entrained dust and sand and transported it to the Coachella Valley. These natural events have been flagged in the U.S. EPA Air Quality System (AQS) database to be excluded for comparison to the NAAQS, as allowed by the U.S. EPA Exceptional Events Rule. Further documentation and U.S. EPA concurrence is pending.

After application of the U.S. EPA Exceptional Event Rule (and its predecessor, the Natural Events Policy) to high wind natural events in the Coachella Valley, no days since the mid-1990s have exceeded the federal 24-hour PM₁₀ standard at Indio or Palm Springs. As a result, AQMD requested that U.S. EPA redesignate the Coachella Valley

from nonattainment to attainment of the PM₁₀ NAAQS. Further action on this request by U.S. EPA is pending¹¹.

After flagging the high-wind natural events that exceeded the 24-hour PM₁₀ federal standard, the federal PM₁₀ standard was not exceeded in the Riverside County part of SSAB in 2011. The next highest PM₁₀ 24-hour concentration in the Coachella Valley was 120 µg/m³, 77 percent of the 24-hour NAAQS. The former annual average PM₁₀ federal standard (50 µg/m³) was not exceeded, even with the exceptional events included. The highest annual average PM₁₀ concentration in the Coachella Valley in 2011 was 32.6 µg/m³ (65 percent of the revoked annual federal standard), with the exceptional events excluded. When considering the form of the federal PM₁₀ standards, after consideration for the exceptional events, the 3-year (2009-2011) 24-hour PM₁₀ design value for the Coachella Valley was 105 µg/m³ (68 percent of the NAAQS) and the annual design value was 31 µg/m³ (56 percent of the revoked annual PM₁₀ NAAQS).

In 2011, the state 24-hour PM₁₀ standard (50 µg/m³) was exceeded on 19 days (21 days if the high-wind events are included) in the Coachella Valley, which is 5.2 percent of the sampling days (using FRM and FEM data combined). The peak value of 120 µg/m³, not including the exceptional events, was 238 percent of the state 24-hour standard. The state annual standard (20 µg/m³) was also exceeded. The annual average PM₁₀ concentration of 32.6 µg/m³ was 151 percent of the state standard.

For each routine District ambient air monitoring station, the annual arithmetic mean, percent of sampling days exceeding state and federal standards, and maximum 24-hour average concentrations are shown in Tables A-6 to A-8 in the Attachment for the years 1995-2011. Please refer to Appendix II from the 2003 AQMP for the 1976-1989 prior-year statistics and to Appendix II from the 2007 AQMP for 1990-2005 data.

Ozone (O₃)

Ozone in the atmosphere of the Riverside County portion of SSAB is both directly transported from the Basin and formed photochemically from precursors emitted upwind. These precursors are emitted in greatest quantity in the coastal and central Los Angeles County areas of the Basin. The Basin's prevailing sea breeze causes polluted air to be transported inland. As the air is being transported inland, ozone is formed, with peak concentrations occurring in the inland valleys of the Basin in an area extending from eastern San Fernando Valley through the San Gabriel Valley into the Riverside-San

¹¹ U.S. EPA has requested additional temporary PM₁₀ monitoring in the southeastern Coachella Valley to further assess windblown dust in that area; this project is currently ongoing.

Bernardino area and the adjacent mountains. As the air is transported still further inland into the desert areas, ozone concentrations typically decrease somewhat due to dilution, although ozone standards can still be exceeded. Ozone concentrations and the number of days exceeding the federal ozone standard are greatest in summer; there are typically no exceedances during the winter months.

In 2011, the 1979 1-hour federal ozone standard level was not exceeded in the Coachella Valley, with 2011 being the fourth consecutive year with no exceedances of the former short-term standard. The maximum 1-hour concentration measured was 0.124 ppm, just below (99 percent of) the former 1-hour federal standard (0.125 ppm exceeds). The former (1997) 8-hour federal ozone standard was exceeded on 18 days. The current, more stringent, 2008 8-hour federal standard (0.075 ppm) was exceeded on 54 days. The maximum 8-hour ozone concentration was 0.098 ppm (130 percent of the 2008 standard and 115 percent of the 1997 standard).

The state 1-hour and 8-hour ozone standards were exceeded on 25 days and 78 days, respectively, in the Coachella Valley in 2011. The maximum 1-hour average O₃ concentration (0.124 ppm) was 136 percent of the state 1-hour standard (0.09 ppm). The maximum 8-hour average O₃ concentration (0.098 ppm) was 138 percent of the state 8-hour standard (0.070 ppm). The 1-hour ozone health advisory level (0.15 ppm) has not been exceeded in the Coachella Valley area since 1999. No stage 1 ozone episode levels (0.20 ppm) have been recorded in the Coachella Valley area since 1989.

Tables A-2 through A-5 in the Attachment show the number of days exceeding the federal 8-hour and 1-hour ozone standards, as well as the 4th highest 8-hour average and maximum 1-hour concentrations, at all routine District air quality monitoring stations including the two Coachella Valley sites, for the period 1995-2011. Please refer to Appendix II from the 2003 AQMP for the 1976-1989 prior-year statistics and to Appendix II from the 2007 AQMP for 1990-2005 data. Figure 3-5 shows the trend of the total number of days exceeding federal (2008 8-hour and former 1979 1-hour) and state (8-hour and 1-hour) ozone standards at Coachella Valley monitoring sites for the years 1990-2011. Figure 3-6 shows the trend of the maximum 1-hour and 8-hour ozone concentrations in the Coachella Valley from 1990 through 2011.

FIGURE 3-5
 Coachella Valley Federal and State Ozone Trends, 1990-2011
 (Number of Days Exceeding Standards)

FIGURE 3-6

Trends of Coachella Valley Maximum 1-hour and 8-hour Ozone Concentrations, 1990-2011

Carbon Monoxide (CO)

Carbon monoxide was measured at one Coachella Valley air monitoring station in 2011. Neither the federal nor state standards were exceeded. The maximum 8-hour average CO concentration recorded in 2011 (0.6 ppm) was less than 7 percent of both the federal (9 ppm) and state (9.0 ppm) standards. The maximum 1-hour CO concentration (3.0 ppm) was 8 percent of the federal (35 ppm) and 15 percent of the state (20 ppm) 1-hour CO standards. Historical carbon monoxide air quality and trends in the Riverside county SSAB area shows that the area has not exceeded the federal CO standards in nearly three decades.

The annual maximum 8-hour CO concentrations at all District air monitoring stations, including the Coachella Valley, are shown in Table A-13 in the Attachment, for the period 1995-2011.

Nitrogen Dioxide (NO₂)

Nitrogen dioxide was measured at one station in the Coachella Valley in 2011. The maximum 1-hour average NO₂ concentration (44.7 ppb) was 44 percent of the new (2010) federal 1-hour standard (100 ppb) and 25 percent of the state 1-hour standard (180 ppb). The maximum annual average NO₂ concentration (8.0 ppb) was 15 percent of the federal annual standard (53 ppb) and 27 percent of the state annual standard (30 ppb).

The annual averages and annual maximum 1-hour average concentrations for each monitoring station in the District (including the Coachella Valley) for the years 1995-2011 are shown in Tables A-14 and A-15, in the Attachment.

Sulfur Dioxide (SO₂)

Sulfur dioxide concentrations were not measured in the Riverside County SSAB in 2011. Historical measurements have shown SO₂ concentrations to be well below the state and federal standards and there are no significant emissions sources of SO₂ in the Coachella Valley.

Sulfate (SO₄²⁻)

Sulfate from PM₁₀ was measured at one station in the Coachella Valley in 2011. The maximum 24-hour average sulfate concentration was 5.7 µg/m³ (23 percent of the 25 µg/m³ state sulfate standard). There is no federal sulfate standard. The maximum 24-hour average concentrations at each District air monitoring station, including the Coachella Valley, for the years 1995-2011 are shown in Table A-17 in the Attachment.

Lead (Pb)

Lead concentrations were not measured at either of the two Coachella Valley air monitoring stations in 2011. Measurements in past years have shown concentrations to be less than the state and federal standards and no major sources of lead emissions are located in the Coachella Valley.

BASE AND FUTURE YEAR EMISSION INVENTORY

NOVEMBER 2012

**SOUTH COAST AIR QUALITY MANAGEMENT DISTRICT
GOVERNING BOARD**

CHAIRMAN: WILLIAM A. BURKE, Ed.D.
Speaker of the Assembly Appointee

VICE CHAIR: DENNIS YATES
Mayor, Chino
Cities of San Bernardino

MEMBERS:

MICHAEL D. ANTONOVICH
Supervisor, Fifth District
County of Los Angeles

JOHN J. BENOIT
Supervisor, Fourth District
County of Riverside

MICHAEL A. CACCIOTTI
Mayor, South Pasadena
Cities of Los Angeles County/Eastern Region

JOSIE GONZALES
Supervisor, Fifth District
San Bernardino County Representative

RONALD O. LOVERIDGE
Mayor, City of Riverside
Cities Representative, Riverside County

JOSEPH K. LYOU, Ph.D.
Governor's Appointee

JUDITH MITCHELL
Councilmember, Rolling Hills Estates
Cities of Los Angeles County/Western Region

SHAWN NELSON
Supervisor, Fourth District
County of Orange

CLARK E. PARKER, Ph.D.
Senate Rules Appointee

JAN PERRY
Councilmember, Ninth District
City of Los Angeles

MIGUEL A. PULIDO
Mayor, Santa Ana
Cities of Orange County

EXECUTIVE OFFICER:

BARRY R. WALLERSTEIN, D. ENV.

Table of Contents

CHAPTER 1 INVENTORY DEVELOPMENT

Background	III-1-1
Air Contaminants	III-1-2
Inventory Source Categories	III-1-4
Inventory Type	III-1-24

CHAPTER 2 SUMMARY OF EMISSIONS

Baseline Emission Inventories	III-2-1
Base Year Emissions.....	III-2-1
Emission Trend Analysis	III-2-42
VOC Emissions.....	III-2-50
NOx Emissions	III-2-50
PM2.5 Emissions	III-2-51
Impact of Growth	III-2-51
General Conformity Budget.....	III-2-51
Pre-Base-Year Offsets	III-2-52
Uncertainty in the Inventory	III-2-54
Controlled Emission Inventories	
Emission Impacts of AQMD Programs	III-2-56
SIP Set Aside Accounts	III-2-57
Proposed Control Measures	III-2-58
CEPA Emission Calculations	III-2-60
CARB Emission Data Reports System	III-2-61

Inventory Source Categories

Stationary Sources

Mobile Sources

Inventory Type

Average Annual Day Inventory

Planning Inventory

BACKGROUND

To protect the public health and welfare, federal and state standards limit concentration levels of air contaminants in ambient air. An emission inventory of air pollutants and their sources is essential to identify the major contributors of air contaminants and the measures required to reduce air pollution. 2008 is the base year used to project future year emissions for the Draft Final 2012 Air Quality Management Plan (AQMP). The 2008 base year emissions inventory reflects adopted District air regulations that are implemented as of June, 2012 and CARB rules adopted by August 2011. Both the federal and state Clean Air Acts specify 1990 as the base year to measure emission reduction progress. In these inventories, only anthropogenic sources (i.e., those associated with human activity) are considered.

This appendix includes six attachments: Attachment A – Average Annual Emissions Summary by Major Source Category; Attachment B – Summer Planning Emissions Summary by Major Source Category; Attachment C – Top South Coast Air Basin (SCAB) VOC and NO_x producers which emitted equal to or greater than ten (10) tons per year in 2008; Attachment D – On-Road Emissions by Vehicle Category; Attachment E – Emissions from Diesel Fuel Combustion by Major Source Category; and Attachment F – 2008 Base Year Greenhouse Gas Emission Inventory Methodology and 2008 Greenhouse Gas Emissions Summary by Major Source Category. The years of 2008, 2014, 2017, 2019, 2023, and 2030 are provided in Attachments A, B, D and E, except year 2017 in Attachment D. Since Year 2017 transportation activity data is not provided by Southern California Association of Governments (SCAG), year 2017 on-road data is derived from the interpolation of the data between 2014 and 2019.

Information necessary to produce the emission inventory for the Basin is obtained from the District and other governmental agencies, including California Air Resources Board (CARB), California Department of Transportation (Caltrans), and SCAG. Each of these agencies is responsible for collecting data (e.g., industry growth factors, socio-economic projections, travel activity levels, emission factors, emission speciation profile, and emissions) and developing methodologies (e.g., model and demographic forecast improvements) required to generate a comprehensive emissions inventory. Entire statewide emissions inventories are compiled and maintained by CARB in its emission related information databases named California Emission Inventory Development and Reporting System (CEIDARS), and California Emission Forecasting and Planning Inventory System (CEFIS). CARB is the agency responsible for developing the emissions inventory for all the mobile sources, except the aircraft. CARB provided on-

road and most of the off-road inventories from its EMFAC 2011 and 2011 In-Use Fleet Off-Road Models. Caltrans provides SCAG with information regarding highway projects. SCAG incorporates these data into their Travel Demand Model for estimating/projecting vehicle miles traveled (VMT) and speeds. SCAG's socio-economic and transportation activities projections in their 2012 Regional Transportation Plan (RTP) are applied in the Draft Final 2012 AQMP. On-road emissions are derived from the emission factors in CARB's EMFAC2011 and transportation activities and speed distribution from SCAG's Travel Demand Model.

AIR CONTAMINANTS

Currently, air quality standards exist for the following criteria air contaminants: ozone (O₃), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), carbon monoxide (CO), fine suspended particulate less than 10 microns (PM₁₀), fine particulate less than 2.5 microns (PM_{2.5}), lead, and sulfate. This appendix presents emission levels in the Basin for the criteria air contaminants and their precursors. Specifically, data are included for emissions of total organic gases (TOG), volatile organic compounds (VOC), oxides of nitrogen (NO_x), oxides of sulfur (SO_x), CO, particulate matter (PM), PM₁₀, PM_{2.5}, and ammonia (NH₃).

Ozone is formed from photochemical reactions involving other air contaminants so it is not inventoried. Although air quality standards for NO_x and SO_x are based on NO₂ and SO₂, respectively, emissions of NO_x and SO_x are in the emissions inventory because multiple species of NO_x and SO_x contribute to the formation of particulate, and NO_x and VOC react in the presence of sunlight to produce ozone.

TOG incorporates all gaseous compounds containing the element carbon with the exception of the inorganic compounds, CO, carbon dioxide (CO₂), carbonic acid, carbonates, and metallic carbides. VOC, a subset of TOG, includes all organic gases in TOG except acetone, ethane, methane, methylene chloride, methylchloroform, perchloroethylene, methyl acetate, parachlorobenzotrifluoride, and a number of Freon-type gases. It should be noted that this definition of VOC is different from the one used by the CARB, which includes some compounds not considered as VOCs according to U.S. EPA. Table III-1-1 lists the compounds that are exempt in U.S. EPA's VOC list, but are included in CARB's VOC list. Certain CFCs are still included in CARB's VOC list. According to CARB, the total emission inventory difference between U.S. EPA VOC and CARB's VOC is very small.

PM represents all airborne particulate matter. Important subsets of PM are PM10 and PM2.5. In the Draft Final 2012 AQMP, the amount of VOC in TOG and the amount of PM10 and PM2.5 in PM are calculated for each process primarily using species and size fraction profiles provided by CARB. Besides average annual day emissions that are reported for all criteria pollutants, summer planning inventories (VOC and NOx) are reported for ozone purposes.

INVENTORY SOURCE CATEGORIES

Stationary Sources

Stationary sources of emissions are grouped into two categories - point sources and area sources. Point source emissions are from facilities having one or more pieces of equipment registered and permitted with the District. Therefore, the District is able to collect facility emission-related information from the larger of these facilities. Area source emissions are from numerous small facilities or pieces of equipment, such as gasoline-dispensing facilities, residential water heaters, consumer products and architectural coatings, for which locations may not be specifically identified. For modeling purposes, area source emissions are spatially allocated to grid cells using demographic data (e.g., population, housing, and land use).

Point Sources

The 2008 point source emission inventory is based on the emissions data reported by point source facilities in the calendar year 2008 Annual Emissions Reporting (AER) Program. This program applies to facilities emitting 4 tons or more of VOC, NO_x, SO_x, or PM or emitting more than 100 tons of CO per year, as specified in Rule 301(e). Facilities subject to the AER Program calculate and report their emissions primarily based on their throughput data (e.g., fuel usage, material usage), appropriate emission factors or source tests, and control efficiency (if applicable). Under the calendar year 2008 AER Program, approximately, 1,800 facilities reported their annual emissions to the District. Emissions from smaller industrial facilities not subject to the AER program, which represent a small fraction of the overall inventory, are included as part of the area source inventory.

In order to prepare the point source inventory, emissions data for each facility were categorized based on EPA's Source Classification Codes (SCCs) for each emission source category. Since the AER program collects emissions data on an aggregate basis (i.e., equipment and processes with same emission factor are grouped and reported together), facility's equipment permit data were used in conjunction with the reported data to assign the appropriate SCC codes and develop the inventory at the SCC level. For modeling purposes, facility location is specified in Universal Transverse Mercator (UTM) coordinates. Business operation activity profile is also recorded. Facility business type is assigned to the facilities based on North American Industry Classification System (NAICS) Code according to their primary activity. The growth projections and impact of the AQMP on the local economy are presented by NAICS.

Area Sources

The District and CARB shared the responsibility for developing the 2008 area source emissions inventory for approximately 400 area source categories. Specifically, the District developed the area source inventory for about 150 categories whereas CARB developed the remaining area source categories (such as consumer products, and degreasing). For each area source category, a specific methodology is used for estimating emissions. In the 2008 area source inventory, a number of existing methodologies were used with updated activity data such as fuel data or sales data (e.g., fuel combustion categories, oil/gas production). Five new categories (i.e., LPG transmission, Storage and pipeline cleaning, three architectural coating colorants) were added to the inventory, other existing methodologies were refined based on more recent studies (e.g., landfills, composting waste, consumer products, architectural coatings), and some of the area sources were expanded (i.e., Commercial/Industrial internal combustion to include portable equipment engines).

Changes in Point Sources

The point source inventory continued its downward trend primarily due to the implementation of existing stationary source regulations. As indicated in Figure 1-1, the point sources decreased between 2002 and 2008 in VOC, NO_x and SO_x emissions. The decreases are from 52, 41, and 20 tons per day to 34, 34 and 13 tons per day for VOC, NO_x and SO_x respectively. In addition to the effect of existing regulations, another reason for the decreases is due to the recessionary impacts.

Changes in Area Sources

The area source inventory also decreased between 2002 and 2008 for all criteria pollutants, except NO_x. Figure 1-2 shows VOC, NO_x, SO_x and PM_{2.5} changed from 265, 48, 2, 51 tons per day to 231, 53, 1 and 39 tons per day between 2002 and 2008. The reason for NO_x increase is because the expansion of fuel consumption to include commercial and industrial portable equipment emissions.

Rule Implementation

A list of the District's VOC, NO_x, PM_{2.5} and SO_x emission reduction commitment by measure/adopted date by pollutant since 2007 State Implementation Plan (SIP) is presented in Table III-1-2. Table III-1-3 lists SCAB NO_x, VOC, PM_{2.5}, and SO_x emission progress since 2007 SIP to date on CARB rules for year of 2014 and year 2023.

- a. The 2014 emissions data reflect the 2014 Emissions Inventory that was included in the March 2011 *Progress Report on Implementation of PM2.5 State Implementation Plans*.
- b. The 2023 emissions data tables reflect the 2023 Emissions Inventory that was current as of August 2011.
- c. These are remaining emissions. If achieved emissions are lower than the committed emissions, it means the SIP targets are met.
- d. Includes benefits of local emission reductions that were not reflected in the revised RFP estimates.

Improved/Updated Methodologies

Fuel Combustion Sources - The emissions from commercial and industrial internal combustion engines were updated to include portable equipment emissions which were overlooked in the 2007 AQMP. The update causes increases in emissions for this category.

Landfills - The emission estimation methodology for this area source category was revised to incorporate the CARB's landfill GHG emission inventory data to calculate the amount of Methane (CH₄) being generated in 2008. The TOG and VOC emissions were estimated using the emission factors from the "1982 Task Force Report", which were the same factors used to estimate TOG/VOC emissions for this source category in the 2007 AQMP. The baseline emissions from source category in 2012 AQMP had drastically increased as compared with 2002 baseline used in 2007 AQMP. This was due to erroneous activity data reported by the point sources in 2002.

Metal Coating Operations - This area source category in the 2007 AQMP included the emissions from the small permitted facilities with VOC emissions below 4 tons per year. However, emissions from such smaller permitted facilities maybe underrepresented in the 2007 AQMP. During the amendment development process for Rule 1107, staff discovered numerous small shops using coating materials with compliant high solid concentrations, which are subsequently thinned beyond the allowable limit permitted by Rule 1107. The revised inventory adjusts the 2007 AQMP inventory to account for excess emissions from these coating activities as well.

LPG Transmission - This is a new area source category created to include the fugitive emissions associated with transfer and dispensing of LPG and is based on emission rates derived from AQMD source tests conducted in 2008 and 2011 and on sale volumes provided by the industry association and category breakdowns.

Storage Tanks and Pipeline Cleaning - A new area source category was added to include the emissions from the degassing of storage tanks and pipelines. As part of Rule 1149 amendment, the previous inventory for this category was updated to reflect more frequent degassing events as well as effectiveness of control techniques. It was determined that the actual degassing events were more than triple the amount estimated when the rule was originally developed. It was also assumed that once degassing rule requirements were fulfilled, there were no more fugitive emissions; however, a review of degassing logs indicated that sludge and product residual in the storage tanks significantly increase the emissions emanating from the storage tanks. Finally, the source category was expanded to include previously exempted tanks and pipelines.

Livestock Waste - The inventory for this category was updated to reflect the split of dairy cattle into milking cows, dry cows, calves, and heifers fractions since each has a different VOC emission factor as a function of their manure production.

Gasoline Dispensing - For this source category, the 2008 baseline emissions are the projected values as estimated in 2007 AQMP. However, in the 2007 AQMP, the emissions from gasoline dispensing were adjusted to account for 75% compliance levels identified in various audits conducted by the District since 1997. Based on the recent tests conducted at retail gas dispensing facilities on their In-Station Diagnostic (ISD) System, about 18% of the facilities demonstrated non-compliance (i.e., failed the test). As such, to account for this nonconformance with the requirements, the 75% compliance rate was carried over to 2012 AQMP.

Consumer Products - This category was updated to reflect the three most recent surveys conducted by ARB's Stationary Source Division (SSD) for the years 2003, 2006, and 2008. Together these surveys collected updated product information and ingredient information for approximately 350 product categories. Based on the survey data, CARB staff determined the total product sales and total VOC emissions for the various product categories. Before the emissions inventory was updated, some of the existing categories were split out into more specific categories, others were combined, and new categories were added to better reflect changes in formulations of existing products. The updated survey data reflect VOC reductions from several rulemaking with the net result being an overall emissions decrease. The updates conclude that the projected 2008 emissions in the 2007 AQMP are the same as the 2008 emissions in the Draft Final 2012 AQMP (98 tons per day).

Architectural Coatings - Three new area source categories were added under this category to accurately track the emissions from the colorants. VOC emissions from colorants, pigments added at the point of sale that impart the selected color, had specifically been excluded from Rule 1113, both in terms of the baseline emissions and any VOC restrictions. During the June 3, 2011 Rule 1113 amendment, VOC limits were included in the Rule. The emissions for architectural coatings were also updated to include the 2008 sales and emissions data that the manufacturers submitted under Rule 314 – Fees for Architectural Coatings. Rule 314 requires manufacturers to annually report the quantity and emissions of their architectural coatings sold into or within the District's jurisdiction. This data provides more accurate and updated emission estimates.

Composting - The emission estimation methodology for this area source category was revised to include the emissions from green waste composting covered under District

Rule 1133.3. The 2007 AQMP only included the emissions from co-composting, as it relates to the District Rule 1133.2.

Biogenic Volatile Organic Compounds - Emissions of biogenic volatile organic compounds (BVOCs) were updated to reflect the day specific temperature, relative humidity, and solar radiation inputs used in the ozone and PM_{2.5} air quality modeling. BVOC emissions were modeled for everyday in 2008. The 2008 BVOC inventory was developed by CARB.

Fugitive Dust - Subsequent to the approval of the 2003 AQMP, CARB released updated emission factors for several fugitive dust sources. The Final 2007 AQMP incorporated those updated emission factors and/or 2002 activity data for source categories such as entrained paved and unpaved road dust, construction, windblown dust, and farming operations. One of the more significant changes was that the factors used to quantify the PM_{2.5} fraction of PM₁₀ were updated based on studies by the Dust Emissions Joint Forum of the Western Regional Air Partnership (WRAP). These fractions represented the latest technical information for deriving the PM fine fraction (PM_{2.5-10}) of crustal fugitive dust from various sources, including paved and unpaved roads, agriculture, aggregate handling and storage piles, construction/demolition, and wind erosion. The fractions are currently in AP-42 guidance for fugitive dust sources (EPA, November 2006). As noted in the 2007 AQMP, the unspecified category emissions inventories were developed to reflect emissions from private paved and unpaved roads, and emissions from aggregate processing and storage based on facilities subject to Rule 1156 (cement manufacturing) and Rule 1157 (aggregate and related operations). The 2008 baseline inventory for the 2012 AQMP also includes these updates. In addition, the paved road emissions inventory methodology was modified using the latest AP-42 method for quantifying emissions from paved roads (January 2011). In conjunction with CARB, in using this latest paved road methodology, California-specific PM_{2.5}/PM₁₀ fraction (15%) and silt loading variables were used in lieu of the AP-42 default factors. Overall emission estimates were lower for the 2012 AQMP. Table III-1-4 indicates the changes in PM_{2.5} (tons per day) to the fugitive dust inventories. The updated paved road emissions methodology resulted in a significant reduction in emissions, as did the lower construction emissions which are a result of depressed economy.

TABLE III-1-4

Comparison of 2002 and 2008 PM2.5 Emissions (Tons per day)

SOURCE CATEGORY	2007 AQMP	DRAFT FINAL 2012 AQMP
	2002 Inventory	2008 Inventory
Paved Road Dust	18.9	7.0
Unpaved Road Dust	1.4	0.6
Construction	4.0	2.1
Windblown	0.4	0.3
Farming Operations	0.2	0.3
TOTAL	24.9	10.3

Special Studies

Aircraft – The aircraft emissions inventory is updated for the 2008 base year and the 2035 forecast year based on the latest available activity data and calculation methodologies. A total of 43 airports were identified as having aircraft operations within the District boundaries including commercial air carrier, air taxi, general aviation, and military aircraft operations. The sources of activity data included airport operators (for several commercial and military airports), Federal Aviation Administration’s (FAA) databases (i.e., Bureau of Transportation Statistics, Air Traffic Activity Data System, Terminal Area Forecast), and SCAG’s projections. For commercial air carrier operations, SCAG’s 2035 forecast, which is consistent with the forecast adopted for the 2012 Regional Transportation Plan (RTP), was used reflecting the future aircraft fleet mix. The emissions calculation methodology was primarily based on the application of FAA’s Emissions and Dispersion Modeling System (EDMS) model for airports with detailed activity data for commercial air carrier operations (by aircraft make and model). For other airports and aircraft types (i.e., general aviation, air taxi, military), the total number of landing and takeoff activity data was used in conjunction with the EPA’s average emission factors by major aircraft type (e.g., general aviation, air taxi, military). For the intermediate milestone years, the emissions inventories were linearly interpolated between 2008 and 2035.

Ammonia Sources –New 2008 ammonia emissions inventory has been developed for the Draft Final 2012 AQMP development. In conjunction with the ongoing efforts by CARB to develop a state-wide inventory, the District and CARB staffs have worked extensively to develop a new and comprehensive 2008 ammonia inventory for all ammonia source categories. All source categories were reviewed and updated for

emission factors, activity data, and spatial and temporal surrogates. Two new source categories of wood combustion and off-road mobile sources were added to the 2008 inventory. There has been a change in major ammonia emission sources. In 2002 inventory, major sources were on-road mobile (30%), livestock (22%), and domestic (21%) sources while domestic (23%), on-road mobile (20%), industrial (19%), composting (17%) and livestock (14%) sources are major ammonia sources in new 2008 inventory. 2008 Basin total ammonia emissions is 107 tons per day that is 12 tons per day less than 2002 Basin total ammonia emissions of 119 tons per day. 2008 Basin ammonia emissions from livestock, fertilizer application and on-road mobile emissions are decreased from 2002 emissions while soil, landfill, industrial, and composting emissions are increased from 2002 emissions. This updated ammonia emissions inventory has been used for PM modeling for the Draft Final 2012 AQMP development. Table III-1-5 summarizes the changes to the ammonia inventory.

TABLE III-1-5

Comparison of 2002 and 2008 Ammonia Emissions (Tons per day)

SOURCE CATEGORY	2007 AQMP	DRAFT FINAL 2012 AQMP
	2002 Inventory	2008 Inventory
Livestock	26.0	15.5

Mobile Sources

On-Road Mobile Sources

The Draft Final 2012 AQMP emission estimates for on-road motor vehicles come from applying the emission rates in CARB's EMFAC2011 model to the transportation activity data provided by Southern California Association of Government (SCAG) in its adopted 2012 Regional Transportation Plan (RTP). The California Department of Transportation (Caltrans), the Department of Motor Vehicles (DMV), and SCAG supply CARB with data necessary to develop the on-road mobile source emissions inventory. DMV maintains a count of registered vehicles and Caltrans provides highway network, traffic counts and road capacity data. SCAG maintains the regional transportation model containing the temporal and spatial distribution of motor vehicle activity (travel time, travel speed, and volume of traffic for AM-peak, mid-day, PM-peak, evening and night hours). In addition, SCAG periodically conducts origin and destination surveys to validate the regional transportation model. SCAG also updates a demographic database for population, housing, employment and patterns of land use within the District's jurisdiction.

Emission rate data in the EMFAC2011 are collected from various sources, such as individual vehicles in a laboratory setting, tunnel studies and certification data, etc. Vehicle activity data are obtained from regional planning agencies, such as SCAG. The EMFAC2011 model calculates exhaust and evaporative emission rates by vehicle type for different vehicle speeds and environmental conditions (temperature and relative humidity). Temperature and humidity profiles are used to produce month specific, annual average, and episodic inventories.

Parameters accounted for by the EMFAC2011 include the following: type of emissions control technology, fuel type, distribution of operating speeds, speed and temperature correction factors, and the reduction in emissions resulting from the state's motor vehicle regulatory programs.

The EMFAC2011 includes the following mobile source breakdowns:

- (1) eight vehicle classes (light-duty passenger; light-duty trucks under 3,750 pounds; light-duty trucks between 3,750 pounds and 5,750 pounds; medium-duty trucks between 5,751 pounds and 8,500 pounds; light-heavy-duty trucks between 8,501 pounds and 10,000 pounds; light-heavy-duty trucks between 10,001 pounds and 14,000 pounds; medium heavy duty trucks between 14,001 pounds and 33,000 pounds; and heavy-heavy-duty-trucks for over 33,000 pounds);

- (2) two vehicle fuel types (gas and diesel);
- (3) truck types (ports, agriculture, construction, interstate, out-of-state, public fleet, utility fleet, power take off, tractor);
- (4) instate and out-of-state;
- (5) forty-five calendar years (1990-2035);
- (6) two vehicle exhaust processes (starts and running);
- (7) four evaporative processes (diurnal, hot soak, running loss, and resting loss);
- (8) seven pollutants (HC, CO, CO₂, NO_x, PM, SO_x, lead); and
- (9) fuel consumption.

To develop the detailed emission inputs needed by air quality dispersion models such as the Community Multi-scale Air Quality model (CMAQ) and Comprehensive Air Quality Model with eXtentions (CAMx), emissions from on-road motor vehicles are estimated at the grid level using Caltrans' Direct Travel Impact Model (DTIM). DTIM calculates emissions based on detailed information regarding each link (roadway segment) in an area for each hour of the day. The required inputs of DTIM include traffic volume, traffic speed, vehicle fleet characteristics, ambient temperature, and emission factors of vehicle fleets.

It should be noted that even though the EMFAC2011 is expanded to include more sub-vehicle class categories for some of the major vehicle class categories (i.e., medium-heavy duty diesel trucks & heavy-heavy diesel trucks) based on their weights (heavy or small), types (agricultural, construction, CA international registration plan), by road types (in-state or out-of-state), etc, the on-road mobile sources emissions in the Draft Final 2012 AQMP are reported by major vehicle class categories to compare with previous inventory reporting.

The characteristics of DTIM include:

- (1) emissions calculations based on specific information, such as link speed, link volume, and temperature;
- (2) spatial and temporal distribution of emissions to provide hourly gridded emissions; and,

(3) emission impacts of various types of transportation and regional planning alternatives (e.g., changes in roadway network configuration, or public transportation services).

DTIM reformats and sorts emission rates for all vehicle classes produced by the EMFAC2011. It then produces average emission rates for specific vehicle classes identified by the user. Finally, it produces regional mobile source emissions and hourly gridded mobile emissions. DTIM does this by combining emission rates with vehicle activity estimates derived from a transportation demand model and supplemental information on temperatures and temporal patterns.

The EMFAC2011 was the basis for on-road planning inventories, emission budgets, and rate-of-progress calculations. EMFAC2011 has been updated to:

- Include the impacts of recently adopted diesel regulations including the Truck and Bus Rule and other diesel truck fleet rules: the Pavley Clean Car Standard, and the Low Carbon Fuel Standard.
- Reflect the latest emissions inventory methods for heavy duty trucks and buses, and the impact of the economic recession.

A detailed description of the EMFAC2011 changes is available at CARB's website (<http://www.arb.ca.gov/msei/msei.htm>).

Several additional external adjustments are made to EMFAC2011 to reflect CARB's rules and regulations which were adopted after the development of EMFAC2011. The adjustments include the advanced clean cars regulations adopted in January 2012, reformulated gasoline, and Smog Check improvements. Figure 1-3 compares the 2008 and 2023 on-road baseline emissions between EMFAC2007 V2.3 and EMFAC2012 used in the 2007 AQMP and Draft Final 2012 AQMP, respectively. It should be noted that the comparison for 2008 reflects changes in methodology, but the comparison for 2023 also includes adopted rules and updated growth projections since the release of EMFAC2007. In general, the emissions are lower in EMFAC2011 than in EMFAC2007. The lower emissions can be attributed to additional rules and regulations which reduce emissions, future growth corrections, and recessionary impacts.

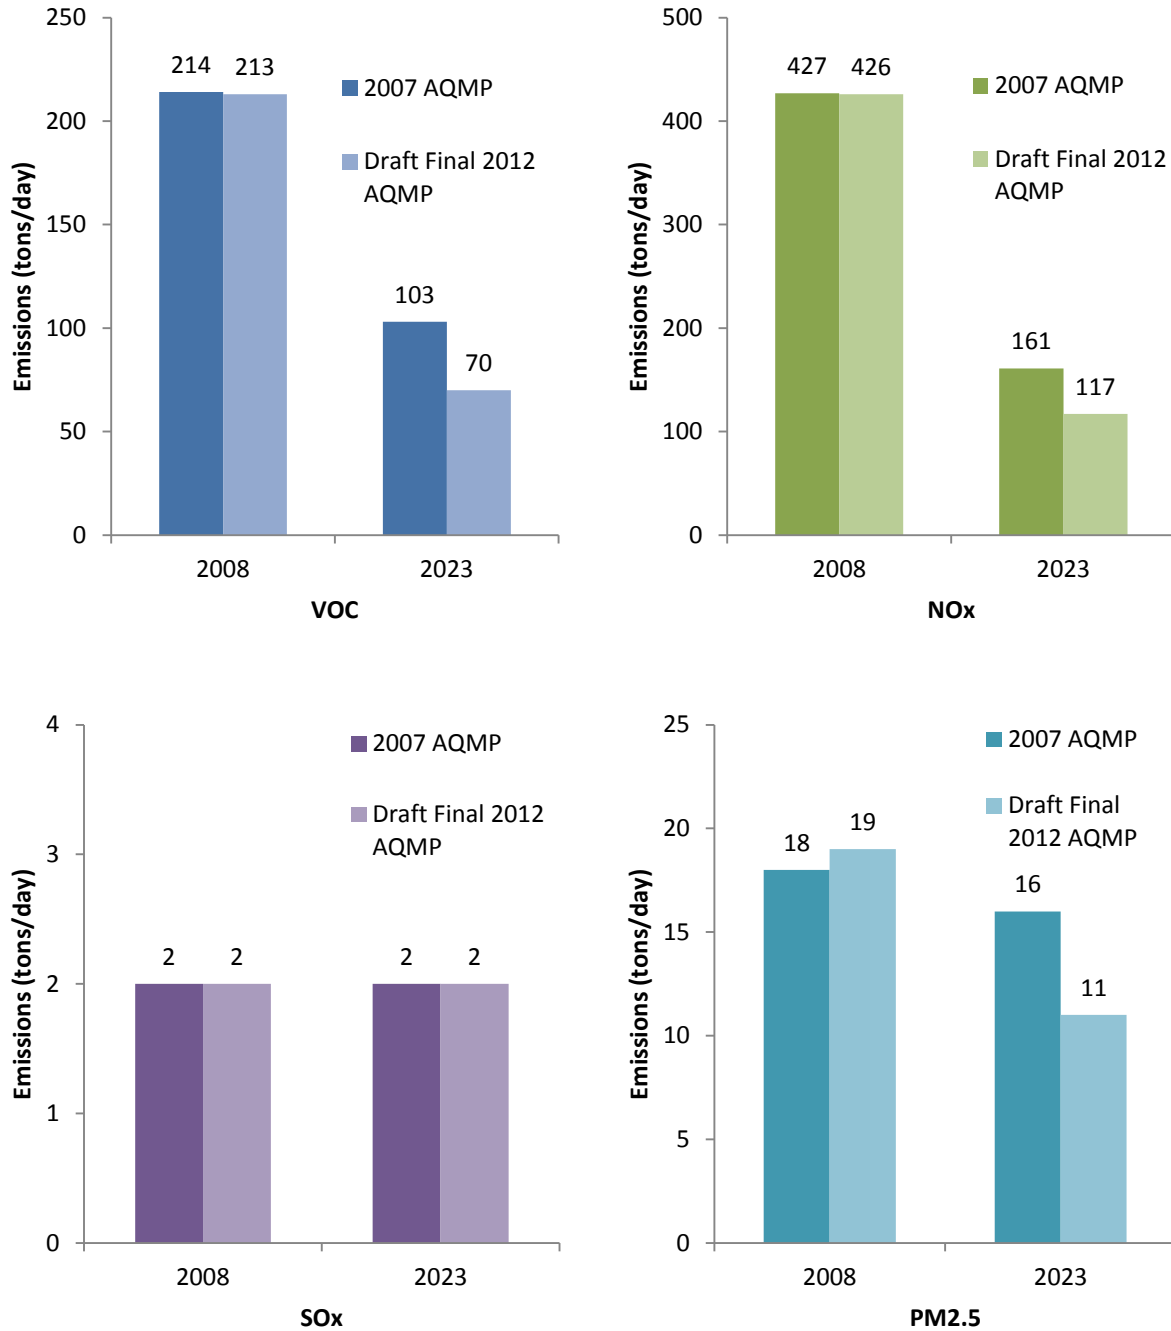

FIGURE III-1-3

Comparison of On-Road Emissions Between EMFAC2007 V2.3 (2007 AQMP) and EMFAC2011 (Draft Final 2012 AQMP)
 (VOC & NOx – Summer Planning; SOx & PM2.5 – Annual Average Inventory)

Off-Road Mobile Sources

Mobile sources not included in the on-road mobile source emissions inventory are considered as off-road mobile sources. CARB uses a number of models to estimate emissions for more than one hundred off-road equipment types. The models account for the effects of various adopted regulations, technology types, and seasonal conditions on emissions. The models combine population, equipment activity, horsepower, load factors, population growth, retirement factors, and emission factors to yield the annual emission by county, air basin or statewide. Temporal usage profiles are used to develop seasonal emission estimates which are then spatially allocated to the county or air basin using surrogates such as population.

The emission inventories were developed using CARB's 2011 In-Use Off-Road Fleet Inventory model for the Draft Final 2012 AQMP. The 2011 In-Use-Off-Road Fleet Inventory model was last updated in 2011 and most data was obtained several years before. It reflects CARB's rules and regulations adopted since the 2007 AQMP. The description of these models is presented as follows:

- **2011 In-Use Off-Road Fleet Inventory Model** - This is an Access database model that forecasts future vehicle population data by type, model year, and horsepower from the Off-Road Simulation Model (OSM). The Model was developed in 2010 to support the analysis for amendments to the In-Use Off-Road Diesel Fueled Fleets Regulation. The equipment population in CARB's In-Use Off-Road Fleet Inventory Model is updated using the equipment population reported to CARB for rule compliance. According to CARB, the total population in 2009 was 26% lower than had been anticipated in 2007 due to fleet downsizing during the recent recession. The equipment hours of use in the Model are updated based on the reported activity data between 2007 and 2009. According to CARB, the new data indicated in most cases 30% or greater reduced activity in 2009 compared to 2007 as a result of the recession. The equipment load factor in CARB's In-Use Off-Road Fleet Inventory model is updated using a 2009 academic study and information from engine manufacturers. According to CARB, the new data suggest the load factors should be reduced by 33%. The model calculates NO_x, PM, and VOC, CO₂ and SO_x emissions. The models can be downloaded from CARB's website at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles
- **Cargo Handling Emission Inventory Model** - This is an Access database model for diesel equipment subject to regulation for Mobile Cargo Handling Equipment at Ports and Intermodal Rail Yards. Cargo handling equipment has been updated for

population, activity, recessionary impacts on growth, and engine load. The updates are based on new information collected since 2005. The new information includes CARB's regulatory reporting data which provides an accounting of all the cargo handling equipment in the state including their model year, horsepower and activity. In addition, the Ports of Los Angeles and Long Beach have developed annual emissions inventories and a number of the major rail yards and other ports in the state have completed individual emission inventories. The model can be downloaded from CARB's website at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles

- **Transportation Refrigeration Unit (TRU) Model** – This is an Access database model for diesel engines subject to Airborne Toxic Control Measure for In-Use Diesel-Fueled Transport Refrigeration Units (TRU) and TRU Generator Sets and Facilities Where TRUs Operate (TRU Rule). The TRU model was developed to support analysis for the 2011 amendments to the TRU Rule. The current inventory is based on updated activity, population, growth and turn-over data, and updated emission factors and takes into consideration the requirements of the TRU Rule. The model can be downloaded from CARB's website at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles
- **Ocean Going Vessel (OGV) Model** – This is an Access database model for marine vessels and engines. Ocean-going vessel emissions in the Draft Final 2012 AQMP include CARB's fuel regulation for ocean-going vessels and the 2007 shore power regulation. In addition, the improvements and corrections include recoding the model for speed, updating auxiliary engine information, updating ship routing, revising vessel speed reduction compliance rates, and an adjustment factor to account for the effects of the recession. In March 2010, the International Maritime Organization (IMO) officially designated the waters within 200 miles of the North American Coast as an Emissions Control Area (ECA). Beginning August 2012, this requires ships that travel these waters to use fuel with a sulfur content of less than or equal to 1.0% and in 2015 the sulfur limit will be further reduced to 0.1%. Additionally, vessels built after January 1, 2016 will be required to meet the most stringent IMO Tier 3 NOx emission levels while transiting within the 200 mile ECA zone. Outer Continental Shelf (OCS) emissions (i.e. emissions from vessels beyond the three-mile state waters line) are included in the ships emissions. The model can be downloaded from CARB's website at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles

- **Commercial Harbor Craft Emission Inventory Models** – These are newly developed models. Three Access database models were developed for diesel engines which are subject to regulation to reduce emissions from diesel engines on commercial harbor craft operated with California Waters and 24 nautical miles of the California baseline (Harbor Craft Rule). One model was originally developed in 2007 to support the analysis for the Harbor Craft Rule. The other two models were developed to support analysis for the 2010 amendments to the rule which added additional vessel categories to the Harbor Craft Rule. The inventory values from the three models are added together to obtain the AQMP values. The model can be downloaded from CARB's website at http://www.arb.ca.gov/msei/categories.htm#offroad_motor_vehicles
- **Aircraft** - The aircraft emissions inventory is updated for the 2008 base year and the 2035 forecast year based on the latest available activity data and calculation methodologies. A total of 43 airports were identified as having aircraft operations within the District boundaries including commercial air carrier, air taxi, general aviation, and military aircraft operations. The sources of activity data include airport operators (for several commercial and military airports), FAA's databases (i.e., Bureau of Transportation Statistics, Air Traffic Activity Data System, Terminal Area Forecast), and SCAG. For commercial air carrier operations, SCAG's 2035 forecast, which is consistent with the forecast adopted for the 2012 RTP, reflects the future aircraft fleet mix. The emissions calculation methodology is primarily based on the application of FAA's Emissions and Dispersion Modeling System (EDMS) model for airports with detailed activity data for commercial air carrier operations (by aircraft make and model). For other airports and aircraft types (i.e., general aviation, air taxi, military), the total number of landing and takeoff activity data is used in conjunction with the EPA's average emission factors by major aircraft type (e.g., general aviation, air taxi, military). For the intermediate milestone years, the emissions inventories are linearly interpolated between 2008 and 2035.
- **Locomotives** – The locomotive inventories reflect the 2008 U.S.EPA locomotive regulations and adjustments due to the economic activity.

Figure 1-4 shows a comparison of the off-road baseline emissions in the 2007 AQMP and Draft Final 2012 AQMP. In general, the emissions are lower in the 2011 In-Use Off-Road Fleet Inventory model, except for 2008 SO_x emissions. The projected 2008 off-road NO_x emissions in the 2007 AQMP have 339 tons per day. The 2008 base year off-road NO_x emissions in the Draft Final 2012 AQMP are 208 tons per day. The 2011

In-Use Off-Road Fleet Inventory emissions are low because more rules and regulations adopted since 2007 OFFROAD model are included, updated data are used, and future growth corrections and recession impact are included. The higher 2008 SOx emissions estimated reflects the delay in the implementation of the ocean going vessels fuel SOx standard.

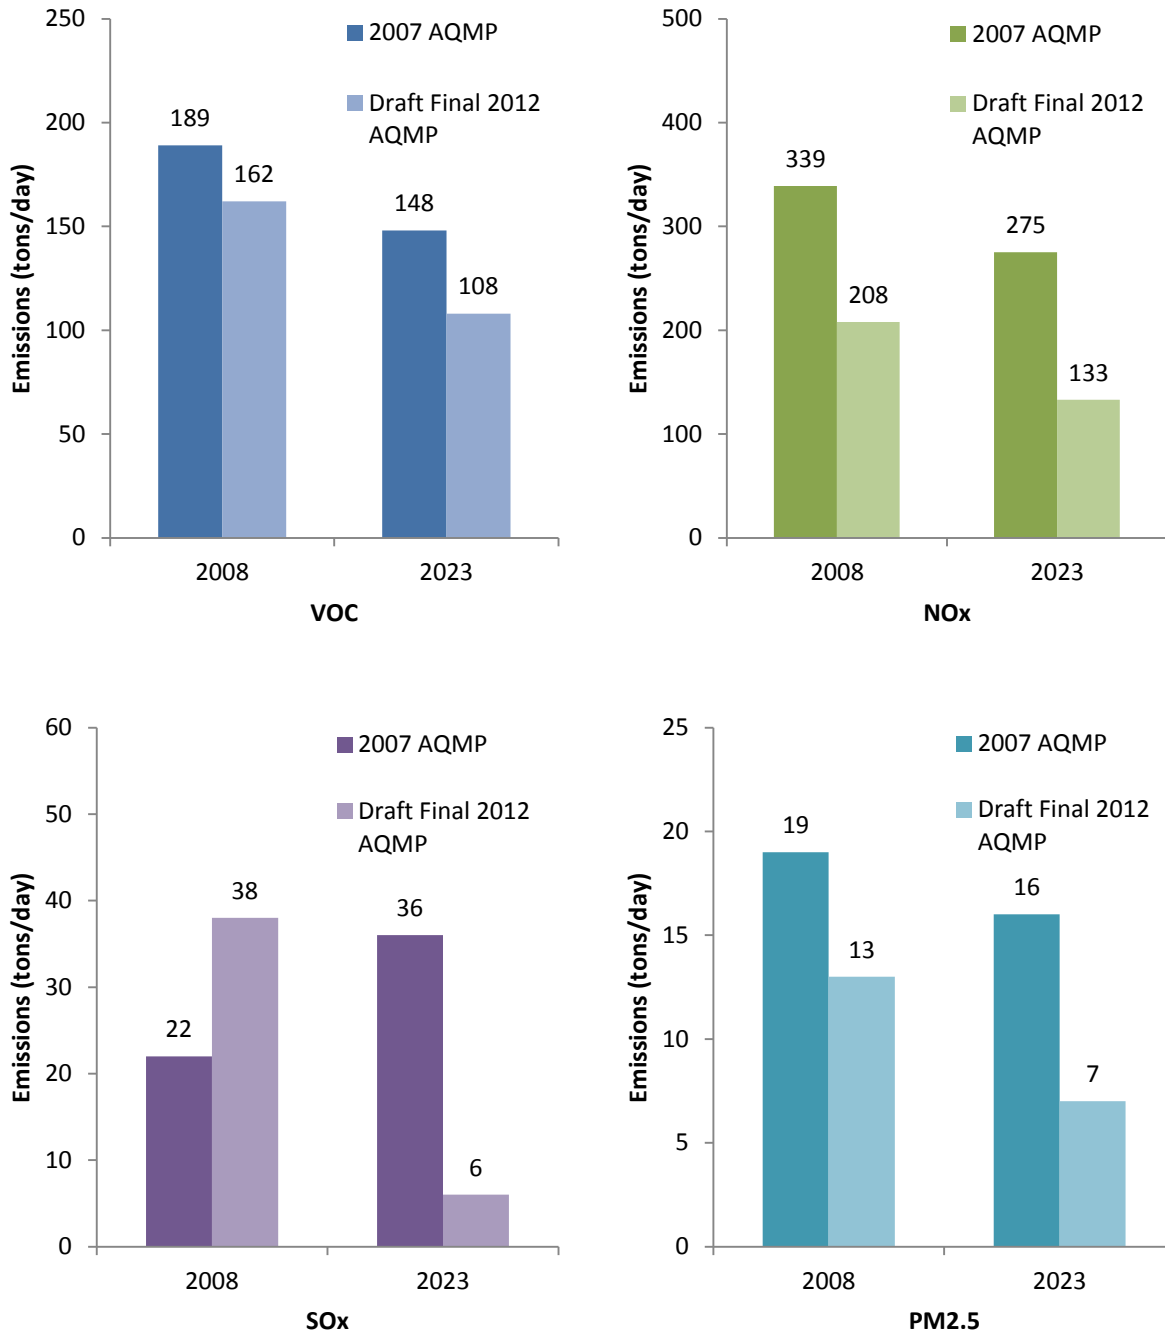

FIGURE III-1-4

Comparison of Off-Road Emissions Between 2007 AQMP and Draft Final 2012 AQMP (VOC & NOx – Summer Planning; SOx & PM2.5 – Annual Average Inventory)

INVENTORY TYPE

Different inventories are prepared for the Draft Final 2012 AQMP for regulatory and SIP performance tracking, and transportation conformity. Two inventory types are included in the Draft Final 2012 AQMP. They are annual average inventory and summer planning inventory.

Average Annual Day Inventory

The average annual day emissions inventory was derived primarily by dividing the annual total emissions by 365, except for the emissions derived from CARB's EMFAC2011 (on-road mobile sources) and In-Use Off-Road Fleet Inventory (most off-road mobile sources) models. In addition, the average annual day inventory was developed for all criteria pollutants regardless of their attainment status. The average annual day emissions are used to estimate cost-effectiveness of proposed control measures and future tracking of AQMP implementation (e.g., annual progress report on rule adoption).

Planning Inventory

Summer planning inventory provides the basis for tracking emission reduction progress specified by the federal Clean Air Act (CAA) and California Clean Air Act (CCAA). The CAA requires the District to produce a plan for reducing all non-attainment pollutants or their precursors by fifteen percent between 1990 and 1996, and three percent each year thereafter, averaged every consecutive three years until reaching the attainment date. The CCAA requires emission reductions by five percent or more per year, averaged every three consecutive years until 2000. In addition, the CAA specifies 1990 as the base year, whereas the CCAA specifies 1987 as the base year.

SCAB is designated as an extreme non-attainment area for Ozone for the federal air quality standards, and a non-attainment area for Ozone for the state air quality standards. The intent of the summer planning inventory is to characterize emission levels representative of those that occur during the typical season of air quality violations. The summer, or ozone, planning inventory contains emissions of ozone precursors (i.e. VOC and NOx) during the summertime.

The challenge of bringing the Basin air quality into compliance with state and federal ozone air quality standards is complicated by the fact that ambient concentrations of ozone are typically at their highest during the summer (defined as May through October for planning purposes). Any strategy designed to mitigate air pollution in the Basin must consider this summer variation in ambient air quality.

CARB has developed guidelines for the development of planning inventories. For point sources emission estimates represent an “average annual operating day.” Emissions from point sources are calculated by dividing the total annual emissions produced by a source by the number of days the source was in operation. For example, if a company emitted 150 tons in a year and the production lines operated 5 days a week for 40 weeks, then the average operating emissions from this facility are calculated to be 150 tons divided by 200 days or 0.75 tons per day.

For area and other mobile sources, planning emissions represent an “average seasonal operating day.” As an example, VOC emissions produced by asphalt road-paving operations are calculated by taking into account the variation in monthly levels and weekly operating days for paving activity during the year. Road paving varies from maximum rates during the summer season. Paving activity varies throughout the week with, on average, five operating days in a week. The allocation of annual area source emissions among the seasons is based on estimated relative monthly and weekly emissions patterns. As pointed out earlier, sources included in CARB’s In-Use Off-Road Fleet Inventory model include seasonal activity and temperature profiles which are used to develop the planning inventories. CARB’s summer planning on-road emission rates in the EMFAC2011 are applied to incorporate with SCAG’s updated activity data in the 2012 RTP.

BASELINE EMISSION INVENTORIES

Base Year Emissions

The 2008 emission inventory is used as the base year inventory to project future year emissions. It represents the most recent and comprehensive inventory development. Attachment C lists SCAB top VOC and NO_x producers which emitted equal to or greater than ten (10) tons per year in 2008. The total VOC emissions from these facilities represent 70% of the total point sources VOC emissions and 8% of the total stationary VOC emissions. The total NO_x emissions from these facilities represent 84% of the total point sources NO_x emissions and 29% of the total stationary sources NO_x emissions. The stationary sources emissions result primarily from the combustion of fuels, evaporation of solvents or fuels, and processing of materials. Hence, stationary sources are grouped under fuel combustion; waste disposal; cleaning and surface coatings; petroleum production and marketing; industrial processes; solvent evaporation; and other miscellaneous processes.

Mobile sources are divided into two source categories: 1) on-road, and 2) other (off-road) mobile sources. On-road mobile sources include light-duty passenger vehicles; light-, medium-, and heavy- heavy duty trucks; motorcycles; urban buses; school buses and motor homes. Other mobile sources include aircraft; trains; ships and commercial boats; off-road recreational vehicles; off-road equipment; farm equipment; and fuel storage and cargo handling equipment.

Table III-2-1A compares the annual average emissions between the 2008 base year in the Draft Final 2012 AQMP and the projected 2008 emissions in the 2007 AQMP by major source category for VOC and NO_x, while Table III-2-1B compares the annual average emissions between the 2008 base year in the Draft Final 2012 AQMP and the projected 2008 emissions in the 2007 AQMP for SO_x and PM_{2.5}. Due to the economic recession which began in 2007, it is expected that the 2008 base year emissions should be lower than the projected 2008 emissions. Yet, several categories show higher emissions in the 2008 base year in the 2012 AQMP, such as fuel consumption, waste disposal, petroleum production and marketing for VOC; fuel consumption for NO_x; off-road emissions for SO_x; and industrial processes for PM_{2.5}. As mentioned earlier the differences are due to the methodology updates, implementation delays and inclusion of overlooked emissions.

Future Year Emissions

Future baseline emissions, assuming no additional air quality regulations are introduced, are given in this appendix for the years 2014, 2017, 2019, 2023, and 2030. These emissions are forecast from the 2008 base year by incorporating the controls implemented under AQMD rules adopted as of June 2012, and CARB adopted by August 2011, and a specific set of growth rates from SCAG for population, industry, and motor vehicle activity. Growth projections from SCAG were replaced for certain categories where more specific information is available to improve emission forecasts.

For example, 2011 California Gas Fuel Report's energy demand forecasts for natural gas, including the energy efficiency, are used to forecast the emissions of those source categories. Several external adjustments are made to include CARB's rules adopted after August 2011, and emission reductions are not included in the EMFAC2011 or In-Use Off-Road Fleet Inventory models. These external adjustments in the Draft Final 2012 AQMP include large spark ignition engines, non-agricultural internal combustion engines, advanced clean vehicles (LEVIII), Smog Check improvement, pleasure craft, and locomotives.

The impact of New Source Review and emissions budgeted for several District programs are addressed in the Controlled Emission Data section. Due to the adoption of the Regional Clean Air Incentive Market (RECLAIM) program in October 1993, emissions are divided into two categories, RECLAIM and non-RECLAIM. Future emissions from RECLAIM sources are estimated based on their allocations specified by District Rule 2002. The methodology used to forecast emissions for non-RECLAIM sources is described in the following sections. Baseline emissions for future years are obtained using the following equation:

$$(F.Y.)_i = (B.Y.)_i(C.F.)_i(G.F.)_i$$

where (F.Y.)_i is the forecast emissions of an air pollutant in the South Coast Air Basin for a future year. (B.Y.)_i refers to the base year emissions of the air pollutant (i.e., 2008). The control factor, (C.F.)_i, is an indicator of the level of control on a specific source category as a result of adopted state and local air quality regulations. (G.F.)_i is a growth factor determined for different categories of industry and socioeconomic data.

Control Factors

The impact of AQMD rules adopted or amended with compliance dates after 2008 are included in the baseline emission forecasts by means of control factors. Control factors were developed in reference to 2008 and applied to source categories and/or specific industries affected by the adopted rules/amendments. For industry, the standard industrial codes (SIC) system is used, and for equipment, EPA's SCC system is used. A control factor (C.F.)_i is calculated by the following equation for an individual source category:

$$(C.F.)_i = 1 - \text{Control Efficiency}$$

Control efficiency is mostly based on estimates projected during rulemaking. Control factors represent the remaining emissions after a rule or regulation is implemented after

2008. Table III-2-2 lists control factors for the years 2014 and 2023 for District rules with post-2008 compliance dates.

Growth Factors

For growth purposes, facility business type is assigned to the facilities based on North American Industry Classification System (NAICS) Code according to their primary activity. Growth projections by NAICS were developed by SCAG. The Draft Final 2012 AQMP growth data is based on SCAG's 2012 RTP. The data was adjusted with the most recent data from Bureau of Labor Statistics (BLS), California Department of Finance (DOF), California Employment Development Department and U.S. Census Bureau (Census). The SCAG's 2012 RTP growth estimates are lower than SCAG's 2008 RTP for the following reasons: (1) Recent population projections from BLS, DOF and Census indicate that SCAG region will face significant slow growth, which will affect long-term employment growth in SCAG region. This is due to the aging trend of the baby-boomer population and the recessionary impacts; (2) The Draft Final 2012 AQMP employment growth is adjusted by both the economic recession and globalization. Since the employment forecast is based on a historical trend, sluggish job growth in recent years translates into slower short-term and long-term employment growth for the SCAG region.

Each emission inventory source grows based on its growth surrogate. Growth surrogates include industry output growth, employment growth, demographic growth and others. The selection of the surrogate by which emission growth is projected depends on the type of activity. For instance, manufacturing sectors use output growth as surrogate. Output growth is the product of employment and productivity. Employment growth is chosen for labor intensive sectors, such as construction and laundering. Certain emission sources use demographic data as their surrogate, such as architectural coatings (housing units as surrogate) and composting (population as surrogate). Some growth projections are from ARB's special studies or Southern California Gas Company 2011 Gas Fuel Report for natural gas combustion related categories.

TABLE III-2-2A

Control Factors by District Rules with Post-2008 Compliance Dates

*Adopted or amended as of June 2012. Only rules with emissions impact after 2008 are listed.

** Emission reductions from biogas are adjusted in Section of "SIP Set Aside Account".

*** Emission reductions are annual average emissions presented in sequence.

The demographic forecasts from the year 2008 to the years 2023, and 2030 for population, housing, employment, and motor vehicle activity are shown in Table III-2-3.

TABLE III-2-3

Baseline Demographic Forecasts in the Draft Final 2012 AQMP

CATEGORY	2008	2023 (% GROWTH)		2030 (% GROWTH)	
Population (Millions)	15.6	17.3	11%	18.1	16%
Housing Units (Millions)	5.1	5.7	12%	6.0	18%
Total Employment (Millions)	7.0	7.7	10%	8.1	16%
Daily VMT (Millions)	379	396	4%	421	11%

Current forecasts indicate that this region will experience a population growth of 11 percent by the year 2023 with a 4 percent increase in vehicle miles traveled (VMT); and a population growth of 16% by the year 2030 with a 11% increase in VMT.

As compared to the projection from the 2007 AQMP, the current projection for the Draft Final 2012 AQMP for the year 2030 shows about a 1.5 million (7.6%) decrease in population, 900,000 (10%) decrease in total employment and 32 million miles (7.1%) decrease in the daily VMT forecast.

Table III-2-4 shows the relative distribution of population by county in the Basin for the years 1997, 2002, 2008, 2014, 2023, and 2030. By 2030 the population in Los Angeles County is projected to increase by 12 percent from 2008 levels, compared with increases for Orange, San Bernardino, and Riverside counties of 14 percent, 39 percent, and 24 percent respectively.

TABLE III-2-4

Population Distribution by County in SCAB (in Thousands)

YEAR	LOS ANGELES	ORANGE	RIVERSIDE	SAN BERNARDINO	BASIN TOTAL
1997	8,881	2,750	1,072	1,250	13,954
2002	9,486	2,931	1,278	1,410	15,105
2008	9,398	2,989	1,683	1,510	15,580
2014	9,648	3,119	1,842	1,592	16,201
2023	10,107	3,316	2,114	1,745	17,282
2030	10,509	3,408	2,335	1,878	18,130

* Source – SCAG socio-economic data (11/11)

Growth factors for specified ranges of NAICS categories were projected by SCAG, and are based on predictions of growth for different industrial sectors per county. SCAG has provided growth factors for the years 2005, 2011, 2012, 2015, 2018, 2020, 2023, 2025, and 2030. The growth factors for other years are interpolated. Table III-2-5 lists the point sources growth surrogate by NAICS. Table III-2-6 has the area sources growth surrogate by source category. Tables III-2-7 to III-2-10 illustrate the growth factors for point sources by NAICS for years of 2014, 2019, 2023 and 2030 in the Draft Final 2012 AQMP. Tables III-2-11 to III-2-14 contain the growth factors for years of 2014, 2019, 2023, and 2030 in the Draft Final 2012 AQMP for the area sources by source category.

Emission Trend Analysis

Figures 2-1 through 2-4 present the relative contributions by source categories (i.e., point, area, on-road, and off-road) to total emission levels in 2008 annual average (VOC, NO_x, CO, SO_x and PM_{2.5}), 2008 summer planning (VOC and NO_x), 2023 annual average (VOC, NO_x, CO, SO_x and PM_{2.5}) and 2023 summer planning (VOC and NO_x), respectively. As seen in the figures, in 2008 (average annual day) on-road and off-road mobile sources are major contributors of CO (95 percent), NO_x (88 percent), SO_x (75 percent) and VOC (57 percent) emissions. Top fine particulate matter (PM_{2.5}) producers include cooking (14%); residential fuel consumption (10%); and entrained road dust (10%). For 2023 (average annual day), mobile sources continue to be major contributors to total CO and NO_x emissions by approximately 90 percent, 78 percent, respectively. However, contribution to VOC and SO_x by mobile sources is reduced due to CARB regulations over time. Area sources become major contributors to VOC emissions (from 38 percent in 2008 to 53 percent in 2023). Figures 2-5 through 2-8 illustrate the emission trends by pollutant (VOC, NO_x, PM_{2.5}, and SO_x) for 2008, 2014, 2019, and 2023 respectively.

FIGURE III-2-8
SOx Emission Trend by Source Category – Average Annual Day

VOC Emissions

As presented in Figure III-2-5, emissions from area sources, off-road mobile sources and on-road mobile sources all show a significant decrease over time. Between 2008 and 2023, summer planning VOC emissions from off-road mobile sources are expected to fall from 162 tons per day to 108 tons per day, while on-road emissions should fall from 213 tons per day to 70 tons per day. Area source reductions are derived mainly from the AQMD's adopted rules for architectural coatings (Rule 1113), refinery flares (Rule 1118), greenwaste composting operations (Rule 1133.3), consumer paint thinners and multi-purpose solvents (Rule 1143) and metalworking fluids and direct-contact lubricants (Rule 1144). Off-road reductions result primarily from turnover to cleaner off-road equipment, pleasure craft and off-road recreational vehicles. Since its adoption in 1990, California's Low Emission Vehicle I (LEV I) program has produced significant emission reductions from on-road passenger vehicles by relying on a systems-wide approach to achieve reductions from fuels and mobile source exhaust and evaporative emissions. Both LEV I and LEV II, adopted in 1998, include four primary elements: (1) increasingly stringent exhaust emission standards, (2) an increasingly stringent annual fleet average standard for non-methane organic gas (NMOG), (3) banking and trading provisions, and (4) a requirement that a specific percentage of vehicles be Zero Emission Vehicles (ZEVs), vehicles with no emissions. Under LEV II, sport utility vehicles, pick-up trucks, and mini-vans must achieve the same emission standards as cars, beginning in 2004-2007. Additional VOC emission reductions are from the adoption of the LEV III program.

NO_x Emissions

Figure III-2-6 illustrates the NO_x emissions by major source category. Summer planning NO_x emissions are projected to decrease from both off-road mobile (208 tons per day to 133 tons per day) and on-road mobile (426 tons per day to 117 tons per day) sources from 2008 to 2023. The on-road reductions largely reflect the cleaner in-use heavy-duty trucks and buses. Reductions from on-road emissions are also projected for light- and medium-duty vehicles through the adoption of the LEV VIII program with more stringent tail-pipe and greenhouse gas standards for light- and medium-duty vehicles. Off-road NO_x emission reductions result primarily from cleaner in-use off-road equipment (over 25 horse power); ship auxiliary engine cold ironing & clean technology; cleaner main ship engines.

PM2.5 Emissions

Figure III-2-7 shows the PM2.5 emission trend. A good portion of the emissions are from dust. The projected dust inventories in 2008 and 2023 for paved and unpaved roads are both 8 tons per day (annual average inventory).

SOx Emissions

Figure III-2-8 illustrate the SOx emissions trend. The significant decrease in SOx emissions between 2008 and 2014 (from 54 tons per day to 18 tons per day) is due to the full implementation of the SOx RECLAIM and implementation of the cleaner sulfur content marine fuels.

Impact of Growth

The Draft Final 2012 AQMP forecasts the 2030 emissions inventories “with growth” through a detailed consultation process with the Southern California Association of Governments (SCAG). The region is likely to see a 16% growth in population, 18% growth in housing units, 16% growth in employment, and 11% growth in vehicle miles traveled between 2008 and 2030. To illustrate the impact of demographic growth on emissions, year 2030 no-growth emissions were estimated by removing the growth factors from the 2030 baseline emissions. Table III-2-15 presents the comparison of the projected 2030 emissions with and without growth. It should be noted that in this analysis, the benefit of potential applications of BACT under New Source Review (NSR) is not included. The growth impacts to year 2030 for VOC, NOx, CO, SOx and PM2.5 are 77, 76, 311, 5 and 11 tons per day respectively.

General Conformity Budget

EPA’s General Conformity rule (40 CFR part 93, subpart B, and 40 CFR Part 51, Subpart W, as adopted by reference in SCAQMD Rule 1901, September 1994) establishes an applicability test for determining which Federal actions are subject to the conformity requirement for the nonattainment or maintenance areas. If a proposed action results in emissions increases which are less than the de minimis thresholds for the relevant pollutants or precursors, then no conformity determination needs to be made. If the emissions from a proposed action exceed the de minimis threshold for any given pollutant (or precursor) for which the area is designated as maintenance or in nonattainment, then the Federal agency must make a positive conformity determination for that pollutant(s) on the basis of one of the criteria listed in 40 CFR 93.158 before the project can proceed. The conformity determination must demonstrate that the emissions from the proposed project are accounted for in the most recently approved SIP. The

South Coast Air Basin is designated as an extreme nonattainment area for ozone and as a nonattainment area for PM_{2.5}. The general conformity de minimis threshold is 10 tons per year of VOC and 10 tons per year of NO_x for the extreme ozone nonattainment areas; and 100 tons per year of PM_{2.5} for the PM_{2.5} nonattainment areas.

Based on historical records none of the projects requiring general conformity determinations received by the District exceeded the PM_{2.5} threshold. Rather, NO_x is the main pollutant of concern, with emissions occurring primarily during the two to three year construction phase of projects. To streamline the review process and to facilitate the conformity determination, two separate VOC and NO_x general conformity budgets are established: 1 tpd of NO_x and 0.2 tpd of VOC are set aside for this purpose every year, starting in 2013 until 2030, from the projected emission growth in the Draft Final 2012 AQMP. This set aside account will be re-evaluated in the next AQMP for need and adequacy based on the data gathered at that time. These set-aside emissions in the Draft Final 2012 AQMP represent less than 1% and 2% of projected mobile source growth in emissions shown in Table 2-15 for VOC and NO_x, respectively.

The District will set up a tracking system for projects requiring conformity determinations on a first come first serve basis. The District will debit the project emissions from the applicable set aside accounts until it is depleted. The unused portion cannot be carried forward to the following year. For those projects that come in after the conformity budget is exhausted, the corresponding federal agency will have to go through the regular general conformity determination process to demonstrate that these emissions are accounted for in the SIP. The set aside accounts will be revised and updated via AQMP/SIP revisions.

Southern California Edison (SCE) is currently in the process of, or has plans to construct six linear transmission line projects which would traverse federal lands within the jurisdiction of the District. The projects are: (1) Devers-Palo Verde NO. 2 Transmission Project (DPV2); (2) Tehachapi Renewable Transmission Project (TRTP); (3) Falcon Ridge Substation Project (Falcon Ridge); (4) Path 42 Upgrade Project (Path 42); (5) West of Devers Interim Project (WOD Interim); and (6) West of Devers Upgrade Project (WOD Upgrade). SCE submitted to the District the NO_x emissions estimates expected to be generated during the construction of these transmission lines from 2012 and 2022. The total estimated NO_x emissions from these six projects within the South Coast Air Basin are 95 tons per year for 2012; 55 tons per year for year 2013; 10 tons per year for year 2014; 20 tons per year for 2015; 50 tons per year for 2016 and 2017; and 20 tons per year for 2018 through 2022. These emissions have been accounted for in the general conformity set aside account for NO_x.

Pre-Base-Year Offsets

The District's growth projections include pre-base year emissions, consistent with the requirements of 40 CFR § 51.165(a)(3)(i)(C)(I). To the extent offsets are required under NSR for permitted facilities to be sited or expanded in this region, pre-2008 emission credits authorized under District's Reg XIII can be used and are explicitly identified and accounted for in the Draft Final 2012 AQMP through growth projections, up to the amounts shown in Table III-2-15. While Table III-2-15 includes projected growth in certain sources not subject to NSR, the AQMP does not limit growth to individual source categories. Therefore, Table III-2-15 explicitly identifies pre-base-year offsets in the amounts up to the difference between the growth and no-growth projections for the point and area source categories that are potentially subject to NSR and could potentially require the use of pre-base-year offsets. *See* 57 Fed. Reg. 13,498.

This growth presents a formidable challenge to our air quality improvement efforts, because the projected growth will offset the impressive progress made in reducing VOC and NOx and PM2.5 emissions through adopted regulations. Meeting U.S. EPA's current and future more stringent air quality standards will require the continuation of aggressive emissions reductions efforts from all levels of government.

TABLE III-2-15

Growth Impact to 2030 Emissions* in Tons per Day

Total	77	76	311	5	11

*Annual Average Inventory

It should be noted that the AQMP is designed to accommodate growth. Therefore, the proposed control measures are sufficient to reduce emissions while allowing growth. For permitted stationary sources, offsets are required under the federal and state new source review programs. To the extent offsets are required, either via the open market trades or accessing the District's R1315 bank, pre-2008 emission credits can be used and these emissions are accounted for in the SIP through growth projections as shown in Table III-2-15. However, It needs to be emphasized that AQMP emissions reflect projected actual emissions for the source category, not potential to emit or allowable emissions and do not include offset ratio greater than one for ceratain pollutants.

UNCERTAINTY IN THE INVENTORY

An effective AQMP relies on an adequate emission inventory. Over the years, significant improvements have been made to quantify emission sources for which control measures are developed. Increased use of continuous monitoring and source tests has contributed to the improvement in point source inventories. Technical assistance to facilities and auditing of reported emissions by the District also have improved the accuracy of the emissions inventory. Area source inventories that rely on average emission factors and regional activities have inherent uncertainty. Industry-specific surveys and source-specific studies during rule development have provided much-needed refinement to the emissions estimates.

Mobile source inventories remain the greatest challenge due to the constantly new collected information from the large number and types of equipment and engines. Every AQMP revision provides an opportunity to further improve the current knowledge of mobile source inventories. The Draft Final 2012 AQMP is not an exception. As described earlier, many improvements were made to EMFAC2011 and such work is still ongoing. However, it should be acknowledged that there are still areas that could be significantly improved if better data were available. Technology change and improvement in the area of electric, hybrid, flexible fuel, and fuel cell vehicles, or the change in future gasoline prices, all add uncertainty to the on-road emissions inventory.

Additionally, the latest recession started in 2007. The recession was unforeseen and was not considered in the 2007 AQMP. As we prepare the Draft Final 2012 AQMP, we are still in the midst of economic recovery. The impact of this recession is deep and thus adds to the uncertainty in the emissions provided here. Relative to future growth, there are many challenges with making accurate projections, such as where vehicle trips will occur, the distribution between various modes of transportation (such as trucks and trains), as well as estimates for population growth and changes to the number and type of

jobs. Forecasts are made with the best information available; nevertheless, they contribute to the overall uncertainty in emission projections. Fortunately, AQMP updates are generally performed every three to four years; thereby allowing for frequent improvements to the inventories.

CONTROLLED EMISSION INVENTORIES

This section describes the methodology used to estimate the controlled and remaining emissions after the proposed control measures in the Draft Final 2012 AQMP are implemented for the years 2014 and 2023. Emission reductions are derived by applying the control efficiency of a control measure to the projected baseline inventories. In addition to the proposed control measures, the impacts of phase-out VOC and SIP Reserve set aside tracking and other budgeted emissions for various District programs are also discussed in this section.

To project emission reductions and remaining emissions from the implementation of the proposed control measures, a mathematical algorithm called Controlled Emissions Projection Algorithm (CEPA) is used. CEPA is developed to calculate projected remaining emissions and/or emission reductions for specified control scenarios. CEPA is briefly discussed in this section. A more comprehensive and extensive discussion of CEPA is presented in Technical Report III-A of the 1991 AQMP.

Since 1998, the District has been implementing several funding incentive programs for the replacement or retrofit of heavy duty diesel vehicles, including the Carl Moyer and Lower Emission School Bus programs, Proposition 1B Goods Movement program, and the SOON off-road equipment program. Over the years, thousands of diesel engines in the on-road and off-road sectors have been converted to natural gas, repowered, or retrofitted with particulate traps to achieve significant emissions reductions.

Based contracts awarded and executed since the 2007 AQMP under the Proposition 1B and Carl Moyer programs, the typical useful life of the vehicles, and the expected emissions benefits in 2014 beyond the benefits included in the future-year baseline inventory, an additional 16 tons/day of NO_x emissions reductions, 0.28 tons/day of VOC emissions reductions, and 0.46 tons/day of direct PM_{2.5} emissions reductions will be achieved in 2014. These contracts continue to be closely tracked and the resulting level of emission reductions will be confirmed once achieved. The District has dedicated staff performing field audits to ensure that the agreed upon protocols are followed. Based on past contract performance, emission reductions from these awarded contracts were discounted by 30 percent to reflect the fact that occasionally, contract awards are not completed and monies are returned.

Table III-2-16 summarizes emission reductions in 2014 from the mobile source incentive programs. It should be noted that these surplus reductions, attributable to accelerated fleet turnover or early compliance with state regulations, will diminish over time given that the baseline emissions inventory already incorporates normal fleet turnover and rule compliance.

TABLE III-2-16

Summary of Emissions Reductions from Mobile Source Incentive Programs
(2014 Tons per Day)

	VOC	NO_x	PM_{2.5}
Carl Moyer Programs	0.28	8.0	0.20
Proposition 1B Incentive Funding	--	7.6	0.26
Total	0.28	15.6	0.46

Emission Impacts of AQMD Programs

There are several District regulatory programs that have specific impacts on future emissions through certain “set-aside” or exemption provisions. As a result, special emission accounts were created for the Draft Final 2012 AQMP to track these emissions. For air quality modeling purposes, these emissions (except RECLAIM allocations) are distributed across the entire non-RECLAIM point source.

SIP Set Aside Accounts

Background

The Draft Final 2012 AQMP includes a few accounts to track growth from emission trade-offs from regulatory programs, and a SIP Reserve for potential technology assessments (Table III-2-17). The methodology and assumptions used to develop these tracking accounts for the Draft Final 2012 AQMP are discussed in detail below. It should be noted that emission increases or decreases discussed herein are in reference to the projected AQMP baseline.

VOC Emissions from Phase-Out of Toxics

Due to increasing focus on air toxic controls certain amount of conversion from toxics to VOCs may be inevitable in the future. Therefore, three tons per day are included for potential VOC emission increases to reduce toxics, such as controlling of methylene chloride in coating stripping applications may increase VOC emissions.

SIP Reserve for Potential Technology Assessments

To achieve air quality goals, adopted and amended rules and regulations that rely on technology forcing emission limits are often needed. Technology forcing emission limits are designed to provide ample time for the development and implementation of new air pollution technologies. In the event, however, that the new air pollution control technology does not come to fruition by the implementation date of the adopted or amended rule there may be a need to delay or relax the future emission limits. The SIP Reserve is designed to ensure that delaying or relaxing future emission limits for technology forcing rules will not interfere with the Basin's attainment demonstration. In addition, the SIP Reserve allows the District to adopt and amend rules with technology forcing limits, while maintaining SIP approvability if a rule relaxation or delay is needed.

The potential delay of R1110.2 biogas engine reductions beyond 2014 was included in the estimates for 2011.

TABLE III-2-17

Summary of SIP Set-Aside Accounts for the Draft Final 2012 AQMP
(2014/2023 Tons per Day)

	VOC	NO _x
VOC Emissions from Phase-out of ODC or Toxics	1/3	N/A
SIP Reserve (Technology Assessment)	0/2	1/2
Total Addition to Controlled SIP Inventories	1/5	1/2

Proposed Control Measures

In order to assess emission reduction potential and remaining emissions from proposed control measures, a control factor profile needs to be developed identifying source category targeted by a measure, its control efficiency, and implementation schedule.

Control Efficiency/Control Factor

One factor that determines the effectiveness of a control measure is its control efficiency (CE), expressed in percentage. Control efficiency is dependent on the specific control technologies proposed, and each control measure may have one or more technology options available. If there is only one feasible control technology in a control measure, its control efficiency is primarily based on an engineering evaluation of the proposed technology. However, if several control technologies are available to control an emission source, the average control efficiency is used. If multiple control technologies are proposed to reduce emissions from various steps of an operation, a weighted average control efficiency is developed to represent an overall control of the emission sources. Once the control efficiency of a control measure is determined, it is used to estimate emission reductions of the proposed measure. Control efficiencies for the proposed control measures are identified and discussed in detail in Appendix IV of the Draft Final 2012 AQMP.

The control factor (CF) is used to estimate remaining emissions once a proposed control measure is implemented. A control factor equal to 0 indicates complete emission control or 100 percent efficiency. A control factor equal to 1 indicates no emission control or emissions remain unchanged. A high control factor value indicates a low control efficiency. As the control efficiency goes up, the control factor value goes down. The equation to calculate a control factor follows:

$$\mathbf{CF = 1 - (CE/100)}$$

And, the remaining emissions can be calculated as:

$$\mathbf{REM = BE * CF}$$

Where REM is Remaining Emissions, and BE is Baseline Emissions

The Draft Final 2012 AQMP has many milestones for which emission reduction progress needs to be projected. As a result, control factors for each milestone year were developed. The control factor profile for each measure is developed considering the following factors:

- proposed adoption date;
- implementation lead time; and
- phase-in period, if any.

The adoption date as proposed in the Draft Final 2012 AQMP is the date the District or other agency is expected to adopt the control measure as a rule. The implementation lead time reflects the time allowed for the emission sources to install controls. When a rule is implemented, it is not unusual that it may have multiple interim implementation dates prior to full implementation. This is because the requirements in a rule may require two or three phases to reach the final emission target (e.g., a technology-forcing regulation). Or, a rule may regulate such a large population of equipment that it is impractical to implement it all at once, and it becomes administratively necessary to phase in its implementation. In either case, a control profile would indicate an initial implementation date and an ending implementation date. The adoption and implementation schedule of the proposed control measures is presented in Chapter 4 of the Draft Final 2012 AQMP.

Impact Factors

Each proposed control measure describes specific emission sources subject to potential controls. Based on the description of these sources, corresponding sources as tracked in the emission inventory are identified. In general, emission sources are grouped by major source category, which can be further subcategorized into point sources denoted by Source Classification Codes (SCC) and area sources denoted by Category Emission Source (CES) Codes. To track emission reductions more accurately, the control factors at the SCC/CES level become necessary.

An SCC, an 8-digit EPA code, is used to identify emissions from a point source at the equipment level. A CES, a 5-digit CARB code, is used to describe an area source for which emissions are distributed across the region with no specific locations.

For some measures the controls apply not only to the type of equipment, but also to the industries engaged in a particular activity. In those cases, control factors will be developed by pairing SCCs and Standard Industrial Classification (SIC) Codes to clearly and specifically point out the emission sources in the inventory that the measure is designed to reduce. Such SCC/SIC pairs significantly enhance the ability to quantify emissions closely following the intent of a proposed control measure.

There are instances where an SCC or CES category is not fully impacted by a control measure. As a result, an impact factor (IF) is developed as a weighing factor for such an adjustment. The following equation illustrates how the impact factor (IF) is included in the CF calculation.

$$CF = 1 - ((CE / 100) \times IF)$$

Impact factors will accurately track the measure's baseline emissions, and calculate more accurate reductions from the proposed control measures.

CEPA Emission Calculations

The District uses the CEPA program to calculate emission projections for the proposed AQMP control measures. Based on the control factor profile and projected baseline emissions, CEPA estimates emission reductions and remaining emissions for future years by pollutant (i.e., summer VOC and NO_x; winter CO and NO₂; and average annual day for VOC, NO_x, CO, SO_x and PM₁₀).

CEPA allows interaction of multiple control measures affecting a specific emission source, avoiding double counting of emission reductions from additional measures. It

also provides flexibility in analyzing various scenarios and improves accuracy by standardizing calculation methodologies.

To run CEPA, the program requires four data input files. These input files are as follows:

1. Master Measure File - This file contains all the measures proposed in the AQMP. There is one master measure file in the CEPA program.
2. Scenario File - This file is a listing of selected measures to characterize emission reductions, and is a subset of the master measure file. For example, it can contain a group of control measures for mobile sources only, or a group of measures to be implemented by U.S. EPA.
3. Control Factor File - This file shows control factor by pollutant by SCC/SIC (or CES/CES) pairs for each control measure in a specified year.
4. Baseline Emission File - This file contains projected emission data (tons per day) for future years based on the 2008 emissions inventory. There are different types of baseline emission data available for CEPA runs. These are the average annual day emissions inventory with pollutants VOC, NO_x, CO, SO_x, PM₁₀; and PM_{2.5}; and the planning inventory with pollutants VOC and NO_x during summer, and CO and NO₂ during winter.

CEPA calculates the remaining emissions at the SCC/SIC level. It can generate many types of emission summary reports or electronic files. For example, the program can provide composite control factors for on-road mobile sources in sixteen categories used in the air quality modeling analysis or composite control factors from all the proposed control measures in the scenario file. It can also provide remaining emissions by SCC/SIC or CES/CES pairs; by major source category; or by SIC. It can present emission reductions by each control measure in the absence of other competing measures; or reductions for each control measure following a pre-determined implementation sequence. The result of CEPA runs will be presented in Appendix V of the Draft Final 2012 AQMP.

CARB Emission Data Reports System

As mentioned in Chapter 1, of this appendix the entire emission inventories are compiled and maintained by CARB in its statewide emission related information databases named California Emission Inventory Development and Reporting System (CEIDARS), and California Emission Forecasting and Planning Inventory System (CEFIS).

In both systems, emissions are tracked by CARB's coding method called Emission Inventory Codes (EIC code). The EIC code is a 14-digit number arranged into four fields: major category, source category, materials description and emission sub-category. For example, EIC 210-200-3300-0000 is for dry cleaning using perchloroethylene. 210 indicates this source is under laundering group. 200 means the source category is dry cleaning. 3300 refers to the material perchloroethylene. 0000 implies there is no sub-category for this particular source. EIC separates emission sources into four major divisions: stationary, area, non-anthropogenic, and mobile source. This coding system allows flexibility in how sources are selected, sorted and grouped to fit users' needs. EIC links area sources and point sources together to allow a computer program to automatically reconcile point and area source emissions. In the Draft Final 2012 AQMP, all the emission summary reports are based on CARB's EIC codes. Because only the anthropogenic sources are included in this document, all summary reports in appendices include three major divisions. They are stationary, area, and mobile source.
