In general, it is expected that the 2012 AQMP control measures would reduce emissions of TACs. The basis for this conclusion is that many TACs are also classified as VOCs. To the extent that control measures reduce VOC emissions, associated TAC emission reduction could occur as well. CTS-01, CTS-02, CTS-03 and CTS-04 are expected to reduce VOCs by reducing solvent content of coatings, mold release and consumer products.

As Subchapter 4.4, the toxicity of future coating formulations is generally less or no worse than conventional solvents overall but if a facility changes from using water-based products to using products that are reformulated with chemicals that may have new or different health hazards, significant adverse health hazard impacts could occur from using some low VOC reformulated products. However, as with the use of all chemicals, facilities and their workers would be required to continue to comply with existing health protective procedures when handling both flammable and toxic materials. Further, water-based coatings and products tend to contain less flammable and less toxic materials than solvent-based coatings and products. Consequently, future reformulated coatings and solvents are not expected to increase exposures to TAC emissions.

FUG-01, FUG-02 and FUG-03 would reduce VOCs from vacuum trucks; LPG transfer and dispensing; and equipment with fugitive emissions at oil and gas production facilities, petroleum and chemical products processing, storage and transfer facilities, marine terminals, and other sources. MCS-01 would adopt additional retrofit technology, which depending on the source and control technology, would reduce criteria pollutants.

BCM-01, BCM-03, CMB-01, CMB-02, CMB-03, INC-01, IND-01, MSC-03 would reduce combustion emissions through the replacement of existing equipment with more efficient equipment, emission control technology or changes to processes at refineries. The reduction of combustion emission would reduce combustion TACs.

Some measures for motor vehicle and transportation source categories (ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06 and ADV-07) would reduce emissions of diesel exhaust particulate, which is a known carcinogen, and toxic components of gasoline such as benzene, toluene, and xylene. These control measures would result in replacing existing vehicles or equipment with more efficient vehicle or equipment, zero emission electric vehicles or equipment, or alternative fueled vehicles or equipment. Combustion emissions of alternative fuels have trace amounts of methanol and aldehyde, but, generally, are considered to be cleaner and less toxic than diesel or gasoline fueled vehicles. Emissions from power generating equipment may include trace amounts of benzene, aldehydes, metals, and polynuclear aromatic hydrocarbons. However, if the process being electrified was previously powered by direct combustion of fossil fuels, then electrification is expected to result in an overall decrease in toxic emissions.

The overall impacts associated with implementation of the 2012 AQMP are an overall reduction in TACs. Therefore, no significant impacts from TACs have been identified.

PROJECT-SPECIFIC MITIGATION: No significant secondary air quality impacts from TACs have been identified so no mitigation measures are required.

REMAINING SECONDARY AIR QUALITY IMPACTS: The air quality analysis concluded that potential secondary air quality impacts from TACs would be less than significant, no mitigation measures were required, so secondary air quality impacts from TACs remain less than significant.

4.2.6.4 Global Warming

The 2012 AQMP as a whole is expected to promote a net decrease in GHG emissions, in part, because most GHG emissions in the district are generated by combustion processes. To the extent that 2012 AQMP control measures reduce or eliminate combustion processes in favor of near zero or zero emission technologies, GHG emission reduction co-benefit would also be expected to occur. The control measures that have potential GHG emissions impacts are presented in Table 4.2-8. The relative impacts (e.g., either an increase (+) or decrease (-)) are presented along with the activities associated with the impact (e.g., construction necessary to implement the control measure).

TABLE 4.2-9

Potential Impacts on Climate Change and Global Warming

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	CONTROL MEASURE GHG IMPACT^(a)
ONRD-04	Accelerated Retirement of Older On-Road Heavy-Duty Vehicles (NOx, PM)	Incentives replace heavy-duty vehicles with newer or new vehicles. Priority would be placed on replacing older diesel trucks in Mira Loma.	- (conversion to alt fuels/reduction in conventional fuels) - (replacement with more efficient engines,
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace up to 1,000 heavy-duty vehicles with low-emitting vehicles or zero-emission container movement systems.	+ (construction) - (electrification, conversion to alt fuels/reduction in conventional fuels)
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment (NOx)	Accelerate Tier 0 and Tier 1 equipment replacement with Tier 4 equipment, use of air pollution control technologies (e.g., advanced fuel injection, air induction, and after-treatment technologies).	+ (increased energy, reduced fuel economy associated with add-on control equipment) - (replacement with more efficient engines, conversion to alt fuels/reduction in conventional fuels)
OFFRD-02	Further Emission Reductions from Freight Locomotives (NOx, PM)	Replace existing engines (Tier 0 through Tier 3 engines) with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	+ (increased energy, alt fuels, reduced fuel economy associated with add-on control equipment) - (replacement with more efficient engines)
OFFRD-03	Further Emission Reductions from Passenger Locomotives (NOx)	Repower existing Tier 0 and Tier 2 engines with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	+ (engine repower, increased energy, reduced fuel economy associated with add-on control equipment) - (replacement with more efficient engines,
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels at Berth	Shore power of vessels at berth, use of air pollution control technologies on exhaust gases from auxiliary engines and boilers (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	+ (construction, increased energy, reduced fuel economy associated with add-on control equipment) - (electrification)
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure, construction battery charging and fueling infrastructure. Alternatively, if battery, fuel cell or other zero/near zero emission technologies progress sufficiently, the need for wayside power for rail or trucks may be diminished or eliminated.	+ (construction, increased energy) - (electrification, conversion to alt fuels/reduction in conventional fuels)

TABLE 4.2-9 (CONCLUDED)

Potential Impacts on Climate Change and Global Warming
from Implementation of 2012 AQMP Control Measures

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	CONTROL MEASURE GHG IMPACT^(a)
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric, magnetic, battery-hybrid system, or fuel cell infrastructure, construct battery charging or fueling infrastructure.	+ (construction, increased energy) - (electrification, conversion to alt fuels reduction in conventional fuels)
ADV-03	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment (NOx)	Construct electric gantry cranes, construct battery charging or fueling infrastructure, and use of alternative fuels.	+ (construction, increased energy) - (electrification, conversion to alt fuels reduction in conventional fuels)
ADV-04	Actions for the Deployment of Cleaner Commercial Harborcraft (NOx)	Construct battery charging or fueling infrastructure, use of air pollution control equipment (e.g., SCR, use of alternative fuels).	+ (construction, increased energy, reduced fuel economy associated with add-on control equipment)
ADV-05	Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels (NOx)	Employ after treatment control technologies such as SCR and sea water scrubbers, and use of alternative fuels.	+ (construction, increased energy, reduced fuel economy associated with add-on control equipment)
ADV-06	Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment (NOx)	Construct battery charging or fueling infrastructure, and increased use of alternative fuels	+ (construction, increased energy) - conversion to alt fuels/reduction in conventional fuels)
ADV-07	Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines (NOx)	Use alternative fuels, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction.	- (conversion to alt fuels/reduction in conventional fuels)

- (a) + Control measure is expected to result in an increase in GHG emissions
- Control measure is expected to result in a decrease in GHG emissions

A number of mobile source control measures would reduce GHG emissions through accelerated penetration of partial zero-emission and zero emission vehicles and use of alternative fuels such as natural gas, the combustion of which generates less GHG emissions than diesel fuel. The 2012 AQMP reported a 2008 GHG inventory of 154.82 million metric tons, of which 11.66 million metric tons are associated with power generation. Implementation of the proposed control measures is expected to reduce GHG emissions consistent with the AB32 scoping plan. However, an increase in electricity demand to implement Control Measures ONRD-01, ONRD-02, ONRD-03, ADV-01, and ADV-02 is expected to be about 1,691.2 GWh in 2023 and produce approximately 0.171 million metric tons of greenhouse gas emissions or approximately 0.11 percent of the 2008 greenhouse gas inventory for the district.

The reduction in petroleum fuels demand from implementation of Control Measures ONRD-01, ONRD-02, ONRD-03, and ONRD-04 is expected to be 60,150,808 gallons in 2023 (see Table 4.3-6), of which it is assumed 27,608,834 gallons would be motor gasoline

with a CO₂ emission factor of 8.78 kg/gal and 40,087,519 gallons would be diesel fuel with a CO₂ emission factor of 10.05 kg/gal. The greenhouse gas emissions would be reduced by slightly more than 0.648 metric tons in 2023 when adjusting for nitrous oxide and methane emissions. Therefore, overall reduction in GHG emissions from implementation of Control Measures ONRD-01, ONRD-02, ONRD-03, and ONRD-04 would be approximately 0.477 million metric tons and no significant impact to GHG emissions would be expected as shown in Table 4.2-9.

TABLE 4.2-10

Estimated GHG Emission Impacts from
Control Measures ONRD-01, ONRD-02, ONRD-03, and ADV-02

Description	CO ₂ Emissions (million metric tons)	CO ₂ eq Emissions (million metric tons)
Increased Electricity	0.1712	0.1715
Change in Gasoline Use	-0.2424	-0.2447
Change in Diesel Use	-0.4029	-0.4033
Net Change in Emissions	-0.4741	-0.4765

(a) Source: 2012 AQMP Appendix III.

Negative numbers represent emission reductions.

Control Measures BCM-03, CMB-01, CMB-02, CMB-03, IND-01, MCS-01, MCS-02, MCS-03, INC-01, FUG-01, FUG-02, FUG-03, OFFRD-01, OFFRD-04, OFFRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06 are expected to have GHG emissions associated with construction. Construction emissions impacts are amortized over a 30-year timeframe. As such, individual projects typically do not generate significant GHG impacts during the construction phase.

Control Measures BCM-03, CMB-01, IND-01, MCS-01, FUG-01, FUG-02, INC-01, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-05 have the potential to increase energy demand by implementing control measures that would use electricity to power add-on control devices or power catenary systems for fixed-route mobile sources. Projects involving catenary systems would reduce diesel combustion emissions. As with the on-road control measures discussed previously, converting from diesel-fired sources to electricity generated by primarily natural gas, GHG emissions are expected to decrease. Projects to install catenary systems are expected to require project-specific CEQA review where global climate change and ozone depletion would be analyzed. Add-on control devices are sized for the specific source that is being controlled, as such the additional energy demand is highly variable from source to source. The energy to power these control measures is expected to be provided by public utility companies. As discussed in Subchapter 4.3 of this [Final Program EIR](#), additional power generating facilities are expected due to general growth, but no new power generating facilities are expected as a result of implementing the 2012 AQMP. Power generating facilities are subject to AB-32 and will be required to reduce GHG emissions by 2020. Therefore, the additional energy necessary to implement add-on control devices and catenary systems are not expected to have significant GHG emissions.

Control Measures IND-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-06, and ADV-07 have the potential to require the use of alternative fuels. Both the use and production of alternative fuels is expected to decrease emissions as discussed previously in the Potential Impacts from Mobile Sources. Alternative fuels generate less GHG emissions when combusted compared to gasoline and diesel and generate less GHG emissions from production when compared to petroleum products. Therefore, no increase in GHG emissions is expected from the use of alternative fuels and no significant impacts are expected.

Based on the analysis presented above, global climate change and ozone depletion impacts are expected to be less than significant.

PROJECT-SPECIFIC MITIGATION: No significant air quality impacts from GHG emissions have been identified so no mitigation is required.

REMAINING AIR QUALITY IMPACTS: The air quality analysis concluded that potential secondary air quality impacts from GHG emissions would be less than significant, no mitigation measures were required, so secondary air quality impacts from GHG emissions remain less than significant.

4.2.6.5 Stratospheric Ozone Depletion

PROJECT-SPECIFIC IMPACTS: None of the control measures are expected to require the use of stratospheric ozone depleting substances. None of the control measures are expected to require additional control of stratospheric ozone depleting substances. Therefore, no adverse stratospheric ozone depleting impacts are expected from the proposed project.

PROJECT-SPECIFIC MITIGATION: No significant air quality impacts from stratospheric ozone depletion have been identified so no mitigation is required.

REMAINING AIR QUALITY IMPACTS: The air quality analysis concluded that potential secondary air quality impacts from stratospheric ozone depletion would be less than significant, no mitigation measures were required, so secondary air quality impacts from stratospheric ozone depletion remain less than significant.

4.2.7 Summary of Air Quality Impacts

The following is the summary of the conclusions of the analysis of secondary air quality impacts associated with implementation of the 2012 AQMP.

- **Construction Activities:** The emissions associated with construction activities due to the implementation of the control measures in the 2012 AQMP were considered to be significant for CO and PM10 emissions.
- **Secondary Emissions from Increased Electricity Demand:** While there may be an increase in electricity, the existing air quality rules and regulations are expected to

minimize emissions associated with increased generation of electricity. The impacts associated with secondary emissions from increased electricity demand are expected to be less than significant.

- Secondary Emissions from the Control of Stationary Sources: No significant secondary air quality impacts from control of stationary sources were identified associated with implementation of the 2012 AQMP.
- Secondary Emissions from Change in Use of Lower VOC Materials: The secondary air quality impacts associated with reformulated products are expected to be less than significant.
- Secondary Emissions from Mobile Sources: The overall impact of mobile sources due implementation of the control measures has been considered less than significant for all pollutants.
- Secondary Emissions from Increased Use of Fuels due to Reduction in Fuel Economy: The reduction in fuel economy is expected to be about one percent for the affected sources so a potential increase in fuel use could occur. However, the overall focus of the 2012 AQMP is to reduce PM_{2.5} and ozone emissions, which is primarily driven by increasing use of cleaner fuels. Therefore, the impact of fuel economy is expected to be less than significant.
- Secondary Emissions from Miscellaneous Sources: The impacts of the control measures on secondary emissions from miscellaneous sources were determined to be less than significant.
- Non-Criteria Pollutants: Electrification may cause greater emissions of benzene, aldehydes, metals, and polycyclic aromatic hydrocarbons from fuel-based power generating facilities. However, if the process being electrified was previously powered by direct combustion of fossil fuels, then electrification may result in an overall decrease in toxic emissions. No significant secondary air quality impacts were identified from non-criteria pollutants, so no mitigation measures are required.
- Global Warming and Ozone Depletion: The 2012 AQMP is expected to have a net effect of reducing emissions of compounds that contribute to global warming and ozone depletion so that no significant adverse impacts are expected.
- Ambient Air Quality: The 2012 AQMP is expected to: 1) attain the 24-hour federal PM_{2.5} by 2014 (see Figure 4.2-3); 2) implement specific measures to implement Clean Air Action §182 (e)(5) to assist in attaining the eight-hour ozone standard by 2023; 3) maintain compliance with state and federal NO₂ standards (even considering the increase in population growth); 4) maintain compliance with state and federal SO₂ standards (even considering the increase in population growth); and, 5) maintain compliance with the federal 24-hour average PM₁₀ standard.

FIGURE 4.2-3

Projection of Future Air Quality in the Basin in Comparison with the Federal Standards.

Summary of PM_{2.5} Control Measure Impacts: The air quality impacts associated with PM_{2.5} Control Measures (BCM-03, CMB-01, IND-01, and MCS-01) were evaluated and determined to be significant for construction activities and less than significant for secondary emissions from increased electricity demand, control of stationary sources, change in use of lower VOC materials, mobile sources, increase in use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion.

Summary of Ozone Control Measure Impacts: The air quality impacts associated with the 23 Ozone Control Measures (see Table 4.2-1) were evaluated and determined to be significant for construction activities and less than significant for secondary emissions from increased electricity demand, control of stationary sources, change in use of lower VOC materials, mobile sources, increase in use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion.

SUBCHAPTER 4.3

ENERGY

Introduction

2012 AQMP Control Measures with Potential Energy Impacts

Significance Criteria

Potential Energy Impacts and Mitigation Measures

Summary of Energy Impacts

4.3 ENERGY

4.3.1 Introduction

This subchapter examines impacts on the supply and demand of energy sources from proposed control measures in the 2012 AQMP. All control measures in the 2012 AQMP were evaluated to determine whether or not they could generate direct or indirect energy impacts based on the anticipated methods of control. Some of the measures would require increased energy use, for example through increased pumping loads or more extensive exhaust filtering systems. Other measures would alter the form of energy used, for example switching from gasoline or diesel power to alternative fuels such as hydrogen, natural gas, and electricity.

4.3.2 2012 AQMP Control Measures with Potential Energy Impacts

The energy impact analysis in this [Final](#) Program EIR identifies the net effect on energy resources from implementing the 2012 AQMP. All control measures were analyzed to identify both beneficial effects (energy conserving) and adverse impacts (energy consuming).

Implementing some of 2012 AQMP control measures could increase energy demand in the region from affected facilities. Specifically some types of control equipment would increase demand for electrical power to operate the equipment, natural gas for combustion devices, natural gas used as an alternative clean fuel for mobile sources, etc.

Evaluation of control measures was based on examination of the impact of the control measures and technologies in light of current energy trends. Evaluation of control methods for each control measure indicated that there are 25 control measures that could have potential energy consumption or conserving impacts. As shown in Table 4.3-1, three control measures related to PM2.5 emission reductions and 22 control measures related to emission reductions from ozone precursors are expected to have energy impacts.

4.3.3 Significance Criteria

Implementation of the 2012 AQMP would be considered to have significant adverse energy impacts if any of the following conditions occur:

- The project would result in the use of renewable and non-renewable fuel or energy resources, in a wasteful manner.
- The project conflicts with adopted energy conservation plans or standards.
- The project would result in substantial depletion of existing energy resource supplies.
- The project would increase demand for utilities impacts the current capacities of the electric and natural gas utilities.

- The project would increase demand for energy resources by one percent or more of the baseline energy demand.

TABLE 4.3-1

Control Measures with Potential Secondary Energy Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	ENERGY IMPACT
Short-Term PM2.5 Control Measures			
BCM-01	Further Reductions from Residential Wood Burning Devices (NOx)	Lower current mandatory Basin-wide wood burning curtailment threshold from 35 $\mu\text{g}/\text{m}^3$ to 30 $\mu\text{g}/\text{m}^3$.	Potential increased demand for natural gas.
BCM-03 (formerly BCM-05)	Emission Reductions from Under-Fired Charbroilers (PM2.5)	Add-On Control Equipment with Ventilation Hood Requirements (e.g., ESPs, HEPA filters, wet scrubbers, or thermal oxidizers)	Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel demand during construction and/or filter replacement.
BCM-04 (formerly MCS-04B)	Further Ammonia Reductions from Livestock Waste (NH3)	Reducing pH level in manure through the application of acidifier sodium bisulfate to	Potential increase in diesel fuel demand use for delivery and application of acidifier.
CMB-01	Further NOx Reductions from RECLAIM – Phase I and Phase II (NOx)	RECLAIM sources will be examined for further reductions for this control measure and potential rule making. Control technologies could include: elective catalytic reduction, low NOx burners, NOx reducing catalysts, oxy-fuel furnaces, and selective non-catalytic reduction	Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel demand during construction and related ammonia and/or catalyst replacement.
CMB-02	NOx Reductions from Biogas Flares (NOx)	Replacement of existing biogas flares with more efficient biogas flares	Potential increase in diesel-fuel demand during construction.
CMB-03	Reductions from Commercial Space Heating (NOx)	This control measure seeks emission reductions from unregulated commercial fan-type central furnaces used for space heating.	Potential increase in diesel-fuel demand during construction.
IND-01	Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities (NOx, SOx, PM2.5)	Environmental lease conditions, port rules, tariffs or incentives	Additional emission controls could result in increased electricity. Incentives to purchase electric or gaseous fueled equipment could cause potential increase in electricity and natural gas demand. Potential increase in alternative fuels. Potential increase in diesel-fuel demand during construction.

TABLE 4.3-1 (CONTINUED)

Control Measures with Potential Secondary Energy Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	ENERGY IMPACT
Ozone Control Measures			
CTS-02	Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants (VOC)	Reduce the allowable VOC content in product formulations by using alternative low-VOC products or non-VOC product/equipment	Potential increase in electricity use for application and/or control
FUG-01	Further VOC Reductions from Vacuum Trucks (VOC)	VOC control devices such as carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers, liquid scrubbers and positive displacement (PD) pumps	Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel demand during construction and related ammonia and/or catalyst replacement.
FUG-02	Emission Reduction from LPG Transfer and Dispensing – Phase II (VOC)	Expand applicability of rule to LPG transfer and dispensing at facilities other than those that offer LPG for sale to end users included currently exempted facilities	Potential increase in diesel-fuel demand during construction and inspection and monitoring.
FUG-03	Further VOC Reductions from Fugitive VOC Emissions (VOC)	Upgrade inspection/maintenance rules to at least a self-inspection program, or to an optical gas imaging-assisted LDAR program where feasible; use of new technologies to detect and verify VOC fugitive emissions	Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel demand during construction and inspection and monitoring/inspections.
MCS-01	Application of All Feasible Measures Assessment (All Pollutants)	Control measure could require new retrofit technology control standards as new BARCT standards become available.	Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel demand during construction and/or related transportation.
MCS-02	Further Emission Reductions from Green Waste Processing (Chipping and Grinding Operations not associated with composting) (VOC)	Require chipped or ground greenwaste material to be covered after chipping or grinding or removed from site; and seasonal covering of chipped or ground greenwaste material.	Potential increase in diesel-fuel related transportation.
MCS-03	Improved Start-up, Shutdown and Turnaround Procedures (All Pollutants)	Diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability.	Reduction of process gas vented to flares. Potential increase in diesel-fuel during construction.

TABLE 4.3-1 (CONTINUED)

Control Measures with Potential Secondary Energy Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	ENERGY IMPACT
Ozone Control Measures			
INC-01	Economic Incentive Programs to Adopt Zero and Near-Zero Technologies (NOx)	Installation of cleaner, more efficient combustion equipment, such as boilers, water heaters and commercial space heating or installation of control technologies including fuel cells, diesel particulate filters (DPF), NOx reduction catalysts, alternative electricity generation, such as wind and solar, battery electric, hybrid electric, and usage of low NOx and alternative fuels such as natural gas	Incentives to purchase electric or gaseous fueled equipment could cause potential increase in electricity and natural gas demand. Potential increase in electricity and/or natural gas for control technologies. Potential increase in diesel-fuel during construction and related filter and/or catalyst replacement.
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles (VOC, NOx, PM)	Incentives to replace older vehicles with electric or hybrid vehicles	Incentives to purchase electric vehicle could result in an increase in electricity.
ONRD-02	Accelerated Retirement of Older Light-Duty and Medium-Duty Vehicles (VOC, NOx, PM)	Incentives to replace older light- and medium-duty vehicles with low-emitting vehicles.	Incentives to purchase electric vehicle could result in an increase in electricity.
ONRD-03	Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium Heavy-Duty Vehicles (NOx, PM)	Incentives to replace older medium-duty vehicles with low-emitting vehicles. Highest priority would be given to zero-emission vehicles and hybrid vehicles with a portion of their operation in an "all electric range" mode.	Incentives to purchase electric vehicle could result in an increase in electricity and increase the use of alternative fuels.
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace older medium- and heavy-duty vehicles with low- and zero emitting vehicles.	Incentives to purchase low emission vehicles could result in an increase in electricity and increase the use of alternative fuels.
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment (NOx)	Accelerate equipment repowering; use of air pollution control technologies (e.g., advanced fuel injection, air induction, and after-treatment technologies).	Potential increase in the use of alternative fuels.

TABLE 4.3-1 (CONTINUED)

Control Measures with Potential Secondary Energy Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	ENERGY IMPACT
Ozone Control Measures			
OFFRD-02	Further Emission Reductions from Freight Locomotives (NO _x , PM)	Repower existing engines with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Potential increase in fuel use from the use of more efficient engines; minor decrease in fuel use from loss of efficiency to control technologies, and increase in alternative fuels associated with repowered engines.
OFFRD-03	Further Emission Reductions from Passenger Locomotives (NO _x , PM)	Repower existing engines with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Potential increase in fuel use from the use of more efficient engines; minor increase in fuel economy from loss of efficiency to control technologies, and increase in alternative fuels associated with repowered engines.
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels at Berth (VOC, NO _x , PM)	Shore power of vessels at berth; use of air pollution control technologies on exhaust gases from auxiliary engines and boilers (e.g., SCRs, DPM filters, electric batteries, and alternative fuels). May increase the use or installation of new local electricity generation.	Potential increase in electricity use associated with increased use of shore-side power and additional air pollution control technologies and minor increase in fuel economy from loss of efficiency to control technologies. Potential increase in diesel-fuel during construction.
OFFRD-05	Emission Reductions from Ocean-Going Marine Vessels (NO _x)	Enhance Ports' existing financial incentive programs for early deployment of Tier 2 and Tier 3 vessels calling at the Ports.	Potential increase in electricity use associated with increased use of shore-side power and additional air pollution control technologies and minor decrease in fuel use from loss of efficiency to control technologies. Potential increase in diesel-fuel demand during construction.
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NO _x)	Construct "wayside" electric or magnetic infrastructure; construction battery charging and fueling infrastructure	Reduced emission standards could result in an increase in electricity and increase the use of alternative fuels. Potential increase in diesel-fuel demand during construction.

Control Measures with Potential Secondary Energy Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	ENERGY IMPACT
Ozone Control Measures			
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NO _x)	Construct "wayside" electric or magnetic infrastructure; construct battery charging or fueling infrastructure.	Measure could result in an increase in electricity and increase the use of alternative fuels. Potential increase in diesel-fuel demand during construction.
ADV-03	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment (NO _x)	Construct electric gantry cranes; construct battery charging or fueling infrastructure; use of alternative fuels and fuel additives	Measure could result in an increase in electricity and increase the use of alternative fuels. Potential increase in diesel-fuel demand during construction.
ADV-04	Actions for the Deployment of Cleaner Commercial Harborcraft (NO _x)	Construct battery charging or fueling infrastructure; use of air pollution control equipment (e.g., SCR; use of alternative fuels and fuel additives).	Measure could result in an increase in electricity and increase the use of alternative fuels. Potential increase in diesel-fuel demand during construction. Increase in fuel consumption from loss of efficiency from control equipment.
ADV-05	Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels (NO _x)	Employ aftertreatment control technologies such as SCR and wet/dry scrubbers; use of alternative fuels.	Measure could result in an increase in electricity and increase the use of alternative fuels. Potential increase in diesel-fuel demand during construction. Increase in fuel consumption from loss of efficiency from control equipment.
ADV-06	Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment (NO _x)	Construct battery charging or fueling infrastructure; increased use of alternative fuels and fuel additives.	Measure could result in an increase in electricity and increase the use of alternative fuels.
ADV-07	Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines (NO _x)	Use alternative fuels and fuel additives, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction.	Measure could result in an increase use of alternative fuels.

4.3.4 Potential Energy Impacts and Mitigation Measures

4.3.4.1 Electricity

Potential electric energy impacts relative to the energy baseline are discussed below. The potential increase in electricity use due to implementation of the 2012 AQMP is partially associated with the potential installation of add-on control equipment. A number of control measures could result in the installation of add-on control equipment including BCM-03 - Emission Reductions from Under-Fired Charbroilers, CMB-01 - Further NO_x Reductions from RECLAIM –Phase II, IND-01 - Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities (if triggered), FUG-01 - ~~Further~~ VOC Reductions from Vacuum Trucks, FUG-03 - Further ~~VOC~~ Reductions from Fugitive VOC Emissions, MCS-01 - Application of All Feasible Measures Assessment, and INC-01 -- Economic Incentive Programs to Adopt Zero and Near-Zero Technologies. There is also a potential increase in electricity use associated with the electrification of mobile sources or control equipment for mobile sources, including IND-01, INC-01, ONRD-01 - Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles, ONRD-02 - Accelerated Retirement of Older Light-Duty and Medium-Duty Vehicles, ONRD-03 - Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium Heavy-Duty Vehicles, ONRD-05 - Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards, OFFRD-01 - Extension of the SOON Provision for Construction/Industrial Equipment, OFFRD-02 - Further Emission Reductions from Freight Locomotives, OFFRD-03 - Further Emission Reductions from Passenger Locomotives, OFFRD-04 - Further Emission Reductions from Ocean-Going Marine Vessels at Berth, ADV-01 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles, ADV-02 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives, ADV-03 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment, ADV-04 - Actions for the Deployment of Cleaner Commercial Harborcraft, ADV-05 - Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels, and ADV-06 - Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment.

Stationary and Area Sources - A number of control measures could result in the installation of add-on control equipment including BCM-03, CMB-01, IND-01, CTS-02, FUG-01, FUG-03, MCS-01, and INC-01. Add-on control equipment can reduce air emissions in a number of different ways (e.g., filters to remove particulates, or units that produce a chemical reaction to remove a pollutant), but they generally require energy to function. The use of add-on air pollution controls (e.g., wet scrubbers, low NO_x burners, and catalysts) could result in an increase in electricity demand. For example, a wet gas electrostatic precipitator (ESP) and wet gas scrubber (WGS) were installed on the Fluid Catalytic Cracking Unit (FCCU) at the ConocoPhillips Los Angeles Refinery. The estimated electricity required to operate the ESP and WGS was about 715 kilowatts (kW) (SCAQMD, 2007). FCCUs are large emission sources and the electricity used for the ESP and WGS at the ConocoPhillips Refinery would be representative of control equipment for large sources. Energy use for smaller sources would be less. The specific potential increase in the amount of electricity use due to the implementation of the 2012 AQMP is unclear at

this time as specific information regarding the number and size of the control units are currently unknown. Additionally, alternative processing equipment is expected to be the primary method of control for some of the control measures. For example, the primary method of control of VOC emissions from coatings and solvents (CTS-01 and CTS-02) is expected to be reformulation of coatings and solvents along with more efficient application techniques, and not add-on control equipment which would be largely expected to be energy neutral.

Mobile Sources - Mobile source control measures in the 2012 AQMP are expected to increase the electricity demand in the district. A number of control measures would result in an increase in electricity demand associated with the electrification of mobile sources, including IND-01, ONRD-01, ONRD-02, ONRD-03, ONRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06. This is expected to shift some of the fuel source of cars, trucks, off-road vehicles and marine vessels to electricity, as well as, create an additional electrical load demand due to CNG recharging. The CEC estimates there were about 10,000 electric vehicles on the road operating in California in 2011 with an estimated electricity consumption of 100 gigawatts per hour (gWh). The CEC projects anywhere from 835,000 to 3,575,000 electric vehicles by 2022 depending on the energy demand scenario. These vehicles will require 2,200 gWh for the low demand scenario and more than 7,000 gWh in the high scenario (CEC, 2012j).

The estimated baseline electricity use in Los Angeles, Orange, Riverside, and San Bernardino counties was about 115,000 gWh in 2010 (CEC, 2012b). Therefore, currently electric vehicles are a small portion of the overall electricity used (less than 0.1 percent). CEC estimates that an increase in electricity demand of about 18 percent will occur between 2010 and 2023 with an annual average growth rate of about 1.3 percent (CEC, 2012j). Assuming a similar annual growth rate between 2023 and 2030, about 148,750 gWh will be required in 2030 (see Table 4.3-2).

The potential increase in electricity can be estimated for Control Measures ONRD-01, ONRD-02, ONRD-03, and ONRD-05 where the increase in the number of hybrid/zero emission vehicles introduced can be estimated (see Table 4.3-2)¹. As shown in Table 4.3-2, the estimated increase in electricity associated with associated with ONRD-01, ONRD-02, ONRD-03, and ONRD-05 is about 446.2 gWh. In 2023, the increase in electricity would represent a 0.4 percent increase in electricity since 2010 (baseline). ADV-01 could result in the construction of "wayside" electric or magnetic power built into roadway infrastructure to boost the pulling capacity or range of the heavy-duty vehicles. The "wayside" electric or magnetic power for appropriately equipped heavy-duty trucks would require additional electricity. The recently circulated Draft EIR for the I-710 Corridor Project included an alternative that evaluated impacts from installing "wayside" electric roadway infrastructure and an estimated electricity demand between 157 and 183 GWh per year (Caltrans, 2012) In addition to the I-710 Corridor Project, ADV-01 identifies the 60 freeway as an east-west

¹ It should be noted that the specific technologies to be employed to comply with these 2012 AQMP control measures is unknown. However, to present a worst-case analysis of potential electricity demand impacts, for the purposes of this analysis, it is assumed that all affected mobile sources would be powered by electricity. Similarly, this worst-case assumption does not assume that the SCAQMD endorses electricity technologies over other compliant technologies.

corridor that has potential location for additional “wayside” electric roadway infrastructure. There is currently a pilot project under consideration to install catenary lines at one of two sites, a site along the Terminal Island Freeway or on Navy Way at the Port of Los Angeles. To estimate the potential electrical demand for a “wayside” electric roadway infrastructure on the 60 freeway, it is assumed that the electrical demand per mile would be equivalent to that estimated for the I-710 Corridor Project with a distance twice as long. Therefore, the estimated electrical demand for the 60 freeway would be between 320 and 380 GWh. The use of “wayside” electric roadway infrastructure elsewhere in the district would be speculative at this time. Therefore, the estimated electrical demand associated with ADV-01 is 563 GWh (see Table 4.3-2).

ADV-02 could result in the construction of "wayside" electric or magnetic power built into railway infrastructure to convert diesel locomotives to electrical traction motors. The “wayside” electric or magnetic power would require additional electricity. ADV-02 would convert 300 line haul, 140 switcher, and 52 passenger diesel locomotives to “wayside” electric infrastructure. Based on an annual fuel use of 34.7 million gallons of diesel fuel, the estimated electrical demand would be 880 GWh (see Table 4.3-2). The 880 GWh assumes 56 percent diesel engine efficiency, 95 percent electrical traction efficiency, and seven percent transmission loss.

^e Table 3.3-1

ADV-03 would result in the deployment of zero and near-zero emission cargo handling equipment which could result in an increase in electricity use (e.g., electric gantry cranes).

The Southern California International Gateway Project (Los Angeles Harbor Department, 2011) is proposing to use electric gantry cranes to move cargo from trucks to rail. The estimated increase in electricity to operate the electric gantry cranes ranges from 5,500,000 to 8,700,000 kWh for industrial uses that include electric gantry crane operations (as well as rail track signals/ lighting, site and security lighting, administrative offices, and maintenance and repair building operations). The use of the electric gantry cranes are the largest portion of the estimated electricity use at this facility. While this is only an example of electricity use for cargo handling equipment, the electrification of cargo handling equipment throughout the ports could require a substantial amount of electricity.

Control Measure IND-01 is a backstop measure that would require the ports to control stationary and mobile sources at the port and port-related facilities in the event that controls at the ports are needed or the emission targets assumed in the 2012 AQMP for the port-related sources are not met. One goal of the ports' Clean Air Action Plan and IND-01 is to move all container berths, cruise ship operations, and other frequent visitors calling at the ports to shore-side power and to move other vessel types toward alternative hotelling emissions reduction technologies. With regard to shore-side power, the two ports are in different positions from an infrastructure standpoint. Generally, the Port of Los Angeles has the main electrical trunk lines in place from which to "step down" and condition power for ships. The Port of Long Beach, on the other hand needs to bring new electrical service lines from Interstate 405 into the Harbor District to supply the appropriate power, which will require significant infrastructure improvements (PLAX/PLB, 2010).

Over the next five years, the Port of Los Angeles proposes to conduct a massive infrastructure improvement program to make alternative marine power (referred to as AMP) available at a number of berths at container, liquid bulk terminals, cruise terminals, and dredge plug-in locations. The Port of Los Angeles is expected to have alternative marine power available at 24 berths by 2014 (PLAX/PLB, 2010). However, since IND-01 is a backstop measure so it is unclear if it would need to be implemented and, if it would need to be implemented, to what extent it would need to be implemented. Further, details of the measure and the means for reducing emissions have not been identified; electricity usage from this measure cannot be estimated at this time.

OFFRD-05 - Emission Reductions from Ocean-Going Marine Vessels may increase electricity use to shore power marine vessels at berth. This control measure would provide incentives for the cleanest marine vessels (e.g., Tier III) to visit the ports. Although not anticipated, electrical power for hotelling operations could be provided to these ships via electrical cables using shorepower. Shorepower can be locally generated at the port or obtained from the grid. Shorepower can be locally generated using clean technologies such as fuel cells, gas turbines, microturbines, and combined cycle units. Due to technical and operational (e.g., frequency of calls) reasons, however, cold ironing may not be a viable option for all types of ships.

The Port of Long Beach is actively implementing its shore power program. In 2006, the port began improvements on the shore power infrastructure at the BP terminal at berth T121. Construction is completed and since mid-2009, the shore power infrastructure has been operational and is being used. Over the next five years, the port will continue to undergo

electrical infrastructure improvements, constructing an additional 6.6 kV sub-transmission line to serve the Port of Long Beach Harbor District, and completing infrastructure improvements for the remaining container terminals, electric dredge plug-ins, and additional infrastructure for electrification of certain types of yard equipment. Over 23 berths at container terminals at the Port of Long Beach are scheduled to be shore power ready by the end of 2014 (PLAX/PLB, 2010).

The EIR prepared for the Middle Harbor development in the Port of Long Beach estimated that the electricity consumption would be about 986 megawatt-hours for the Middle Harbor container terminal operations that would include shore-to-ship power (“cold-ironing”) and connections to buildings and other wharf structures (e.g., lighting). While the increase demand was considered extensive, it was determined to not be substantial relative to the existing and project regional electricity supply (Port of Long Beach, 2009).

Based on the above information, since the means of reducing emissions and the details of whether local or grid power have not been established, electricity usage associated with OFFRD-05 cannot be estimated at this time.

In spite of energy conservation programs in California, it is likely that additional power plants will be required to supply the projected electricity due to general population growth, both in California and outside of California. Increased demand for electricity would occur with or without implementing the 2012 AQMP. Currently, there are a number of power plant projects planned in southern California to meet future needs. Relative to the existing electricity use and the projected future peak electricity demand, implementation of all the control measures is expected to result in an overall increase in 2023 of approximately 1.5 percent of the existing electricity use of 115,000 GW-h (see Table 4.3-2). While this increase is expected to be within the electric generating capacity of the region, an increase in electricity of one percent or greater exceeds the SCAQMD’s energy significance threshold. Thus, the electric energy impacts from the implementation of the 2012 AQMP are expected to be significant.

Conclusion: Electricity - The electric energy impacts presented above for those control measures where sufficient data exist, are expected to be conservative. The demands for electricity associated with increased electrification of mobile sources could be partially offset by charging equipment (e.g., electric vehicles) at night when the electricity demand is low, thus minimizing impacts on peak electricity demands. Further, the analysis assumes that all sources affected by a control measure that has the potential to increase demand for electricity, would use electricity rather than the more likely result of multiple types of energy being used. In addition, any increase in electricity demand would likely result in a concurrent reduction in demand for other types of fuels, particularly petroleum-based fuels. The 2012 AQMP is not expected to result in the use of large amounts of fuel or energy resources or result in the use of fuel or energy resources in a wasteful manner. However, the 2012 AQMP includes incentives to shift from diesel and gasoline fuel use to increased electrification of stationary and mobile sources. Depending on the location and the amount of energy use (e.g., port projects), electricity portions of energy conservation plans may need to be updated. Therefore, the proposed project may conflict with existing adopted energy conservation plans. Therefore, the 2012 AQMP could result in a substantial increase in

electricity (greater than one percent of the existing electricity use in the Basin), and increased electricity demand is potentially significant.

The 2012 AQMP includes strategies that promote energy conservation (EDU-01) without identifying specific targets; therefore, its benefits have not been quantified in this analysis. Nonetheless, the 2012 AQMP impacts on electricity resources are potentially significant.

Project-Specific Mitigation: Mitigation measures are required as potentially significant impacts on electricity demand associated with the 2012 AQMP have been identified. As individual control measures are promulgated as new rules or rule amendment, specific mitigation measures will be identified as necessary to minimize electricity impacts. Mitigation measures are expected to include the following:

- E-1 Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.
- E-2 Utilities should increase capacity of existing transmission lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- E-3 Project sponsors should submit projected electricity calculations to the local electricity provider for any project anticipated to require substantial electricity consumption. Any infrastructure improvements necessary should be completed according to the specifications of the electricity provider.
- E-4 Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.
- E-5 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging charging of electrical vehicles and other mobile sources during off-peak hours.
- E-6 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of catenary or way-side electrical systems developed for transportation systems to operate during off-peak hours.
- E-7 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of electrified stationary sources during off-peak hours (e.g., cargo handling equipment).

Remaining Electricity Impacts: The preceding analysis concluded that significant adverse electricity consumption impacts could be created by the proposed project because the potential 2023 electricity usage increase would exceed baseline electricity consumption by 1.5 percent. In spite of implementing the above mitigation measures, electricity consumption impacts would remain significant.

4.3.4.2 Natural Gas

Project-Specific Impacts: Control measures in the 2012 AQMP may result in an increase in demand for natural gas associated with stationary sources due to the need for additional emission controls (e.g., BCM-03, CMB-01, IND-01, FUG-01, MCS-01, INC-01, ADV-01, ADV-02, ADV-03, ADV-04, and ADV-05). Other control measures are expected to encourage the use of natural gas as a fuel to offset the use of petroleum fuels including ONRD-01, ONRD-02, ONRD-03, ONRD-05, ADV-04, and ADV-06. In addition, increased demand for electricity will require additional natural gas, as most of the power plants in California are operated using natural gas.

Total natural gas (utility) consumption in California in 2010 was approximately 4,729 million cubic feet per day with about 36.5 percent of the natural gas consumed in Los Angeles, Orange, Riverside, and San Bernardino counties (see Table 4.3-3). The residential, commercial, industrial, and electrical generation sectors account for approximately 25, 10, 17, and 39 percent, respectively, of total statewide natural gas (utility) consumption. The demand for natural gas in southern California is expected to increase by approximately 0.20 percent from 2010 to 2020². The projected per capita consumption is lower than previously projected because of higher natural gas prices than previously anticipated. Natural gas for vehicle fuel use has steadily grown to where it totaled about 33 million cubic feet per day, which is about, about 0.70 percent of the total statewide natural gas (utility) use (California Gas Report, 2010).

TABLE 4.3-3

Natural Gas (Utility) Impacts for Los Angeles, Orange, Riverside, and San Bernardino Counties (Million Cubic Feet/Year)

NATURAL GAS USE	2010	2020 ^a	2030 ^a
Baseline	1,726	1,730	1,735

Source: California Gas Report, 2012

^a Projections based on CEC, 2012j

Mobile Sources - According to the CEC, there were about 24,819 light-duty natural gas vehicles and about 11,500 heavy-duty natural gas vehicles in California in 2009 (CEC, 2011). The CEC expects a steady increase in natural gas consumption used as an alternative fuel (see Table 4.3-4), but since there is currently no policy mandate to directly incentivize the production of more natural gas vehicles, penetration of these vehicles in the light-duty sector is relatively low compared to other alternative fuel technologies (CEC, 2012j).

Some of the control measures in the 2012 AQMP could result in an increase in the use of natural gas in medium- and heavy-duty on road vehicles. Expanded use of alternative fuels in medium-duty and heavy-duty trucks using more efficient, advanced natural gas engine

² [Review of the 2012 California Gas Report, indicates SoCalGas projects total gas demand to grow at an annual rate of 0.12% from 2011 to 2030. Over the forecast period 2012-2030, demand is expected to exhibit annual decline \(of 0.13%\) from the level in 2012 due to modest economic growth. However, since the CEC's future natural gas demand provides a conservative analysis and future natural gas demand impacts are concluded to be significant, it is not necessary to revise the analysis.](#)

technologies would be expected to reduce projected diesel-fuel use. Natural gas medium- and heavy-duty vehicles are an attractive environmental option to diesel fueled vehicles because they emit fewer criteria pollutants and toxic components. However, the limited availability of refueling facilities and typically higher vehicle purchase prices has affected the sale of light-duty natural gas fuel vehicles (CEC, 2011). Further, hybrid vehicles and zero emission electric vehicles are further along in the development phase and expected to be the preferred source of power as opposed to natural gas.

TABLE 4.3-4

Projected Petroleum Fuel Displaced with Natural Gas in California

FUEL TYPE	2010	2020
Natural Gas Vehicle Fuel Consumption in California (billion cubic feet)	12.1	16.1
Estimated Natural Gas Vehicle Fuel Consumption in Southern California (billion cubic feet)	9.9	12.8
Petroleum Fuel Displaced in California (million gallons gasoline equivalents)	95.5	127.1
Petroleum Fuel Displaced in Southern California (million gallons gasoline equivalents)	78.2	101.0

Source: California Gas Report, 2012

Stationary Sources - For stationary sources, natural gas is already BACT, so new equipment would already be required to use natural gas. Under the 2012 AQMP control measures, a slight increase in natural gas demand is expected from the use of add-on air pollution controls associated with NO_x emission reduction, add-on controls associated with VOC emission reductions, and add-on controls associated with particulate matter control. The amount of natural gas to run these control devices is unknown because the number of equipment required and the equipment sizes are not known. ~~Alternative processing~~ Replacement or retrofitted equipment is expected to be the primary method of control (e.g., the primary method of control for CMB-01 is expected to be new low NO_x burners). Low NO_x burners ~~which~~ are not expected to result in an increase in natural gas consumption, because this would require replacing one type of burner with a more efficient burner.

Approximately 39 percent of the natural gas consumed in California is used at power plants to generate electricity. Southern California Edison will need to add additional electricity generating capacity to accommodate the increase in population growth. The increased electricity demand expected in the Basin would be generated by natural gas fueled power plants resulting in an increased demand for natural gas, the amount of which is currently unknown.

FUG-01 may result in an increase in natural gas used to combust VOC emissions from vacuum trucks used to remove materials from storage tanks, vessels, sumps, boxes and pipelines. SCAQMD staff estimates that 27 million cubic feet per year of natural gas may be used to combust fugitive VOCs from storage tanks, vessels, sumps, boxes and pipelines pulled by a vacuum truck. The amount of natural gas used to combust fugitive VOCs in FUG-01 would be less than the amount of natural gas reductions expected from other

control measures (see Table 4.3-6). The increased demand for an additional 27 million cubic feet per year [associated with implementing](#) 2012 AQMP Control Measure FUG-01 would represent an increase in natural gas demand of 1.6 percent compared to the year 2010 natural gas baseline demand of the 1,726 million cubic feet per year. Therefore, the proposed project could be significant for natural gas use.

Project-Specific Mitigation: Mitigation measures are required as potentially significant impacts on natural gas resources associated with the 2012 AQMP have been identified. As individual control measures are promulgated as new rules or rule amendment, mitigation measures will be identified as necessary to ensure that natural gas impacts remain less than significant. Mitigation measures are expected to include the following:

- E-8 Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation.
- E-9 Utilities should increase capacity of existing natural gas lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- E-10 Project sponsors should submit projected natural gas calculations to the local natural gas provider for any project anticipated to require substantial natural gas consumption. Any infrastructure improvements necessary should be completed according to the specifications of the natural gas provider.
- E-11 Project sponsors should include energy analyses in environmental documentation with the goal of conserving energy through the wise and efficient use of energy.
- E-12 Project sponsors should evaluate the potential for reducing peak energy demand by encouraging the use of natural gas stationary sources during off-peak hours.

Remaining Natural Gas Energy Impacts: The preceding analysis concluded that significant adverse natural gas consumption impacts could be created by the proposed project because natural gas usage would exceed the 2010 natural gas consumption by 1.6 percent. In spite of implementing the above mitigation measures, natural gas consumption impacts would remain significant.

4.3.4.3 Petroleum Fuels

General growth in the district is expected to result in a substantial increase in the use of petroleum fuels between current conditions and 2035. Table 4.3-5 summarizes the expected increases in fuel usage, as predicted by SCAG's transportation and air quality model, between 2011 and 2035 with the investments in the Regional Transportation Plan (RTP) and without the RTP.

TABLE 4.3-5

Projected Transportation Fuel Consumption in Southern California
(thousand gallons per day)

YEAR	FUEL CONSUMPTION	PERCENT INCREASE OVER 2011
2011	16,630	--
2035 (without 2012-2035 RTP/SCS)	20,274	8.8
2035 (with 2012-2035 RTP/SCS)	15,342	-17.6

Source: California Gas Report, 2012

Implementation of the 2012 AQMP is expected to result in a decrease in the future increased demand for petroleum fuels (e.g., diesel, distillate, residual oil, and gasoline) due to mobile source control measures (Tables 4.3-5 and 4.3-6), as well as a potential increase in engine efficiency associated with the retrofit of new engines. Control measures that are expected to result in a decrease in the demand for petroleum fuels include control measures that would result in the installation of new engines in mobile sources, which tend to be more fuel efficient, result in the use of alternative fuels, or result in an increase in electrification of mobile sources, which would eliminate the use of petroleum fuels from mobile sources. Control Measures ONRD-01, ONRD-03, and ONRD-05 are expected to encourage the introduction of about 15,000 zero to partial zero emissions vehicles. The estimated reduction in fuel use is shown in Table 4.3-6. Other control measures that are expected to result in a decrease in petroleum fuel use include OFFRD-01 (repower at least 1,200 locomotive engines with Tier 4 engines using control equipment), OFFRD-03 (replace 30 tier zero locomotives with Tier 4 engines using control equipment), and OFFRD-04 (an additional 25 percent of vessel calls would deploy shorepower technologies or alternative forms of emission reductions). Specific reduction in fuel use from these three control measures, however, is not known at this time. ADV-01 and ADV-02 may result in a decrease in diesel fuel use should “wayside” electrical infrastructure be implemented for specific freeway routes and locomotives (e.g., 300 line haul, 140 switcher, and 52 passenger). The estimated diesel fuel reduction from ADV-01 is not known, however, ADV-02 is estimated to reduce diesel fuel use by 34.7 million gallons per year.

TABLE 4.3-6

Estimated Reduction in Petroleum Fuels Associated with 2012 AQMP Control Measures
(gallons per year)

CONTROL MEASURE	2013	2023
ONRD-01 – Incentivize light- and medium-duty trucks (9,000 vehicles) ^a	663,157	5,968,421
ONRD-02 – Accelerated retirement and replacement of pre-1992 light- and medium-duty vehicles (18,000 vehicles) ^a	1,326,315	11,936,842
ONRD-03 – Encourage the introduction of hybrid and zero-emission vehicles (5,000 vehicles) ^b	1,509,091	7,545,455
ADV-02 – Electrification of 492 locomotive engines ^c		34,700,000
Total	3,498,563	60,150,718

^a Based on 12,600 miles/year and 19 miles/gallon.

^b Based on 16,600 miles/year and 11 miles/gallon.

^c Estimated assuming electrification of locomotives is the selected technology.

Some of the control measures are also expected to result in the installation of retrofit equipment (catalysts, PM traps, etc.) including OFFRD-01, OFFRD-02, and OFFRD-03 (Table 4.3-7). These control measures would be expected to result in both reductions as well as increases in petroleum fuel use. An increase in the use of add-on control equipment associated with mobile sources could result in an increase in the use of petroleum fuels because add-on control devices, such as diesel particulate filters, SCRs, catalytic controls, etc., generally result in a decrease in engine efficiency. The use of SCR and diesel particulate filters on construction equipment, for example, could result in an increase in fuel use for the retro-fitted equipment. The amount of additional fuel that would be required would be dependent on the type of control equipment installed and the energy requirement to operate the equipment. However, mobile sources that would have newer engines installed would be expected to result in an increase in efficiency and decrease in fuel use, the amount of which is currently unknown.

Additional diesel fuel may also be required for operational activities under control measures such as FUG-03 - Further ~~VOC~~ Reductions from Fugitive VOC Emissions, which would require additional monitoring and inspection; MCS-02, which may require additional haul trips to remove green waste; and BCM-04, which would require delivery and application of acidifiers. Details of these activities and which facilities may be affected are not known at this time, so the amount of additional diesel fuel cannot be estimated at this time.

TABLE 4.3-7

Off-Road Equipment and Related Control Equipment

CONTROL MEASURE	TYPE OF EQUIPMENT	TYPES OF EMISSION CONTROLS	ASSUMED NUMBER OF UNITS AFFECTED
OFFRD-01	Off-road diesel construction vehicles	SCR, Diesel particulate filters	1,200
OFFRD-02	Freight locomotive (line haul)	SCR, Diesel particulate filters	300
OFFRD-02	Freight locomotive (switcher)	SCR, Diesel particulate filters	140
OFFRD-03	Passenger locomotives	SCR, Diesel particulate filters	52

Construction activities that could be required to implement control measures in the 2012 AQMP would also increase the use of gasoline and diesel, including BCM-03, CMB-01, CMB-02, CMB-03, IND-01, FUG-01, FUG-02, FUG-03, MCS-01, MCS-02, MCS-03, INC-01, ONRD-05, OFFRD-01, OFFRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06. Construction activities could be required under a number of the control measures to develop transportation infrastructure (e.g., overhead catenary lines), install air pollution control equipment, and further develop electricity to support electrification of sources. The amount of petroleum fuels required would depend on the extent of the specific construction activities. Larger construction projects, which would use the most fuels, are likely to require project specific CEQA review and their specific energy requirements would be evaluated at that time. However, there are currently adequate fuel supplies in California. In fiscal year 2011, 14,728,734,063 gallons of gasoline and 2,564,017,901 gallons of diesel were sold in California (California State Board of Equalization, 2012). Construction activities are temporary and all construction equipment will cease once construction activities are finished. As the use of petroleum fuels in other mobile sources decreases, there is likely to be an excess availability of gasoline and diesel. Implementation of the 2012 AQMP is expected to result in an overall reduction in the use of petroleum fuels (see Table 4.3-6). Therefore, no significant adverse impacts on petroleum fuels are expected due to implementation of the 2012 AQMP.

Emissions from mobile sources are the largest contributors to emissions in the district. Overall, implementation of the 2012 AQMP is expected to result in a large reduction in emissions from mobile sources. Many of the emission reductions associated with the 2012 AQMP are expected to come from mobile sources. In order to achieve the necessary emission reductions, it is expected that a reduction in the use of petroleum fuels would be necessary. Therefore, overall the 2012 AQMP is expected to result in a reduction in the use of gasoline and diesel fuels, because of requirements resulting in higher energy efficiencies or displacement by alternative clean fuels. The largest reductions in use of petroleum-based fuels are expected from the on-road mobile source sector switching to electricity or alternative clean fuels. For on-road mobile sources, the combination of fleet standards for

both light- and heavy-duty vehicles, as well as trip reduction measures, produce these large reductions in the use of petroleum-based fuels (see Tables 4.3-4 and 4.3-6). Therefore, implementation of the 2012 AQMP is not expected to result in a significant increase on petroleum fuel use.

Project Specific Mitigation Measure: No significant impacts on petroleum fuels associated with the 2012 AQMP were identified because of anticipated reduction in future demand so that no mitigation measures are required.

Remaining Petroleum Fuel Impacts: Since potential petroleum fuel energy demand impacts are expected to be less than significant and no mitigation measures are required, impacts remain less than significant.

4.3.4.4 Alternative Fuels

General growth in the district is expected to result in a substantial increase in the use of petroleum fuels between current conditions and 2035. Table 4.3-5 summarizes the expected increases in fuel usage, as predicted by SCAG's transportation and air quality model, between 2011 and 2035 with the investments in the RTP and without the RTP.

The 2012 AQMP continues to call for progressively lower vehicle emissions through the lowering of vehicle emission standards. These proposed control measures for on- and off-road mobile sources are expected to cause a shift from conventional petroleum fuels to alternative fuels such as CNG and hydrogen. (Please note that the impacts associated with reformulated petroleum fuels (e.g., emulsified diesel fuels and reformulated fuels) are included under the discussion of petroleum fuels as they are predominately comprised of petroleum-based fuels). Control measures [that](#) may increase the use of alternative fuels include IND-04, ONRD-03, ONRD-05, OFFRD-01, OFFRD-03, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07.

The use of alternative fuels in California's transportation energy market continues at a gradual pace, but could be limited by a variety of market and regulatory uncertainties. Continuing progress in reducing new gasoline vehicle emissions is having an important effect on auto industry development and marketing of alternative fuel vehicles. The use of cleaner-burning alternative fuels such as CNG is not receiving as much emphasis in light-duty vehicle emission-reducing strategies as previously expected. The combination of gasoline reformulation and advances in automotive emission control technology appears to be making the exhaust emission levels required by California's low-emission vehicle standards achievable without relying on the use of alternative fuels. Therefore, the demand for alternative fuels would depend on their marketing strategies and the development of infrastructure to affect consumer choice.

4.3.4.4.1 *Electricity and Natural Gas*

The use of electricity and natural gas as alternative fuels for mobile vehicles was discussed in the previous subsections 4.3.4.1 Electricity and 4.3.4.2 Natural Gas.

4.3.4.4.2 *Biodiesel*

The advantages of biodiesel include decreased net carbon dioxide, hydrocarbon, carbon monoxide, and particulate matter emissions, and fuel properties similar to petroleum diesel for ease of use in diesel engines. Its disadvantages include poorer cold flow characteristics, lower heating values, and mostly reported higher NOx emissions. There are 16 biodiesel production facilities in California with an annual production capacity of 84.5 million gallons. This production capacity is sufficient to supply California's total "proportional share" of biodiesel under the 2007 Renewable Fuel Standard (RFS2) under EISA of 2007. The CEC states that demand for biodiesel may be necessary by obligated parties in California to help achieve compliance with the California Low Carbon Fuel Standard (LCFS) requirements (CEC, 2011). However, to the extent that low and zero emission technologies are implemented as a result of implementing 2012 AQMP control measures, it is likely that biodiesel demand would decline similar to any declines in demand for diesel fuel.

4.3.4.4.3 *Ethanol and E85*

There are a number of 2012 AQMP control measures that identify alternative fuels as a potential compliance option. Since many of the control measures ultimately call for low or zero emitting equipment it is unclear whether or not ethanol or ethanol blends would be used as a compliance option, but it is assumed that there could be increased demand for ethanol and ethanol blends as combustion fuels.

Currently, most of the ethanol used in California is imported from corn based ethanol plants in the Midwest. There are two facilities in Southern California (one in Carson and one in Colton) that are capable of receiving unit trains of ethanol. Together, they import 672,000 gallons per year of ethanol (CEC, 2011). In addition, there are five corn-based ethanol facilities in California. Three of the five California corn-based ethanol facilities are operating with a collective production capacity of nearly 170 million gallons per year (CEC, 2011). Two of the California facilities remain idle, because of poor economic conditions, with a combined capacity of 71 million gallons per year. All California facilities that are currently idle are assumed to be fully operational at their rated nameplate capacity of nearly 71 million gallons per year beginning January 2013 (CEC, 2011). The potential production capacity, including future ethanol production facilities, for advanced biofuels ethanol production in California is estimated by CEC staff at approximately 502 million gallons per year (CEC, 2011). Based on this information, it is likely that there is sufficient ethanol production capacity to meet any increased demands by 2012 AQMP control measures.

4.3.4.4.4 *Methanol and M85*

Since M85 is no longer sold in California, M85 is not expected to be affected by AQMP control measures.

4.3.4.4.5 *Hydrogen*

There is growing interest and financial support for the use of hydrogen-powered fuel cells to power cars, trucks, homes and business. Hydrogen vehicles in California consist of

demonstration fuel cell passenger cars, internal combustion engine passenger cars, fuel cell buses, and hybrid fuel cell buses. The California Fuel Cell Partnership, a public-private partnership between interested industry and state and local government agencies, has been leading the coordination of fuel cell vehicle demonstrations in California. To date, 250 hydrogen fuel cell vehicles have been placed on California's roads in demonstration projects (CEC, 2011).

Hydrogen fuel cells are proven technology, but more work is needed to make them cost-effective for use in cars, trucks, homes or businesses. Hydrogen fuel cells create electricity to power cars with minimal pollution. California has been developing the infrastructure of a hydrogen highway, the California Hydrogen Highway Network (CaH2Net). The mission of CaH2Net is to assure that hydrogen fueling stations are in place to meet the demands of fuel cell and other hydrogen vehicle technologies. The first hydrogen station was opened on April 20, 2004 and there are now 23 hydrogen fueling stations in California. Although the specific station numbers originally called for 50 to 100 stations by 2010, there has been a strategic refocusing on putting additional emphasis on creating clusters of hydrogen fueling stations in key urban areas such as Los Angeles and Orange counties, Sacramento, and the San Francisco Bay area (CARB, 2011).

One of the goals of the 2012 AQMP is to shift from conventional petroleum based fuels to less polluting alternative transportation fuels, including hydrogen. Although the 2012 AQMP does not mandate hydrogen fuel use by fleet operators, it does call for further technology demonstration and deployment. Therefore, without regulatory requirements or market incentives, the use of hydrogen fuel in the 2020 timeframe attributable to the 2012 AQMP, increased demand impacts for hydrogen fuel is not expected to be significant.

4.3.4.4.6 *Propane (LPG)*

There are a number of 2012 AQMP control measures that identify alternative fuels as a potential compliance option. Since many of the control measures ultimately call for low or zero emitting equipment it is unclear whether or not LPG would be used as a compliance option, but it is assumed that there could be increased demand for LPG as combustion fuels. Propane is an unregulated fuel in California (except for storage and safety issues), no data is collected by the state on LPG sales or usage.

Propane vehicle conversions were negatively affected by the EPA's addendum to Memorandum 1A, which led to decreases in the number of vehicle conversions. The supply of propane used in transportation is expected to be sufficient in the near future, both worldwide and in the United States (U.S. DOE, 2010), should LPG-fueled vehicles meet the applicable vehicle tailpipe standards.

Project Specific Mitigation: Based on the above information, potential alternative energy demand impacts are expected to be less than significant so that no mitigation measures are required.

Remaining Alternative Energy Impacts: Since potential alternative energy demand impacts are expected to be less than significant and no mitigation measures are required, impacts remain less than significant.

4.3.4.5 Renewable Energy

A number of 2012 AQMP control measures would encourage the use of clean fuels and alternative fuels or electrification of equipment. For example, Control Measures INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-05, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06 may result in the use of more electric or hybrid vehicles or equipment.

There are number of different types of renewable energy sources such as wind turbines, windmills, windpumps, or sails; hydroelectric; geothermal; and solar thermal and photovoltaic. No 2012 [AQMP](#) control measures were identified that would directly or indirectly adversely affect these renewable sources of electricity. With regard to potential electricity impacts from the 2012 AQMP, refer to subsection 4.3.4.1.

Two control measures may affect biomass/biogas sources: CMB-02 and MCS-02. CMB-02 would require the replacement of existing biogas flares with new biogas flares. The new biogas flares would be more efficient, but would not alter the amount of biogas combusted in the flares. MCS-02 would require that chipped or ground greenwaste be covered to the extent possible. MCS-02 may also require additional best management practices or controls, but is not expected to affect the amount of biomass processed.

California's Renewables Portfolio Standard requires the use of 33 percent renewable energy by 2020. No control measures in the 2012 AQMP would interfere with complying with the renewable energy requirement. Control measures in the 2012 may increase demand for electricity, but this would have no effect on electricity generating sources, either renewable or conventional energy generating sources.

Project Specific Mitigation: Based on the above information, potential renewable energy impacts are expected to be less than significant so that no mitigation measures are required.

Remaining Renewable Energy Impacts: Since potential renewable energy demand impacts are expected to be less than significant and no mitigation measures are required, impacts remain less than significant.

4.3.5 Summary of Energy Impacts

The following is the summary of the conclusions of the analysis of energy impacts associated with implementation of the 2012 AQMP.

- **Electricity:** Implementation of the 2012 AQMP control measures is expected to result in an overall increase. While this increase is expected to be within the electric generating capacity of the region, an increase in electricity of greater than one percent represents a substantial increase in electricity use. Thus, the energy impacts associated with electricity demand from the implementation of the 2012 AQMP are considered to be significant.
- **Natural Gas:** The energy impacts associated with implementation of the control measures and strategies in the 2012 AQMP are expected to result in an increase in

natural gas demand. The increased demand for natural gas is considered to be significant.

- **Petroleum Fuels:** The energy impacts associated with implementation of the control measures and strategies in the 2012 AQMP are expected to result in a reduction in use (less demand) of petroleum fuels so that no significant impacts on petroleum fuels are expected.
- **Alternative Fuels:** Although an increase in demand for hydrogen as a transportation fuel is expected due to implementation of the control measures and strategies in the 2012 AQMP, this increase is not expected to be significant since hydrogen is not widely available and its use is currently limited. Hydrogen is available or the feedstock that produces it is generally available. Future demand is expected to be met through increased production. The energy impacts associated with the future use of hydrogen is expected to be less than the current strategy that uses predominately petroleum based fuels so that no significant hydrogen demand impacts are expected.
- **Renewable Energy:** No 2012 AQMP control measures were identified that would adversely affect renewable energy production or interfere with the goals and requirements of the Renewables Portfolio Standard.

Summary of PM2.5 Control Measure Impacts: Energy impacts associated with PM2.5 control measures were evaluated and determined to be less than significant for electricity, natural gas, petroleum fuels, and alternative fuels impacts.

Summary of Ozone Control Measure Impacts: Energy impacts associated with the ozone control measures (22 control measures, see Table 4.3-1) were evaluated and determined to be significant for electricity and natural gas; and less than significant for petroleum fuels, and alternative fuels impacts.

SUBCHAPTER 4.4

HAZARDS AND HAZARDOUS MATERIALS

Introduction

2012 AQMP Control Measures with Potential Hazards and Hazardous Materials Impacts

Significance Criteria

Potential Hazards and Hazardous Materials Impacts and Mitigation Measures

Summary of Hazards and Hazardous Materials Impacts

4.4 HAZARDS AND HAZARDOUS MATERIALS

4.4.1 Introduction

Hazards and hazardous materials impacts are related to the risks of explosions or the release of hazardous substances in the event of an accident or upset conditions. The Initial Study for the 2012 AQMP identified the following types of control measures as having potentially significant hazards and hazardous materials impacts: 1) use of reformulated coatings, solvents, and consumer products; 2) increase in the transportation and disposal of reformulated products; 3) the use of ammonia in selective catalytic reduction (SCR) or selective non-catalytic reduction (SNCR) air pollution control technology; 4) use of alternative fuels; and, 5) use of catalysts.

4.4.2 2012 AQMP Control Measures with Potential Hazards and Hazardous Materials Impacts

The 2012 AQMP continues the air quality management strategy of advancing clean technologies and promoting their use. In particular, some control measures in the 2012 AQMP promote greater use of reformulated low VOC consumer products such as coatings, adhesives, solvents and lubricants, potentially resulting in additional hazards associated with their use while other control measures encourage the use of alternative fuels which could increase hazards associated with the use of these fuels. Each control measure proposed in the 2012 AQMP was evaluated and 24 control measures were identified as having potential adverse hazard impacts. Table 4.4-1 contains a summary of the 2012 AQMP control measures (e.g., three PM_{2.5} control measures and 21 ozone precursor control measures) which may result in the use of compliance options that could generate significant hazard impacts.

TABLE 4.4-1

Control Measures with Hazards and Hazardous Materials Impacts

Control Measure	Control Measure Title (Pollutant)	Control Methodology	Hazard Impact
SHORT-TERM PM_{2.5} CONTROL MEASURES			
CMB-01	Further NO _x Reductions from RECLAIM (NO _x)	Cement kilns, glass furnaces, and gas turbines were not subject to reduction in the 2005 RECLAIM rule amendment. These sources will be examined for further reductions in this control measure and potential rule making. SCR, SNCR, low NO _x burners, and NO _x reducing additives (catalysts).	Potential exposure to toxic air contaminant (ammonia) associated with SCRs and SNCR during storage, transport, use and accidental release. Potential increase in the quantity of hazardous materials (e.g., catalysts) associated with shipping, handling, storage, use, and disposal.

TABLE 4.4-1(Continued)

Control Measures with Hazards and Hazardous Materials Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	HAZARD IMPACT
SHORT-TERM PM2.5 CONTROL MEASURES			
IND-01	Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities	Environmental lease conditions, port rules, tariffs or incentives.	Use of alternative fuels can result in hazard impacts. Potential exposure to toxic air contaminant (ammonia) associated with SCRs during with storage, transport, use and accidental release.
MCS-01	Application of All Feasible Measures	SCAQMD would adopt and implement new retrofit technology control standards as new BARCT standards become available.	Use of alternative fuels can result in hazard impacts. Potential exposure to toxic air contaminant (ammonia) associated with SCRs during with storage, transport, use and accidental release. Reformulating coatings with more toxic or flammable solvents could cause fire, accidental release, offsite/onsite exposure and worker risk.
OZONE CONTROL MEASURES			
CTS-01	Further VOC Reductions from Architectural Coatings (Rule 1113) (VOC)	Reduce the allowable VOC content in product formulations by using alternative low-VOC products and use application techniques with greater transfer efficiency.	Reformulating coatings with more toxic or flammable solvents could cause fire, accidental release, offsite/onsite exposure and worker risk.
CTS-02	Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants (VOC)	Reduce the allowable VOC content in product formulations by using alternative low-VOC products or non-VOC products/equipment.	Reformulating coatings with more toxic or flammable solvents could cause fire, accidental release, offsite/onsite exposure and worker risk.
CTS-03	Further VOC Reductions from Mold Release Products (VOC)	Limitation of VOC content for mold release products.	Reformulating coatings with more toxic or flammable solvents could cause fire, accidental release, offsite/onsite exposure and worker risk.
CTS-04	Further VOC Reductions from Consumer Products (VOC)	Eliminate or revise the exemption for low vapor pressure solvents in consumer products.	Reformulating consumer products with more toxic or flammable solvents could cause fire, accidental release, offsite/onsite exposure, and worker risk.
FUG-01	Further VOC Reductions from Vacuum Trucks (VOC)	VOC control devices such as carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers, liquid scrubbers and positive displacement (PD) pumps.	Hazardous waste from spent carbon, use of ammonia to operate condensers, hazardous waste from operating scrubbers, hazardous waste of spent catalyst from operating thermal oxidizers.

TABLE 4.4-1 (Continued)

Control Measures with Hazards and Hazardous Materials Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	HAZARD IMPACT
OZONE CONTROL MEASURES			
INC-01	Economic Incentive Programs to Adopt Zero and Near-Zero Technologies (NOx)	Installation of cleaner, more efficient combustion equipment, such as boilers, water heaters and commercial space heating or installation of control technologies including fuel cells, diesel particulate filters (DPF), NOx reducing additives (catalysts), alternative electricity generation, such as wind and solar, battery electric, hybrid electric, and usage of low NOx and alternative fuels such as natural gas.	Use of alternative fuels can result in hazard impacts. Potential increase in the quantity of hazardous materials (e.g., catalysts) associated with shipping, handling, storage, use, and disposal.
MCS-03	Improved Start-up, Shutdown and Turnaround Procedures (All Pollutants)	Diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability	Equipment modifications may pose safety issues.
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles (NOx)	Incentives to replace older vehicles with electric or hybrid vehicles.	Use of alternative fuels can result in hazard impacts.
ONRD-03	Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium Heavy-Duty Vehicles (NOx)	Incentives to replace older medium-duty vehicles with low-emitting vehicles. Highest priority would be given to zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode.	Use of alternative fuels can result in hazard impacts.
ONRD-04	Accelerated Retirement of Older Heavy-Duty Vehicles (NOx)	Incentives replace heavy-duty vehicles with newer or new vehicles. Priority would be placed on replacing older diesel trucks in Mira Loma.	Use of alternative fuels can result in hazard impacts.
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace up to 1,000 heavy-duty vehicles with low-emitting vehicles or zero-emission container movement systems.	Use of alternative fuels can result in hazard impacts.

TABLE 4.4-1 (Continued)

Control Measures with Hazards and Hazardous Materials Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	HAZARD IMPACT
OZONE CONTROL MEASURES			
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment (NOx)	Accelerate Tier 0 and Tier 1 equipment replacement with Tier 4 equipment, use of air pollution control technologies (e.g., advanced fuel injection, air induction, and after-treatment technologies).	Use of alternative fuels can result in hazard impacts.
OFFRD-02	Further Emission Reductions from Freight Locomotives (NOx)	Replace existing engines (Tier 0 and Tier 2 engines) with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Use of alternative fuels can result in hazard impacts. Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release.
OFFRD-03	Further Emission Reductions from Passenger Locomotives (NOx)	Repower existing Tier 0 and Tier 2 engines with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Use of alternative fuels can result in hazard impacts. Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release.
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels While at Berth (NOx)	Shore power of vessels at berth, use of air pollution control technologies on exhaust gases from auxiliary engines and boilers (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Use of alternative fuels can result in hazard impacts. Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release.
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure; construct battery charging and fueling infrastructure. Alternatively, if battery, fuel cell or other zero/near zero emission technologies progress sufficiently, the need for wayside power for rail or trucks may be diminished or eliminated.	Use of alternative fuels can result in hazard impacts.
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric, magnetic, battery-hybrid system, or fuel cell infrastructure, construct battery charging or fueling infrastructure.	Use of alternative fuels can result in hazard impacts.

TABLE 4.4-1 (Concluded)

Control Measures with Hazards and Hazardous Materials Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	HAZARD IMPACT
OZONE CONTROL MEASURES			
ADV-03	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment (NOx)	Construct electric gantry cranes, construct battery charging or fueling infrastructure, and use of alternative fuels.	Use of alternative fuels can result in hazard impacts.
ADV-04	Actions for the Deployment of Cleaner Commercial Harborcraft (NOx)	Construct battery charging or fueling infrastructure, use of air pollution control equipment (e.g., SCR, and use of alternative fuels).	Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release.
ADV-05	Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels (NOx)	Employ aftertreatment control technologies such as SCR and sea water scrubbers, and use of alternative fuels.	Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release.
ADV-06	Actions for the Deployment of Cleaner Off-Road Equipment (NOx)	Construct battery charging or fueling infrastructure, and increased use of alternative fuels.	Use of alternative fuels can result in hazard impacts.
ADV-07	Actions for the Deployment of Cleaner Aircraft Engines (NOx)	Use alternative fuels, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction.	Use of alternative fuels can result in hazard impacts.

4.4.3 Significance Criteria

Impacts associated with hazards and hazardous materials will be considered significant if any of the following criteria are met:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.
- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

4.4.4 Potential Hazards and Hazardous Materials Impacts and Mitigation Measures

4.4.4.1 Reformulated Coatings, Solvents, and Consumer Products

PROJECT-SPECIFIC IMPACTS: The 2012 AQMP control measures that could require reformulation of coatings, adhesives, solvents, lubricants, mold release agents, and consumer products are MCS-01, CTS-01, CTS-02, CTS-03, and CTS-04. To meet the lowered future VOC content limits, these products are expected to be reformulated. While reformulated products would be expected to have lower VOC contents, the reformulations could have widely varying flammability and health effects, depending on the chemical characteristics of the replacement solvents chosen. While most reformulations are expected to be made with water, which is not flammable and does not have adverse health impacts, other reformulations could be made with an exempt, but extremely flammable solvent, such as acetone. Acetone is an exempt compound from air quality rules and regulations because of its low reactivity. In addition, coatings, solvents and consumer products can also be reformulated with other solvents that are not exempted from the definition of a VOC in SCAQMD's Rule 102, but that also have flammability and health effects issues.

Table 4.4-2 identifies a list of typical conventional solvents and possible replacement solvents that may be used in the manufacture of coatings, adhesives, solvents, lubricants, mold release agents, and consumer products along with their chemical characteristics pertaining to whether each substance is fire hazard.

As illustrated in Table 4.4-2, the flammability classifications by the NFPA are the same for acetone as well as for other conventional solvents that are currently used in existing formulations such as tertiary butyl acetate (T-BAc), toluene, xylene, methyl ethyl ketone (MEK), isopropanol, butyl acetate, and isobutyl alcohol. Because acetone has the lowest flash point of all the chemicals listed, from a flammability perspective, reformulations made with acetone would represent the worst-case. However, it is important to note that acetone also has one of the highest LEL, 2.6 percent by volume, which means that acetone vapors will not cause an explosion unless the vapor concentration exceeds 26,000 ppm.

In contrast, a conventional solvent such as toluene can cause an explosion at 1.3 percent by volume or 13,000 ppm, which poses a much greater risk of explosion when compared to acetone. Similarly, the concentration of xylene, another conventional solvent, that can cause an explosion is even lower than toluene at 1.0 percent by volume or 10,000 ppm. However, facility operators are required to follow operating guidelines when working with flammable chemicals. These guidelines specify well-ventilated areas, as prescribed by the fire department codes, so that it would be difficult to achieve the LEL concentrations when working with flammable chemicals.

TABLE 4.4-2

Chemical Characteristics for Conventional and Potential Replacement Coating Solvents

CAS No.	Chemical Compound	Auto-ignition Temperature (°F)	Boiling Point (@760 mmHg, °F)	Evaporation Rate @ 25 °C (Butyl Acetate = 1)	Flash Point (°F)	LEL/UEL ^a (% by Vol.)	Vapor Pressure (mmHg @ 20 °C)	NFPA Flammability Rating ^b	Flammability ^c

^a Lower Explosive Limit / Upper Explosive Limit

^b NFPA Flammability Rating: 0 = Not Combustible; 1 = Combustible if heated; 2 = Caution: Combustible liquid flash point of 100° to 200°F; 3 = Warning: Flammable liquid flash point below 100°F; 4 = Danger: Flammable gas or extremely flammable liquid

^c The Consumer Products Safety Commission (CPSC) has Labeling and Banning Requirements for Chemicals and Other Hazardous Substances which are located in 15 U.S.C. §1261 and 16 CFR Part 1500. Specifically, the flammability of a product is defined in 16 CFR Part 1500.3 (c)(6) and is based on flash point. For example, a flammable liquid needs to be labeled as: 1) "Extremely Flammable" if the flash point is below 20 °F; 2) "Flammable" if the flash point is above 20 °F but less than 100°F; or, 3) "Combustible" if the flash point is above 100 °F up to and including 150 °F.

While a “worst-case” flammability scenario could be that all of the affected 2012 AQMP coatings, solvents and consumer products would be reformulated with acetone to meet the interim and final VOC content limits, due to lower costs, most future reformulated products will likely be reformulated using primarily water. Water-based coatings are generally not flammable and typically have a lower NFPA classification, and a lower CPSC classification, when compared to coatings formulated with conventional solvents.

Chemistry classes at all levels from grade school to universities, as well as industrial laboratories, use acetone for wiping down counter tops and cleaning glassware. Additional uses for acetone include solvent for paint, varnish, lacquers, inks, adhesives, floor coatings, and cosmetic products including nail polish and nail polish remover. Further, it is currently used widely in coating and solvent formulations.

Labels and MSDSs accompanying acetone-based products caution the user regarding acetone’s flammability and advise the user to “*keep the container away from heat, sparks, flame and all other sources of ignition. The vapors may cause flash fire or ignite explosively. Use only with ventilation.*” All of the large coating manufacturers currently offer pure acetone for sale with similar warnings. The Uniform Fire Code (UFC) treats solvents such as acetone, butyl acetate, and MEK as Class I Flammable Liquids. Further, the UFC considers all of these solvents to present the same relative degree of fire hazard (SCAQMD, 2003).

A list of conventional and potential replacement solvents and their related health hazards information are shown in Table 4.4-3. As illustrated in Table 4.4-3, some of the potential replacement solvents have lower or less severe TLVs, PELs, IDLHs than some of the conventional solvents. For example, acetone would be considered to have less health hazards than all of the conventional solvents listed. However, there are some replacement solvents that could have higher, more severe, or unknown toxicological effects. For example, the diisocyanate group of solvents appear to have more severe toxicological effects than the listed traditional solvents.

In addition to the health hazard values summarized in Table 4.4-3, there are several chemicals listed that are toxics, identified as TACs, including but not limited to the following: ethylbenzene, formaldehyde, methyl ethyl ketone (MEK), methyl isobutyl ketone (MIBK), toluene, triethylamine, and xylene. The use of materials that contain toxic compounds is of particular concern, in both existing formulations as well as reformulated products, to the SCAQMD and other agencies such as EPA, CARB, OSHA, and the Office of Environmental Health Hazard Assessment (OEHHA) (which is part of the California Environmental Protection Agency (Cal/EPA)), because some of the TACs used in some coatings are considered carcinogens (cancer-causing) such as formaldehyde while others may have other non-cancer health effects¹.

¹ Formaldehyde, toluene, triethylamine, and xylene are classified as having both chronic and acute health effects; ethylbenzene as having chronic health effects and zinc oxide proposed as having chronic health effects; MEK as having acute health effects with future proposed risk value for chronic; and, cobalt compounds as having future proposed risk values. In addition, MIBK is classified by EPA as a HAP, but the toxicology assessment is not finalized.

144-19-4	Trimethyl 1,3-pentanediol	0	N/A	N/A	N/A	Mild irritation - eye, nose, skin, respiratory, digestive

^a NFPA Health Rating: 0 = No unusual hazard; 1 = Caution: May be irritating; 2 = Warning: May be harmful if inhaled or absorbed; 3 = Warning: Corrosive or toxic. Avoid skin contact or inhalation; 4 = Danger: May be fatal on short exposure. Specialized protective equipment required.

^b TLV = Threshold Limit Value, a recommended guideline established by the American Conference of Governmental Industrial Hygiene (ACGIH)

^c PEL = Permissible Exposure Limit, established by OSHA

^d IDLH = Immediately Dangerous to Life and Health, established by NIOSHA

For these reasons, there are two local rules that regulate TAC emissions in coatings: SCAQMD Rule 1401 – New Source Review of Toxic Air Contaminants, and SCAQMD Rule 1402 – Control of Toxic Air Contaminants From Existing Sources. Rule 1401 applies to new and modified facilities, including coating facilities, and Rule 1402 applies to facility-wide risk at existing facilities. Since the majority of coating facilities located within SCAQMD’s jurisdiction are existing sources, the requirements in Rule 1402 are the main drivers for reducing overall risk and, therefore, TAC emissions from this industry.

For reasons of cost and to provide flexibility with stringent coating VOC content requirements the SCAQMD has received requests to exempt two chemicals from the definition of a VOC in SCAQMD’s Rule 102: tertiary butyl acetate (T-Bac) and dimethyl carbonate (DMC). T-BAc is not currently identified in any of SCAQMD’s rules as a TAC. T-BAc has been delisted as a VOC by the U.S. EPA², but it has not been delisted as a VOC by CARB or the SCAQMD. When delisting a compound from the definition of VOC, EPA only considers reactivity and does not address whether the compound is toxic or has global warming or stratospheric ozone depleting potential. T-BAc is not currently classified as a hazardous air pollutant under the federal Clean Air Act. T-BAc possesses a low photochemical reactivity as well as some other physical and chemical properties that are considered desirable by its manufacturer’s representatives. However, T-BAc may be unsuitable for consideration as a potential replacement for all conventional solvents because of T-BAc’s potential toxicity. Specifically, T-BAc has the potential to form a metabolite called tert-butyl alcohol (TBA) which has cancer potency and acute noncarcinogenic values established by OEHHA. According to Acute Toxicity and Cancer Risk Assessment Values for TBA, (Budroe, et al., 2004), “TBA should be considered to pose a potential cancer risk to humans because of the metabolic conversion to TBA.”

Under limited and prescribed circumstances, the SCAQMD incorporated limited use exemptions for T-BAc into SCAQMD Rules 1113 - Architectural Coatings, and 1151 - Motor Vehicle and Mobile Equipment Non-Assembly Line Coating Operations) to provide potential compliance flexibility while limiting use of T-BAc because of the potential toxic concerns.

DMC is also not currently identified in any of SCAQMD’s rules as a TAC. EPA revised the federal VOC definition to exclude DMC based on its negligible photochemical reactivity³. DMC is also currently not identified as a HAP under the federal Clean Air Act nor is it classified as an ozone depleting substance. No exposure guidelines have been established for DMC by the American Conference of Governmental Industrial Hygienists (ACGIH), or by the National Institute for Occupational Safety and Health (NIOSH). DMC is of concern because it forms a metabolite (an intermediate product of metabolism) consisting of methanol, which is a carcinogen.

² U.S. EPA. 2004. Revision to Definition of Volatile Organic Compounds – Exclusion of t-Butyl Acetate, 40 CFR Part 51, Federal Register 69298, November 29, 2004. (<http://www.gpo.gov/fdsys/pkg/FR-2004-11-29/pdf/04-26069.pdf>)

³ U.S. EPA. 2009. Air Quality: Revision to Definition of Volatile Organic Compounds- Exclusion of Propylene Carbonate and Dimethyl Carbonate, 40 CFR Part 51, Federal Register 3437, January 21, 2009. (<http://www.gpo.gov/fdsys/pkg/FR-2009-01-21/pdf/E9-1150.pdf>)

Thus, when coatings and other products are reformulated as part of implementing the various control measures proposed in the 2012 AQMP, manufacturers could potentially use replacement chemicals that could pose new or different health risks, but SCAQMD Rule 1401 and 1402 would limit potential exposures to nearby receptors. Further, as was the case with the limited use exemption of T-Bac in Rules 1113 and 1151, future SCAQMD rulemaking would require individual evaluation of replacement chemicals that could pose health risks.

When comparing the conventional solvents listed in Table 4.4-3, some of the replacement solvents (e.g., triethylamine) are likely to be present in trace amounts and accidental releases would be considered a one-time event that would be neutralized and cleaned up before all the solvent has evaporated, so no new chronic health risk is expected. As shown in Table 4.4-3, the toxicity of replacement materials is generally less or no worse than conventional solvents overall but if a facility changes from using water-based products to using products that are reformulated with chemicals that may have new or different health hazards, significant adverse health hazard impacts could occur from using some low VOC reformulated products. However, as with the use of all chemicals, facilities and their workers would be required to continue to comply with existing health protective procedures when handling both flammable and toxic materials. In addition, any increase in the future use of low VOC compliant coating materials that are reformulated with water would be expected to result in a concurrent reduction in the number of accidental releases of high VOC coating materials. As a result, the net number of accidental releases would be expected to remain constant, allowing for population growth in southern California.

Regarding fire hazards, if manufacturers use solvents such as Texanol, propylene glycol, etc., in future compliant water-borne coatings, significant adverse hazard impacts would not be expected to occur because in general these solvents are either equivalent or less flammable solvent per the NFPA ratings. However, if manufacturers reformulate with acetone, then more acetone-based (and extremely flammable) products would be on the market. Similarly, if manufacturers reformulate with products that have increased flammability than products manufactured with conventional solvents, consumers who may be used to a higher VOC product with lower flammability, may be unaware that the reformulated products may have chemicals with increased flammability and an increased risk when used.

Lastly, in general, water-based coatings and products tend to contain less flammable and less toxic materials than solvent-based coatings and products. While the continued and potentially increased use of waterborne coatings and products would generally be expected to reduce the overall hazard impacts associated with solvent-based products, a switch from currently using water-based products to reformulated solvent-based products could offset any reduction realized. Without knowing how many facilities currently using water-based products would switch to using reformulated solvent-based products as a result of implementing the 2012 AQMP control measures, significant impacts on fire hazards associated with reformulated coatings, solvents and consumer products could occur. Therefore, hazards and hazardous materials impacts associated with increased flammability of potential replacement solvents are concluded to be significant.

PROJECT-SPECIFIC MITIGATION: Since hazards and hazardous materials impacts associated with increased flammability of potential replacement solvents, reformulated coatings and consumer products were identified, the following mitigation measures are necessary and required as part of future rule development pertaining to reformulated products:

HZ-1: Add consumer warning requirements for all flammable and extremely flammable products; and,

HZ-2: Add requirements to conduct a public education and outreach program in joint cooperation with local fire departments regarding flammable and extremely flammable products that may be included in consumer paint thinners and multi-purpose solvents.

REMAINING IMPACTS: The fire hazard impacts are expected to be significant prior to mitigation. While the SCAQMD cannot predict which coatings, solvents and consumer products each affected facility might choose to use in the future as reformulations become available, the mitigation measure is expected to be effective at informing consumers about the potential fire hazards associated with reformulated products. Thus, after mitigation, no remaining significant impacts on fire hazards are expected.

4.4.4.2 Use of Alternative Fuels

The 2012 AQMP would establish in-use strategies that may require or promote the use of alternative fuels including Control Measures IND-01, INC-01, ONRD-01, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07. Control Measure IND-01 is the only control measure developed for PM_{2.5} emission reductions and the rest of the control measures were developed for ozone precursor reductions. Use of alternative fuels in place of conventional fuels may present a potential safety issue due to the increased transport, use and handling of alternative fuels. All fuels are flammable; therefore, their use could result in increased hazards associated with their transport and use.

4.4.4.2.1 *Methanol/Methanol Blends*

Methanol or methyl alcohol is a clear colorless liquid which is commercially manufactured from natural gas in the U.S. At its peak, nearly six million gasoline gallon equivalents of methanol blends were used annually in alternative fuel vehicles in the U.S. Methanol use in vehicles has declined dramatically since the early 1990s, and automakers no longer manufacture methanol vehicles (DOE, 2012).

Methanol is often designated at M100, which is 100 percent methanol, or M85, which are 85 percent methanol and 15 percent gasoline. Pure methanol has low flame luminosity, making it difficult to see fires, particularly in daylight. However, the addition of gasoline to M85 increases both the luminosity and the fuel volatility. The increased luminosity produces a visible flame, and the latter effect generally makes the vapors present in the fuel tank too rich to be flammable.

The bulk transfer of methanol is usually done in standard petroleum tanker trucks. There is no reason to expect that methanol transport will be more dangerous than gasoline or diesel transport. There are, however, certain physical properties of methanol that must be addressed during transport and storage when compared to gasoline or diesel. First, methanol (M100 and M85) is incompatible with several types of materials typically used in petroleum storage and transfer systems. Therefore, it is necessary to take special precautions in selecting material for these purposes. Second, pure methanol (M100) vapor/air mixtures at ambient temperatures and pressures can create a flammable mixture in the ullage space of a storage tank. Therefore, it is important to ensure that there are strong safeguards against any ignition sources inside tanks and that vent lines or other openings have flame arrestors. Furthermore, any fill lines must extend below the liquid methanol level to provide a seal between an external ignition source and the vapor/air mixture in the tank. M85 vapors are primarily composed of gasoline, and should not change the fire hazard of transfer and storage relative to gasoline (DOT, 1995).

Methanol has been used for car racing in the U.S. The main reason for this choice was its safety compared to gasoline. Methanol is harder to ignite, creates less radiant heat, can be controlled/extinguished with water, and burns without producing black smoke, facilitating rescue. For regular driving, methanol offers a substantial decrease in the risks of fuel fire deaths compared to gasoline for the same reasons as in racing. For M100 a 90 percent reduction in fuel related automotive fires is projected, while a smaller reduction of 40 percent is projected for M85 (MIT, 2010).

PROJECT-SPECIFIC IMPACTS - METHANOL: Compared with diesel fuel and gasoline the following can be stated with respect to methanol:

- Diesel fuel and gasoline contain components that are considerably more hazardous than methanol. For example, diesel fuel contains highly toxic polynuclear aromatic hydrocarbons (PAHs) and gasoline contains an array of toxic compounds, including benzene, a known carcinogen;
- Diesel fuel and gasoline vapors are heavier than air (for a specific gravity of air =1, gasoline is 3.4 and diesel is greater than 4). Methanol is heavier than air but lighter (specific gravity is 1.11) than gasoline and diesel fuel and disperses more readily in air than gasoline or diesel fuel;
- Methanol has a higher auto ignition temperature (793 degrees Fahrenheit [°F]) than diesel fuel (500 °F) or gasoline (500 °F);
- Methanol is more difficult to ignite since it has a “lower flammability limit” that is higher (5.5 percent) than gasoline (approximately one percent) or diesel fuel (0.5 percent);
- Unlike gasoline, methanol can ignite in enclosed spaces such as fuel tanks since its upper flammability limit is 15 percent and it is slightly heavier than air. For gasoline in a confined space, the vapor concentration exceeds the higher flammability limit (7.6 percent) and is therefore too high to ignite in the tank. Modifications such as materials

inside the fuel tank that can arrest and quench flame propagation and modifications to isolate the tank from sparks and ignition sources are required to avoid ignition in the fuel tanks; and,

- In case of fire, methanol can be extinguished with water while water on gasoline or diesel fuel spreads the fire.

In 2005 California stopped the use of methanol after 25 years and 200,000,000 miles of operation. There are currently no fueling stations in the state. Although there is still some interest in methanol as a vehicle fuel, there is great emphasis on research and development of other alternative fuels. Consequently, it is not expected that methanol use will increase substantially.

PROJECT-SPECIFIC MITIGATION - METHANOL: Less than significant impacts on hazards associated with the use of methanol as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS - METHANOL: The hazard impacts associated with using methanol as an alternative fuel are expected to be less than significant. Thus, no remaining hazard impacts associated with methanol use are expected.

4.4.4.2.2 *Ethanol/Ethanol Blends*

Like methanol, ethanol is a clear colorless organic liquid with physical and chemical properties which do not change from source to source like conventional fuels. In the U.S., ethanol is typically produced from corn or other grain products, while some imported ethanol is produced from sugar cane. For commercial or industrial use, pure ethanol (E100) is usually denatured with a small amount of gasoline or similar substance to avoid federal alcoholic beverage tax and intentional ingestion. Heavy duty vehicles use E95 (95 percent ethanol and five percent gasoline) or E93 (93 percent ethanol, five percent methanol, and two percent kerosene). Light and medium duty vehicles use E85 (85 percent ethanol and 15 percent gasoline). Vapors from ethanol blended fuels will exhibit similar flammability characteristics as gasoline. There are currently 48 E85 fueling stations that are open to the public in California (U.S. DOE, 2012).

The bulk transfer of ethanol is usually done in standard petroleum tanker trucks. Since the NFPA classification of ethanol is the same as gasoline or diesel (Class IB flammable liquid), there is no reason to expect that ethanol transport will be more dangerous than gasoline or diesel transport. There are, however, certain physical properties of ethanol that must be addressed during transport and storage when compared to gasoline or diesel. First, ethanol is incompatible with some types of materials used in petroleum storage and transfer systems; therefore, it is necessary to take some precaution to assure ethanol capable materials are used. Second, like M100, E100 vapor/air mixtures at ambient temperatures and pressures can create a flammable mixture in the ullage space of a storage tank. Therefore, it is important to ensure that there are strong safeguards against any ignition sources inside tanks and that vent lines or other openings have flame arrestors. Furthermore, any fill lines must extend below the liquid ethanol level to provide a seal between an external ignition source

and the vapor/air mixture in the tank. Ethanol blended fuel vapors are primarily composed of gasoline, and should not change the fire hazard of transfer and storage relative to gasoline (DOT, 1995).

PROJECT-SPECIFIC IMPACTS – ETHANOL/ETHANOL BLENDS: Compared with diesel fuel and gasoline the following can be stated with respect to ethanol:

- Diesel fuel and gasoline contain components that are considerably more hazardous than ethanol. For example, diesel fuel contains highly toxic polynuclear aromatic hydrocarbons (PAHs) and gasoline contains an array of toxic compounds, including benzene, a known carcinogen;
- Diesel fuel and gasoline vapors are heavier than air (for a specific gravity of air =1, gasoline is 3.4 and diesel is greater than 4). Ethanol is heavier than air but lighter (specific gravity is 1.6) than gasoline and diesel fuel and disperses more readily in air than gasoline or diesel fuel;
- Ethanol has a higher auto ignition temperature (684 degrees Fahrenheit [°F]) than diesel fuel (500 °F) or gasoline (500 °F);
- Ethanol is more difficult to ignite since it has a “lower flammability limit” that is higher (3.3 percent) than gasoline (approximately one percent) or diesel fuel (0.5 percent);
- Unlike gasoline, ethanol can ignite in enclosed spaces such as fuel tanks since its upper flammability limit is 15 percent and it is slightly heavier than air. For gasoline in a confined space, the vapor concentration exceeds the higher flammability limit (7.6 percent) and is therefore too high to ignite in the tank. Modifications such as materials inside the fuel tank that can arrest and quench flame propagation and modifications to isolate the tank from sparks and ignition sources are required to avoid ignition in the fuel tanks; and,
- In case of fire, ethanol can be extinguished with water while water on gasoline or diesel fuel spreads the fire.

Based upon the preceding information, hazards associated with ethanol are approximately equivalent or less compared to conventional fuels. Therefore, increased usage of ethanol with a concurrent decline in usage of conventional fuels will not significantly alter existing hazards associated with mobile source fuels. Consequently, increased usage of ethanol is not expected to generate significant adverse hazard impacts.

PROJECT-SPECIFIC MITIGATION – ETHANOL/ETHANOL BLENDS: Less than significant impacts on hazards associated with the use of ethanol or ethanol blends as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – ETHANOL/ETHANOL BLENDS: The hazard impacts associated with using ethanol and ethanol blends as an alternative fuel are expected to be

less than significant. Thus, no remaining hazard impacts associated with ethanol and ethanol blend use are expected.

4.4.4.2.3 *Compressed Natural Gas (CNG)*

Natural gas is a mixture of hydrocarbons, mainly methane, that are in gaseous form at ambient temperature and pressure. It is also odorless and tasteless; therefore, an odorant is added so personnel in the vicinity of a leak can detect the presence of natural gas before it has reached the flammability limit in the area. Unlike other alternative fuels, natural gas already has an extensive distribution system and supply network. The issues of bulk transfer and storage are very different from other fuels, which are usually transported via tanker truck. CNG is generally produced onsite using compressors fed from a nearby natural gas pipeline. The typical range of methane in pipeline quality natural gas is approximately 80 to 95 percent. However, CARB has specified that the methane content to be greater than 88 percent for vehicular grade CNG. Typical on-board pressures for CNG range from 3,000 to 3,600 pounds per square inch gauge (psig) (DOT, 1995). There are currently 140 CNG refueling stations that are open to the public in California, and a few manufactures offer home refueling options (U.S. DOE, 2012).

The SCAQMD has had a history of promoting the use of CNG in the past and few issues have arisen from the transport of CNG, as most refueling applications have relied on the existing natural gas pipeline infrastructure. Furthermore, CNG compositions and storage cylinders in vehicles follow NFPA 52 (CNG Vehicular Fuel Systems) and Society of Automotive Engineers (SAE) J1616 (Recommended Practice for CNG Fuel) specifications. These specifications limit the potential hazards related to CNG leaks related to fuel storage and use in vehicles. Furthermore, natural gas has a higher flammability limit (five percent) than gasoline (one percent) or diesel (0.5 percent). Natural gas also has a lower ignition temperature (1,200 °F) than gasoline or diesel (500 °F). Other hazards associated with compressed fuels are projectiles from openings and freeze burns from rapid vaporization.

The main additional hazard associated with the use of CNG versus conventional fuels is the exposure to high pressures employed during storage, dispensing and operations. Due to these high pressures a large amount of gas could escape in a short amount of time and, if present under flammable conditions, could explode in the presence of an ignition source. Another potentially significant hazard is a release of natural gas during vehicle maintenance (DOT, 1995).

PROJECT-SPECIFIC IMPACTS - CNG: Compared with diesel fuel and gasoline the following can be stated with respect to CNG:

- Diesel fuel and gasoline are toxic to the skin and lungs while CNG is not;
- Diesel fuel and gasoline vapors are heavier than air (for specific gravity of air =1, gasoline is 3.4 and diesel fuel is >4). CNG is lighter than air (specific gravity is 0.55) and disperses more readily in air;

- CNG has a higher auto ignition temperature (1,200 °F) than diesel fuel (500 °F) or gasoline (500 °F);
- CNG is more difficult to ignite since it has a “lower flammability limit” that is higher (5.3 percent) than gasoline (one percent) or diesel fuel (0.5 percent); and,
- Natural gas can be directly shipped via pipelines to the compressor station, rather than by on-road delivery trucks, and has less delivery accident risk than vehicle shipments.
- Based upon the preceding information, hazards associated with CNG are approximately equivalent or less compared to conventional fuels. Therefore, increased usage of CNG with a concurrent decline in usage of conventional fuels will not significantly alter existing hazards associated with mobile source fuels. Consequently, increased usage of CNG is not expected to generate significant adverse hazard impacts.

PROJECT-SPECIFIC MITIGATION – CNG: Less than significant impacts on hazards associated with the use of CNG as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – CNG: The hazard impacts associated with using CNG as an alternative fuel are expected to be less than significant. Thus, no remaining hazard impacts associated with CNG use are expected.

4.4.4.2.4 *Liquefied Natural Gas (LNG)*

Natural gas can be liquefied by refrigerating it below -160 degrees Celsius or -260 degrees Fahrenheit at relatively low pressure (20 to 150 psig). Like CNG, there are NFPA standards (NFPA 59A – Standards for Production, Storage, and Handling of LNG and NFPA 57 – Standard for LNG Vehicular Fuel Systems) for the handling, storage, production, and use of LNG, especially in vehicles. However, unlike CNG, most LNG is not generated on-site. Instead, LNG is typically delivered via insulated double walled tanker trucks to distribution facilities. The double walled construction of the LNG tanker trucks are more robust than standard petroleum tanker trucks, therefore, the transport of LNG is safer from spills and tank ruptures during accidents than conventional fuel tanker trucks.

PROJECT-SPECIFIC IMPACTS – LNG HEALTH IMPACTS: The safety issues associated with LNG are similar to CNG, with the added hazards of handling a cryogenic liquid and the vaporization of the liquid. The cryogenic liquids have the potential to burn workers who come into contact with the liquid or uninsulated surfaces. This hazard can be mitigated by proper personal protective equipment and training. The vaporization of LNG in storage tanks can potentially cause a boiling liquid expanding vapor explosion (BLEVE). For a BLEVE to occur there would need to be a catastrophic failure of all safety measures, including safety relief valves and burst discs, built into the vessel the design code.

The main additional hazard associated with the use of LNG versus conventional fuels are personal injuries from contact with a cryogenic liquid and the potential for a large fire

stemming from release in the case of an accident (e.g., a tanker truck accident or storage tank failure). Another potentially significant hazard is a release of natural gas during vehicle maintenance (DOT, 1995).

Hazards associated with LNG are that, under certain conditions, it may explode or catch on fire. LNG is not explosive or flammable in unconfined areas⁴. However, as it warms and expands to a gas it becomes flammable at a concentration between five and 15 percent.

LNG is comprised mostly of methane, but may contain ethane, propane and other heavier gaseous hydrocarbons. The main acute health effect associated with ammonia vapor is asphyxia. Asphyxia is the condition of severely depleting the oxygen supply to the body. Methane causes asphyxia by displacing oxygen in air. Asphyxiation can occur when oxygen concentrations drop below 18 percent. Oxygen is displaced to 18 percent at a concentration of 14 percent methane. Unconsciousness from central nervous system depression occurs at 30 percent methane⁵. The potential adverse health effects of oxygen deficiency are summarized in Table 4.4-4.

TABLE 4.4-4
Effects of Oxygen Deficiency

Amount of Oxygen Deficiency	Effects of Oxygen Deficiency
12-16 percent	Breathing and pulse rate are increased, with slight muscular incoordination
10-14 percent	Emotional upsets, abnormal fatigue from exertion, disturbed respiration
6-10 percent	Nausea and vomiting, inability to move freely, collapse, possible lack of consciousness
Below 6 percent	Convulsive movements, gasping, possible respiratory collapse and death

It is unlikely that off-site receptors would be exposed to LNG concentrations that would generate adverse health effects, because the lower explosive limit (LEL) for methane is five percent (50,000 ppm). The LEL is the concentration at which there is enough of the given gas to ignite or explode.

The methodology used for estimating the potential risk from a vapor explosion is that developed for off-site consequence analysis for the Risk Management Program (RMP) under 40 CFR 68 (EPA, 1999). For an RMP off-site consequence analysis, a gaseous release is assumed to produce a vapor explosion that results in a blast impact. For a vapor explosion, the significance level is a pressure wave (blast) of one pound per square inch (psi) and the metric examined is the modeled distance to the significant overpressure level.

⁴ Federal Energy Regulatory Commission, <http://www.ferc.gov/o12faqpro/default.asp?Action=Q&ID=470>

⁵ Canadian Centre for Occupational Health and Safety, http://www.ccohs.ca/oshanswers/chemicals/chem_profiles/methane/health_met.html

Other safety issues associated with LNG are similar to those discussed previously for CNG, with the added hazards associated with handling a cryogenic liquid. The hazards posed by the use of LNG versus gasoline and diesel fuel are:

- Diesel fuel and gasoline are toxic to the skin and lungs and LNG is not;
- Diesel fuel and gasoline vapors are heavier than air (for specific gravity of air = 1, gasoline is 3.4, diesel is greater than 4). LNG is lighter than air (specific gravity is 0.55) and disperses more readily in air;
- LNG has a higher auto ignition temperature (1,200 °F) than diesel (500 °F) or gasoline (500 °F). LNG is more difficult to ignite since it has a “lower flammability limit” that is higher (5.3 percent) than gasoline (one percent) or diesel fuel (0.5 percent);
- Cryogenic liquids such as LNG have the potential risk to workers of burns (frost-bite) that can be suffered if workers come in contact with the liquid or with surfaces that are not insulated. Proper safety equipment and training can minimize these hazards; and,
- Since LNG is a cryogenic liquid, in the event of a release from an aboveground storage tank or tanker truck, a fraction of the liquid immediately flashes off to gas while the remainder will pool and boil violently emitting dense vapor. The liquid transitions to dense vapor and the dense vapor transitions to gas as the liquid and vapor draw heat from the surroundings. If a source of ignition is present, the boiling liquid, vapor cloud and gas could explode and burn, threatening surrounding facilities and other storage vessels.

Based upon the preceding information, health hazards associated with LNG are approximately equivalent or less compared to conventional fuels. Therefore, increased usage of LNG with a concurrent decline in usage of conventional fuels will not significantly alter existing health hazards associated with mobile source fuels. Consequently, increased usage of LNG is not expected to generate significant adverse health hazard impacts.

PROJECT-SPECIFIC MITIGATION – LNG HEALTH IMPACTS: Less than significant impacts on health hazards associated with the use of LNG as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – LNG HEALTH IMPACTS: The health hazard impacts associated with using LPG as an alternative fuel are expected to be less than significant. Thus, no remaining health hazard impacts associated with LPG use are expected.

PROJECT-SPECIFIC IMPACTS – LNG TRANSPORTATION RELEASE: LNG is non-toxic, disperses more readily in air than conventional fuels, and has more rigorous standards for transportation. It is expected that affected facilities will receive LNG from a local supplier located in the district. Deliveries of LNG would be made to the other affected facilities by tanker truck via public roads. The transport of LNG is regulated by the U.S. DOT. LNG trucks are double-walled aluminum and are designed to withstand accidents during the transport of LNG. LNG is loaded into delivery tanks at atmospheric pressure,

which would be at its boiling point of -260°F (-162°C). The LNG is maintained at this temperature by evaporation of the boiling LNG and venting of the evaporated LNG. Because the vent is closed during shipment, the pressure in the tank builds and the temperature of the LNG increases. The FMCSA analyzed releases from delivery tanks with an average pressure of 30 psig, which would be -230°F (-146°C). At 30 psig, approximately 30 percent of the LNG will flash into vapor when released.

Transportation Release Scenarios: These LNG transport release scenarios were analyzed in the December 2007 Final EA for Proposed Amended Rule 1110.2 – Emissions from Gaseous- and Liquid-Fueled Internal Combustion Engines (ICEs) (SCAQMD No. 280307JK). The following description of LNG transportation and consequences is taken from the Federal Motor Carrier Safety Administration (FMCSA)⁶.

Four scenarios were identified as having major consequences:

1. Release of LNG into a pool that evaporates and disperses without ignition. Approximately 40 percent of the liquefied LNG immediately flashes into vapor. The temperature of the liquid pool would be -44 °F (-42°C) and would therefore damage exposed vegetation and people.
2. A flammable cloud is formed that contacts an ignition source. The flame front can flash back and set the liquid pool on fire. Quantities of LNG shipped by truck would not typically cause vapor cloud explosions.
3. A boiling liquid expanding vapor explosion (BLEVE) occurs. BLEVEs would occur when an LNG tank is exposed to fire and the increase in pressure within the tank exceeds the capacity of the relief valve.
4. The tank ruptures, rockets away and ignites.

RMPComp was used for the consequence analysis for these four scenarios. The adverse impacts from the four scenarios were determined to be:

1. The area of the pool was estimated by assuming a depth of one centimeter as described in Example 29 in the EPA's Risk Management Program Guidance for Offsite Consequence Analysis⁷. A 6,000 gallon LNG pool would be 24,448 square feet. This distance would be a "worst-case" since as the LNG pool expands from the tank it will warm and evaporate.
2. A pool fire of 6,000 gallons that is released in one minute would result in a heat radiation endpoint (five kilowatts/square meter) of 0.2 mile. If a vapor cloud fire occurs, the estimated distance to the lower flammability limit would be 0.3 mile.

⁶ Federal Motor Carrier Safety Administration, Comparative Risks of Hazardous Materials and Non-Hazardous Materials Truck Shipment Accidents/Incidents, Final Report, March 2001, www.fmcsa.dot.gov/documents/hazmatriskfinalreport.pdf.

⁷ U.S. EPA, Risk Management Program Guidance for Offsite Consequence Analysis, EPA 550-B-99-009, April 1989.

3. Based on 10,000 gallons the BLEVE would result in a fireball that may cause second-degree burns out to 0.3 mile.
4. The “worst-case” release estimate for 10,000 gallons in RMP*Comp is 0.3 mile from the vapor cloud explosion. Since, it is unclear as to how far away the tank would travel, it was assumed that the adverse impact would be 0.3 mile from where the tank lands. Damage to property and persons may occur from physical impact from the rocketing tank.

During transportation of LNG, it was estimated that the adverse impacts from various releases would extend 0.3 mile. Because sensitive receptors may be within the endpoints above, the accidental release of LNG during transport could cause significant adverse hazards.

Based upon the preceding information, increased transport of LNG may substantially alter existing transportation hazards associated with mobile source fuels. Consequently, increased usage of LNG is expected to generate significant adverse hazard impacts during transport.

PROJECT-SPECIFIC MITIGATION – LNG TRANSPORTATION RELEASE:

Potentially significant impacts on hazards impacts associated with the transportation of LNG as an alternative fuel are expected, so mitigation measures are necessary and required. Recommend mitigation would be to implement the following design measures that are typically required by local fire departments:

HZ-3: Install secondary containment (e.g., berms).

HZ-4: Install valves that fail shut.

HZ-5: Install emergency release valves and barriers around LNG storage tanks to prevent the physical damage to storage tanks or limit the release of LNG from storage tanks.

HZ-6: Perform integrity testing of LNG storage tanks to assist in preventing failure from structural problems. Construct a containment system to be used for deliveries during off-loading operations.

REMAINING IMPACTS – LNG TRANSPORTATION RELEASE: No additional mitigation measures were identified that would reduce the hazard and hazardous material impacts from a transportation release of LNG to less than significant. Therefore, the remaining hazardous and hazardous material impacts from exposure to the one psi overpressure from the cataclysmic destruction of the LNG storage tank are considered to be significant.

4.4.4.2.5 *Liquefied Petroleum Gas (LPG)*

LPG, which is also known as propane, is a mixture of natural gases which are liquefied at ambient temperatures by compressing the gases to pressures above 120 psig. Propane is the major component of LPG, with the minor components being propylene, butane, and butene.

In the U.S., almost all of the propane supply comes from stripping wellhead natural gas or as a by-product of petroleum refining. LPG for vehicle use is at least 95 percent propane and no more than 2.5 percent butane and heavier hydrocarbons. LPG has been used in fleet vehicles since the 1940s, so there is a substantial base of experience with LPG as an automotive fuel.

For a variety of reasons, however, LPG is not considered the alternative fuel of the future. Its place has been taken by natural gas. Consequently, there has been little development in dedicated LPG engine technology. On the other hand, other technologies and their emissions improved tremendously over the last decade. As a result of that development, some of the previous emission reduction advantages of LPG fuel, especially the low CO emissions, are now less pronounced⁸. Consequently, it is not likely that LPG would be used to any great extent providing the fuel for near zero- or zero-emission technologies.

PROJECT-SPECIFIC IMPACTS - LPG: Since LPG is a compressed fuel, it shares many of the physical hazards (projectiles, freeze burns, BLEVE, etc.) of CNG and LNG and storage regulations. However, since LPG is under less pressure and is stored at ambient temperatures, the physical hazards are not as high for storage and transport compared to CNG or LNG. Furthermore, the flammability limit range for LPG is similar to gasoline, but the ignition temperature (920 degrees Fahrenheit) is lower than gasoline or diesel (500 degrees Fahrenheit). Therefore, the hazard from transport and storage of LPG should not be significantly different from the transport and storage of gasoline or diesel (DOT, 1995).

The main additional hazard associated with the use of LPG versus conventional fuels is the potential of a large fire stemming from a release in the case of an accident (e.g., a tanker truck accident). Another potentially significant hazard is a release of LPG during vehicle maintenance.

Compared with diesel fuel and gasoline the following can be stated about LPG:

- Diesel fuel and gasoline are toxic to the skin and lungs and LPG is not;
- Diesel fuel and gasoline vapors are heavier than air (for specific gravity of air =1, gasoline is 3.4, diesel fuel is 4.0). LPG is lighter than gasoline and diesel fuel but heavier than air (specific gravity is 1.52). It disperses more readily in air than gasoline or diesel fuel;
- LPG has a higher auto ignition temperature (920 °F) than diesel fuel (500 °F) or gasoline (500 °F);
- LPG is more difficult to ignite since it has a “lower flammability limit” that is higher (2.0 percent) than gasoline (one percent) or diesel fuel (0.5 percent).

Based upon the preceding information, hazards associated with LPG are approximately equivalent or less as compared to conventional fuels. Therefore, increased usage of LPG with a concurrent decline in usage of conventional fuels will not significantly alter existing

⁸ Net Technologies, Inc. How Clean Are LPG Engines. <http://www.nett.ca/faq/lpg-3.html>.

hazards associated with mobile source fuels. Consequently, increased usage of LPG is not expected to generate significant adverse hazard impacts.

PROJECT-SPECIFIC MITIGATION – LPG: Less than significant impacts on hazards associated with the use of LPG as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – LPG: The hazard impacts associated with using LPG as an alternative fuel are expected to be less than significant. Thus, no remaining hazard impacts associated with LPG use are expected.

4.4.4.2.6 *Biodiesel*

Biodiesel is a fuel derived from biological sources such as vegetable oils or animal fats. The process for creating biodiesel involves mixing the oil with alcohol (e.g., methanol or ethanol) in the presence of a chemical such as sodium hydroxide. This process produces a methyl ester if methanol is used or an ethyl ester if ethanol is used. Methyl ester from soy beans is more economical to produce, and, therefore, is more common in the U.S. Biodiesel can be used pure (B100) or blended with conventional diesel. The most common blended biodiesel is B20, which is 20 percent biodiesel and 80 percent conventional diesel.

PROJECT-SPECIFIC IMPACTS – BIODIESEL: Biodiesel fuels are derived from vegetable oils and/or animal fats, the transport of which do not pose any significant hazards, as compared to conventional fuels which are derived from crude oil. Biodiesel and biodiesel blends have a higher flash point and lower vapor pressure than conventional diesel. This makes biodiesel safer to store and transport than conventional diesel. Furthermore, biodiesel is less toxic and more biodegradable than conventional diesel, so the environmental impacts from a spill would be less than for a spill of conventional diesel fuel. However, biodiesel has some compatibility issues with certain rubbers and plastics when compared to conventional diesel. Those leak hazards can be mitigated by using the proper material for seals, fittings, and hoses used for storage and transport. Therefore, the hazard from transport and storage of biodiesel and biodiesel blends should not be significantly different from the transport and storage of conventional diesel (DOT, 1995).

Biodiesels are considered safer than conventional diesels; therefore, increased usage of biodiesel with a concurrent decline in usage of conventional diesel will not significantly alter existing hazards associated with mobile source fuels. Consequently, increased usage of biodiesel is not expected to generate significant adverse hazard impacts.

PROJECT-SPECIFIC MITIGATION – BIODIESEL: Less than significant impacts on hazards associated with the use of biodiesel as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – BIODIESEL: The hazard impacts associated with using biodiesel as an alternative fuel are expected to be less than significant. Thus, no remaining hazard impacts associated with biodiesel use are expected.

4.4.4.2.7 *Hydrogen*

Hydrogen is the simplest, lightest and most plentiful element in the universe. In its normal gaseous state, hydrogen is a colorless, odorless, tasteless, non-toxic and burns invisible. Most hydrogen is made from natural gas through a process known as steam reforming. Reforming separates hydrogen from hydrocarbons by adding heat. Hydrogen can also be produced from a variety of sources including water and biomass. Hydrogen can be used as a combustion fuel or in fuel cell vehicles to produce electricity to power electric motors. There is currently one commercially available fuel cell vehicle sold in the U.S., the Honda Clarity. Honda planned to have about 200 Clarities available for lease by 2010, but the actual number of Clarities on the road is estimated at 50 (AP, 2010). The majority of hydrogen powered vehicles on the road at this time are used for research and development or fleet use.

PROJECT-SPECIFIC IMPACTS - HYDROGEN: The generation and distribution of hydrogen as a consumer product is also still in developmental stages. Currently there are 23 hydrogen refueling stations, nine of which have public access (U.S. DOE, 2012). Most of the refueling stations depend on bulk liquid hydrogen delivery; however, a few hydrogen gas pipeline stations and on-site steam reformer stations exist. The physical hazards associated with bulk liquid transport and storage are similar to LNG, as they are both cryogenic liquids. The physical hazards associated with pipeline and steam reformer stations are similar to CNG, as they are both compressed gases. In general, the fire hazards associated with hydrogen spills or leaks is higher than conventional fuels. This is due to the wide flammability range and low ignition energy of hydrogen. However, hydrogen tanks are built to more rigorous standards than conventional fuel tanks, which reduces the likelihood of spills or leaks.

The main additional hazard associated with the use of hydrogen versus conventional fuels is the difficulty in seeing hydrogen fires and potentiality of a large fire stemming from a release in the case of an accident (e.g., a tanker truck accident). Another potentially significant hazard is a release of hydrogen in an enclosed space (e.g., garage or vehicle maintenance facility).

Compared with diesel fuel and gasoline, the following can be stated about hydrogen:

- Diesel fuel and gasoline are toxic to the skin and lungs and hydrogen is non-toxic and non-reactive, so if released, it does not present a health hazard to humans.
- Diesel fuel gasoline vapors are heavier than air (for specific gravity of air = 1, gasoline is 3.4, diesel fuel is 4.0) while hydrogen is 14 times lighter than air. If released, hydrogen will quickly dissipate into the atmosphere.
- Hydrogen has an extremely low ignition energy requirement; about 20 microjoules can ignite hydrogen/air, which is about 10 times less than what is required to ignite a gasoline/air mixture (LLNL, 2007).
- Hydrogen is clear, odorless, and tasteless. It burns with an extremely hot, but nonluminous flame which is difficult to see. The flame of burning hydrogen has few warning properties.

- Hydrogen has an unusually large flammability range and can form ignitable mixtures between four and 75 percent by volume in air. Given confinement and good mixing, hydrogen can be detonated over the range of 18 to 59 percent by volume in air.

Hydrogen is non-toxic and disperses more readily in air than gasoline or diesel. Based upon the preceding information, hazards associated with hydrogen are approximately equivalent or less when compared to conventional fuels. Furthermore, hydrogen is limited in its use as a transportation fuel. In 2007, there were 6,675,888 automobiles, commercial vehicles, and motorcycles registered in the County of Los Angeles alone (LADOT, 2009). The 2012 AQMP projects that the population of zero or near-zero vehicles will increase by about 37,000 vehicles, which means hydrogen is expected to make up a very small portion of transportation fuel (e.g., less than 0.1 percent). While hydrogen fuel cell technology is promising, its use in the future is dependent on many things (cost-effectiveness of the technology, availability of hydrogen, etc.), so that the extent to which it may be used in the future to replace petroleum fuels is currently unknown and, therefore, speculative. For these reasons, the use of hydrogen fuel is not expected to generate significant adverse hazard impacts.

PROJECT-SPECIFIC MITIGATION – HYDROGEN: Less than significant impacts on hazards associated with the use of hydrogen as an alternative fuel are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – HYDROGEN: The hazard impacts associated with using hydrogen as an alternative fuel are expected to be less than significant. Thus, no remaining hazard impacts associated with hydrogen use are expected.

4.4.4.2.8 *Electric/Hybrid*

Electric (EVs) and hybrid vehicles (hybrids) both use electricity as part of their fuel system. EVs rely purely on electric power stored in batteries. Hybrids also use batteries as part of their fuel supply; however, hybrids supplement their electric demand by using gasoline engines to generate either mechanical or electric power on demand. Since gasoline is a conventional fuel, any difference in hazards associated with hybrid vehicles would be from the batteries. The most common battery technologies used in modern EVs and hybrids are nickel-metal hydride (NiMH) and lithium ion (Li-ion) (Hybrid, 2008).

PROJECT-SPECIFIC IMPACTS – ELECTRIC/HYBRID: NiMH batteries can generate hydrogen gas if overcharged, which can lead to explosions without proper venting. In 1996, the International Center for Technology Assessment (ICTA) conducted a comprehensive review of the safety concerns associated with the use of EVs. The ICTA found risk of hydrogen emissions during stressful conditions has been virtually eliminated by the use of seals and proper valve regulation. By following the National Electric Codes (NECs) and the Society of Automotive Engineers (SAE) recommended safety practices and guidelines for the operation and maintenance of EVs and hybrids, any hydrogen gas risk during battery recharging would be eliminated (ICTA, 1996).

Li-ion batteries can be fire hazards. There are a few reported cases of fires caused by Li-ion batteries in EVs. In response to these fires, the National Highway Traffic Safety Administration (NHTSA) performed an investigation on the fire hazards associated with Li-ion batteries in EVs. The NHTSA concluded that EVs do not pose a greater risk of fire than gasoline-powered vehicles. The NHTSA also developed an interim guidance, with the assistance of the NFPA, Department of Energy, and others, to increase and identify the appropriate safety measures for handling an EV or hybrid automobile accident (NHTSA, 2012).

Furthermore, all electrical propulsion vehicles must comply with Federal Motor Vehicle Safety Standard (FMVSS) 305. FMVSS 305 specifies performance requirements for limitation of electrolyte spillage, retention of propulsion batteries, and electrical isolation of the chassis from the high-voltage system during a crash event. FMVSS assures that accidents involving EVs and hybrids cause no more electrical hazard than a gasoline- or diesel-powered vehicle.

Electric propelled vehicles are considered less hazardous than conventional fuel vehicles. The 2012 AQMP expects to replace 37,000 conventional fuel vehicles with alternative-fueled vehicles by 2025, which would generally result in a reduction in hazards associated with conventional fueled vehicles.

PROJECT-SPECIFIC MITIGATION – ELECTRIC/HYBRID: Less than significant impacts on hazards associated with the use of batteries in electric/hybrid vehicles are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – ELECTRIC/HYBRID: The hazard impacts associated with using batteries in electric/hybrid vehicles are expected to be less than significant. Thus, no remaining hazard impacts associated with using batteries for these types of vehicles are expected.

4.4.4.2.9 *Summary of Hazards from Alternative Fuels*

PROJECT-SPECIFIC IMPACTS – ALTERNATIVE FUELS SUMMARY: As shown in Table 4.4-5, the energy content of alternative fuels is lower than conventional fuels which means that more fuel is needed in an alternative fuel-powered vehicle to achieve the same range as a conventional fuel-powered vehicle. Thus, more tanker deliveries to supply refueling stations would be required to provide the same available energy as conventional fuels. Since the probability of accidents is related to the amount of miles traveled, proportionally more delivery accidents can be expected with alternative fuels than conventional fuels (assuming that they are delivered from similar source locations in similar sized tankers). However, the truck accident rate is small, on the order of one accident per five million miles traveled and the accident rate with chemical releases is even less. Furthermore, any increase in alternative fuels use would decrease the use of conventional fuels, so hazards associated with transportation and storage of all of the alternative fuels, except LNG would not be a significant risk factor. During transportation of LNG, it was estimated that the adverse impacts from various releases would extend 0.3 mile. Because

sensitive receptors may be within the endpoints above, the accidental release of LNG during transport could cause significant adverse hazards.

TABLE 4.4-5

Equivalent Fleet Miles
Associated with Alternative Clean-Fuels

FUEL TYPE	BY MASS	BY VOLUME
Diesel	1.00	1.0
CNG/LNG	1.15	1.9
LPG	1.15	2.1
Ethanol	1.90	2.3
Methanol	2.50	2.7

Source: Clean Air Program: Summary of Assessment of the Safety, Health, Environmental and System Risks of Alternative Fuels. (DOT, 1995)

There are various existing regulations and recommended safety procedures that, when employed, will reduce any slightly higher hazards impacts associated with use of alternative clean fuels to the same or lower level as for conventional fuels. Table 4.4-6 summarizes some of the regulations and safety procedures associated with use of alternative fuels. When affected vehicle owners and maintenance personnel comply with existing regulations and recommended safety procedures, hazards impacts associated with the use of alternative fuels will be the same or less than those of conventional fuels. Accordingly, significant hazards impacts are not expected from the implementation of the 2012 AQMP control measures that encourage the use of alternative fuels.

TABLE 4.4-6

Summary of Hazards and Existing Safety Regulations/Procedures
Associated with Alternative Clean-Fuels

FUEL TYPE	HAZARD	REGULATION/PROCEDURE
Methanol	Methanol can ignite in enclosed spaces such as fuel tanks since its upper flammability limit is 15 percent and it is slightly heavier than air.	Modifications such as materials inside the fuel tank that can arrest and quench flame propagation and modifications to isolate the tank from sparks and ignition sources are required to avoid ignition in the fuel tanks.
Ethanol	Pure ethanol can ignite in enclosed spaces such as fuel tanks since its upper flammability limit is 19 percent and it is slightly heavier than air.	Modifications such as materials inside the fuel tank that can arrest and quench flame propagation and modifications to isolate the tank from sparks and ignition sources are required to avoid ignition in the fuel tanks.

TABLE 4.4-6 (Continued)

Summary of Hazards and Existing Safety Regulations/Procedures
Associated with Alternative Clean-Fuels

FUEL TYPE	HAZARD	REGULATION/PROCEDURE
CNG	CNG bottles are typically stored outside and are required to be above ground (NFPA 52) as opposed to below ground for gasoline or diesel tanks. There is a risk of vehicles colliding with the bottles causing a gas release.	Collisions can be mitigated by the installation of curbing and bollards to protect the tanks from vehicle operations (LAF57.42.16).
	Releasing gas in a maintenance shop can potentially create explosive hazards.	Installation of methane detection systems in the shop can provide early detection of leaks and alert the maintenance personnel. (If integrated with vent systems, vents are not required to operate continuously - CFC 2903.2.5). Ignition sources can be reduced/eliminated by ensuring that all electrical systems in the shop are explosion proof (smoking and open flames are prohibited under CFC 2901.7). Providing adequate ventilation can prevent the occurrence of explosive conditions (required under CFC 2903.1). Procedures can be established to ensure that all vehicles requiring maintenance are defueled and depressurized before admission to the maintenance depot.
LNG	LNG is a cryogenic liquid and has the potential risk to workers of burns (frostbite) that can be suffered if workers come in contact with the liquid or with surfaces that are not insulated.	Proper safety equipment and training can mitigate these hazards.
	Releasing LNG in an enclosed area where there are potential ignition sources such as a maintenance shop may pose an explosive hazard. (A flammable concentration within an enclosed space in the presence of an ignition source can explode).	Installation of flammable gas detection systems in a maintenance shop can provide early detection of leaks and alert the maintenance personnel (which is required for LNG under CFC2903.3). Ignition sources can be reduced/eliminated by ensuring that all electrical systems in the shop are explosion proof (smoking and open flames are prohibited under CFC 2901.7). Providing adequate ventilation can prevent the occurrence of explosive conditions (required under CFC2903.1). Vehicle fuel shut-off valves shall be closed prior to repairing any portion of the vehicle fuel system (CFC2903.4.1). Vehicles fueled by LNG, which may have sustained damage to the fuel system, shall be inspected for integrity with a gas detector before being brought into the garage (CFC2903.4.2). Procedures can be established to ensure that all vehicles are defueled prior to maintenance.

TABLE 4.4-6 (Concluded)
 Summary of Hazards and Existing Safety Regulations/Procedures
 Associated with Alternative Clean-Fuels

FUEL TYPE	HAZARD	REGULATION/PROCEDURE
LNG	LNG is generally stored above ground. Since it is a cryogenic liquid, in the event of a release, a fraction of the liquid immediately flashes off to gas while the majority of the remainder will pool and boil violently emitting dense vapor. If a source of ignition is present, the boiling liquid, dense vapor and gas could explode and burn threatening surrounding facilities and other storage vessels.	Tanks can be protected by containment dikes (required if neighboring tanks can be affected LAF57.42.11) and physically separated LAF57.42.10) so that they do not interact in case of a fire or explosion. Deluge systems can be installed to cool neighboring tanks in case of a fire.
Biodiesel	Certain materials used in conventional petroleum storage are not compatible with pure biodiesel.	Use biodiesel compatible plastic and rubber for fittings.
Hydrogen	Releasing gas in enclosed spaces with its related explosive hazards may pose an explosive hazard. (A flammable concentration within an enclosed space in the presence of an ignition source can explode).	Installation of combustible gas detection systems can provide early detection of leaks. Ignition sources can be reduced/eliminated by ensuring that all electrical systems in the shop are explosion proof. Providing adequate ventilation can prevent the occurrence of explosive conditions. Procedures can be established to ensure that all vehicles are defueled prior to maintenance.
EV and Hybrid Vehicles	Certain types of batteries that are used in commercially available electric vehicles emit hydrogen during the charging process. Emission of hydrogen gas in an enclosed setting such as a garage presents the potential for the accumulation of flammable concentrations.	Forced ventilation can prevent build-up but if ventilation fails, a hazardous condition can occur. NEC and SAE recommended practices provide strict guidance for eliminating hydrogen gas risk.
	Li-ion batteries that are used in some commercially available electric vehicles can combust spontaneously.	Reinforced casing and battery cooling systems can prevent the combustion of Li-ion batteries. FMVSS 305 and SAE recommendations provide guidance for eliminating combustion risk.

CWC = California Fire Code
 FMVSS = Federal Motor Vehicle Safety Standard
 NEC = National Electric Code
 LAF57 = City of Los Angeles Fire Code. It is expected that cities in Orange, Riverside, and San Bernardino Counties have in place similar regulations.

CWC = California Fire Code
 NFPA = National Fire Protection Association
 SAE = Society of Automotive Engineers

Use of alternative fuels will require additional knowledge and training of owners/operators of fueling stations regarding maintaining and operating alternative fuel refueling stations and emergency responders. Further, as use of alternative fuels increases in the district, use of conventional fuels such as gasoline and diesel will decline. As a result, explosion and flammability hazards associated with conventional fuels will also decline. In addition, hazards and hazardous clean-up associated with accidental releases of conventional fuels, especially diesel, are reduced with increasing use of alternative fuels.

PROJECT-SPECIFIC MITIGATION - ALTERNATIVE FUELS SUMMARY: When users of alternative fuels comply with existing regulations and recommended safety procedures, hazards impacts associated with the use of alternative clean-fuels are expected to be the same or less than those of conventional fuels. Accordingly, hazards impacts from the increased use of alternative fuels are expected to be similar to or less than hazards associated with conventional fuels. Therefore, significant hazard impacts are not expected from the increased use of alternative fuels and no mitigation measures are required.

The transportation analysis demonstrated that, of all the alternative fuels analyzed, only LNG was estimated to have significant adverse hazards impacts during various transportation release scenarios. Because significant hazard impacts during transportation of LNG are expected, mitigation measures are required to be identified.

Lastly, the hazard impacts associated with using batteries in electric/hybrid vehicles were concluded to be less than significant. Because no significant hazard impacts were identified that pertain to using batteries in electric/hybrid vehicles, no mitigation measures are required.

REMAINING IMPACTS – ALTERNATIVE FUELS SUMMARY: The hazard impacts associated with alternative fuels and using batteries in electric/hybrid vehicles are expected to be less than significant, except for LNG transportation which was shown to have significant hazards impacts requiring mitigation. However, no additional mitigation measures were identified that would reduce the hazard and hazardous material impacts from a transportation release of LNG to less than significant. Therefore, the remaining hazardous and hazardous material impacts from exposure to the one psi overpressure from the cataclysmic destruction of the LNG storage tank are considered to be significant.

For all other alternative fuels (e.g., other than LNG) and batteries for electric/hybrid vehicles, no remaining hazard impacts are expected.

4.4.4.3 Ammonia Use in SCRs and SNCRs

Implementation of some control measures proposed in the 2012 AQMP could result in the use of SCR or SNCR technology to reduce NO_x emissions including CMB-01, IND-01, MSC-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-04, and ADV-05. Greater use of SCRs and SNCRs may occur on industrial combustion sources such as boilers and heaters, as well as large diesel engines on mobile sources to reduce NO_x, including off-road diesel engines (e.g., locomotive engines and marine vessel engines).

SCR is post-combustion control equipment for NO_x control of existing combustion sources like boilers, steam generators and process heaters that is capable of reducing NO_x emissions by as much as 90 percent or higher. A typical SCR system design can consist of an ammonia storage tank, ammonia vaporization and injection equipment, an SCR reactor with catalyst, ancillary electronic instrumentation and operations control equipment. In some situations, an SCR system may also utilize a booster fan for the flue gas exhaust and an exhaust stack. The way an SCR system reduces NO_x is through a matrix of nozzles injecting a mixture of ammonia and air directly into the flue gas exhaust stream from the

combustion equipment. As this mixture flows into the SCR reactor that is replete with catalyst, ammonia and oxygen (from the air), the flue gas exhaust reacts primarily (i.e., selectively) with NO and NO₂ to form nitrogen and water in the presence of a catalyst. The amount of ammonia introduced into the SCR system is approximately a 1.0-to-1.05 molar ratio of ammonia to NO_x for optimum control efficiency, though the ratio may vary based on equipment-specific NO_x reduction requirements. The ammonia injection rate is also regulated by the fuel flow rate to the unit.

SNCR is another post-combustion control technique typically used to reduce the quantity of NO_x produced in the hot flue gas, by injecting ammonia. The main differences between SNCR and SCR is that the SNCR reaction between ammonia and NO_x in the hot flue gas occurs without the need for a catalyst, but at much higher temperatures (i.e., between 1200 °F to 2000 °F). With a control efficiency ranging between 80 and 85 percent, SNCR does not achieve as great of NO_x emission reductions as SCR. The need for the exhaust temperature to be high also limits the applicability of SNCR. SNCR would not be considered equivalent to BARCT alone, but it could be used if combined with other technologies.

In SCR and SNCR technology, ammonia or urea is used to react with the NO_x, either in the presence of a catalyst or without a catalyst, respectively, to form nitrogen gas and water. Ammonia is the primary hazardous chemical identified with the use of air pollution control equipment (e.g., SCR and SNCR systems). Ammonia, though not a carcinogen, can have chronic and acute health impacts. Therefore, a potential increase in the use of ammonia may increase the current existing risk setting associated with deliveries (i.e., truck and road accidents) and onsite or offsite spills for each facility that currently uses or will begin to use ammonia. Exposure to a toxic gas cloud is the potential hazard associated with this type of control equipment. A toxic gas cloud is the release of a volatile chemical such as anhydrous ammonia that could form a cloud that migrates off-site, thus exposing individuals. Anhydrous ammonia is heavier than air such that when released into the atmosphere, would form a cloud at ground level rather than be dispersed “Worst-case” conditions tend to arise when very low wind speeds coincide with the accidental release, which can allow the chemicals to accumulate rather than disperse. Though there are facilities that may be affected by the proposed 2012 AQMP control measures that are currently permitted to use anhydrous ammonia, for new construction, however, current SCAQMD policy no longer allows the use of anhydrous ammonia. Instead, to minimize the hazards associated with ammonia used in the SCR or SNCR process, aqueous ammonia (100 percent anhydrous ammonia diluted with water to 19 percent by volume), is typically required as a permit condition associated with the installation of SCR or SNCR equipment for the following reasons: 1) 19 percent aqueous ammonia does not travel as a dense gas like anhydrous ammonia; and, 2) 19 percent aqueous ammonia is not on any acutely hazardous material lists unlike anhydrous ammonia or aqueous ammonia at higher percentages. For these safety reasons, aqueous ammonia is recommended for use in these technologies.

In addition, safety hazards related to the transport, storage and handling of ammonia exist. Ammonia has acute and chronic non-cancer health effects and also contributes to the formation of ambient PM₁₀ and PM_{2.5} emissions under some circumstances. Since ammonia is not typically considered to be a flammable compound, other types of hazard

impacts such as fires and explosions are not expected to occur and, therefore, will not be evaluated as part of this hazards analysis. To further evaluate the potential for significant adverse environmental impacts due to an accidental release of ammonia, various scenarios were evaluated that could occur during the onsite storage, transportation, and transfer of ammonia. These scenarios and their consequences are discussed in detail below.

PROJECT-SPECIFIC IMPACTS – WATER QUALITY: A spill of any of the hazardous materials (including ammonia) used and stored at any of the affected facilities could occur under upset conditions such as an earthquake, tank rupture, or tank overflow. Spills could also occur from corrosion of containers, piping and process equipment; and leaks from seals or gaskets at pumps and flanges. A major earthquake would be a potential cause of a large spill. Other causes could include human or mechanical error. Construction of the vessels, and foundations in accordance with the California Building Code requirements helps structures to resist major earthquakes without collapse, but may result in some structural and non-structural damage following a major earthquake. As required by U.S. EPA's spill prevention control and countermeasure regulations, all of the affected facilities are currently required to have emergency spill containment equipment and would implement spill control measures in the event of an earthquake. Storage tanks typically have secondary containment such as a berm, which would be capable of containing 110 percent of the contents of the storage tanks. Therefore, should a rupture occur, the contents of the tank would be collected within the containment system and pumped to an appropriate storage tank.

Spills at affected industrial or commercial facilities would be collected within containment structures. Large spills outside of containment areas at affected facilities that could occur when transferring the material from a transport truck to a storage tank are expected to be captured by the process water system where they could be collected and controlled. Spilled material would be collected and pumped to an appropriate tank or sent off-site if the materials cannot be used on-site.

PROJECT-SPECIFIC MITIGATION – WATER QUALITY: Because of the containment system design, spills are not expected to migrate from the facility and as such, potential adverse water quality hazard impacts are considered to be less than significant. Since hazard impacts that would affect water quality are expected to be less than significant, no mitigation measures are necessary or required.

REMAINING IMPACTS – WATER QUALITY: The hazard impacts associated with ammonia use potentially impacting water are expected to be less than significant. Thus, no remaining hazard impacts are expected.

PROJECT-SPECIFIC IMPACTS – TRANSPORTATION RELEASE: It is expected that affected facilities will receive ammonia from a local ammonia supplier located in the greater Los Angeles area. Deliveries of aqueous ammonia would be made to the other affected facilities by tanker truck via public roads. The maximum capacity of an ammonia tanker truck is approximately 7,000 gallons.

Transportation Release Scenario 1: This aqueous ammonia truck transport release scenario is taken from the Final Environmental Impact Report for Los Angeles Department Of Water And Power's (LADWP) Installation Of Five Combustion Turbines At The Harbor Generating Station (HGS), Installation Of Three Selective Catalytic Reduction Systems At

The modeling⁹ was based on U.S. EPA's RMP Guidance for toxic releases and explosions. The RMP*Comp model was used to calculate size of the impact zones for explosions and toxic releases. Note that the concentration of aqueous ammonia used at the project sites was expected to be 29.5 percent. To calculate ammonia emissions for modeling purposes, U.S. EPA's data for aqueous ammonia with a 30 percent concentration was used since 29.5 percent concentration data were not available. Appendix D of the Final EIR for the LADWP project provides a more detailed discussion of the modeling approach and shows the results of the RMP*Comp model and the Screen3 model. For all toxic releases, the surrounding terrain was assumed to be "rural," consistent with SCAQMD guidance. This reduced the dispersion of the modeled compound with distance and is a more conservative assumption than assuming "urban" dispersion.

The hazard analysis for the HGS also evaluated the probability or frequency of an accidental release. The expected accident frequency of an accidental ammonia release was expected to increase because there would be one extra ammonia truck delivery per week. However, the truck accident rate is approximately one per 8.7 million miles traveled and a major release in an accident is about one in forty. One additional delivery per week of about 21 miles estimated distance would not introduce a significant incremental risk over the current situation. The frequency would change from about one per 300,000 years for a major 5,000-gallon release to one per 150,000 years. Because the HGS was already receiving 39.5 percent aqueous ammonia by truck, this result did not exceed the existing risks from an accidental release of ammonia and for this project, was concluded to be less than significant. Had this risk scenario represented a new hazard risk, the conclusion would most likely have been that hazard risks from the accidental release would have been considered significant.

The hazard analysis included an estimate for the HGS site of the impact of the unconfined release of 5,000 gallons of aqueous ammonia in a tanker truck accident in an open area (minimum dispersion with distance). The 5,000 gallons spreads in all directions in an unconfined manner to a depth of one centimeter on an impervious surface (U.S. EPA "worst-case" assumptions). Based on these extremely conservative assumptions, the toxic impact distance from the spill was estimated to be 2,300 meters.

The analysis of hazard impacts for the LADWP project also included an estimate for the accidental release of ammonia transported to the Valley Generating Station (VGS) site. The results were based on the impact of an unconfined release of 5,000 gallons of aqueous ammonia in a tanker truck accident in an open area (minimum dispersion with distance). The 5,000 gallons spread in all directions in an unconfined manner to a depth of one centimeter on an impervious surface (U.S. EPA "worst-case" assumptions). Based on these

⁹ This analysis uses the *Final Environmental Impact Report for the Scattergood Generating Station, And The Installation Of One Combustion Turbine At The Valley Generating Station* (SCH. No. 2000101008; SCAQMD, 2001), as a surrogate for transport release scenario 1.

extremely conservative assumptions and using the endpoint of an ammonia concentration of 200 ppm, the toxic impact distance from the spill was estimated to be 2,300 meters. Similar to the result for the HGS, this result represents an existing accidental release of ammonia consequence and, therefore, was concluded to be less than significant. Had this been the result for a new project the conclusion would likely have been significant. The expected accident frequency will be based on one delivery per month. The truck accident rate is approximately one per 8.7 million miles traveled and a major release in an accident is about one in 40. One delivery per month of about 36 miles distance would not introduce a significant risk. The expected frequency of a release is about one per 800,000 years.

Transportation Release Scenario 2: To evaluate the hazard impacts from an accidental release of ammonia during ammonia transport, this analysis uses as a surrogate the project at the ConocoPhillips Carson Refinery in which a SCR was installed on boiler #10 and an associated 10,000 gallon aqueous ammonia storage tank (19 percent ammonia) was constructed. This scenario¹⁰ is used as an example of the type of project that could occur in the future as a result of complying with 2007 AQMP measures. This project required approximately six additional aqueous ammonia truck transport trips per month. Although truck transport of aqueous ammonia and other hazardous materials is regulated for safety by the U.S. Department of Transportation, there is a possibility that a tanker truck could be involved in an accident that would cause its contents to spill. The factors that enter into accident statistics include distance traveled and type of vehicle or transportation system. Factors affecting automobiles and truck transportation accidents include the type of roadway, presence of road hazards, vehicle type, maintenance and physical condition, driver training, and weather. A common reference frequently used in measuring risk of an accident is the number of accidents per million miles traveled. Complicating the assessment of risk is the fact that some accidents can cause significant damage without injury or fatality and as a result are not always reported.

Every time hazardous materials are moved from the site of generation, opportunities are provided for an accidental (unintentional) release. A study conducted by the U.S. EPA indicates that the expected number of hazardous materials spills per mile shipped ranges from one in 100 million to one in one million, depending on the type of road and transport vehicle used. The U.S. EPA analyzed accident and traffic volume data from New Jersey, California, and Texas, using the Resource Conservation and Recovery Act Risk/Cost Analysis Model and calculated the accident involvement rates presented in Table 4.4-7. This information was summarized from the Los Angeles County Hazardous Waste Management Plan (Los Angeles County, 1988).

¹⁰ This scenario uses the *Final Negative Declaration for: ConocoPhillips Los Angeles Refinery Carson Plant SCR Unit Project*, SCH. No. 2004011066, SCAQMD 2004, as a surrogate for transport release scenario 2.

^a Average number for transport on interstates, highways, and urban roadways.

In the study completed by U.S. EPA, cylinders, cans, glass, plastic, fiber boxes, tanks, metal drum/parts, and open metal containers were identified as usual container types. For each container type, the expected fractional release en route was calculated. The study concluded that the release rate for tank trucks is much lower than for any other container type (Los Angeles County, 1988).

The accident rates developed based on transportation in California were used to predict the accident rate associated with trucks transporting aqueous ammonia to the facility. Assuming an average truck accident rate of 0.28 accident per million miles traveled (Los Angeles County, 1988), the estimated accident rate associated with transporting aqueous ammonia for the ConocoPhillips project is 0.00101, or about one accident every 992 years.

The actual occurrence of an accidental release of a hazardous material cannot be predicted. The location of an accident or whether sensitive populations would be present in the immediate vicinity also cannot be identified. In general, the shortest and most direct route that takes the least amount of time would have the least risk of an accident. Hazardous material transporters do not routinely avoid populated areas along their routes, although they generally use approved truck routes that take population densities and sensitive populations into account.

The hazards associated with the transport of regulated (CCR Title 19, Division 2, Chapter 4.5 or the California Accidental Release Prevention Program requirements) hazardous materials, including aqueous ammonia, would include the potential exposure of numerous individuals in the event of an accident that would lead to a spill. Factors such as amount transported, wind speed, ambient temperatures, route traveled, distance to sensitive receptors are considered when determining the consequence of a hazardous material spill.

In the unlikely event that the tanker truck would rupture and release the entire 7,000 gallons of aqueous ammonia, the ammonia solution would have to pool and spread out over a flat surface in order to create sufficient evaporation to produce a significant vapor cloud. For a road accident, the roads are usually graded and channeled to prevent water accumulation and a spill would be channeled to a low spot or drainage system, which would limit the surface area of the spill and the subsequent evaporative emissions. Additionally, the roadside surfaces may not be paved and may absorb some of the spill. In a typical release scenario, because of the characteristics of most roadways, the pooling effect on an impervious surface would not typically occur. As a result, the spilled ammonia would not be expected to form

pools that could evaporate into a toxic cloud at concentrations that could significantly adversely affect residences or other sensitive receptors in the area of the spill.

Based on the low probability of an ammonia tanker truck accident with a major release and the potential for exposure to low concentrations, if any, the conclusion of this analysis was that potential impacts due to accidental release of ammonia during transportation are less than significant.

Transportation Release Scenario 3: This transportation release scenario uses as a surrogate analysis a project at the BP Carson refinery in which SCR was retrofitted onto an existing FCCU and an associated 12,660 gallon aqueous ammonia storage tank (19 percent NH₃) was constructed. The following summarizes the ammonia transport analysis for the BP FCCU project.

This scenario¹¹ consists of an SCR retrofitted onto an existing FCCU and construction of an associated 12,660 gallon aqueous ammonia storage tank (19 percent NH₃). It was estimated to require approximately 35 tanker truck deliveries of aqueous ammonia during the first year of operation (two deliveries after construction to fill the tank plus one delivery every 11 days to replenish the tank during operations). Truck accident rates are approximately one in 8.7-million miles (SCAQMD, 2002). Based upon the projected 35 ammonia deliveries the first year, and a distance of 30 miles from the supplier to the facility, the number of truck-miles associated with the transport of aqueous ammonia is 1,050 truck-miles per year. The expected number of truck accidents associated with the proposed BP Carson project is therefore approximately once every 8,300 years. The likelihood of any release in a transportation accident is one in 10, and that of a large release in a transportation accident is one in 40 (SCAQMD, 2002). The likelihood of a major transportation release after the project is constructed is therefore approximately once per 330,000 years (8,300 times 40). The probability of a transportation accident that would pose a significant risk to the public is therefore insignificant.

In the unlikely event that a major release occurred during a tanker truck accident, the ammonia solution would have to pool and spread out over a flat surface in order to create sufficient evaporation to produce a significant vapor cloud. Roads are usually graded and channeled to prevent water accumulation, and a spill would be channeled to a low spot or drainage system, which would limit the surface area of the spill and the subsequent toxic emissions. Additionally, the roadside surfaces may not be paved and may absorb some of the spill. Without this pooling effect on an impervious surface, the spilled ammonia would not evaporate into a toxic cloud and impact residences or other sensitive receptors in the area of the spill. Therefore, potential impacts due to accidental release of ammonia during transportation are less than significant.

PROJECT-SPECIFIC MITIGATION – TRANSPORTATION RELEASE: The transportation release scenarios in this subsection do not include transport of anhydrous ammonia because SCAQMD has historically found the CEQA analysis of permit

¹¹ This scenario uses the *Final Negative Declaration for: BP Carson Refinery Fluid Catalytic Cracking Unit NOx Reduction Project*. SCH. No. 2002021068; SCAQMD, 2002, as a surrogate for transport release scenario 2.

applications for new projects requiring SCR equipment using anhydrous ammonia to have significant adverse hazards impacts. Anhydrous ammonia impacts can be substantially mitigated through use of aqueous ammonia, which is considered to be feasible mitigation. Similarly, accidental releases of ammonia during transport that may occur in connection with the proposed control measures impacts are considered to be less than significant because the concentration of ammonia transported will be less, at 19 percent by volume as compared to 29.5 percent by volume; consequences of an accidental release during transport would be less than for the LADWP project; although probability would increase, the probability of an accidental release remains relatively remote. SCAQMD Staff recommends that permit applicants use aqueous ammonia at 19 percent or less by volume for any new SCR systems.

REMAINING IMPACTS – TRANSPORTATION RELEASE: The hazard impacts associated with a transportation release are expected to be significant prior to mitigation. Requiring the use of aqueous ammonia, in lieu of anhydrous ammonia, is considered to be feasible mitigation. Thus, after mitigation, no remaining significant impacts on transportation release hazards are expected.

PROJECT-SPECIFIC IMPACTS – AMMONIA TANK RUPTURE ON-SITE:

Storage Tank Rupture Scenario 1: For this project¹², a 10,000 gallon storage tank constructed for an ammonia storage tank release scenario, impacts were calculated for an accidental release of 19 percent aqueous ammonia into a containment dike (see Appendix B of the Final Negative Declaration for the detailed hazards analysis). A series of release and dispersion calculations were completed to quantify the dispersion of ammonia gas evaporating from a pool of aqueous ammonia following a release from a storage tank on the premises of the ConocoPhillips Carson Plant. The dispersion calculations were performed until specific ammonia concentrations were reached in the downwind direction. Two ammonia concentrations were chosen for evaluation:

- **Emergency Response Planning Guide Level 2 (ERPG-2) (200 ppm):** The maximum airborne concentration below which it is believed nearly all individuals could be exposed for up to one hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their ability to take protective action.
- **Emergency Response Planning Guide Level 3 (ERPG-3) (1,000 ppm):** The maximum airborne concentration below which it is believed nearly all individuals could be exposed for up to one hour without experiencing or developing life-threatening health effects.

The hazard zones resulting from liquid releases into the storage containment areas were identified and evaluated to determine the extent and location of the gas cloud containing ammonia. Details on the accidental release modeling assumptions are included in Appendix B of the Final Negative Declaration. The dispersion analysis was completed for a

¹² This scenario uses the *Final Negative Declaration for: ConocoPhillips Los Angeles Refinery Carson Plant SCR Unit Project*, SCAQMD 2004, as a surrogate for a tank rupture scenario.

range of impoundment sizes ranging from 100 to 1,000 feet. The following conclusions were drawn from this analysis:

1. Under “worst-case” atmospheric conditions (e.g., low winds and stable air), the lowest ammonia concentration of interest (ERPG-2 level of 200 ppm), does not reach the closest property line. The liquid impounding area would have to be much larger than 1,000 square feet (ft²) to exceed the ERPG-2 level.
2. Under all other atmospheric conditions (e.g., high winds, less stable atmospheres), the distances to the 200 ppm ammonia concentration level would be shorter.
3. Under no condition does the 1,000 ppm ammonia concentration level extend further than 45 feet from the tank. This distance is always well within the Carson Plant property boundaries.

Based on the above, as long as the containment area is no larger than 1,000 square feet, a release of ammonia from the tank would remain within about 45 feet from the tank, which is well within the boundaries of the Carson Plant. ConocoPhillips proposed a concrete spill containment of 18 feet by 18 feet, for a total of 324 square feet. Therefore, the containment area is less than 1,000 square feet and a release from the ammonia tank is not expected to result in a significant adverse hazard impact.

The modeling analysis completed above for the ammonia tank release would also apply to a release of ammonia when the tank truck is unloaded and transferred to the storage tank. Containment facilities are provided at the truck loading rack to contain ammonia in the event of a spill during transfer activities. The ammonia concentration will be less than the ERPG 2 level of 200 ppm at the facility boundaries, as long as the containment area is limited to 1,000 ft².

Storage Tank Rupture Scenario 2: This tank rupture scenario¹³ is based on retrofitting an existing FCCU with SCR and constructing an associated 12,660 gallon aqueous ammonia storage tank. The following two off-site consequences analyses (OCA) were performed:

1. Complete release of the aqueous ammonia storage tank (10,413-gallon working volume) into a 1,000-square foot diked containment area (25 feet x 40 feet). The bermed area was assumed to empty quickly into a catch basin with sufficient capacity to contain the entire contents of the ammonia tank with freeboard for precipitation and 12,000 gallons of firewater.
2. Complete release of an aqueous ammonia tanker truck (7,000 gallons) into the bermed unloading area. The ammonia then immediately drains into the tank pad containment structure.

RMP guidelines require assessment of the catastrophic failure of the largest storage vessel in a process as part of a RMP analysis. An OCA was therefore performed for a catastrophic rupture of the ammonia tank as a “worst-case” release scenario. The “worst-case”

¹³ This scenario uses the *Final Negative Declaration for: BP Carson Refinery Fluid Catalytic Cracking Unit NOx Reduction Project*: SCH. No. 2002021068; SCAQMD, 2002, as a surrogate for a tank rupture scenario.

meteorological conditions of “F” stability (very stable dispersion conditions) and a wind speed of 1.5 meters per second (m/s) are defined by U.S. EPA to exist during a “worst-case” release (SCAQMD, 2002).

An unloading spill was evaluated as an alternative release scenario. The maximum potential surface area during an unloading spill is identical with that for the tank rupture scenario (1,000 square feet) since the unloading area drains to the storage tank containment structure. The meteorological conditions for an alternative release scenario are less restrictive than the “worst-case” conditions and are defined by U.S. EPA as “D” stability (neutral dispersion conditions) and a wind speed of 3.0 m/s (SCAQMD, 2002). The emission rate during the alternative release scenario is larger than during the “worst-case” release scenario because the wind speed is higher (3.0 m/s versus 1.5 m/s).

The U.S. EPA RMP*Comp (Version 1.06) program was used to perform the OCA hazard assessment for the BP FCCU project. The RMP*Comp model estimates the distance at which the downwind concentration of the spilled material falls below the Emergency Response Planning Guideline Level 2 (ERPG-2) concentration level of 0.14 mg/l (200 ppm). The minimum distance to the toxic threshold concentration allowed by RMP*Comp is 0.1 mile (approximately 200 m).

For the “worst-case” release scenario involving the rupture of the entire storage vessel, the estimated distance to the 200 ppm significance threshold concentration was 0.1 mile. As the tank is located approximately 685 feet (0.13 mile) from the nearest property boundary, the “worst-case” release scenario is not projected to have an off-site impact. Therefore, because the toxic threshold concentration does not extend off-site, the “worst-case” impact is not significant.

The Negative Declaration for the BP FCCU project noted further that the American Institute of Chemical Engineers (AIChE) Center for Chemical Process Safety (AIChE, 1989) has determined that the mean time to catastrophic failure for a metallic storage vessel at atmospheric pressure is 0.985 per million hours (approximately once per 112 years). For aqueous ammonia tanks used at power plants, the California Energy Commission concluded that the catastrophic failure of an aqueous ammonia storage tank is an extremely unlikely event because the probability of a complete tank failure is insignificant, and the risk of failure due to other causes such as external events and human error also is insignificant. In addition, there is no record of any aqueous ammonia storage tank having had a catastrophic failure in recent history. Therefore, the likelihood of a rupture of the aqueous ammonia storage tank occurring is extremely low (SCAQMD, 2002).

For the alternative release scenario involving a tanker-truck unloading accident, the surface area of the release is identical with that for the “worst-case” scenario, but the release rate is greater because of the higher wind speed assumed. However, because the meteorological conditions for an alternative release scenario are less restrictive than that for the “worst-case” scenario, the estimated distance to the toxic threshold concentration (less than 0.1 mile) is less than that for the “worst-case” scenario. This impact was not considered significant because there were no offsite exposure concentrations that exceeded the ERPG-2 level of 200 ppm.

The release of the entire truckload of 7,000 gallons of ammonia in an unloading accident is also a highly unlikely scenario. Leaks of ammonia from a bad connection or damaged hose would be very noticeable and quickly corrected. Should the connection suddenly break, the operator would be able to hit the emergency shut-off valve, hence substantially limiting the amount of spillage. Therefore, should an accident occur, it is likely that less than the entire load would be spilled before the release is controlled. The analysis concluded that both off-site release scenarios would be less than significant. It is expected that these results would be similar for any future SCR (or SNCR) projects at large industrial or commercial facilities.

Storage Tank Rupture Scenario 3: This scenario¹⁴ describes hazard impacts from an accidental release of ammonia from a 5,000 gallon storage tank constructed for an SCR project for a biogas facility. The retrofit of existing ICEs with SCR or NOxTech systems were determined to likely need to install ammonia storage tanks. Based on considerations like available area, amount of ammonia needed per year, etc., SCAQMD staff assumed that the largest ammonia tank installed would be 5,000 gallons. Due to local fire department safety regulations, storage tanks constructed at affected facilities would be surrounded by secondary containment designs (e.g., dykes, berms, etc.). These same containment facilities would be provided at truck loading racks to contain ammonia in the event of a spill during transfer of ammonia from the truck to the storage tank.

The worst-case release scenario would be a catastrophic storage tank failure. The rupture of an ammonia storage tank would release the ammonia into the secondary containment area. Ammonia would then form a liquid pool in the secondary containment area and evaporate. A modeling analysis was performed based on EPA's RMP Guidance for worst-case estimates for toxic releases and explosions. The RMPComp model was used to calculate the size of the impact zones. The EPA endpoint for ammonia exposure is the distance from the spill that is required to reduce the concentration to 0.14 micrograms per liter, the ERPG 2 endpoint for ammonia. The RMPComp program estimates were based on 20 percent aqueous ammonia, which is slightly higher concentration than the 19 percent ammonia proposed for this project. The 20 percent concentration is built into RMPComp and was the closest concentration available for use by the model.

To provide a “worst-case” case analysis for all ammonia tank release scenarios, the following assumptions were made:

- Ammonia tank dimensions were assumed to be twice as wide as they were high;
- The ammonia tank volume was assumed to be 10 percent larger than the nominal containment volume. (For a tank with 5,000-gallon contents, the tank volume was assumed to be 5,500 gallons);
- All dike areas were assumed to have excess capacity of 20 percent more than the tank contents. (The dike capacity for 5,000-gallon contents was assumed to be 6,000 gallons);

¹⁴ This scenario uses the December 2007 Final EA for Proposed Amended Rule 1110.2 – Emissions from Gaseous- and Liquid-Fueled Internal Combustion Engines (ICEs) (SCAQMD No. 280307JK, as a surrogate for a tank rupture scenario.

- All dike walls were assumed to be three feet high;
- For unconfined ammonia spills, the liquid was assumed to spread to a thickness of one centimeter in all directions on a flat impervious surface;
- Rural conditions were conservatively assumed to reduce dispersion.

Based on these assumptions, RMPComp estimated that the toxic endpoint would be 0.1 mile (528 feet) from the ammonia tank. Since biogas engines typically have back-up flare systems, it was assumed that the ICEs would not be sited near the property boundaries. However, based on a survey of biogas facilities, several facilities were found to have biogas engines within 0.1 mile of the property line. Therefore, in the event of an accidental release of ammonia from an ammonia storage tank at affected biogas facilities, offsite receptors could be exposed to ammonia concentrations exceed the ERPG 2 for ammonia, 150 ppm.

According to the American Institute of Chemical Engineers (AIChE) Center for Chemical Process Safety¹⁵, the mean time to catastrophic failure for a metallic storage vessel at atmospheric pressure is 0.985 per million hours (approximately once per 112 years). For aqueous ammonia tanks used at power plants, the California Energy Commission concluded that the catastrophic failure of an aqueous ammonia storage tank is an extremely unlikely event because the probability of a complete tank failure is insignificant, and the risk of failure due to other causes such as external events and human error also is insignificant. In addition, SCAQMD staff is not aware of any aqueous ammonia storage tank that has had a catastrophic failure in recent history. As a result, the likelihood of a rupture of the aqueous ammonia storage tank occurring is extremely low. In spite of this, however, hazard impacts from exposure to ERPG 2 concentrations of ammonia are considered to be significant.

PROJECT-SPECIFIC MITIGATION - AMMONIA TANK RUPTURE ON-SITE: In the event of an accidental release of ammonia from on-site ammonia storage units, potentially significant adverse hazard impacts from exposure to could occur, even if aqueous ammonia is used rather than anhydrous ammonia. Therefore, since hazard impacts pertaining to on-site ammonia tank rupture are expected to be significant, mitigation measures are required. To mitigate potential adverse hazardous impacts from exposure to an accidental release of ammonia, mitigation for the storage of aqueous ammonia would be to require the construction of a combined delivery and storage aqueous ammonia system equipped with the following.

HZ-7: Install safety devices, including but not limited to: continuous tank level monitors (e.g., high and low level), temperature and pressure monitors, leak monitoring and detection system, alarms, check valves, and emergency block valves.

HZ-8: Install secondary containment to capture 110 percent of the storage tank volume in the event of a spill:

¹⁵ AIChE, Guidelines for Process Equipment Reliability Data with Data Tables, Center for Chemical Process Safety 1989.

HZ-9: Install a grating-covered trench around the perimeter of the delivery bay to passively contain potential spills from the tanker truck during the transfer of aqueous ammonia from the delivery truck to the storage facility.

HZ-10: The truck loading/unloading area was designed to be equipped with an underground gravity drain that flows to a large on-site retention basin to provide sufficient ammonia dilution to the extent that no hazards impact is possible in the event of an accidental release during transfer of aqueous ammonia.

REMAINING IMPACTS – AMMONIA TANK RUPTURE ON-SITE: The hazard impacts associated with the potential for an ammonia tank rupturing on-site and causing a release are expected to be significant prior to mitigation. However, requiring the construction of a combined delivery and storage aqueous ammonia system with specific design features to capture any release of aqueous ammonia is considered to be feasible mitigation. Thus, after mitigation, no remaining significant impacts pertaining to on-site ammonia tank rupture hazards are expected.

4.4.4.4 Use of Catalysts

PROJECT-SPECIFIC IMPACTS – USE OF CATALYSTS: Implementing various control measures proposed in the 2012 AQMP could result in the increased use of catalysts as well as an increase in the quantity of catalyst disposed of hazardous materials: 1) in SCRs per Control Measure CMB-01; 2) in NO_x reducing additives (which are made of catalysts) per Control Measures CMB-01 and INC-01; and 3) in thermal oxidizers per Control Measures CMB-01, OFFRD-03, OFFRD-04, ADV-04, ADV-05, and FUG-01.

Catalysts Used in SCRs: There are two main types of catalysts used in SCRs: one in which the catalyst is coated onto a metal structure and a ceramic-based catalyst onto which the catalyst components are calcified. Commercial catalysts used in SCRs are available in two types of solid, block configurations or modules, plate or honeycomb type, and are comprised of a base material of titanium dioxide (TiO₂) that is coated with either tungsten trioxide (WO₃), molybdenic anhydride (MoO₃), vanadium pentoxide (V₂O₅), or iron oxide (Fe₂O₃). These catalysts are used for SCRs because of their high activity, insensitivity to sulfur in the exhaust, and useful life span of approximately five years. Ultimately, the material composition of the catalyst is dependent upon the application and flue gas conditions such as gas composition, temperature, et cetera. A typical catalyst dimension would be approximately 39" x 40" x 12" enclosed in 5" double-wall shell containing insulation. The number of catalyst blocks needed will depend on the quantity of flue gas being treated by the SCR.

The key hazards associated with catalyst use in SCRS are the crushing of the spent catalyst modules and transporting it for disposal or recycling. With respect to hazards and hazardous materials, this means that there will be an increase in the frequency of truck transportation trips to remove the spent catalyst as hazardous materials or hazardous waste from each affected facility. However, facilities that have existing catalyst-based operations currently recycle the catalysts blocks, in lieu of disposal. Moreover, due to the heavy metal content and relatively high cost of catalysts, recycling can be more lucrative than disposal. Thus,

facilities that have existing SCR units and choose to employ additional SCR equipment, in most cases already recycle the spent catalyst and subsequently may continue to do so with any additional catalyst that may be needed.

A number of physical or chemical properties may cause a substance to be hazardous, including toxicity (health), flammability, reactivity, and any other specific hazard such as corrosivity or radioactivity. Based on a hazard rating from 0 to 4 (0 = no hazard; 4 = extreme hazard) located on the MSDS, the hazard rating for silica/alumina catalyst, for example, health is rated 1 (slightly hazardous), flammability is rated 0 (none) and reactivity is rated 0 (none). However, if nickel is deposited on the catalyst, the hazard rating is 2 for health (moderately toxic), 4 (extreme fire hazard) for flammability, 1 for reactivity (slightly hazardous if heated or exposed to water). The particular composition of the catalyst used in the SCR units, combined with the metals content of the flue gas will determine the hazard rating and whether the spent catalyst is considered a hazardous material or hazardous waste. This distinction is important because a spent catalyst that qualifies as a hazardous material could be recycled or reused by another industry (such as in the manufacturing of California Portland cement). However, spent catalyst that is considered hazardous waste must be disposed of in a Class III landfill. Due to the recycling of catalysts, less than significant impacts on hazards and hazardous waste are expected. Refer to Subchapter 4.8 - Solid and Hazardous Waste for a discussion on the disposal of spent catalyst modules.

Use of NO_x Reducing Additives: SCONO_x/EM_xTM technology is a relatively new proprietary post-combustion catalytic oxidation and adsorption process that is undergoing development for controlling NO_x and CO emissions from boiler, steam generator, and process heater applications. The catalyst used in the SCONO_x/EM_xTM system consists of a platinum base with a potassium carbonate adsorption coating over a ceramic substrate and has a catalyst life of three years that is guaranteed by the manufacturer. The catalyst simultaneously oxidizes NO to NO₂, CO to CO₂, and VOCs to CO₂ and water. The NO₂ is adsorbed onto the catalyst surface where it is chemically converted to potassium nitrates and nitrites. The catalyst is then exposed to hydrogen gas produced from reformed natural gas with high pressure steam to regenerate the adsorption layer. Because hydrogen is used for the catalyst regeneration process, a low oxygen atmosphere is necessary to prevent dilution. As such, the catalyst bed is designed with multiple compartments that are equipped with dampers that close at the beginning of the regeneration cycle. The catalyst used in the SCONO_x/EM_xTM process has a life-span of approximately three years

As with catalysts used in SCRs, the key hazards associated with post-catalytic oxidation are associated with the crushing of the spent catalyst and transporting it for disposal or recycling. With respect to hazards and hazardous materials, this means that there will be an increase in the frequency of truck transportation trips to remove the spent catalyst as hazardous materials or hazardous waste from each affected facility. However, due to the high value of platinum (a precious metal), facilities employing post-catalytic oxidation will likely recycle the catalyst, in lieu of disposal, so little hazardous waste would be expected to be and disposed of at a hazardous waste landfill. Thus, due to the recycling of catalysts used in post-combustion catalytic oxidation, less than significant impacts on hazards and hazardous waste are expected.

Catalyst Used in Thermal Oxidizers: The 2012 AQMP could result in the increased use of catalyst used in thermal oxidizers to control emissions. The following control measures could rely on catalytic oxidation technologies for emission control including CMB-01, OFFRD-03, OFFRD-04, ADV-04, and ADV-05. Catalytic oxidation beds in thermal oxidizers generally use a precious metal to aid in the combustion of air pollutants at relatively low temperatures. Thermal oxidizers require periodic replacement of the catalyst bed. The expected life of the catalyst is approximately three to five years, depending on the concentration of materials and type of exhaust flows controlled. Metals used in the catalyst are generally recovered because they are made from precious and valuable metals (e.g., platinum and palladium). Metals can be recovered from approximately 60 percent of the spent catalyst generated from the operation of catalytic oxidizers (SCAQMD, 2003a). These metals could then be recycled. The remaining material would most likely need to be handled as hazardous waste and disposed of at a hazardous waste landfill.

If the catalyst is not hazardous, jurisdiction for its disposal then shifts to local agencies such as regional water quality control boards or county environmental agencies. The RWQCB has indicated that if a spent catalyst is not considered a hazardous waste, it would probably be considered a Designated Waste. A Designated Waste is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state. The type of landfill that the material is disposed at will depend upon its final waste designation. Due to the recycling of catalysts used in catalytic oxidation and the fact that this technology is not expected to be widely used because of cost, less than significant impacts on hazards and hazardous waste are expected.

PROJECT-SPECIFIC MITIGATION – USE OF CATALYSTS: Less than significant impacts on hazards associated with the use of catalysts were identified so no mitigation measures are necessary or required.

REMAINING IMPACTS – USE OF CATALYSTS: The hazard impacts associated with the use of catalysts in various technologies are expected to be less than significant. Thus, no remaining hazard impacts associated with catalyst use are expected.

4.4.4.5 Start-up, Shutdown and Turnaround Procedures

PROJECT-SPECIFIC IMPACTS – START-UP, SHUTDOWN AND TURNAROUND PROCEDURES: The SCAQMD received a comment (see Comment 3-11 and Response to Comment 3-11) on the June 28, 2012 version of the NOP/IS asserting that implementation of Control Measure MCS-03 as proposed in the 2012 AQMP could result in the increased safety issues when diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability during start-up, shutdown and turnarounds of process units. The comment, however, did not identify specify the safety issues of concern. Currently, SCAQMD Rule 1123 - Refinery Process Turnarounds, contains specific exemptions in the rule language that address (and prevent) situations that could potentially damage equipment, cause the malfunction of pollution control or safety devices, or cause violations of safety regulations. As with all control measures and the rule development process, participation by the affected parties, including the refineries and their

representatives, as well as other industries and their representatives, will be paramount in effectively and safely implementing MCS-03.

In its current form, MCS-03 is in its early stages and is very broad and there is insufficient information to be able to identify specific equipment or processes. Start-up, shutdown or turnaround often results in higher emission rates from pieces of equipment that are interconnected, either upstream or downstream, to the equipment undergoing start-up/shutdown. Refinery operations, for example, typically rely on flares to minimize the emissions impact resulting from start-up, shutdown and turnarounds. However, there are adverse environmental impacts associated with the use of flares as well. As a result, there is the potential that MCS-03 could reduce potential hazard impacts, at least at some types of facilities.

As such, to identify any impacts at this time without knowing the specific design features would be speculative. This measure would be implemented in two phases, beginning with a technical assessment to be completed in the 2012/2013 timeframe. Once the technical assessment is completed, phase 2 would include implementing MCS-03 begins, and if a proposed rule or rule amendment is developed as a result, the CEQA document for the proposed rule or rule amendment will identify and analyze the specific environmental impacts at that time.

In conclusion, due to the speculative nature of the potential safety hazards that may be associated with implementing Control Measure MCS-03, no safety hazards can be identified at this time. Thus, no hazard impacts associated with the safety of implementing start-up, shutdown, and turnaround procedures are expected.

PROJECT-SPECIFIC MITIGATION – START-UP, SHUTDOWN AND TURNAROUND PROCEDURES: No impacts on hazards associated with safety issues pertaining to implementing Control Measure MCS-03 were identified so no mitigation measures are necessary or required.

REMAINING IMPACTS – START-UP, SHUTDOWN AND TURNAROUND PROCEDURES: No remaining hazard impacts associated with safety issues pertaining to implementing Control Measure MCS-03 are expected.

4.4.5 Summary of Hazards and Hazardous Materials Impacts

The following is the summary of the conclusions of the analysis of hazard impacts associated with implementation of the 2012 AQMP.

- Reformulated Products: The analysis indicates that the fire hazard impacts associated with reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products are expected to be significant. While an increase of future compliant reformulated materials could be expected to result in a concurrent reduction in the amount of materials formulated with conventional solvents, the possibility exists that facilities currently using water-based products could switch to using reformulated solvent-based products made with acetone or other flammable or extremely flammable

chemicals. The analysis also indicates that the health hazard impacts associated with reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products are expected to be less than significant because even if manufacturers could potentially use replacement chemicals that could pose new or different health risks, SCAQMD Rule 1401 and 1402 would limit potential exposures to nearby receptors. Further, as with the use of all chemicals, conventional or reformulated, facilities and their workers would be required to continue to comply with existing health protective procedures when handling both flammable and toxic materials.

- Use of Alternative Fuels: The hazard impacts associated with the use of all alternative fuels except LNG and the use of batteries in electric/hybrid vehicles due to implementation of the 2012 AQMP control measures were determined to be less than significant when users comply with existing regulations and recommended safety procedures. Hazard impacts associated with the transportation of LNG were determined to be significant, requiring mitigation. Further, significant hazards impacts due to LNG transportation were determined to remain significant after mitigation. Lastly, any increase in the use of alternative fuels will result in a concurrent decrease in the amount of conventional fuels used in the district.
- Ammonia Use in SCRs and SNCRs: The use of ammonia in SCR and SNCR technologies could be potentially significant due to implementation of the control measures. While the use of aqueous ammonia at concentrations less than 20 percent by volume is expected to reduce hazard impacts associated with ammonia use, the potential for an on-site spill of aqueous ammonia could pose a significant hazards impact. Accordingly, significant hazard impacts are expected from the increased use of ammonia in SCR and SNCR technologies and mitigation measures are required.
- Start-up, Shutdown and Turnaround Procedures: No hazard impacts pertaining to safety issues associated with implementing Control Measure MCS-03 were identified.
- Use of Catalysts: The analysis indicates that the hazard impacts associated with the use of catalysts are expected to be less than significant.

Summary of PM_{2.5} Control Measure Impacts: The hazard impacts associated with PM_{2.5} Control Measures (CMB-01, IND-01, and MCS-01) were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products; alternative fuels; ammonia use in SCRs, and fuel additives.

Summary of Ozone Control Measure Impacts: The hazard impacts associated with the Ozone Control Measures (21 control measures, see Table 4.4-1) were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products; all alternative fuels except LNG, and start-up, shutdown and turnaround procedures. Significant hazards impacts due to LNG transportation were determined to remain significant after mitigation.

SUBCHAPTER 4.5

HYDROLOGY AND WATER QUALITY

Introduction

2012 AQMP Control Measures with Potential Hydrology and Water Quality Impacts

Significance Criteria

Potential Hydrology and Water Quality Impacts and Mitigation Measures

Summary of Hydrology and Water Quality Impacts

4.5 HYDROLOGY AND WATER QUALITY

4.5.1 Introduction

This subchapter identifies potential hydrology and water quality impacts that may be generated by implementing the 2012 AQMP. Some of the control measures in the 2012 AQMP may result in impacts on water quality and increased wastewater discharge; water quality impacts associated with the use of alternative fuels; water quality impacts associated with increased use of batteries; increased water demand; and, water quality impacts associated with the use and application of sodium bisulfate for livestock operations.

4.5.2 2012 AQMP Control Measures with Potential Hydrology and Water Quality Impacts

The hydrology and water quality analysis in this Program EIR identifies the potential hydrology and water quality impacts from implementing the 2012 AQMP. All control measures were analyzed to identify the potential hydrology and water quality impacts. The NOP/IS determined that the proposed project could result in potentially significant water quality and water demand impacts.

The evaluation of the control measures was based on an examination of the impacts of the control measures and technologies. The evaluation of the control methods indicate that there are 34 control measures that could have potential water quality and water demand impacts. As shown in Table 4.5-1, four control measures for PM_{2.5} emission reductions and 21 control measures for reduction of ozone precursors were identified as having potential hydrology and water quality impacts.

TABLE 4.5-1

Control Measures with Potential Secondary Hydrology and Water Quality Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	WATER IMPACT
SHORT-TERM PM_{2.5} CONTROL MEASURES			
BCM-03 <i>(formerly BCM-05)</i>	Further PM Reductions from Under-Fired Charbroilers (PM _{2.5})	Add-On Control Equipment with Ventilation Hood Requirements (e.g., ESPs, HEPA filters, wet scrubbers, or thermal oxidizers).	Potential impacts on water demand and wastewater discharge from operating wet ESPs or wet scrubbers.
BCM-04	Further Ammonia Reductions from Livestock Waste	Reducing pH level in manure through the application of acidifier sodium bisulfate.	Potential water quality impacts from applying acidifier sodium bisulfate.
IND-01 ^a	Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities	Environmental lease conditions, port rules, tariffs or incentives.	Potential impacts on water demand and wastewater discharge from operating wet ESPs or wet scrubbers. Use of alternative fuels can result in water quality impacts.

TABLE 4.5-1 (Continued)

Control Measures with Potential Secondary Hydrology and Water Quality Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	WATER IMPACT
SHORT-TERM PM2.5 CONTROL MEASURES			
MCS-01 ^a	Application of All Feasible Measures	SCAQMD District would adopt and implement new retrofit technology control standards as new BARCT standards become available.	Potential impacts on water demand and wastewater discharge from operating wet ESPs or wet scrubbers, use of alternative fuels can result in water quality impacts, increase water demand and wastewater discharges from increased use of water-based formulations.
OZONE CONTROL MEASURES			
CTS-01	Further VOC Reductions from Architectural Coatings (Rule 1113) (VOC)	Reduce the allowable VOC content in product formulations by using alternative low-VOC products and use application techniques with greater transfer efficiency.	Potential impact on water demand and wastewater discharge associated with increased use of water-based formulations.
CTS-02	Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants (VOC)	Reduce the allowable VOC content in product formulations by using alternative low-VOC products or non-VOC products/equipment.	Potential impact on water demand and wastewater discharge associated with increased use of water-based formulations.
CTS-03	Further VOC Reductions from Mold Release Products (VOC)	Limitation of VOC content for mold release products.	Potential impact on water demand and wastewater discharge associated with increased use of water-based formulations.
CTS-04	Further VOC Reductions from Consumer Products (VOC)	Eliminate or revise the exemption for low vapor pressure solvents in consumer products.	Potential impact on water demand and wastewater discharge associated with increased use of water-based formulations.
FUG-01	Further VOC Reductions from Vacuum Trucks (VOC)	VOC control devices such as carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers, liquid scrubbers and positive displacement (PD) pumps.	Increased water demand and increased wastewater discharge associated with air pollution control equipment (e.g., wet scrubbers).
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles (NOx)	Incentives to replace older vehicles with electric or hybrid vehicles.	Use of alternative fuels can result in water quality impacts.
ONRD-02	Accelerated Retirement of Older Light-Duty and Medium-Duty Vehicles (NOx)	Incentives to replace older light- and medium-duty vehicles with new or newer low-emitting vehicles.	Use of alternative fuels can result in water quality impacts.

TABLE 4.5-1 (Continued)

Control Measures with Potential Secondary Hydrology and Water Quality Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	WATER IMPACT
OZONE CONTROL MEASURES			
ONRD-03	Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium Heavy-Duty Vehicles (NOx)	Incentives to replace older medium-duty vehicles with low-emitting vehicles. Highest priority would be given to zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode.	Use of alternative fuels can result in water quality impacts.
ONRD-04	Accelerated Retirement of Older Heavy-Duty Vehicles (NOx)	Incentives replace heavy-duty vehicles with newer or new vehicles. Priority would be placed on replacing older diesel trucks in Mira Loma.	Use of alternative fuels can result in water quality impacts.
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace up to 1,000 heavy-duty vehicles with low-emitting vehicles or zero-emission container movement systems.	Use of alternative fuels can result in water quality impacts.
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment (NOx)	Accelerate Tier 0 and Tier 1 equipment replacement with Tier 4 equipment, use of air pollution control technologies (e.g., advanced fuel injection, air induction, and after-treatment technologies).	Use of alternative fuels can result in water quality impacts.
OFFRD-02	Further Emission Reductions from Freight Locomotives (NOx)	Replace existing engines (Tier 0 and Tier 2 engines) with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Accidental release of ammonia and use of alternative fuels can result in water quality impacts; accidental release issues with acid spill from batteries could affect water quality.
OFFRD-03	Further Emission Reductions from Passenger Locomotives (NOx)	Repower existing Tier 0 and Tier 2 engines with Tier 4 engines with control equipment (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Accidental release of ammonia and use of alternative fuels can result in water quality impacts; accidental release issues with acid spill from batteries could affect water quality.
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels at Berth	Shore power of vessels at berth, use of air pollution control technologies on exhaust gases from auxiliary engines and boilers (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Accidental release of ammonia and use of alternative fuels can result in water quality impacts; accidental release issues with acid spill from batteries could affect water quality.

TABLE 4.5-1 (Concluded)

Control Measures with Potential Secondary Hydrology and Water Quality Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	WATER IMPACT
OZONE CONTROL MEASURES			
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure; construct battery charging and fueling infrastructure. Alternatively, if battery, fuel cell or other zero/near zero emission technologies progress sufficiently, the need for wayside power for rail or trucks may be diminished or eliminated.	Use of alternative fuels can result in water quality impacts, potential water quality impacts from EV battery disposal.
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric, magnetic, battery-hybrid system, or fuel cell infrastructure, construct battery charging or fueling infrastructure.	Use of alternative fuels can result in water quality impacts, potential water quality impacts from EV battery disposal.
ADV-03	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment (NOx)	Construct electric gantry cranes, construct battery charging or fueling infrastructure, and use of alternative fuels.	Use of alternative fuels can result in water quality impacts, potential water quality impacts from EV battery disposal.
ADV-04	Actions for the Deployment of Cleaner Commercial Harborcraft (NOx)	Construct battery charging or fueling infrastructure, use of air pollution control equipment (e.g., SCR, and use of alternative fuels).	Use of alternative fuels can result in water quality impacts, potential water quality impacts from EV battery disposal.
ADV-05	Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels [NOx]	Employ aftertreatment control technologies such as SCR and sea water scrubbers, and use of alternative fuels.	Use of alternative fuels can result in water quality impacts, potential increased water demand and wastewater discharge associated with wet scrubbers.
ADV-06	Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment [NOx]	Construct battery charging or fueling infrastructure, and increased use of alternative fuels.	Use of alternative fuels can result in water quality impacts, potential water quality impacts from EV battery disposal.
ADV-07	Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines(NOx)	Use alternative fuels, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction.	Use of alternative fuels can result in water quality impacts.

- a The specific actions associated with the control measure are unknown and, therefore, the impacts are speculative. In order to provide a conservative analysis, it is assumed that the control measure could require air pollution control technologies that are similar to those that are currently required (e.g., SCR, electrification, use of alternative fuels, etc.), and would have the potential to require construction activities that would generate noise.

4.5.3 Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use more than 262,820 gallons per day of potable water.
- The project increases total demand for water by more than five million gallons per day.

Water Quality:

- The project will cause degradation or depletion of ground water resources substantially affecting current or future uses.
- The project will cause the degradation of surface water substantially affecting current or future uses.
- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.
- The project results in alterations to the course or flow of floodwaters.

4.5.4 Potential Hydrology and Water Quality Impacts and Mitigation Measures

4.5.4.1 Wastewater and Water Quality Impacts

4.5.4.1.1 Wastewater Impacts

PROJECT-SPECIFIC IMPACTS - WASTEWATER: The 2012 AQMP control measures that could require reformulation of coatings, adhesives, solvents, lubricants, mold release agents, and consumer products are MCS-01, CTS-01, CTS-02, CTS-03, and CTS-04. Emission reductions are expected to be achieved through the use of low or zero VOC formulations and reformulation of these materials may generate additional wastewater.

In addition, the 2012 AQMP includes stationary sources that may require add-on control equipment with the potential to generate additional wastewater (BCM-03, BCM-04, IND-01, MCS-01, FUG-01) associated with the use of wet electrostatic

precipitators (ESPs) or wet gas scrubbers (WGS). The extent of the use of these types of control equipment is unknown. However, the use of wet ESPs and WGSs has been shown to be effective at reducing PM_{2.5} emissions and is a potential control methodology.

To meet the lowered future VOC content limits as a result of implementing Control Measures MCS-01, CTS-01, CTS-02, CTS-03, and CTS-04, coatings, adhesives, solvents, lubricants, mold release products, and consumer products are expected to be reformulated. While reformulated products would be expected to have lower VOC contents, the reformulations could have widely varying compositions depending on the chemical characteristics of the replacement solvents chosen. For example, most reformulations are expected to be made with water, but other reformulations could be made with an exempt solvent such as acetone or other solvents that are not exempted from the definition of a VOC in SCAQMD's Rule 102. As a result, for those products reformulated with water, then water would also be used for clean-up and the resultant wastewater material could be disposed of into the public sewer system. Further, other reformulated products made with exempt or non-exempt solvents may also lead to adverse impacts to water resources if clean-up and disposal of reformulated solvents, coatings or products are not handled properly. However, the use of water to reformulate coatings, solvents and products would generally lead to products that would be less toxic than products reformulated with either exempt or non-exempt chemicals (that are typically petroleum-based) and as such, generate fewer impacts to water quality. Lastly, because the development of reformulated products is expected to require the same types of equipment (e.g., spray guns, rollers, and brushes) currently used in coating operations, the corresponding clean-up practices employed to clean the coating equipment would also not be expected to change.

Table 4.5-2 estimates the "worst-case" potential increase of wastewater likely to be received by wastewater treatment plants in the district as a result of the implementing the 2012 AQMP control measures that pertain to product reformulations. The estimated increase in wastewater generated is considered to be within the projected capacity of the local wastewater treatment plants within the district. Wastewater generated from the reformulation of coatings and products is estimated to be about 47,000 gallons per day as compared to the estimated wastewater treatment capacity of about 2,370 million gallons in the district. These are expected to be "worst-case" estimates because a number of these materials already in use are water-borne or low VOC materials. For example, most architectural coatings are already being sold with VOC content limits but Control Measure CTS-01 would further reduce the allowable VOC content from coatings that are already regulated. (The control measure may also require increased transfer efficiency of the coating equipment but no change in the formulation of coatings would be expected.) Further, low VOC mold release products are already being manufactured and sold, so the need for reformulation may be minor or not required at all, depending on the manufacturer.

TABLE 4.5-2

Projected Wastewater Impact from 2012 AQMP Control Measures

Control Measure	POTW Average Wastewater Flow^a (million gal per day)	POTW Treatment Capacity^a (million gal per day)	Estimated Affected Coating Usage (gal per year)	Projected Wastewater Flow (gallon per year)	Projected Wastewater Flow (gallons per day)	Total Impacts, Percent of POTW Average Daily Flow
CTS-01 Architectural Coatings	1,536	2,370	7,610,000 ^b	7,610,000	20,849	0.001
CTS-02 Misc. Coatings, Adhesives, Solvents, Lubricants	1,536	2,370	3,805,000	3,805,000	10,425	0.0007
CTS-03 Mold Release Products	1,536	2,370	1,902,500	1,902,500	5,212	0.0003
CTS-04 Consumer Products	1,536	2,370	3,805,000	3,805,000	10,425	0.0007
Total Wastewater from Reformulated Coatings:			17,122,500	17,122,500	46,911	0.003
BCM-03, BCM-04, IND-09, and MSC-01	1,536	2,370	--	--	2,016,000	0.131
Total for all Control Measures:					2,062,911	0.134

^a See Table 3.5-3.

^b SCAQMD, 2011. Assume 2004 volume to account for decline in economic activity in Southern California.

^c Architectural coatings are the largest coating category. This number represents the total universe of coating categories; however, it is likely that the control measure would only affect a small subset of the total number of coating categories. Miscellaneous Coatings, Consumer products and Consumer Products are assumed to be about 50 percent of the volume of architectural coatings, and mold release products are assumed to be about 25 percent of the volume of architectural coatings.

^d Assumes 20 large wet ESPs/WGSs are installed as part of the AQMP.

As indicated in Table 4.5-1, several control measures proposed in the 2012 AQMP may require add-on control equipment (BCM-03, BCM-04, IND-01, and MSC-01) for stationary sources such as wet ESPs and WGSs, which have been shown to be effective at reducing PM_{2.5} emissions. If installed, wet ESPs and WGSs would require water to operate and thus, would result in the generation of wastewater. However, the extent of the use of these types of control equipment to be used in the future is unknown.

One wet ESP with one WGS were installed on the Fluid Catalytic Cracking Unit (FCCU) at the ConocoPhillips Refinery to reduce SO_x emissions, as well as PM₁₀ and PM_{2.5} emissions. The FCCU is a large source of emissions and the wet ESP and WGS installed were sized accordingly. The environmental analysis for this

project indicated that the expected wastewater discharge from the combined operation of the wet ESP and WGS at ConocoPhillips was about 70 gallons per minute (about 100,800 gallons per day) (SCAQMD, 2007). Wet ESPs and WGSs of this size are primarily designed for large sources within the district (e.g., refineries and other large manufacturing facilities), but these technologies can also be scaled down for use on smaller sources. If the 2012 AQMP control measures encourage the installation of 20 additional wet ESP /WGS systems of this size, about two million gallons per day of wastewater would be generated. Wastewater from larger facilities such as refineries is often treated at existing wastewater treatment facilities operated by the facility, so increased wastewater may not be discharged to publicly owned treatment facilities. However, making the conservative assumption that the 2012 AQMP could result in the construction and installation of 20 large-scale wet ESP/WGS systems, the estimated increase in wastewater would be well within the existing wastewater treatment capacity within the district.

The potential increase in the volume of wastewater estimated as a result of implementing these control measures in the 2012 AQMP is also included in Table 4.5-2. The total increase in potential wastewater from implementing all of the control measures is estimated to be about 2.1 million gallons per day, which represents about a 0.1 percent increase in wastewater generated within the district. Further, the increase in wastewater is well within the capacity of the existing wastewater treatment plants of about 2,370 million gallons. Therefore, the wastewater impacts associated with the 2012 AQMP are expected to be less than significant.

PROJECT-SPECIFIC MITIGATION - WASTEWATER: Less than significant impacts on wastewater generation as a result of implementing the 2012 AQMP are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS - WASTEWATER: The wastewater impacts associated with wastewater generation are expected to be less than significant. Thus, no remaining wastewater impacts are expected.

4.5.4.1.2 *Water Quality Impacts*

PROJECT-SPECIFIC IMPACTS – WATER QUALITY: In the past, concerns have been raised that the increased use of waterborne technologies to meet the lower VOC content limits would result in a greater trend of coating applicators to improperly dispose of the waste generated from these coatings into the ground, storm drains, or sewers systems. However, there is no data to support this contention.

Results from a survey of contractors conducted by the SCAQMD for the November 1996 amendments to SCAQMD Rule 1113 determined that a majority of coating applicators either dispose of the waste material properly as required by the coating manufacturer's MSDS or recycle the waste material regardless of type of coating¹.

¹ SCAQMD, Final Subsequent Environmental Assessment, SCAQMD No. 960626DWS, October 1996.

The survey was prepared to evaluate the replacement of solvent-borne coatings with reformulated, water-borne coatings. In November 2008, a paint manufacturer conducted a survey of 180 Southern California residential and professional painters. The conclusion was that a majority professional painters use hazardous waste disposal services to dispose of coatings instead of air drying coatings and then disposing of as a solid waste. Based upon the survey results, there is no reason to expect that coating contractors would change their disposal practices, especially those contractors that already dispose of wastes properly. Similarly, there is also no evidence that there would be an increase in illegal disposal practices as a result of the proposed control measures.

Potential adverse water quality impacts associated with reformulated products are expected to be minimal since: 1) compliance with state and federal waste disposal regulations would substantially limit adverse impacts; 2) “turn-key” services are available for aqueous (water-based) cleaners; 3) some solvent cleaning operators may currently be disposing of spent material illegally, so one illegal activity would be replaced with another legal activity; and, 4) the amount of wastewater which may be generated from reformulated solvents and from air pollution control equipment is well within the projected receiving capacity of the Publicly Owned Treatment Works (POTWs) in the SCAQMD’s jurisdiction. The treatment of wastewater at POTWs is accomplished under the control of numerous regulatory permits (e.g., National Pollutant Discharge Elimination System Permits or NPDES Permits) which require monitoring of the quality of wastewater on a frequent basis. For example, NPDES permit requirements for a local refinery requires monthly sampling for arsenic, cadmium, chromium, copper, cyanides, lead, mercury, nickel, zinc, silver, total phenol, pH, dissolved sulfides, chlorides, suspended solids, chemical oxygen demand, biochemical oxygen demand and ignitability. Daily sampling is required for ammonia, oil and grease, selenium and thiosulfate.

Since the reformulation of materials or additional use of air pollution control equipment is not expected to generate significant adverse water quality impacts industry-wide, no changes to existing wastewater treatment permits are expected to be required. As a result, it is expected that operators of affected facilities would continue to comply with existing wastewater treatment requirements of the applicable Regional Water Quality Control Boards or sanitation district.

Coating operations currently generate wastewater as part of clean-up activities. In addition, industrial operations that would be expected to use wet ESP/WGS systems are likely to also be large manufacturing facilities that currently generate wastewater. As discussed above, the reformulation of coatings to water-based coatings could have a beneficial effect by reducing the levels of contaminants currently found in the wastewater from these operations because there is an increasing trend toward less toxic waterborne coatings as water-based products are generally less toxic than solvent-based products. The amount of increased wastewater generated from coating operations would be well within the capacity of the region’s POTWs. Consequently, water quality impacts from the 2012 AQMP control measures are not considered significant.

PROJECT-SPECIFIC MITIGATION - WATER QUALITY: Less than significant impacts on water quality as a result of implementing the 2012 AQMP are expected so no mitigation measures are necessary or required.

REMAINING IMPACTS – WATER QUALITY: The water quality impacts associated with implementing the 2012 AQMP are expected to be less than significant. Thus, no remaining water quality impacts are expected.

4.5.4.2 Alternative Transportation Fuels

PROJECT-SPECIFIC IMPACTS – ALTERNATIVE TRANSPORTATION FUELS: The following control measures in the 2012 AQMP may contribute to the increased use of alternative fuels in the SCAQMD's jurisdiction: IND-01, MSC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07. These control measures would generally require the increased use of alternative fuels (e.g., biodiesel fuels, compressed natural gas, liquefied natural gas, and hydrogen).

The SCAQMD amended Rule 431.2 - Sulfur Content of Liquid Fuels, in September 2000, which limited the sulfur content in diesel fuel used in stationary sources to 15 ppm by weight, effective January 1, 2005. Federal law extended this same requirement to also apply to diesel fuel used by mobile sources, effective June 1, 2006. Diesel fuels currently used in California are low sulfur fuels. As such, there is no evidence that the use of low sulfur diesel fuels has resulted in any water quality impacts, as the only difference in the fuel available on the market is the reduced concentration of sulfur.

In general, alternative fuels are expected to be less toxic than conventional fuels and follow a similar path as the low sulfur diesel. Biodiesel is a fuel derived from biological sources such as vegetable oils or animal fats. Biodiesel can be used pure or blended with conventional diesel. Because the biodiesel typically comes from vegetable oils or animal fats, it is generally less toxic and more biodegradable than conventional diesel, so the water quality impacts from a spill of biodiesel would be less than a spill of pure conventional diesel. The most common blended biodiesel is B20, which is 20 percent biodiesel and 80 percent conventional diesel. Therefore, the potential water quality impacts from the transport and storage of biodiesel and biodiesel blends is not expected to be substantially different than the transport and storage of conventional diesel.

The other types of alternative fuels that may be used as part of implementing some control measures in the 2012 AQMP include compressed natural gas, liquefied natural gas and hydrogen. Because all of these fuels exist as a gas at standard temperatures and pressures, a leak of any of these fuels would result in an airborne release, and not a release that could adversely affect water and water quality. There are a number of rules and regulations currently in place that are designed to minimize the potential impacts from underground leaking storage tanks and spills

from fueling activities, including requirements for the construction of the storage tanks, requirements for double containment, and installation of leak detection systems. These regulations would also apply to any leaks of alternative fuels from storage tanks. Thus, the use of alternative fuels is not expected to result in any greater adverse water quality impacts than the use of conventional fuels like diesel or gasoline.

Lastly, none of the alternative fuels require water for their processing or distribution. Thus, any increased use of alternative fuels will not create an additional demand for water.

PROJECT SPECIFIC MITIGATION - ALTERNATIVE TRANSPORTATION FUELS: Less than significant hydrology and water quality impacts were identified from the use of alternative fuels as part of the 2012 AQMP so no mitigation measures are required.

REMAINING IMPACTS – ALTERNATIVE TRANSPORTATION FUELS: The hydrology and water quality impacts associated with implementing the 2012 AQMP are expected to be less than significant. Thus, no remaining hydrology or water quality impacts are expected from the projected increased use of alternative fuels.

4.5.4.3 Electric Vehicles

PROJECT-SPECIFIC IMPACT – ELECTRIC VEHICLES: Implementation of the 2012 AQMP could contribute to an increased use of electric vehicles. Table 4.5-3 estimates the number of electric vehicles that are expected to be put into service as part of implementing Control Measures ONRD-01, ONRD-03, ONRD-04, and ONRD-05. In addition to the control measures identified in Table 4.5-3, a number of other control measures would encourage the use of zero and near-zero emission vehicles and other equipment including ADV-01, ADV-02, ADV-03, ADV-04, ADV-06, and ADV-07. Since some batteries contain toxic materials, water impacts are possible if they are disposed of in an unsafe manner, such as by illegal dumping or by disposal in a landfill.

TABLE 4.5-3

Estimated Increase in Electric Vehicles

CONTROL MEASURE NO.	CONTROL MEASURE DESCRIPTION	ESTIMATED INCREASE IN VEHICLES
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles	Incentivize 9,000 light- and medium-duty vehicles
ONRD-03	Accelerated Penetration of Partial Zero Emission and Aero Emission Medium Heavy-Duty Vehicles	Encourage introduction of 5,000 vehicles
ONRD-04	Accelerated Retirement of Older Heavy Duty Vehicles	Replace 5,000 vehicles
ONRD-05	Further Emission Reductions for Heavy-Duty Vehicles Serving Near-Dock Railyards	Replace 1,000 trucks with zero emission technologies

As interest in the use of electric vehicles has increased over the years, battery technologies have been developing and improving. Most battery technologies employ materials that are recyclable, since regulatory requirements and market forces encourage recycling. California laws create incentives and requirements for disposal of recycling of batteries as follows.

- Under CARB regulations, to certify either a new ZEV or retrofit an existing ZEV, automakers must complete CARB's certification application, which must include a battery disposal plan. Thus, current regulations require ZEV manufacturers to take account for the full life-cycle of car batteries and to plan for safe disposal or recycling of battery materials (SCAQMD, 2007). For example, Toyota offers \$200 per battery to minimize illegal disposal of batteries.
- California law requires the recycling of lead-acid batteries (California Health & Safety Code §25215). Spent lead-acid batteries being reclaimed are regulated under 22 CCR §66266.80 and 66266.81, and 40 CFR part 266, Subpart G.
- California law requires state agencies to purchase car batteries made from recycled material (Public Resources Code §42440).
- As of February 8, 2006, household wastes such as batteries, electronic devices and fluorescent light bulbs may not be disposed of in a landfill by anyone.

Existing battery recovery and recycling programs have limited the disposal of batteries in landfills. For example, the recycling of lead-acid and nickel-cadmium batteries is already a well-established activity. Two secondary lead smelters (facilities that recycle lead-bearing materials) are located within the district. Both of these facilities receive spent lead-acid batteries and other lead bearing material and process them to recover lead and polypropylene (from the battery casings). Acid is collected and recycled as a neutralizing agent in the wastewater treatment system.

The availability of secondary lead smelters for battery recycling reduces the potential for the illegal disposal of batteries.

Implementation of the 2012 AQMP would be expected to result in an increased use of electric vehicles (EVs) and hybrid vehicles (hybrids) which use nickel-metal hydride (NiMH) and lithium ion (Li-ion) batteries, instead of lead-acid batteries. The most common battery technologies used in modern EVs and hybrids are NiMH and Li-ion batteries (Hybrid, 2008). EVs and hybrids both use electricity as part of their fuel system. EVs rely purely on electric power stored in batteries. Hybrids also use batteries as part of their fuel supply; however, hybrids supplement their electrical needs by using gasoline engines to generate either mechanical or electric power on demand. Since gasoline is a conventional fuel, any difference in water quality impacts associated with hybrid vehicles would be from the batteries. The electrolyte in NiMH batteries is an alkaline electrolyte, usually potassium hydroxide, the electrolyte in Li-ion batteries is a lithium salt in an organic solvent, while the electrolyte in lead-acid batteries is a sulfuric acid/water blend.

Batteries in hybrids are much larger than batteries in conventional vehicles. The current hybrid batteries weigh about 110 pounds and are composed of NiMH batteries which are charged by an internal combustion engine driven generator and/or by a regenerative braking system that captures power from deceleration and braking. These batteries have a longer life than conventional lead acid batteries. These high voltage batteries are warranted for 10 years or 150,000 miles under California regulations.

The earliest Toyota Prius and Honda Insight and Civic cars were initially sold through the 2003 model year. The batteries associated with these vehicles are just reaching 10 years of age, so most of the battery waste from the first generation of hybrid vehicles has not yet been created. Two recycling firms that will recycle advanced-technology automotive batteries include North American Operations for Umicore, a Belgium-based metals recycling company, and Toxco, ~~a with~~ U.S. company with a number of facilities located throughout the country.

The NiMH batteries found in hybrid vehicles are basically "zero-landfill" products, meaning that whatever cannot be recycled is typically consumed in the recycling process. The primary metals recovered during recycling are nickel, copper and iron. Some principal rare earth metals, neodymium and lanthanum (Edmunds, 2012), are also recovered. Improper disposal of NiMH batteries poses less environmental hazard than that of lead-acid or nickel-cadmium batteries because of the absence of lead and cadmium, which are considered to be toxic. Most industrial nickel is recycled, due to the relatively easy retrieval of the magnetic element from scrap using electromagnets, and due to its high value.

Li-ion batteries are between 70 and 100 percent recyclable, depending on the particular chemistry of the batteries. There are approximately six different types of Li-ion batteries in use, and more are being developed. The battery types available are differentiated by the chemical formulation of the electrodes including, but not

limited to, cobalt dioxide, nickel-cobalt-manganese (NCM), nickel-cobalt- aluminum (NCA), manganese oxide spinel (MnO), and iron phosphate (FePo). The components of Li-ion batteries that cannot be recycled are mostly consumed as fuel in the furnaces that are used to melt down the metals, which include cobalt, copper, iron, nickel, manganese and, in the future, lithium (Edmunds, 2012).

Because Li-ion batteries have a potential for after-automotive use, destructive recycling can be postponed for years even after an EV or hybrid battery can no longer hold and discharge sufficient electricity to power a car's motor, the battery pack can still carry a tremendous amount of energy. Battery manufacturers project that the battery packs will still be able to operate at approximately 80 percent of capacity at the time they must be retired from automotive use. Auto companies are partnering with battery, recycling and electronics firms to figure out and develop post-automotive markets and applications for Li-ion battery packs (Edmunds, 2012).

The switch to electric batteries has the potential to create water quality impacts from improper disposal. However, the increased use of EVs and hybrids will result in a decrease in the use of lead acid batteries, which use sulfuric acid/ blends as electrolytes and have a much shorter lifespan than NiMH or Li-ion batteries. NiMH and Li-ion batteries are generally recycled because the material within the batteries is valuable. Further some manufacturers offer incentives to prevent illegal disposal of the batteries. Toyota offers \$200 per battery to help prevent improper disposal of hybrid batteries.

While the switch to electric batteries has the potential to create water quality impacts from improper disposal, increased use of EVs and HVs will result in a concomitant decrease in the use of internal combustion engines and a reduction in the impacts of such engines. For instance, decreased use of internal combustion engines such as gasoline- or diesel-burning engines will also result in a decreased generation of used engine oil since electric motors do not employ oil as a lubricant.

Specifically, approximately 294,500 tons per year of waste oil was generated in the Basin in 2011 and about 525,300 tons was generated in California in 2005 (see Chapter 3.6, Solid/Hazardous Waste). Because of the widespread use and volume of waste oil, a portion of waste oil is illegally disposed of via sewers, waterways, on land, and disposed of in landfills. Waste oil that is illegally disposed can contaminate the environment (via water, land or air). The CIWMB has estimated that about 20 million gallons of used motor oil is disposed each year in an unknown manner (CIWMB, 2007). In addition, a substantial amount of motor oil leaks onto the highways from vehicles each year. This motor oil is washed into storm drains and eventually ends up in the ocean.

Since electric motors do not require motor oil as a lubricant, replacing internal combustion engines with electric engines will eliminate the impacts of motor oil use and disposal. For example, a 50 percent penetration of light-duty electric vehicles will result in a corresponding 50 percent reduction in the release of these contaminants into the environment due to illegal disposal (50 percent of 20 million

gallons is 10 million gallons). Release of contaminants due to engine oil that burns up in, or leaks from engines or due to burning of recovered engine oil for energy generation will also be correspondingly reduced. Additional use of electric vehicles is expected to have a beneficial environmental impact by reducing the amount of motor oil used, recycled, potentially illegally disposed, or washed into storm drains and ending up in the ocean.

In conclusion, the illegal disposal of electric batteries has the potential to result in significant water quality impacts by allowing toxic metals or acids to leach into surface or ground waters. However, most car batteries are recycled and EV and hybrid batteries are more valuable than lead-acid batteries, which increases the likelihood that these batteries will also be recycled. For this reason, virtually all of the EV and hybrid batteries will be recycled when compared to lead-acid batteries which do not have a comparable recycling value. Therefore, recycling of EV and hybrid batteries will be greater than for lead-acid batteries used in conventional vehicles, reducing the potential for illegal disposal and potential water quality impacts. Based on the foregoing analysis, less than significant adverse water quality impacts are expected from the increased use of EV and hybrid vehicles.

PROJECT-SPECIFIC MITIGATION – ELECTRIC VEHICLES: Less than significant hydrology/water quality impacts were identified from the increased use of electric vehicles as part of the 2012 AQMP so no mitigation measures are necessary or required.

REMAINING IMPACTS – ELECTRIC VEHICLES: The hydrology and water quality impacts associated with increased use of electric vehicles and hybrid vehicles are expected to be less than significant. Thus, no remaining hydrology or water quality impacts are expected from the projected increased use of these vehicles.

4.5.4.4 Water Demand Impacts

PROJECT-SPECIFIC IMPACT – AIR POLLUTION CONTROL EQUIPMENT: There are several control measures that may require or encourage the use of air pollution control technologies that could result in an increased use of water demand from condensers, carbon absorbers, wet scrubbers, and SCRs. As indicated in Table 4.5-1, the 2012 AQMP includes stationary sources that may require add-on control equipment with the potential to increasing water demand (BCM-03, BCM-04, IND-01, and MSC-01). The use of wet ESPs and WGSs would result in an increase in water demand. The extent of the use of these types of control equipment is unknown. However, the use of wet ESPs and WGSs has been shown to be effective at reducing PM_{2.5} emissions.

As mentioned earlier in this chapter, one wet ESP and one WGS were installed on the FCCU at the ConocoPhillips Refinery to control sulfur oxide emissions, as well as PM₁₀ and PM_{2.5} emissions. The environmental analysis for this project indicated that the expected water demand associated with the WGS was about 300 gallon per minute (432,000 gallons per day) (SCAQMD, 2007). The increase in

water use is greater than the significance threshold of 262,820 gallons of potable water per day. If the 2012 AQMP control measures were to encourage the development of 20 additional wet ESP/WGS systems of this size, the potential water demand would also exceed the five million gallon total water significance threshold. Therefore, the 2012 AQMP could result in potentially significant water demand impacts associated with wet ESP and WGS technologies.

The possible control methods for BCM-03 - Emission Reductions from Under-fired Charbroilers, have yet to be determined because cost-effective controls for the majority of under-fired charbroilers have not yet been developed. BCM-03 is focused on controlling PM10 and PM2.5 emissions; thus, water scrubbing or filtering devices could be employed as add on controls for charbroiler exhaust and these devices would require water for their operation. An alternative to these water-based control technologies is the replacement of under-fired charbroilers with a smokeless broiler, which would prevent grease from dripping onto hot burner components while cooking food. A smokeless broiler is estimated to result in a 75 percent reduction in PM10 emissions and a 71 percent reduction in VOC emissions. Thus, compliance with BCM-03 could be achieved by replacing older broilers with newer, more efficient broilers, which would not require water to operate.

Other types of control measures may have several control technology options to use for compliance, and these add-on control equipment options are generally not expected to result in a significant increase in water demand from their use. For example, particulate control devices such as baghouses and dry filters do not utilize water. These types of control technologies are likely to be used on smaller emission sources as they tend to be more cost effective than wet ESPs and WGSs.

Control Measure IND-01, a backstop measure for ports, could employ WGSs (which would require water to operate) for particulate control. However, IND-01 is expected to rely primarily on the use of a variety of other control methods that do not require water for operation, including cold ironing, alternative fuels, PM filters, et cetera. While there is a variety of add-on control technologies available, and not all of these technologies require water for their operation, implementation of some of the control measures proposed in the 2012 AQMP is expected to result in significant adverse water demand impacts in the event that wet ESP/WGS systems are installed on large emission sources. Table 4.5-4 contains a summary of the potential water demand associated with implementing Control Measures BCM-03, BCM-04, IND-01, and MSC-01.

PROJECT-SPECIFIC IMPACTS – REFORMULATED PRODUCTS: Historically, potential water demand to reformulate conventional coatings into waterborne coatings and to clean up waterborne coatings has not resulted in significant adverse impacts on water demand. Using “worst-case” assumptions, increase water demand from implementing the 2012 AQMP has been estimated in Table 4.5-4 for both manufacturers of waterborne coatings and water used by consumers to clean coating equipment. As shown in Table 4.5-4, water demand associated with the manufacture and clean-up of waterborne formulations is

estimated to be 93,821 gallons per day. This increased water demand does not exceed the SCAQMD's significance thresholds of 5,000,000 gallons per day of total water demand or 262,820 gallons per day of potable water demand.

TABLE 4.5-4

Projected Water Demand from 2012 AQMP Control Measures

CONTROL MEASURE	PROJECTED WATER DEMAND ^a (BILLION GAL PER YEAR)	PROJECTED WATER DEMAND WITH 20% REDUCTION ^b (BILLION GAL PER YEAR)	ESTIMATED COATING SALES ^c (GAL PER YEAR)	PROJECTED MFGR WATER DEMAND, ^d (GAL PER YEAR)	PROJECTED CLEAN UP WATER DEMAND, ^e (GALLONS PER YEAR)	TOTAL IMPACT, ^f (GALLONS PER DAY)
CTS-01 Architectural Coatings	2,517	2,014	7,610,000	7,610,000	7,610,000	41,698
CTS-02 Misc. Coatings, Adhesives, Solvents, Lubricants	2,517	2,014	3,805,000	3,805,000	3,805,000	20,849
CTS-03 Mold Release Products	2,517	2,014	1,902,500	1,902,500	1,902,500	10,425
CTS-04 Consumer Products	2,517	2,014	3,805,000	3,805,000	3,805,000	20,849

BCM-03, BCM-04, IND-09, and MSC-01	2,517	2,014	--	--	--	8,640,000 ^g
Total Estimated Water Demand:						8,733,821

a See Table 3.5-1.

b On November 10, 2009, the state Legislature passed Senate Bill 7 as part of the Seventh Extraordinary Session referred to as SBX7-7. This new law is the water conservation component to the historic Delta legislative package, and seeks to achieve a 20 percent statewide reduction in urban per capita water use in California by December 31, 2020. The projected water demand was reduce by 20 percent pursuant to this legislation.

c Architectural coatings are the largest coating category. Miscellaneous Coatings, Consumer products and Consumer Products are assumed to be about 50 percent of the volume of architectural coatings, and mold release products are assumed to be about 25 percent of the volume of architectural coatings. (SCAQMD, 2011.)

d Assumes that one gallon of water would be used to manufacture one gallons of coating applied. This estimate includes the water used in humidifiers and for purging lines. This volume also assumes as "worst-case" scenario, that all affected coatings used in the district were manufactured here and does not take into consideration the fact that some affect coatings are already waterborne coatings

e Assumes that one gallon of water would be used to clean-up equipment for every gallon of coating applied.

f Total amount of manufactured and clean-up water demand.

g Assumes 20 large ESPs/WGS are installed as part of the AQMP.

PROJECT-SPECIFIC CONCLUSION – WATER DEMAND: The water demand associated with certain air pollution control technologies along with the water demand associated with the use of waterborne coatings could exceed 262,820 gallons per day of potable water demand and could potentially exceed the total water demand of five million gallons per day and is therefore, potentially significant. The source of water will vary from jurisdiction to jurisdiction but can include additional use of ground water resources. Most of the ground water basins used for water supply are managed to minimize and prevent overdraft conditions. The increased water demand is expected to be associated with existing sources within the Basin which already have water conveyance infrastructure. Therefore, the construction of new water conveyance infrastructure is not expected to be required.

PROJECT-SPECIFIC MITIGATION – WATER DEMAND: The mitigation measures that would be implemented for water demand impacts would depend on the characteristics of individual projects, the volume of water expected to be used, and could vary amongst jurisdictions. Typical mitigation measures are expected to include the following types of measures:

- HWQ-1: Local water agencies should continue to evaluate future water demand and establish the necessary supply and infrastructure to meet that demand, as documented in their Urban Water Management Plans.
- HWQ-2: Project sponsors should coordinate with the local water provider to ensure that existing or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements. In accordance with State Law, a Water Supply Assessment should be required for projects that meet the size requirements specified in the regulations. In coordination with the local water provider, each project sponsor will identify specific on- and off-site improvements needed to ensure that impacts related to water supply and conveyance demand/pressure requirements are addressed prior to issuance of a certificate of occupancy. Water supply and conveyance demand/pressure clearance from the local water provider will be required at the time that a water connection permit application is submitted.
- HWQ-3: Project sponsors should implement water conservation measures and use recycled water for appropriate end uses.
- HWQ-4: Project sponsors should consult with the local water provider to identify feasible and reasonable measures to reduce water consumptions.

REMAINING IMPACTS – WATER DEMAND: The impacts of the proposed project on water demand are expected to be significant prior to mitigation. While generally the mitigation measures could help minimize some of the water demand, on an individual facility-basis, the availability of water supplies varies throughout the region, thus, not all mitigation measures will be applied in all situations. For this reason, the mitigation measures are not expected to fully eliminate the potential

water demand impacts. Therefore, water demand impacts generated by the proposed project are expected to remain significant.

4.5.4.5 Application and Use of Sodium Bisulfate

PROJECT-SPECIFIC IMPACTS – SODIUM BISULFATE: Control Measure BCM-04 would control ammonia emissions from livestock operations through the application of sodium bisulfate (SBS). SBS is a hygroscopic salt that acts as an acidifier. SBS has been used to reduce pH levels in dairy bedding (e.g., hay or straw) and manure, which in turn reduces bacterial and ammonia levels. In California, SBS, has also been used by dairies in Tulare, Fresno, Merced, Stanislaus, San Joaquin, Kings, Kern, San Bernardino, Riverside, San Benito and Sacramento, to prevent cow lameness and nuisance flies.

When SBS is applied on manure, research indicates that most ammonia reductions occurred during the first day of SBS application and that ammonia emissions continued to decrease with increasing levels of SBS applications. However, after 24 hours, the reduction rates declined and by day three, the ammonia emissions reduction rates were no longer different between dosages. SBS is most effective in reducing ammonia emissions from dairy corrals at either an application rate of 50 pounds per 1,000 square feet, three times per week; or 75 pounds per 1,000 square feet, two times per week.

While SBS is considered an irritant because of its low pH, it is safe for use in water treatment. In particular, SBS has been used as a disinfectant to prevent damage of the membrane used in reverse osmosis during water treatment. SBS is certified for treating drinking water (e.g., for chlorine removal, corrosion and scale control, and pH adjustment). SBS is used to lower the pH of water for effective chlorination, including water in swimming pools. SBS is also approved as a general use feed additive, including companion animal food. Lastly, SBS is used as a urine acidifier to reduce urinary stones in cats.

SBS is considered Generally Recognized as Safe (GRAS) by the Food and Drug Administration (FDA) and meets their definition of a natural product (FDA, 1998). The FDA has approved of SBS as a food additive and food grade SBS bisulfate is used in a variety of food products, including beverages, dressings, sauces, cake mixes, and fillings. It is also widely used in meat and poultry processing and most recently in browning prevention of fresh cut produce.

Because SBS is a salt, the amount of SBS that is applied needs to be reviewed and controlled to prevent SBS contamination of water runoff that could result in water quality impacts and reduced pH levels. SBS use should be carefully considered in areas that are sensitive to salts and/or in areas with existing high salt loading in the soils. Because SBS loses its effectiveness over time, controlled and monitored application rates of SBS are needed to minimize the potential for water runoff and related water quality impacts.

PROJECT-SPECIFIC MITIGATION – SODIUM BISULFATE: Less than significant hydrology/water quality impacts were identified for the potential use of SBS as part of the 2012 AQMP so no mitigation measures are necessary or required.

REMAINING IMPACTS – SODIUM BISULFATE: The hydrology and water quality impacts associated with increased use of SBS are expected to be less than significant. Thus, no remaining hydrology or water quality impacts are expected from the projected increased use of this chemical.

4.5.4.6 Water Quality Impacts Associated with Increased Ammonia Storage

PROJECT-SPECIFIC IMPACTS – AMMONIA STORAGE: As discussed in Subchapter 4.4 – Hazards and Hazardous Materials, a spill of any hazardous materials including ammonia, could occur under upset conditions. Construction of the vessels and foundations in accordance with California Building Code requirements helps structures resist major earthquakes without collapse, but may result in some structural and non-structural damage following a major earthquake. As required by U.S. EPA’s spill prevention control and countermeasure regulations, all affected facilities are currently required to have emergency spill containment equipment and would implement spill control measures in the event of an earthquake. Storage tanks typically have secondary containment such as a berm, which would be capable of containing 110 percent of the contents of the storage tanks. Therefore, should a rupture occur, the contents of the tank would be collected within the containment system and pumped to an appropriate storage tank.

Spills at affected industrial or commercial facilities would be collected within containment structures. Large spills outside of containment areas at affected facilities could occur when transferring the material from a transport truck to a storage tank; these spills are expected to be captured by the process water system where they could be collected and controlled. Spilled material would be collected and pumped to an appropriate tank or sent off-site if the materials cannot be used on-site.

PROJECT-SPECIFIC MITIGATION – AMMONIA STORAGE: Because of the state- and federally-mandated containment system design, spills are not expected to migrate from the facility in a way that would create significant adverse water quality impacts. Since less than significant hydrology/water quality impacts were identified for the potential storage of ammonia, no mitigation measures are necessary or required.

REMAINING IMPACTS – AMMONIA STORAGE: The hydrology and water quality impacts associated with ammonia storage are expected to be less than significant. Thus, no remaining hydrology or water quality impacts are expected from the projected increased storage of this chemical.

4.5.5 Summary of Hydrology and Water Quality Impacts

The following is the summary of the conclusions of the analysis of energy impacts associated with implementation of the 2012 AQMP.

- Wastewater treatment facilities are expected to have sufficient capacity to handle the estimated increase in wastewater that could be generated from reformulation of products and use of air pollution control equipment (e.g., wet ESPs and WGSs). Therefore, less than significant impacts associated with wastewater treatment or water quality is expected.
- The use of alternative fuels is not expected to result in greater adverse water quality impacts than the use of conventional fuels. Less than significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels.
- It is not expected that the recycling of EV and hybrid batteries would be greater than lead-acid batteries in conventional vehicles because although EV and hybrid batteries are typically larger than lead acid batteries, they typically have a much longer lifetime. As a result, potential illegal disposal and potential water quality impacts would be equivalent to, or possibly less for EV and hybrid batteries compared to lead-acid batteries. Therefore, less than significant adverse water quality impacts are expected from the increased use of EV and hybrid vehicles.
- Water demand associated with the manufacture and use of waterborne coatings, solvents, and other consumer products, and add-on air pollution control technologies such as wet ESPs and WGSs are potentially significant. While mitigation measures as available, they can vary from jurisdiction to jurisdiction, but it is expected that impacts would remain significant even after mitigation measures are implemented.
- The use and application of SBS should be controlled and monitored to prevent water quality runoff and related water quality impacts. Therefore, the use of SBS is expected to create less than significant water quality impacts.
- Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills that may affect water quality are expected to be less than significant.
- Summary of PM2.5 Control Measure Impacts: The hydrology and water quality impacts associated with PM2.5 Control Measures are potentially significant for water demand (BCM-03, IND-01, and MCS-01). The hydrology and water quality impacts associated with wastewater generation and related wastewater quality are less than significant. Further, the use and application of SBS (BCM-04) on water quality is also expected to be less than significant.

Summary of Ozone Control Measure Impacts: The hydrology and water quality impacts associated with Ozone Control Measures are potentially significant for water demand (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01). The water quality impacts associated with wastewater generation and related wastewater quality from 2012 AQMP Control Measures (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01) are less than significant. Less than significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels (IND-01, MSC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07). Similarly, less than significant adverse water quality impacts associated with increase battery use in EV and hybrid vehicles are expected (ONRD-01, ONRD-03, ONRD-04, ONRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-06, and ADV-07). Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills are expected to be less than significant.

SUBCHAPTER 4.6

LAND USE AND PLANNING

Introduction

2012 AQMP Control Measures with Potential Land Use Impacts

Significance Criteria

Potential Impacts and Mitigation

Summary of Land Use Impacts

4.6 LAND USE AND PLANNING

4.6.1 Introduction

This subchapter examines impacts on the potential land use impacts associated with implementation of the proposed control measures in the 2012 AQMP.

4.6.2 2012 AQMP Control Measures with Potential Land Use Impacts

All control measures in the 2012 AQMP were evaluated to determine whether or not they could generate land use impacts based on the anticipated methods of control. Control measures that may result in land use impacts are included in Table 4.6-1. Some of the control measures could require construction activities which could generate land use impacts. Specifically, ONRD-05, ADV-01, and ADV-02 propose to advance zero-emission and cleaner combustion emission technologies for on-road heavy-duty vehicles and locomotives. Possible methods associated with these control measures could result in the construction of "wayside" electric or magnetic power built into roadway infrastructure to boost the pulling capacity or range of the heavy-duty vehicles. This may include battery charging or fueling infrastructure as well as transportation infrastructure such as overhead electrical catenary lines.

4.6.3 Significance Criteria

Implementation of the 2012 AQMP will be considered to have significant adverse land use impacts if any of the following conditions occur:

- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.
- Physically divide an established community.

4.6.4 Potential Impacts and Mitigation

Potential land use impacts associated with the 2012 AQMP are associated primarily with the construction of support systems (e.g., catenary overhead electrical lines or magnetic infrastructure related to operation of zero- and near-zero transport systems). For purposes of evaluating potential land use impacts, it has been assumed herein that no new rail or truck traffic routes would be constructed, but rather that existing truck and rail routes/corridors would be modified. The truck and rail corridors likely to be involved with the 2012 AQMP modifications are located primarily in commercial and industrial zones within the Southern California area. Examples of these areas include, but are not limited to, the Port of Los Angeles (e.g., Navy Way) Port of Long Beach, and industrial areas in and around container transfer facilities (railway and truck routes) near the Terminal Island Freeway, along the Alameda Corridor, as well as inland railyards near downtown Los Angeles. Since only existing transportation routes would be modified (e.g., electric lines installed) and no new

transportation routes are anticipated as part of the 2012 AQMP, no land use conflicts, or inconsistencies with any general plan, specific plan, local coastal program, or zoning ordinance are expected.

TABLE 4.6-1

Control Measures with Potential Land Use Impacts

CONTROL MEASURE	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	LAND USE IMPACT
OZONE CONTROL MEASURES			
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace older medium-duty vehicles with low-emitting vehicles.	Construction and operation of wayside power, catenary lines or other similar technologies could generate land use impacts and divide established communities.
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure, construction battery charging and fueling infrastructure.	Construction and operation of battery charging or fueling infrastructure, as well as transportation infrastructure, could generate land use impacts and divide established communities.
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric or magnetic infrastructure, construct battery charging or fueling infrastructure.	Construction and operation of wayside power, catenary lines or other similar technologies could generate land use impacts and divide established communities.

Construction activities would require the use of heavy equipment to install the electric or magnetic systems. Heavy construction equipment such as backhoes, cranes, aerial lifts, front end loaders, and other types of equipment would be required for installation. The electrical or magnetic systems would be installed within or adjacent to existing roadways. These construction activities are expected to occur along heavily travelled roadways (e.g., roads near the ports, such as Sepulveda Boulevard, Terminal Island Freeway, and Alameda Street). Construction activities may require barriers and closures to protect construction workers, prevent unintentional public entrance to the site, and avoid traffic conflicts.

Therefore, it is possible that construction activities could temporarily disrupt or divide a community. However, because construction of new traffic routes/corridors or widening of existing routes/corridors are not part of the proposed project, once construction activities are finished and the physical barriers removed, no long-term land use impacts are anticipated by the project. Therefore, from a land use perspective, none of the above construction impacts are considered to be significant.

The installation of electric and/or magnetic infrastructure is only expected to occur along existing roadways/freeways and transportation corridors (e.g., Sepulveda Boulevard, Terminal Island Freeway, and Alameda Street). These roads and freeways are already

heavily traveled and in many cases already divide existing communities. For example, through portions of Carson and Los Angeles, the Alameda Corridor separates communities and there are a limited number of streets available to cross the Alameda Corridor in an east/west direction. The same is true with respect to Sepulveda Boulevard and the Terminal Island Freeways – both are heavy transportation corridors with limited opportunities to cross these roadways. Installation of electric and/or magnetic infrastructure will not change the existing condition (i.e., there will be limited opportunities to cross these major transportation corridors); however, the installation of the electric and/or magnetic infrastructure is not expected to create any new barriers or physically divide an established community.

Further, the electric and/or magnetic infrastructure would be expected to be construction within or adjacent to the existing rights-of-way of existing streets and freeways, so no conflict with existing land uses, general plans, specific plans, local coastal program, zoning ordinance, or other policies would be expected.

Any proposed modification to an existing rail or truck traffic route/corridor will require a separate CEQA evaluation. As discussed in Chapter 4.9 - Impacts Transportation and Traffic, Section 4.9.5, the traffic management plan should include identification of alternative routes of travel, which will identify a means of connecting established communities that have been temporarily divided by the construction activities associated with the project.

Project-specific Mitigation: No significant land use impacts were identified for the installation of catenary or overhead power lines associated with the 2012 AQMP so no mitigation measures are required.

Remaining Land Use Impacts: The land use impacts from proposed project are not expected to be significant; therefore, no mitigation measures are required.

4.6.5 Summary of Land Use Impacts

The following is the summary of the conclusions of the analysis of the land use impacts associated with implementation of the 2012 AQMP.

The 2012 AQMP control measures are not expected to conflict with applicable land use plans, policies, or regulations or physically divide an established community. Therefore, no significant adverse land use impacts are expected.

Summary of PM_{2.5} Control Measure Impacts: PM_{2.5} Control Measures were evaluated in the NOP/IS and it was determined that the PM_{2.5} Control Measures would not generate any potentially significant land use impacts.

Summary of Ozone Control Measure Impacts: Three Ozone Control Measures could result in the construction of overhead catenary lines; however, the potential land use impacts associated with the Ozone Control Measures were determined to be less than significant, as no land use conflicts were identified.

SUBCHAPTER 4.7

NOISE

Introduction

2012 AQMP Control Measures with Potential Noise Impacts

Significance Criteria

Potential Noise Impacts and Mitigation

Summary of Noise Impacts

4.7 NOISE

4.7.1 Introduction

This subchapter identifies 2012 AQMP control measures that could result in potential adverse noise impacts. Control measures that may have noise impacts are primarily those associated with construction activities.

4.7.2 2012 AQMP Control Measures with Potential Noise Impacts

All control measures in the 2012 AQMP were evaluated to determine whether or not they could generate noise impacts based on the anticipated methods of control. Control measures that may result in noise impacts are included in Table 4.7-1. Construction activities that could be required to implement the following control measures in the 2012 AQMP, BCM-03 - Emission Reductions from Under-Fired Charbroilers, CMB-01 - Further NO_x Reductions from RECLAIM – *Phase I and Phase II*, CMB-02 - NO_x Reductions from Biogas Flares, CMB-03 - Reductions from Commercial Space Heating, IND-01 - Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities, FUG-01 - ~~Further~~ VOC Reductions from Vacuum Trucks, FUG-02 - Emission Reduction from LPG Transfer and Dispensing – Phase II, FUG-03 - Further ~~VOC~~ Reductions from Fugitive VOC Emissions, MCS-01 - Application of All Feasible Measures Assessment, MCS-03 - Improved Start-up, Shutdown and Turnaround Procedures, INC-01 - Economic Incentive Programs to Adopt Zero and Near-Zero Technologies, OFFRD-04 - Further Emission Reductions from Ocean-Going Marine Vessels at Berth, ONRD-03 - Further Emission Reductions from Passenger Locomotives, ONRD-05 - Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards, ADV-01 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles, ADV-02 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives, ADV-03 - Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment, ADV-04 - Actions for the Deployment of Cleaner Commercial Harborcraft, ADV-05 - Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels, and ADV-06 - Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment. Some of the control measures could require construction activities which could generate noise impacts. Specifically, ONRD-03, ONRD-05, and ADV-01 propose to advance zero-emission and cleaner combustion emission technologies for on-road heavy-duty vehicles. Possible methods associated with this control measure could include cleaner engines using technologies such as electric, battery electric, and fuel cells, as well as alternative and renewable fuels. ONRD-03, ONRD-5 and ADV-01 could also result in the construction of "wayside" electric or magnetic power built into roadway infrastructure to boost the pulling capacity or range of the heavy-duty vehicles. This may include battery changing or fueling infrastructure as well as overhead electrical catenary lines. ADV-02 could require electrification of existing rail lines.

TABLE 4.7-1

Control Measures with Potential Secondary Noise Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	NOISE IMPACT
SHORT-TERM PM2.5 CONTROL MEASURES			
BCM-03 <i>(formerly BCM-05)</i>	Emission Reductions from Under-Fired Charbroilers	Add-On Control Equipment with Ventilation Hood Requirements (e.g., ESPs, HEPA filters, wet scrubbers, and thermal oxidizers).	Construction activities associated with air pollution control equipment could generate noise impacts.
IND-01 ^a	Backstop Measure for Indirect Sources of Emissions from Ports and Port-Related Facilities	Environmental lease conditions, port rules, tariffs or incentives.	Control measure could result in construction activities associated with air pollution control equipment and other control strategies that could generate noise impacts.
MCS-01 ^a	Application of All Feasible Measures Assessment	SCAQMD District will adopt and implement new retrofit technology control standards as new BARCT standards become available.	Control measure could result in construction activities associated with air pollution control equipment and other control strategies that could generate noise impacts.
OZONE CONTROL MEASURES			
CMB-01	Further NOx Reductions from RECLAIM – <i>Phase I and Phase II</i>	Selective catalytic reduction, low NOx burners, NOx reducing catalysts, oxy-fuel furnaces, and selective non-catalytic reduction.	Implementation of BARCT technologies could result in construction activities that would generate noise impacts.
CMB-02	NOx Reductions from Biogas Flares (NOx)	Replacement of existing biogas flares with more efficient biogas flares	Replacement of flares could generate construction noise impacts.
CMB-03	Reductions from Commercial Space Heating (NOx)	This control measure seeks emission reductions from unregulated commercial fan-type central furnaces used for space heating.	Replacement of unregulated commercial fan-type central furnaces could generate noise impacts.
FUG-01	Further VOC Reductions from Vacuum Trucks	VOC control devices such as carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers, liquid scrubbers and positive displacement (PD) pumps.	Construction activities associated with air pollution control equipment could generate noise impacts.
FUG-02	Emission Reduction from LPG Transfer and Dispensing – <i>Phase II</i>	Expand applicability of rule to LPG transfer and dispensing at facilities other than those that offer LPG for sale to end users included currently exempted facilities.	Construction activities associated with air pollution control equipment could generate noise impacts.

TABLE 4.7-1 (CONTINUED)

Control Measures with Potential Secondary Noise Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	NOISE IMPACT
OZONE CONTROL MEASURES			
MCS-03	Improved Start-up, Shutdown and Turnaround Procedures (All Pollutants)	Diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability	Construction activities could generate noise impacts.
INC-01	Economic Incentive Programs to Adopt Zero and Near-Zero Technologies (NOx)	Installation of cleaner, more efficient combustion equipment, such as boilers, water heaters and commercial space heating or installation of control technologies including fuel cells, diesel particulate filters (DPF), NOx reduction catalysts, alternative electricity generation, such as wind and solar, battery electric, hybrid electric, and usage of low NOx and alternative fuels such as natural gas.	Replacement of existing combustion equipment and installation of emissions controls could generate noise impacts.
ONRD-03	Accelerated Penetration of Partial Zero Emission and Zero Emission Light-Heavy- and Medium-Heavy-Duty Vehicles [NOx, PM]	Construct "wayside" electric or magnetic infrastructure, construction battery charging and fueling infrastructure.	Construction activities associated with battery charging or fueling infrastructures, as well as transportation infrastructure, could generate noise impacts.
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards (NOx, PM)	Incentives to replace older medium-duty vehicles with low-emitting vehicles.	Construction activities associated with wayside power, catenary lines or other similar technologies could generate noise impacts.
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels at Berth	Shore power of vessels at berth, use of air pollution control technologies on exhaust gases from auxiliary engines and boilers (e.g., SCRs, DPM filters, electric batteries, and alternative fuels).	Construction activities associated with emission control technologies could generate noise impacts.
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure, construction battery charging and fueling infrastructure.	Construction activities associated with battery charging or fueling infrastructures, as well as transportation infrastructure, could generate noise impacts.

TABLE 4.7-1 (CONCLUDED)
Control Measures with Potential Secondary Noise Impacts

CONTROL MEASURE	CONTROL MEASURE TITLE (POLLUTANT)	CONTROL METHODOLOGY	NOISE IMPACT
OZONE CONTROL MEASURES			
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric or magnetic infrastructure, construct battery charging or fueling infrastructure.	Construction activities associated with wayside power, catenary lines or other similar technologies could generate noise impacts.
ADV-03	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment (NOx)	Construct electric gantry cranes, construct battery charging or fueling infrastructure, use of alternative fuels and fuel additives.	Construction activities associated with emission control technologies could generate noise impacts.
ADV-04	Actions for the Deployment of Cleaner Commercial Harborcraft (NOx)	Construct battery charging or fueling infrastructure, use of air pollution control equipment (e.g., SCR, use of alternative fuels and fuel additives).	Construction activities associated with emission control technologies could generate noise impacts.
ADV-05	Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels [NOx]	Construction of control technologies such as SCR and wet/dry scrubbers, use of alternative fuels.	Construction activities associated with emission control technologies could generate noise impacts.
ADV-06	Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment [NOx]	Construct battery charging or fueling infrastructure, increased use of alternative fuels and fuel additives.	Construction activities associated with emission control technologies could generate noise impacts.

- a. The specific actions associated with the control measure are unknown and, therefore, the impacts are speculative. In order to provide a conservative analysis, it is assumed that the control measure could require air pollution control technologies that are similar to those that are currently required (e.g., SCR, electrification, use of alternative fuels, etc.) and would have the potential to require construction activities that would generate noise.

4.7.3 Significance Criteria

Implementation of the 2012 AQMP would be considered to have significant adverse impact on noise or vibration if any of the following conditions occur:

- Construction noise levels exceed the local noise ordinances or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three decibels (dBA) at the site boundary. Construction noise levels will be considered significant if they exceed federal Occupational Safety and Health Administration (OSHA) noise standards for workers.

- The proposed project operational noise levels exceed any of the local noise ordinances at the site boundary or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three dBA at the site boundary.
- Construction and operation would have a significant vibration impact if ground vibration levels for residential structures would exceed 72 VdB for frequent events (70+ vibration events), 75 VdB for occasional events (30-70 events), and/or 80 VdB for infrequent events (e.g., 30 or fewer events) such as the acceptability limits prescribed by the Federal Transit Administration.

4.7.4 Potential Noise Impacts and Mitigation

Construction Activities: Potential noise impacts associated with the 2012 AQMP relate primarily to the construction activities associated with air pollution control equipment and construction of support systems (e.g., wayside power, catenary overhead electrical lines, battery charging or fueling infrastructures related to operation of zero- and near-zero transport systems). Control Measures ONRD-03, ONRD-05, and ADV-01 could require the installation of catenary overhead electrical lines within or adjacent to existing roadways, streets, freeways, and/or transportation corridors. ADV-02 could require the installation of electrical or magnetic infrastructure along rail lines. For purposes of evaluating potential noise impacts, it has been assumed herein that no new rail or truck traffic routes would be constructed, but rather some of these existing routes/corridors will be modified to include catenary overhead electrical lines or magnetic lines. A number of control measures could result in the construction of air pollution control equipment including BCM-03, IND-01, MCS-01, CMB-01, FUG-01, FUG-02, INC-01, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06.

The existing rail and truck routes/corridors likely to be modified are located primarily in commercial and industrial zones within the Southern California area. Examples of these areas include, but are not limited to, the Port of Los Angeles, Port of Long Beach, and industrial areas in and around container transfer facilities (rail and truck) near the Terminal Island Freeway, along the Alameda Corridor, as well inland railyards near downtown Los Angeles. Construction activities may also occur at stationary sources where air pollution control equipment or new equipment may be installed.

Construction activities may require the use of heavy construction equipment. As specific construction projects are not currently proposed, the specific types of construction equipment necessary to implement the proposed control measures are not currently known. The noise levels from typical construction equipment are presented in Table 4.7-2.

The construction equipment noise sources identified in Table 4.7-2 represent typical construction equipment that range from 72 dBA to over 100 ~~decibels~~ (dBA) for activities such as pile driving. The construction equipment, hours of operations, number of pieces of equipment operating at the same time, and construction phases, would vary depending on the specific project; therefore, the construction noise levels are also expected to vary. Each construction phase would use a combination of equipment and personnel that would vary throughout that phase. In addition, construction phases could overlap at the site. This

would lead to a variety of possible construction activities and equipment that may occur at any given time throughout the construction process.

Construction activities would generate noise from heavy construction equipment and construction-related traffic. A typical construction site would be expected to generate noise levels of about 85 dBA at 50 feet from the center of construction activity. Most of the construction noise sources would be located at or near ground level, which would help attenuate noise levels. The estimated noise from a representative construction site at increasing distances from the site is provided in Table 4.7-3.

TABLE 4.7-2

Noise Level Ranges of Typical Construction Equipment

EQUIPMENT	TYPICAL RANGE IN DECIBELS (dBA) ^a
Truck	82-95
Front Loader	73-86
Backhoe	73-95
Vibrator	68-82
Saws	72-82
Pneumatic Impact Equipment	83-88
Jackhammers	81-98
Pumps	68-72
Generators	71-83
Compressors	75-87
Concrete Mixers	75-88
Concrete Pumps	81-85
Pile Driving (peaks)	95-107
Tractor	77-98
Scrapers, Graders	80-93
Pavers	85-88
Cranes	75-89

^a City of Los Angeles, 2006. Levels are in dBA at 50-foot reference distance.

TABLE 4.7-3

Noise Level Attenuation at a Representative Construction Site

DISTANCE FROM CONSTRUCTION NOISE SOURCE	ESTIMATED NOISE LEVEL (dBA)
50	85
100	79
200	73
400	67
800	61
1,600	55
3,200	49
6,400	43

Assuming construction activities of about 85 dBA at 50 feet from the center of construction activity and using an estimated six dBA reduction for every doubling of distance, the noise levels are expected to decrease about 61 dBA at about 800 feet from construction activities.

The potential noise impact of construction activities would vary depending on the existing noise levels in the environment and the location of sensitive receptors (e.g., residents, hotels, hospitals, etc.) from proposed construction activities. Because no specific projects are currently proposed, the noise impacts are speculative. Nonetheless, construction activities associated with control measures in the 2012 AQMP could occur throughout the Basin. The 2012 AQMP may require existing commercial or industrial owners/operators of affected facilities to install air pollution control equipment or modify their existing operations to reduce stationary source emissions. Potential modifications would occur at facilities typically located in appropriately zoned industrial or commercial areas. Installing air pollution control equipment could generate noise impacts, but virtually all of the control equipment would be installed within industrial and commercial facilities, so that construction noise impacts at stationary sources on sensitive receptors are expected to be less than significant.

The 2012 AQMP may also require construction of overhead catenary lines or other similar technologies along existing roadways and transportation corridors. Noise levels from the existing roadways and transportation corridors that could be impacted by these control measures (e.g., ONRD-03, ONRD-05, ADV-01 and ADV-02) are expected to be high as they are heavily traveled transportation corridors (e.g., Terminal Island Freeway and Alameda Street). The construction of catenary lines or similar technologies would result in additional noise sources (e.g., heavy construction equipment) near these transportation corridors. There are residential areas and other sensitive receptors near some of these transportation corridors that include: 1) the western portions of the City of Long Beach near and adjacent to the Terminal Island Freeway and near Sepulveda Boulevard; 2) residents in the City of Wilmington near Alameda Street; and, 3) residents in the City of Carson and other cities and jurisdictions along Alameda Street. Some of these residents are located within several hundred feet of the existing roadways so noise levels associated with construction activities could be in the range of 65-75 dBA, which could result in noise increases of three dBA or greater and generate significant impacts.

Vibration associated with ground-borne sources is generally not a common environmental problem. However, construction activities such as blasting, pile driving, and heavy earth-moving equipment are potential sources of vibration during construction activities. As described for construction noise impacts, some residents are located with several hundred feet of the existing roadways and construction activities could result in noticeable vibration impacts.

Project construction would involve equipment and activities that may have the potential to generate groundborne vibration. In general, demolition of structures during construction generates the highest levels of vibration. The FTA has published standard vibration levels and peak particle velocities for construction equipment operations (FTA, 2006). The approximate velocity level and peak particle velocities for large construction equipment are listed in Table 4.7-4. Ground-borne vibration is quantified in terms of decibels, since that

scale compresses the range of numbers required to describe the oscillations. The FTA uses vibration decibels (abbreviated as VdB) to measure and assess vibration amplitude. In the United States, vibration is referenced to one micro-inch/sec (25.4 micro-mm/sec) and presented in units of VdB.

The FTA recommends using an estimated six VdB reduction for every doubling of distance (FTA, 2006). Using the FTA methodology, the VdB would range from 40 to 82 VdB within 200 feet from construction activities, depending on the type of equipment used. The predicted vibration during construction activities can be compared to the significance threshold of 72 VdB. Vibration from construction activities could exceed the 72 VdB threshold for structures and sensitive receptors within 200 feet of construction activities, if certain types of construction equipment are used. Therefore, vibration impacts associated with construction activities are potentially significant.

TABLE 4.7-4
Representative Construction Equipment Vibration Impacts

EQUIPMENT	APPROXIMATE PEAK PARTICLE VELOCITY AT 25 FT. (INCHES/SECOND)^a	APPROXIMATE VELOCITY LEVEL AT 25 FT. (VdB)^a	APPROXIMATE VELOCITY LEVEL AT 200 FT. (VdB)^a
Pile Driver typical	0.644	100	82
Vibratory Roller	0.210	94	76
Large Bulldozers	0.089	87	69
Loaded Trucks	0.076	86	68
Jackhammer	0.035	79	61
Small Bulldozer	0.003	58	40

a. Source: FTA, 2006. Data reflects typical vibration level.

Construction activities are often limited to daytime hours to prevent noise impacts during the more sensitive nighttime hours. However, transportation-related construction activities often occur during the evening/nighttime hours to minimize traffic impacts during the more heavy traffic periods. For example, construction activities related to catenary overhead lines may occur during the evening/nighttime hours to minimize traffic conflicts, as construction would be expected along existing roads and transportation corridors. Therefore, there is the potential for significant noise and vibration impacts during construction activities.

Workers exposed to noise sources in excess of 90 dBA for an eight-hour period would be required to wear hearing protection devices that conform to Occupational Safety and Health Administration/National Institute for Occupational Safety and Health (NIOSH) standards.

Operational Activities: As discussed above, the 2012 AQMP may require existing commercial or industrial owners/operators of affected facilities to install air pollution control equipment or modify their existing operations to reduce stationary source emissions. Potential modifications would occur at facilities typically located in appropriately zoned industrial or commercial areas. Installing air pollution control equipment on stationary sources could generate noise and vibration impacts, but virtually all of the control equipment would be installed within industrial and commercial facilities. Further, noise

requirements and noise ordinances would continue to apply to stationary sources, so that noise impacts on sensitive receptors are expected to be less than significant.

Wayside electrification/magnetizing could be installed as a result of implementing Control Measures ONRD-03, ONRD-05, ADV-01 and ADV-02. Installation of catenary lines/rail electrification would likely occur along existing transportation corridors and railways and is not expected to require constructing new roadways or corridors. It is not expected that trucks and locomotives using wayside sources of electricity electric would be louder than non-electrified mobile sources. Indeed, electric motors connected to wayside power would likely be quieter than diesel mobile sources because electric motors have fewer moving parts. Further, wayside power would likely be installed on major transportation corridors where noise levels are already high and, often, are the major noise sources in many areas, especially industrial areas and near the ports. Therefore, operational noise and vibration impacts associated with the 2012 AQMP are expected to be less than significant.

Noise Impacts Mitigation: The impact of the proposed project on local noise levels during construction, although temporary in nature, could be significant. In order to mitigate potential noise impacts during construction activities, project-specific information would be necessary in order to first identify the specific impacts (e.g., project location, distance of roadway to be altered, etc.) to develop appropriate mitigation measures.

Ultimately, mitigation measures for construction would need be identified on a project-by-project basis and would be the responsibility of the lead agencies based on their underlying legal authority to mitigate project impacts. For example, in the Draft Program EIR prepared for SCAG's 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy, mitigation measure TR29 (MM-TR29) identifies noise mitigation measures during construction as follows:

NO-1: To reduce noise impacts due to construction, project sponsors may require construction contractors to implement a site-specific noise reduction program, subject to the Lead Agency (or other appropriate government agency) review and approval, which includes the following measures:

- Equipment and trucks used for project construction may utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).
- Except as may be exempted by the Lead Agency (or other appropriate government agency), impact tools (e.g., jack hammers, pavement breakers, and rock drills) used for project construction may be hydraulically or electrically powered to avoid noise associated with compressed air exhaust from pneumatically powered tools. However, where use of pneumatic tools is unavoidable, an exhaust muffler on the compressed air exhaust may be used; this muffler can lower noise levels from the exhaust by up to about 10 dBA. External jackets on the tools themselves may be used, if such jackets are commercially available and this could achieve a reduction of five dBA. Quieter procedures may be used, such as drills rather than impact equipment, whenever such procedures are available and consistent with construction procedures.

- Stationary noise sources may be located as far from adjacent sensitive receptors as possible and they may be muffled and enclosed within temporary sheds, incorporate insulation barriers, or use other measures as determined by the Lead Agency (or other appropriate government agency) to provide equivalent noise reduction.

NO-2: Prior to the issuance of a building permit, along with the submission of construction documents, each project sponsor may submit to the Lead Agency (or other government agency as appropriate) a list of measures to respond to and track complaints pertaining to construction noise. These measures may include:

- A procedure and phone numbers for notifying the Lead Agency staff and local Police Department (during regular construction hours and off-hours);
- A sign posted on-site pertaining with permitted construction days and hours and complaint procedures and who to notify in the event of a problem. The sign may also include a listing of both the Lead Agency and construction contractor's telephone numbers (during regular construction hours and off hours);
- The designation of an on-site construction complaint and enforcement manager for the project;
- Notification of neighbors and occupants within 300 feet of the project construction area at least 30 days in advance of extreme noise generating activities about the estimated duration of the activity; and
- A preconstruction meeting may be held with the job inspectors and the general contractor/on-site project manager to confirm that noise measures and practices (including construction hours, neighborhood notification, posted signs, etc.) are completed.

NO-3: Project sponsor may implement use of portable barriers in the vicinity of sensitive receptors during construction including construction of subsurface barriers, debris basins, and storm water drainage facilities.

NO-4: For projects that require pile driving or other construction noise above 90 dBA in proximity to sensitive receptors, to further reduce potential pier drilling, pile driving and/or other extreme noise generating construction impacts greater than 90dBA, a set of site-specific noise attenuation measures may be completed under the supervision of a qualified acoustical consultant. Prior to commencing construction, a plan for such measures may be submitted for review and approval by the Lead Agency (or other appropriate government agency) to ensure that maximum feasible noise attenuation would be achieved. This plan may be based on the final design of the project. A third-party peer review, paid for by the project sponsor, may be required to assist the Lead Agency in evaluating the feasibility and effectiveness of the noise reduction plan submitted by the project sponsor. The criterion for approving the plan may be a determination that maximum feasible noise attenuation would be achieved. The noise reduction plan may include, but not be limited to, an evaluation of implementing the following measures. These attenuation measures may include as many of the following control strategies as applicable to the site and construction activity:

- Erect temporary plywood noise barriers around the construction site, particularly along on sites adjacent to residential buildings;
- Implement “quiet” pile driving technology (such as pre-drilling of piles, the use of more than one pile driver to shorten the total pile driving duration), where feasible, in consideration of geotechnical and structural requirements and conditions;
- Utilize noise control blankets on the building structure as the structures are erected to reduce noise emission from the site;
- Evaluate the feasibility of noise control at the receivers by temporarily improving the noise reduction capability of adjacent buildings by the use of sound blankets for example and implement such measure if such measures are feasible and would noticeably reduce noise impacts; and
- Monitor the effectiveness of noise attenuation measures by taking noise measurements.

NO-5: Noise generated from any rock-crushing or screening operations performed within 3,000 feet of any occupied residence may be mitigated by the project sponsor by strategic placement of material stockpiles between the operation and the affected dwelling or by other means approved by the local jurisdiction.

NO-6: Where feasible, pile holes may be pre-drilled to reduce potential noise and vibration impacts.

NO-7: As necessary, each project sponsor may retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent historic or other structure subject to damage, and design means and construction methods to not exceed the thresholds.

NO-8: Project sponsors may comply with all local sound control and noise level rules, regulations, and ordinances.

NO-9: As part of the appropriate environmental review of each project, a project specific noise evaluation may be conducted and appropriate mitigation identified and implemented.

Remaining Noise Impacts: The noise impacts from the proposed project are expected to be significant prior to mitigation. While generally mitigation measures could help minimize some of the noise impacts, SCAQMD cannot predict how a future lead agency might choose to mitigate a particular significant noise impact. Thus, the potential exists for future noise impacts to be significant even after feasible mitigation measures are identified and imposed. Therefore, noise impacts that may occur as a result of implementing the 2012 AQMP are expected to remain significant.

4.7.5 Summary of Noise Impacts

The following is the summary of the noise and vibration impacts associated with implementation of the 2012 AQMP.

- Noise and vibration impacts would be temporary in nature and related solely to construction activities, but could be significant.
- No modification to existing rail or truck traffic routes/corridor is expected; therefore, noise and vibration impacts associated with operational activities are expected to be less than significant.

Summary of PM_{2.5} Control Measure Impacts: PM_{2.5} Control Measures were evaluated and it was determined that noise and vibration impacts would be limited to construction activities associated with air pollution control activities. Construction noise/vibration impacts associated with these activities are expected to be less than significant as they will occur within appropriately zoned industrial and commercial areas, impacts are temporary and limited to construction activities, and construction noise/vibration impacts to sensitive receptors would not be expected.

Summary of Ozone Control Measure Impacts: Three Ozone Control Measures could result in the construction of overhead catenary lines. The potential noise/vibration impacts of the Ozone Control Measures during the construction phases were determined to be significant, mitigation measures were imposed, however, construction noise/vibration impacts could remain significant in areas where sensitive receptors are located near transportation corridors.

SUBCHAPTER 4.8

SOLID AND HAZARDOUS WASTE

Introduction

2012 AQMP Control Measures with Potential Solid and Hazardous Waste Impacts

Significance Criteria

Potential Aesthetics Impacts and Mitigation Measures

Project Specific Mitigation

Summary of Solid and Hazardous Waste Impacts

4.8 SOLID AND HAZARDOUS WASTE

4.8.1 Introduction

This subchapter identifies potential solid and hazardous waste impacts that may be generated by implementing the 2012 AQMP. The potential impacts to the generation of solid and hazardous waste associated with the implementation of the 2012 AQMP are described below.

The analysis of solid and hazardous waste impacts assumes that safety and disposal procedures required by various agencies in the state of California will provide reasonable precautions against the improper disposal of hazardous wastes in a municipal waste landfill. Because of state and federal requirements, some facilities are attempting to reduce or minimize the generation of solid and hazardous waste by incorporating source reduction technologies to reduce the volume or toxicity of waste generated, including improving operating procedures, using less hazardous or non-hazardous substitute materials, and upgrading or replacing inefficient processes.

4.8.2 2012 AQMP Control Measures with Solid and Hazardous Waste Impacts

Implementing some of the 2012 AQMP control measures could increase the generation and disposal of solid and hazardous waste in the region. Specifically, some control measures will encourage the use of electric vehicles which could result in an increase in waste associated with spent batteries. Other control measures could increase the generation of solid or hazardous waste due to installation of air pollution control equipment, such as activated carbon, filters, and catalysts. Finally, other control measures would encourage the early retirement of older equipment and replacement with newer and lower emission technology equipment which would generate additional waste. Table 4.8-1 lists the 2012 AQMP control measures with potential adverse solid and hazardous waste impacts through the addition of materials requiring disposal.

Evaluation of control methods for each control measure indicated that there are 23 control measures that could have potential solid and hazardous waste impacts. As shown in Table 4.8-1, three PM_{2.5} control measures and 20 ozone control measures could have significant impacts on solid and hazardous wastes.

TABLE 4.8-1

Control Measures with Potential Solid and Hazardous Waste Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	POTENTIAL SOLID AND HAZARDOUS WASTE IMPACT
Short-Term PM2.5 Control Measures			
CMB-01	Further NO _x Reductions from RECLAIM [NO _x] –Phase I & II	Installation of SCR systems and burner replacement.	Potential increase in solid waste due to burner replacement & SCR catalyst disposal.
BCM-03 <i>(formerly BCM-05)</i>	Emission Reductions from Under-Fired Charbroilers [PM2.5]	Control options include ESPs, HEPA filters, wet scrubbers, and thermal oxidizers.	Potential increase in solid waste associated with air pollution control equipment (e.g., filters).
IND-01 ^a	Backstop Measure for Indirect Sources of emissions from Ports and Port-Related Facilities	Potential control measures include electrification of sources, early retirement of equipment, air pollution control equipment on sources, use of alternative fuels.	Potential increase in solid waste due to early retirement of equipment, solid was associated with air pollution control equipment, EV battery disposal.
MCS-01 ^a	Application of All Feasible Measures Assessment	Implement new retrofit technology control standards as new BARCT standards become available.	Potential increase in solid waste associated with air pollution control equipment (e.g., filters, early retirement of equipment).
Ozone Control Measures			
CMB-02	NO _x Reductions from Biogas Flares	Construction of replacement flares.	Potential increase in solid waste from replacing old flares with new flares.
CMB-03	Reductions from Commercial Space Heating	Burner replacement.	Potential increase in solid waste due to burner replacement.
INC-01	Economic Incentive Programs to Adopt Cleaner, More Efficient Combustion Equipment [All Pollutants]	Control technologies for funding include fuel cells, diesel particulate filters (DPF), NO _x reduction catalysts, alternative electricity generation, such as wind and solar, battery electric, hybrid electric, and usage of low NO _x and alternative fuels such as natural gas.	Potential increase in solid waste due to combustion equipment replacement, generation of solid waste from air pollution control equipment (e.g. used filters), and EV battery disposal.
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles [VOC, NO _x , PM]	Implement rebate incentive program to purchase low-emitting vehicles.	Potential increases in solid waste from EV battery disposal and early retirement of vehicles.
ONRD-02	Accelerated Retirement of Older Light- and Medium-Duty Vehicles [VOC, NO _x , PM]	Continue Enhanced Fleet Modernization Program (EFMP) through 2023.	Potential increase in solid waste generation from early retirement of vehicles and EV battery disposal.
ONRD-03	Accelerated Penetration of Partial Zero Emission and Zero Emission Light-Heavy- and Medium-Heavy-Duty Vehicles [NO _x , PM]	Would continue the state hybrid truck and bus voucher incentive project (HVIP) through 2023. Use of electric and alternative fuel vehicles.	Potential increase in solid waste generation from early retirement of vehicles and EV battery disposal.

TABLE 4.8-1 (CONTINUED)

Control Measures with Potential Solid and Hazardous Waste Impacts

CONTROL MEASURES	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	POTENTIAL SOLID AND HAZARDOUS WASTE IMPACT
Ozone Control Measures			
ONRD-04	Accelerated Retirement of Older On-Road Heavy-Duty Vehicles [NO _x , PM]	Incentives to purchase low-emitting vehicles.	Potential increase in solid waste generation from early retirement of vehicles and EV battery disposal.
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards [NO _x , PM]	Accelerated use of hybrid electric or fuel cell trucks.	Potential increase in solid waste generation from early retirement of vehicles and EV battery disposal.
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment [NO _x]	Extend SOON program from 2014 to 2023. Use of electric and alternative fuel construction/industrial equipment.	Potential increase in solid waste generation from early retirement of equipment and EV battery disposal.
OFFRD-02	Further Emission Reductions from Freight Locomotives [NO _x , PM]	Replace existing engines with Tier 4 engines with control equipment (e.g., SCRs).	Potential increase in solid waste generation from early retirement of locomotive engines, solid waste generated from air pollution control equipment, and EV battery disposal.
OFFRD-03	Further Emission Reductions from Passenger Locomotives [NO _x , PM]	Repower existing engines with Tier 4 engines with control equipment (e.g., SCRs).	Potential increase in solid waste generation from early retirement of locomotive engines, solid waste generated from air pollution control equipment (e.g., DPM filters and catalyst), and EV battery disposal.
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels While at Berth [NO _x , PM]	Calls for increased percentage of ships at berth to cold iron.	Potential increase in solid waste generation from air pollution control equipment (e.g., catalysts) from ships at berth.
ADV-01	Actions for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles [NO _x]	Use of electric and alternative fuel vehicles.	Potential increase in solid waste generation from early retirement of vehicles and EV battery disposal.
ADV-02	Actions for the Deployment of Zero- and Near-Zero Emission Locomotives [NO _x]	Use of electric and alternative fuel locomotives.	Potential increase in solid waste due to locomotive replacement and from EV battery disposal.
ADV-03	Actions for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment [NO _x]	Use of electric and alternative fuel cargo handling equipment.	Potential increase in solid waste due to CHE replacement and from EV battery disposal.
ADV-04	Actions for the Deployment of Cleaner Commercial Harbor Craft [NO _x]	Use of electric and alternative fuel harbor craft and use of control equipment such as SCRs.	Potential increase in solid waste due to harbor craft replacement, EV battery disposal, and disposal of SCR catalyst.

ADV-05	Actions for the Deployment of Cleaner Ocean-Going Marine Vessels [NOx]	Use of electric and alternative fuel marine vessels. Use of control technologies such as SCR, wet/dry scrubbers, etc.	Potential increase in solid waste due to vessel replacement, EV battery disposal, and scrubber/catalyst disposal.
ADV-06	Actions for the Deployment of Cleaner Off-Road Equipment [NOx]	Use of electric and alternative fuel off-road equipment.	Potential increase in solid waste due to off-road equipment replacement and from EV battery disposal.
ADV-07	Actions for the Deployment of Cleaner Aircraft Engines [NOx]	Potential low emission aircraft technologies include alternative fuels, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction.	Potential increase in solid waste due to replacement of aircraft engines and burners.

- a The specific actions associated with the control measure is unknown and, therefore, the impacts are speculative. In order to provide a conservative analysis, it is assumed that the control measure could require air pollution control technologies that are similar to those that are currently required (e.g., SCR, electrification, use of alternative fuels, etc.), and would have the potential to require construction activities that would generate noise.

4.8.3 Significance Criteria

Impacts to solid and hazardous waste facilities will be considered significant if any of the following occur:

- Published national, state, or local standards relating to solid waste are exceeded.
- The generation and disposal of solid or hazardous waste, when combined with existing waste generation, exceeds the capacity of designated landfills.

4.8.4 Potential Impacts and Mitigation

The goal of the 2012 AQMP is to improve air quality, however, some types of air pollution control equipment have the potential to create cross-media impacts. For example, removing pollutants from equipment exhaust streams may produce liquid or solid wastes that may require further treatment or disposal to publicly owned treatment works (POTWs) or landfills, respectively. Specifically, hazardous and non-hazardous waste maybe generated by some types of air pollution control equipment such as electrostatic precipitators, carbon adsorption [units](#), oxidation devices, wet scrubbers, baghouses, and filtration equipment. Several control measures have been proposed in the 2012 AQMP which may require the use of these

types of pollution control equipment (see Table 4.8-1). Solid waste impacts from these control measures are described in the following subsections.

4.8.4.1 Spent Batteries from Electric Vehicles

PROJECT-SPECIFIC IMPACTS: The following control measures encourage early retirement of older vehicles and replacement with electric or hybrid vehicles and could result in an increase in waste generated from batteries: IND-01, INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, and ADV-06. The most common battery currently used in gasoline and diesel powered vehicles within the district is the lead-acid battery found in conventional automobiles and trucks. These batteries are disposed of through the well established lead recycling industry by companies such as Quemetco and Exide in southern California. Zero and Near-Zero Emission Vehicles operate with different battery types than the lead-acid battery. The common battery types available for hybrid and electric powered vehicles are nickel metal hydride (NiMH) and lithium ion (Li-ion).

The 2012 AQMP projects substantial penetration of fuel cell, electric and electric hybrid vehicles by 2023 as part of mobile source pollution control measures. The suggested control measures that have additional requirements for Zero and Near-Zero Emission Vehicles are shown in Table 4.8.2. The batteries that could power these vehicles have useful lives similar to or less than the life of a vehicle. Since some batteries contain toxic materials, the increased use of batteries may result in an incremental increase in solid and hazardous waste impacts. In addition, environmental impacts could occur if batteries were disposed of in an unsafe manner, such as illegal dumping or by disposal in an unlined landfill.

TABLE 4.8-2

Control Measures and Vehicle Retirement Quantities

CONTROL MEASURE	NUMBER OF VEHICLES
ONRD-01 – Incentivize light- and medium-duty trucks	9,000 vehicles
ONRD-02 – Accelerated retirement and replacement of pre-1992 light- and medium-duty vehicles	18,000 vehicles
ONRD-03 – Encourage the introduction of hybrid and zero-emission vehicles	5,000 vehicles
ONRD-04 – Accelerated retirement and replacement of pre-2010 heavy duty vehicles	5,000 vehicles
ONRD-05 – Replace 1,000 trucks with zero-emission vehicles	1,000 vehicles

Source: CEC, 2012a

The primary battery used in hybrid cars is the NiMH type. NiMH batteries are considered to be less toxic than lead-acid batteries. Another type is Li-ion batteries

which are being developed for the next generation of hybrid cars, and may ultimately be the battery to power all electric vehicles. The reason for this is that the Li-ion battery has a higher energy density, allowing them to hold the most energy by weight or by volume. Additionally, the Li-ion battery is less toxic than both the lead-acid and NiMH batteries.

Planning is already underway to deal with tens of thousands of exhausted NiMH batteries from conventional hybrids and Li-ion batteries from electric cars. While there are more than two million conventional and plug-in hybrids and electric cars on the road in the U.S. alone, none have been around long enough to start contributing a meaningful flow of batteries to the recycling industry. Most hybrid batteries seem to be able to outlive the ten-year/100,000-mile warranties that they carried from the automakers, and many battery and automotive industry insiders say there appears to be no reason that Li-ion batteries will not last for 150,000 miles or more (Edmunds, 2012).

Recycling is an important aspect of battery life. The Li-ion batteries used in most EVs and plug-in hybrids, and the NiMH batteries used in most conventional hybrids, are not considered toxic. Both types, unlike conventional 12-volt lead-acid car batteries, are considered safe for landfills. But, since landfill space is at a premium, it is more beneficial for the environment and the economy if spent advanced-technology batteries are reduced to their components, which can be reused instead of being sent to landfills. Automakers, and the auto dismantling industry and its designated recyclers, are posed to handle the recycling of NiMH and Li-ion batteries (Edmunds, 2012).

Recycling is expected to help keep battery costs down because it will permit the reuse of the metals and rare-earth compounds that make these batteries work, which is cheaper than mining and processing all-new material. With Li-ion batteries accounting for as much as half the cost of a new EV, reducing battery costs through recycling will go a long way toward making electric-drive vehicles competitive with conventional cars. Having a market for used batteries will also help increase the resale value of electric-drive vehicles to the benefit of consumers. Additionally, advanced battery recycling helps reduce CO₂ emissions and energy use from processing new material (Edmunds, 2012).

The NiMH batteries found in hybrid vehicles are basically "zero-landfill" products. Whatever cannot be recycled is consumed in the recycling process, leaving no trash behind. The primary metals recovered are nickel, copper and iron. The principal rare earths are neodymium and lanthanum (Edmunds, 2012).

Li-ion batteries now are somewhere between 70 and 100 percent recyclable, depending on the particular chemistry of the batteries. There are approximately six different types in use, and more are being developed. The types are differentiated by the chemical formulation of the electrodes. These types include, but are not limited to, cobalt dioxide, nickel-cobalt-manganese (NCM), nickel-cobalt- aluminum (NCA), manganese oxide spinel (MnO), and iron phosphate (FePo). The

components of Li-ion batteries that cannot be recycled are mostly consumed as fuel in the furnaces that are used to melt down the metals, which include cobalt, copper, iron, nickel, manganese and, in the future, lithium (Edmunds, 2012).

Li-ion batteries have a potential after-automotive use that can postpone destructive recycling for years. Even when an EV or hybrid battery can no longer hold and discharge sufficient electricity to power the car's motor, the pack can still carry a tremendous amount of energy. Battery manufacturers project the packs will still be able to operate at approximately 80 percent of capacity when they must be retired from automotive use. Auto companies are partnering with battery, recycling and electronics firms to figure out and develop post-automotive markets for lithium-ion battery packs (Edmunds, 2012).

For instance, several major power utilities are working with companies, including General Motors, Ford, Toyota and Nissan, to explore the use of the batteries for stationary storage of the power produced in off-peak periods by wind turbines and solar generation stations. Li-ion packs also are being tested as backup power storage systems for retail centers, restaurants and hospitals, as well as for residential solar power systems (Edmunds, 2012).

Two recycling firms have the technology to recycle NiMH and Li-ion batteries. One of these companies is the Belgium-based metals recycling company Umicore, who is preparing for the time when advanced-technology automotive battery recycling companies will be handling battery packs from hundreds of thousands of hybrids and EVs each year. Umicore is the European leader and is expanding in the U.S. The other company, Kinsbursky Brothers, handles most North American advanced automotive battery recycling through a joint venture with longtime battery recycling company Toxco. The Kinsbursky Brothers' Toxco operation appears to be the recycler most widely used by companies that sell hybrids and EVs in North America. The company also receives batteries from carmakers in Europe. (Edmunds, 2012).

Each operation uses a proprietary system and both now are concerned mainly with recycling NiMH batteries. Both companies also are handling small volumes of Li-ion packs as they work with automakers to develop the best recycling processes. Because of the sales pace for EVs and hybrid cars and trucks, it is expected that a commercially viable recycling market would take at least a decade to develop (Edmunds, 2012).

Both companies process batteries from automakers and dismantlers. Battery packs typically have a recycling-information sticker on them so wrecking yards, garages, and car dealers can get instructions for directing "end-of-life" batteries to the proper recycling operation. Toyota offers a \$200-per-pack bounty to encourage dealers and others to turn in spent packs rather than discarding them. Once the packs are at the proper distribution point, the recyclers break down their constituent parts to salvage any wiring, electrical components and plastics that can be separately recycled (Edmunds, 2012).

Currently, Umicore does the initial component separation in Germany and soon will be conducting the process at a North American facility being built in Maxton, North Carolina. The battery cells will continue to be shipped to Umicore's industrial-scale pilot recycling plant in Hoboken, Belgium. The Hoboken facility put the cells through a process that separates their content into metal alloys and a slag that, when NiMH batteries are being recycled, concentrates the rare earth elements they contain. The recycler sells the metals to battery makers for reuse. The rare-earth concentrate from NiMH batteries is sold for reprocessing. Umicore sells the slag from Li-ion batteries to cement makers, who use it as an aggregate that helps strengthen concrete (Edmunds, 2012).

At Toxco, the process also starts by gathering batteries at a variety of collection points from automakers and wrecking yards. The company sends the batteries to facilities in Trail, British Columbia, and Lancaster, Ohio, where they are flash-frozen to ensure that the lithium does not cause a fire when the cells are broken into. Then metal shredders tear them apart. Toxco is increasing capacity at its Ohio facility under a federal grant it received in 2009. The additional space and new equipment will help the company improve the cost-effectiveness of lithium battery recycling (Edmunds, 2012).

Most battery and fuel cell technologies currently employ materials that have high economic value and, therefore, are recyclable. Additionally, both regulatory requirements and market forces require and encourage recycling. The following is a brief listing of some of the more important Federal and California regulations that have created requirements and incentives for the proper disposal and recycling of EV battery packs:

- The federal Battery Act promulgated in 1996 requires that each regulated battery be labeled with a recycling symbol. NiCad batteries must be labeled with the words “NiCad” and the phrase “Battery must be recycled or disposed of properly.” Lead-acid batteries must be labeled with the words “Lead,” “Return,” and “Recycle.”
- Current California and federal regulations require ZEV manufacturers to take into account the complete life-cycle of car batteries and to plan for safe disposal and/or recycling of battery materials.
- The California Health and Safety Code does not allow the disposal of lead-acid batteries at a solid waste facility or on or in any land, surface waters, water courses, or marine waters. Legal disposal methods for used lead-acid batteries are to recycle/reuse the battery or to dispose of it at a hazardous waste disposal facility. A lead-acid battery dealer is required to accept spent batteries when a new one is purchased.
- California Public Resources Code requires state agencies to purchase car batteries made from recycled material.

- The Universal Waste Rule requires that spent batteries exhibiting hazardous waste characteristics and that are not recycled need to be managed as hazardous waste. This includes lead-acid and NiCad batteries.
- Car manufacturers offer incentives to recycle batteries (e.g., Toyota offers \$200 for spent battery packs to help promote battery recycling).

Recycling of lead-acid and nickel-cadmium batteries is a well-established activity. Eighty percent of lead consumed in the United States is used to produce lead-acid batteries and the lead recovery rate from batteries is approximately 80 to 90 percent. The remainder is plastic and fluids (e.g., sulfuric acid). According to the Lead-Acid Battery Consortium, 95 to 98 percent of all battery lead is recycled.

Because most EV batteries are recycled, it is unlikely that the increase in battery use would create a significant adverse affect on landfill capacity in California. As mentioned earlier, electric batteries generally hold significant residual value, and 95 to 98 percent of all lead-acid batteries are recycled. In addition, the electric batteries that would power EVs are packaged in battery packs and cannot be as easily disposed of as a single 12-volt conventional vehicle battery. It should be noted that the increased operation of EVs associated with the implementation of the 2012 AQMP may actually result in a reduction of the amount of solid and hazardous waste generated in the SCAQMD's jurisdiction, as NiMH and Li-ion batteries have a much longer life span than conventional lead-acid batteries. Further, their size (over 100 pounds) makes them more difficult to handle and transport for unauthorized disposal. Additionally, the advanced-technology automotive battery recycling industry is setting up operations in states and countries where processing will have no impact on landfills either locally or within the state. Further, EVs do not require the various oil and gasoline filters that are required by vehicles using internal combustion engines. Furthermore, EVs do not require the same type or amount of engine fluids (oil, antifreeze, etc.) that are required by vehicles using internal combustion engines. Used oil and antifreeze are considered hazardous wastes under California regulations.

Even though batteries are comprised of materials with economic value, the increased use of electric batteries may require efforts at preventing disposal of spent batteries in municipal landfills or via illegal dumping. Illegal or improper disposal of electric batteries could result in significant solid waste impacts by allowing hazardous wastes to be disposed in municipal landfills. However, the recycling of batteries is required under law. Further some manufacturers pay \$200 for used EV/hybrid batteries. The value, size, and length of life of NiMH and Li-ion batteries are such that recycling is expected to be more predominate than with lead acid batteries. Therefore, the use of EVs and hybrids are not expected to result in an increase in the illegal or improper disposal of electric batteries. Further, batteries associated with electric and hybrid cars are required to be recycled. Therefore, no significant increase in the disposal of hazardous or solid waste is expected due to increased use of electric or hybrid vehicles.

PROJECT-SPECIFIC MITIGATION: Based on the above information, neither solid nor hazardous waste impacts from increased use of electric or hybrid cars associated with the 2012 AQMP are expected to exceed the applicable solid and hazardous waste significance thresholds. Therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: There are no remaining solid and hazardous waste impacts since no significant impacts are expected due to increased use of electric or hybrid cars, and therefore, no mitigation measures are required.

4.8.4.2 Solid Waste Impacts Due to Air Pollution Control Technologies

Table 4.8-1 identifies those proposed control measures that may have potential project specific impacts on solid waste due to the addition of pollution control equipment that use filters, catalysts, etc., to collect and control pollutants, which may eventually need to be disposed and/or replaced. The following proposed control measures could potentially require or incentivize the use of pollution control equipment that use filters, catalysts, etc.: Control Measures BCM-03, MCS-01, CMB-01, INC-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-04, and ADV-05. It is difficult to quantify the number of facilities that would employ these types of equipment, the rate of disposal necessary to maintain the equipment, type of waste generated by the equipment (e.g., hazardous or non-hazardous) and the timing by which these technologies would come into use. However, known control technology historically used is examined qualitatively in the following paragraphs.

4.8.4.2.1 *Filters/Precipitators*

PROJECT-SPECIFIC IMPACTS: While it is speculative to identify the number of facilities and the quantity of equipment that would utilize filters/precipitators as a result of the proposed control measures, the quantity of particulate matter collected on filters and from electrostatic precipitators is expected to be small. Diesel particulate filters are estimated to collect about 10 to 150 grams of material per vehicle per year (CARB, 2002) which is expected to be considered as hazardous waste. The amount of material collected from these types of control equipment is expected to be minor as described in the following paragraphs and could be handled within the capacity of existing disposal facilities.

The diesel PM filter system consists of a filter positioned in the exhaust stream designed to collect a significant fraction of the PM emissions while allowing the exhaust gases to pass through the system. Since the volume of PM generated by a diesel engine is sufficient to fill up and plug a reasonably sized filter over time, some means of disposing of this trapped PM must be provided. The most promising means of disposal is to burn or oxidize the PM in the filter, thus regenerating, or cleansing, the filter.

A complete filter system consists of the filter and the means to facilitate the regeneration (if not a disposable type filter).. The exhaust temperature of diesel engines is not always sufficient to initiate regeneration in the filter. However, a number of techniques are available to bring about regeneration of filters. It is not uncommon for some of these various techniques to be used in combination. Some of these methods include:

- Using a catalyst coated on the filter element. The application of a base or precious metal coating applied to the surface of the filter reduces the ignition temperature necessary for oxidation of the particulate;
- Using a NO_x conversion catalyst upstream of the filter to facilitate oxidation of NO to NO₂ which adsorbs on the collected PM, substantially reducing the temperature required to regenerate the filter;
- Using fuel-borne catalysts to reduce the temperature required for ignition of the accumulated material;
- Throttling the air intake to one or more of the cylinders, thereby increasing the exhaust temperature;
- Using fuel burners, electrical heaters, or combustion of atomized fuel by catalyst to heat the incoming exhaust gas to a temperature sufficient to ignite the PM;
- Using periodically compressed air flowing in the opposite direction of the PM from the filter into a collection bag which is periodically discarded or burned; and
- Throttling the exhaust gas downstream of the filter. This method consists of a butterfly valve with a small orifice in it. The valve restricts the exhaust gas flow, adding back pressure to the engine, thereby causing the temperature of the exhaust gas to rise and initiating combustion.

While it is speculative to identify the number of facilities and the quantity of equipment that would utilize filters as a result of the proposed control measures, the quantity of additional filters being disposed of is expected to be small and could be handled within the capacity of existing disposal facilities. Additionally, the volume of particulate material collected on filters is very small (150 grams per vehicle per year). Based on the above considerations, no significant adverse solid and hazardous waste impacts are anticipated to occur from the use of particulate filters or traps.

State law requires hazardous waste generators to attempt to recycle their wastes before disposing them. The Office of Environmental Health Hazards Assessment (OEHHA) has implemented a hazardous waste exchange program to promote the use, reuse, and exchange of hazardous wastes. The program is designed to assist

generators of hazardous wastes to recycle their wastes and encourage the reuse of the wastes. The DTSC also publishes a directory catalog of industrial waste recyclers annually so that industries will know where to buy, sell, or exchange their wastes.

PROJECT SPECIFIC MITIGATION: Based on the above information, neither solid nor hazardous waste impacts from using particulate filters are expected to exceed the applicable significance thresholds because most of the additional waste generated is expected to be relatively small. Therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: Since no significant adverse solid and hazardous waste impacts are expected due to the use of particulate filters, mitigation measures are not required, and solid and hazardous waste impacts remain less than significant.

4.8.4.2.2 *Carbon Adsorption*

PROJECT-SPECIFIC IMPACT: While none of the proposed solid and hazardous waste control measures specifically designate the use of carbon adsorption as air pollution control equipment, some do encourage a variety of options which could include carbon adsorption. Carbon adsorption is used to control VOC emissions primarily from stationary sources. The amount of solid waste, which may be generated by the carbon adsorption process would depend on the number of carbon adsorbers installed, the operating characteristics, and the frequency of carbon replacement. Most of the control measures have alternative methods of compliance (e.g., reformulation of material).

If carbon adsorption systems are used, the amount of hazardous waste generated on an annual basis is expected to be minimal. Most activated carbon used in carbon adsorption control devices is reclaimed and reactivated, resulting in negligible impacts on solid waste disposal facilities. Activated carbon can have a useful lifetime of five to 10 years; however, the operating characteristics of the control device may result in a shorter lifetime.

Spent carbon is usually recycled and reused rather than disposed in landfills. Most facilities contract out with vendors that take the spent carbon and deliver regenerated carbon. Another alternative to the land disposal of regenerated carbon is to burn the spent carbon in a thermal incinerator. With thermal incineration, the organic materials contained in the carbon are oxidized to carbon dioxide, water, and in most cases, harmless combustion by-products. Incineration destroys the toxic constituents and significantly reduces the volume of carbon to be disposed of, thus reducing solid waste impacts. The disadvantage of incineration is that without additional add-on control devices, there may be an increase in criteria pollutant emissions.

Further, it is not expected that carbon adsorption will be used in a majority of the cases where it is as a control option. It is expected that facilities will continue to choose other more cost-effective options to comply with control measures. Based on

these considerations, the solid waste impacts resulting from the use of carbon adsorption are expected to be less than significant.

PROJECT SPECIFIC MITIGATION: Based on the above information, neither solid nor hazardous waste impacts from using carbon adsorption control equipment are expected to exceed the applicable significance thresholds because most of the additional waste generated is expected to be relatively small. Therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: Since no significant adverse solid and hazardous waste impacts are expected due to the use of carbon adsorption control equipment, mitigation measures are not required, and solid and hazardous waste impacts remain less than significant.

4.8.4.2.3 Particulate Traps/Prefilters/Filters/HEPA Filters

PROJECT-SPECIFIC IMPACTS: A number of control measures in the 2012 AQMP could require the collection and disposal of additional particulate matter including BCM-03, MCS-01, INC-01, and OFFRD-03. These measures could result in increased collection of particulate matter that would then need to be disposed.

Baghouses, pre-filters, filters, and HEPA filters collect particulate emissions from stationary and mobile sources of particulate emissions. These types of filtration control equipment can effectively remove particulate matter, including heavy metals, asbestos, as well as other toxic and nontoxic compounds. Polytetrafluoroethylene (PTFE) membranes or HEPA filters can increase a system's removal efficiency up to 99.9 percent. In general, as particulate size decreases, the surface area to volume ratio increases, thus, increasing the capacity of these filters to adsorb smaller particles (including hazardous materials). An increase in the use of membranes and filters may result in an incremental increase of solid waste requiring disposal in landfills over what would be produced if the [2012 AQMP](#) were not adopted. In some cases, waste generated will be hazardous (e.g., the collection of toxic emissions). The increase in the amount of waste generated from the use of filters and the collection of additional particulate matter is expected to be minimal, because filtration control equipment is already used in practice or required by existing rules, especially for stationary sources. Control measures that may include filtration control equipment will generally require increased control efficiencies and/or better housekeeping and maintenance requirements for the filtration devices. As a result the incremental amount of material collected by filters is expected to be small. Further, the larger filters used in baghouses are cleaned and reused, so minimal additional waste would be expected from collecting more PM due to greater efficiency. Therefore, the potential impacts from the use of additional filtration equipment on solid and hazardous waste generation are less than significant.

PROJECT SPECIFIC MITIGATION: Based on the above information, neither solid nor hazardous waste impacts from using baghouses, pre-filters, filters, and HEPA filters are expected to exceed the applicable significance thresholds because

the most of the additional waste generated is expected to be relatively small. Therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: Since no significant adverse solid and hazardous waste impacts are expected due to the use of baghouses, pre-filters, filters, and HEPA filters, mitigation measures are not required, and solid and hazardous waste impacts remain less than significant.

4.8.4.2.4 *Catalytic Oxidation*

PROJECT-SPECIFIC IMPACTS: The 2012 AQMP could result in the increased use of catalytic oxidation to control emissions. The following control measures could rely on catalytic oxidation technologies for emission control: Control Measures CMB-01, OFFRD-03, OFFRD-04, ADV-04, and ADV-05. Catalytic oxidation beds generally use a precious metal to aid in the combustion of air pollutants at relatively low temperatures. Catalytic oxidizers require periodic replacement of the catalyst bed. The expected life of the catalyst is approximately three to five years, depending on the concentration of materials and type of exhaust flows controlled. Metals used in the catalyst are generally recovered because they are made from precious and valuable metals (e.g., platinum and palladium). Metals can be recovered from approximately 60 percent of the spent catalyst generated from the operation of catalytic oxidizers (SCAQMD, 2003a). These metals could then be recycled. The remaining material would most likely need to be disposed of at a hazardous waste landfill.

If the catalyst is not hazardous, jurisdiction for its disposal then shifts to local agencies such as regional water quality control boards (RWQCBs) or county environmental agencies. The RWQCB has indicated that if a spent catalyst is not considered a hazardous waste, it would probably be considered a Designated Waste. A Designated Waste is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state. The type of landfill that the material is disposed at will depend upon its final waste designation. Due to the recycling of catalysts used in catalytic oxidation and the fact that this technology is not expected to be widely used because of cost, no significant impacts on waste disposal are expected.

PROJECT SPECIFIC MITIGATION: Based on the above information, neither solid nor hazardous waste impacts from using catalytic oxidation control technologies are expected to exceed the applicable significance thresholds because the most of the additional waste generated is expected to be relatively small. Therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: Since no significant adverse solid and hazardous waste impacts are expected due to the use of

catalytic oxidation control technologies, mitigation measures are not required, and solid and hazardous waste impacts remain less than significant.

4.8.4.3 Solid Waste Impacts Due to the Retirement of Equipment

Control Measures IND-01, MCS-01, CMB-01, CMB-02, CMB-03, INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, ADV-01, ADV-02, ADV-05, ADV-06, and ADV-07 could result in the early retirement of equipment (e.g., burners, on-road trucks and vehicles, off-road vehicles, gasoline fueled engines, diesel fueled engines, and locomotive and aircraft engines). Solid waste impacts could occur since the older equipment or vehicle parts would be taken out of service in the district and scrapped and disposed of in district landfills. It is expected that some older trucks, vehicles, and locomotive engines could be relocated to other areas, such as Mexico.

Approximately 80 percent of a vehicle can be recycled and reused in another capacity. Batteries, catalytic converters, tires, and other recoverable materials (e.g., metal components) are removed and the metal components of the vehicle are shredded. The shredded material is then sent for recovery of metal content. Therefore, the amount of solid waste landfilled as a result of the proposed control measures would be relatively small since most of the parts being replaced have commercial value as scrap metal. Currently, there are a limited number of vehicles and parts that can be scrapped per year because of the limited number of scrapping and recycling facilities in the district. It is expected that gasoline and diesel engines could also be recycled for metal content, or rebuilt and sold to other areas. It is expected that parts and equipment would be scrapped in the near future, regardless of the [2012 AQMP](#) control measures as they are older vehicles or have older components. The primary solid waste impact is expected to be accelerated replacement and disposal of equipment and parts before the end of their useful life. Further, these control measures are not expected to mandate that older vehicles, engines, or other equipment be scrapped. The control measures are expected to allow a number of different control methods to comply with the required emission reductions. The most cost effective control measures would be expected to be implemented. Control measures that would require new equipment will generally require that retirement occurs as the life of the old equipment is exhausted and new equipment is put into service. Based on the above, scrap metal from vehicle and engine replacements are expected to be recycled and not disposed of in landfills. Any small increase that may occur from miscellaneous parts is expected to be within the total permitted capacity of over 100,000 tons per day for all facilities in the district, so that no significant impacts would be expected.

The California Integrated Waste Management Act of 1989 (AB 939) requires cities and counties in California to reduce the amount of solid waste disposed in landfills by 25 percent by 1995 and by 50 percent by 2000, through source reduction, recycling and composting activities. Later legislation mandates a 50 percent diversion requirement be achieved every year. SB 1016 (Wiggins) – Diversion: Alternative Compliance System (effective January 1, 2009) moves CalRecycle from

the previously existing solid waste diversion accounting system to a per capita disposal based system. SB 1016 does not change the 50 percent requirement in AB 939, rather measures it differently. Compliance is the same under the new system as it was under the old system. To evaluate compliance, CalRecycle will look at a jurisdiction's per capita disposal rate as an indicator of how well its programs are doing to keep disposal at or below a jurisdiction's unique 50 percent equivalent per capita disposal target. The 50 percent equivalent per capita disposal target is the amount of disposal a jurisdiction would have had during the base period had it been at exactly a 50 percent diversion rate. The target is calculated using the average of 2003-2006 per capita generation for each jurisdiction. The generation average is then divided in half to determine the 50 percent equivalent per capita disposal target. This number does not determine compliance. Compliance is based on CalRecycle evaluating that a jurisdiction is continuing to implement the programs it chooses and is making progress in meeting its target (CalRecycle, 2012a).

In 2010, California's statewide disposal was 30.4 million tons and population was 37.2 million residents. This resulted in a per resident disposal rate of 4.5 pounds/resident/day. The rate was the same in 2009 (CalRecycle, 2012c).

Almost all (99 percent) of California's 30.4 million tons of disposed ~~waste~~ waste was ~~were~~ landfilled in California, while approximately one percent was exported to landfills out of state. An additional 0.8 million tons were transformed at three permitted waste-to energy plants in California, but not included in the disposal rate estimate because of provisions in the law that allow limited diversion credit for transformation (CalRecycle, 2012c).

California's disposal of 30.4 million tons in 2010 is a slight decline of 0.7 million tons from 2009. However, it is 13.6 million tons less than the high of 44 million tons in 1989, and 12.1 million tons less than the second highest amount of 42.5 million tons recently recorded in 2005. In 2010, the per employee disposal rate reached a historic low of 11.7 pounds per employee per day, per resident "diversion rate equivalent" was 65 percent, and per employee "diversion rate equivalent" was 63 percent (CalRecycle, 2012c).

In the future, it is anticipated that the California economy will rebound and solid waste generation will increase as people find work, build more, produce more, and buy more. Statewide disposal is expected to increase in the likely event of an economic rebound. If these increased flows of materials are not planned for, they may end up in landfills rather than being recycled back into the economy.

Many cities and counties had not met the 20 and 50 percent waste reduction goals of AB 939 prior to the adoption of the 50 percent equivalent per capita disposal target associated with SB 1016. Table 4.8-3 shows that within the counties within the district as well as statewide, targets are still short of meeting diversion standards. The generation of additional waste associated with control measures in the 2012 AQMP could impact the abilities of cities and counties to further reduce wastes. However, as discussed above the increase in solid waste that is expected to be

diverted to a landfill is small and many of the waste streams are recyclable. Therefore, the 2012 AQMP is not expected to have adverse impacts on landfills.

TABLE 4.8-3

Summary of Per Capita Target Compliance (2010)

LOCATION	NUMBER OF JURISDICTIONS WITHIN LOCATION	NUMBER OF JURISDICTIONS MEETING POPULATION TARGET	PERCENT OF JURISDICTIONS MEETING POPULATION TARGET	NUMBER OF JURISDICTIONS MEETING EMPLOYEE TARGET	PERCENT OF JURISDICTIONS MEETING EMPLOYEE TARGET
State of California	415	18	4%	51	12%
Los Angeles County	74	2	3%	4	5%
Orange County	35	1	3%	2	6%
Riverside County	25	0	0%	4	16%
San Bernardino County	26	0	0%	2	8%

Source (CalRecycle, 2012b)

PROJECT SPECIFIC MITIGATION: Due to the monetary value of scrapped engines, vehicles and equipment, significant solid or hazardous impacts associated with the early retirement of such equipment were not identified, are not significant and, therefore, no mitigation measures are required.

REMAINING SOLID AND HAZARDOUS WASTE IMPACTS: Since no significant adverse solid and hazardous waste impacts are expected due to scrapped engines, vehicles and equipment, mitigation measures are not required, and solid and hazardous waste impacts remain less than significant.

4.8.5 Summary of Solid and Hazardous Waste Impacts

The following is a summary of the conclusions of the analysis of solid and hazardous wastes impacts associated with implementation of the 2012 AQMP.

- **Spent Batteries:** The analysis indicates that no significant solid and hazardous waste impacts associated with spent batteries are likely to occur because due to battery recycling. Lead acid batteries are currently required to be recycled. NiMH and Li-ion batteries more common with EVs and hybrids have a long battery life, are valuable, and usually have a monetary incentive associated with return of the battery to the

manufacturer. Two firms in the United States are currently recycling NiMH and Li-ion batteries. For these reasons, the increased use of EVs and hybrids are not expected to result in a significant increase in the illegal disposal of batteries.

- **Solid and Hazardous Waste Impacts due to Air Pollution Control Technologies:** No significant solid and hazardous waste impacts were identified due to air pollution control technologies as part of the 2012 AQMP. The solid and hazardous waste impacts associated with the use of carbon adsorption are considered less than significant, since spent carbon is usually recycled and reused rather than disposed in landfills. The increase in the amount of waste generated from the use of filters and the collection of additional particulate matter from the control technologies are expected to be minimal as the amount of material collected is small. Finally the impacts associated with catalytic oxidation are not expected to be significant because the catalysts used are largely recycled; therefore, no significant impacts on solid or hazardous waste disposal are expected.
- **Early Retirement of Equipment:** Control measures that would require new equipment can require that retirement occurs as the life of the old equipment is exhausted and new equipment is put into service. For equipment that may be retired before the end of its useful life, that equipment may be reused in areas outside the district. Equipment with no remaining useful life is expected to be recycled for metal content. Therefore, no significant solid and hazardous waste impacts were identified due to implementation of the control measures.

Summary of PM_{2.5} Control Measure Impacts: The impacts associated with PM_{2.5} Control Measures were evaluated and determined to be less than significant for solid and hazardous waste generation (CMB-01, BCM-02, BCM-03, BCM-04, IND-01, EDU-01 and MCS-01).

Summary of Ozone Control Measure Impacts: The Ozone Control Measures were evaluated and determined to be less than significant for solid and hazardous waste generation (CMB-01, CMB-02, CMB-03, INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07).

SUBCHAPTER 4.9

TRANSPORTATION AND TRAFFIC

Introduction

2012 AQMP Control Measures with Potential Traffic Impacts

Significance Criteria

Potential Impacts and Mitigation

Summary of Traffic Impacts

4.9 TRANSPORTATION AND TRAFFIC

4.9.1 Introduction

This subchapter examines impacts on the potential transportation and traffic impacts associated with implementation of the proposed control measures in the 2012 AQMP.

4.9.2 2012 AQMP Control Measures with Potential Traffic Impacts

All of the proposed control measures in the 2012 AQMP were evaluated and only three control measures, ONRD-05, ADV-01, and ADV-02, were found to potentially impact traffic.

ONRD-05 identifies as compliance options zero-emission container movement technologies (e.g., no creation of tailpipe emissions) for vehicles or systems that transport containers between marine ports and near-dock railyards¹. Zero-emission container movement systems include, but are not limited to, on-road technologies such as battery-electric trucks, fuel cell trucks, hybrid-electric trucks with all-electric range and zero-emission hybrid or battery-electric trucks with “wayside” power (such as electricity from overhead wires). The measure could also be implemented by constructing zero-emission fixed guideway systems in the roadway such as electric, maglev or linear synchronous motor propulsion. If implemented, ONRD-05 would require an additional demand for electricity to be powered by grid electricity stored in a battery, by electricity produced onboard the vehicle through a fuel cell, or by “wayside” electricity from outside sources by constructing new overhead catenary lines or wires on roadways between the marine ports and the near-dock railyards.

ADV-01 identifies as compliance options advance on-road freight transport equipment that is powered by clean energy technologies, such as advanced engine controls for more efficient combustion, electric hybrid systems and zero-emission technologies such as electric, battery-electric, and fuel cells, and a greater use of alternative and renewable fuels. Under ADV-01, an additional demand for electricity is also likely and could be supplied by the construction of overhead catenary electrical lines adjacent to and within existing streets and roadways. Lastly, implementation of ADV-01 could also result in the construction of “wayside” electric or magnetic power built into the existing roadway infrastructure to boost the pulling capacity or range of the heavy-duty vehicles as well as battery changing or fueling infrastructure.

ADV-02 focuses on deploying zero- and near-zero emission locomotives. The following technologies could be applied toward achieving zero emissions from freight and passenger locomotives: overhead catenary electrical lines, “wayside” electric or magnetic power built into the existing railway infrastructure, linear synchronous motor technology, battery-hybrid systems, fuel cells, and alternative fuels such as LNG.

Table 4.9-1 contains a summary of these control measures and their corresponding potential traffic impacts.

¹ Near-dock railyards are railyards located less than five miles from marine terminals.

TABLE 4.9-1

Control Measures with Potential Traffic Impacts

CONTROL MEASURE	CONTROL MEASURE DESCRIPTION (POLLUTANT)	CONTROL METHODOLOGY	TRAFFIC IMPACT
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Servicing Near-Dock Railyards (NOx, PM)	Incentives to replace up to 1,000 heavy-duty vehicles with low-emitting vehicles or zero-emission container movement systems.	<p>Potential traffic impacts due to the construction of overhead catenary lines and fixed guideway systems.</p> <p>Potential traffic impacts associated with operation activities associated with transportation infrastructure improvements (e.g., dedicating an existing truck lane exclusive to vehicles using the overhead catenary electrical lines or fixed guideway systems).</p>
ADV-01	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles (NOx)	Construct "wayside" electric or magnetic infrastructure; construct battery charging and fueling infrastructure. Alternatively, if battery, fuel cell or other zero/near zero emission technologies progress sufficiently, the need for wayside power for rail or trucks may be diminished or eliminated.	<p>Potential traffic impacts associated with construction activities to develop electrical-support systems (e.g., overhead catenary electrical lines and battery charging stations) and fueling infrastructure adjacent to and within existing streets and roadways.</p> <p>Potential traffic impacts associated with operation activities associated with transportation infrastructure improvements (e.g., dedicating an existing truck lane exclusive to vehicles using the overhead catenary electrical lines).</p>
ADV-02	Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives (NOx)	Construct "wayside" electric, magnetic, battery-hybrid system, or fuel cell infrastructure, construct battery charging or fueling infrastructure.	Potential traffic impacts from construction of overhead catenary electrical lines, "wayside" electric or magnetic infrastructure.

4.9.3 Significance Criteria

Implementation of the 2012 AQMP will be considered to have significant adverse transportation and traffic impacts if any of the following conditions occur:

- Peak period levels on major arterials are disrupted to a point where level of service (LOS) is reduced to D, E or F for more than one month.
- An intersection's volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- The project conflicts with applicable policies, plans or programs establishing measures of effectiveness, thereby decreasing the performance or safety of any mode of transportation.
- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 employees.
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day.
- Increase customer traffic by more than 700 visits per day.

4.9.4 Potential Impacts and Mitigation

Potential traffic impacts associated with the 2012 AQMP during construction relate primarily to the construction of the following support systems: 1) catenary overhead electrical lines; 2) battery charging stations; 3) fueling infrastructure; 4) "wayside" electric; and, 5) magnetic infrastructure. Potential traffic operational impacts associated with the 2012 AQMP relate primarily to dedicating an existing truck lane exclusive to vehicles using the overhead catenary electrical lines. For purposes of evaluating potential traffic impacts, it has been assumed herein that no new rail or roadways will be constructed, but rather some of the existing routes/corridors may be modified.

PROJECT-SPECIFIC IMPACTS: The existing rail and truck routes/corridors likely to be modified are located primarily in commercial and industrial zones within the Southern California area. Examples of these areas include, but are not limited to, the Port of Los Angeles, Port of Long Beach, and industrial areas in and around container transfer facilities (rail and truck) near the Terminal Island Freeway, along the Alameda Corridor, as well as inland facilities. Since only existing transportation routes would be modified, no new roadways or railways are anticipated as part of the proposed project.

Construction Activities: Implementation of Control Measures ONRD-05 and ADV-01 could require the installation of catenary overhead electrical lines and fixed guideway systems, battery charging stations, and fueling infrastructure within or adjacent to existing roadways, streets, freeways, and/or transportation corridors. Implementation of Control Measure ADV-02 could require the installation of catenary overhead electrical lines or electrical or magnetic infrastructure along rail lines. Construction activities would generate traffic associated with construction worker vehicles and trucks delivering equipment, materials and supplies to the project site during the duration of the construction activities. Heavy construction equipment such as backhoes, cranes, cherry pickers, front end loaders and other types of equipment would be used to carry-out the aforementioned construction activities. Construction activities would be expected to occur within or adjacent to existing roadways which could require lane closures to protect construction workers and avoid traffic conflicts. These construction activities are expected to occur along heavily travelled roadways (e.g., roads near the ports, such as Sepulveda Boulevard, Terminal Island Freeway, on Navy Way at the Port of Los Angeles, and Alameda Street). Construction traffic could potentially result in increased traffic volumes on heavily traveled streets and require temporary lane closures. Construction activities may result in the following impacts:

- Temporary reduction in the level of service on major arterials.
- Temporary closure of a roadway or major arterial.
- Temporary closure of a railroad line.
- Temporary impact on businesses or residents within the construction area.
- Removal of on-street parking.
- Conflicts with public transportation system (e.g., temporary removal of bus stops).

Construction activities necessary to modify existing rail and truck routes/corridors would vary depending on the location, and the specific traffic impacts are unknown. As such, to identify any impacts at this time without knowing the specific design features would be speculative. When the details become available, project-specific impacts would require a separate CEQA evaluation. However, the above listed construction traffic impacts, although temporary in nature, could be significant and result in a reduction of LOS at local intersections and potentially impact roadways within the applicable county's congestion management plan.

Operational Activities: Because Control Measures ONRD-05, ADV-01, and ADV-02 would apply to existing transportation corridors, no new streets, roads, freeways, or rail lines are expected to be needed as part of implementing the 2012 AQMP. However, implementation of Control Measures ONRD-05 and ADV-01 may contribute to significant adverse operational traffic impacts on roadways because transportation infrastructure improvements pertaining to overhead catenary electrical lines could require the dedication of an existing lane exclusive to vehicles using the overhead catenary electrical lines or fixed guideway systems. The dedication of an existing lane would mean that other vehicles would have reduced access to available driving lanes. Thus, a reduction in the number of

available lanes on a roadway to accommodate vehicles using the overhead catenary electrical lines could adversely affect traffic and congestion for all other vehicles on the road.

The number of plug-in hybrid vehicles, battery electric vehicles, and fuel cell vehicles that will be driving on district roadways are projected to substantially increase between year 2013 and year 2025, because Control Measure ONRD-03 would accelerate the penetration of zero emission vehicle trucks (1,000 zero emission vehicle trucks by 2023). This means from 2013 to 2023 there would be approximately 91 more zero emission vehicle trucks per year (e.g., 1,000 trucks per year divided by 11 years equals 91 trucks per year). In addition, Control Measure ONRD-05 calls for 1,000 more zero emission vehicle trucks by 2020. This means approximately 167 additional zero emission vehicle trucks per year from 2015 to 2020. (As a reminder, ONRD-05 only affects trucks going from the ports to near-dock transfer nodes. By definition near-dock means within five miles of the ports.) Table 4.9-2 contains a summary of the projected increases over the baseline of near-zero and zero emission vehicles that may result from implementing Control Measures ONRD-03 and ONRD-05.

TABLE 4.9-2
 Projected Increases Near-Zero and Zero Emission Vehicles
 from ONRD-03 and ONRD-05

YEAR	BASELINE NEAR-ZERO & ZERO EMISSION VEHICLES	ADDITIONAL NEAR-ZERO & ZERO EMISSION VEHICLES FROM ONRD-03	ADDITIONAL NEAR-ZERO & ZERO EMISSION VEHICLES FROM ONRD-03	TOTAL ADDITIONAL VEHICLES FROM ONRD03 + ONRD-05
2013	23,055	91	--	23,146
2014	31,160	91	--	31,251
2015	45,146	91	167	45,404
2016	59,976	91	167	60,234
2017	74,839	91	167	75,097
2018	105,211	91	167	105,469
2019	147,767	91	167	148,025
2020	201,256	91	167	201,514
2021	262,241	91	--	262,332
2022	332,639	91	--	332,730
2023	412,355	91	--	412,446
2024	500,607	--	--	500,607
2025	595,397	--	--	595,397

Source: Communication with ARB Staff, Mobile Source Division, August 14, 2012.

Similarly, implementation of ADV-02 may alter railway traffic due to infrastructure improvements pertaining to overhead catenary electrical lines. However, specific design features are unknown at this time. As such, to identify any impacts at this time without knowing the specific design features would be speculative. Nonetheless, when details of the

project become available, any proposed modifications to an existing rail or truck traffic route/corridor will require a separate CEQA evaluation to analyze specific traffic impacts and identify appropriate mitigation measures. Never-the-less, a reduction in the number of available lanes on a roadway to accommodate vehicles using the overhead catenary electrical lines could adversely affect traffic and congestion for all other vehicles on the road.

PROJECT-SPECIFIC MITIGATION: The impact of the proposed project on traffic and circulation during construction, although temporary in nature, could be significant. In addition, the impact of the proposed project on traffic and circulation during operation, could be significant if an existing roadway is dedicated exclusively as a truck lane for vehicles using the overhead catenary electrical lines or fixed guideway systems because traffic patterns and congestion may be altered. In order to mitigate potential construction and operation traffic impacts, project-specific information would be necessary in order to first identify the specific impacts (e.g., project location, distance of roadway to be altered, etc.) to develop appropriate mitigation measures.

Ultimately, mitigation measures, both for construction and operation, would need be identified on a project-by-project basis and would be the responsibility of the lead agencies based on their underlying legal authority to mitigate project impacts. For example, in the Draft Program EIR prepared for SCAG's 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy, mitigation measure TR29 (MM-TR29) identifies mitigation measures for traffic congestion management during construction as follows:

TT-1: Project sponsors and construction contractors can and should meet with the appropriate Lead Agency (or other government agency) to determine traffic management strategies to reduce, to the maximum extent feasible, traffic congestion and the effects of parking demand by construction workers during construction of this project and other nearby projects that could be simultaneously under construction. The project sponsor should develop a construction management plan for review and approval by the Lead Agency (or other government agency as appropriate). The plan should include at least the following items and requirements:

- A set of comprehensive traffic control measures, including scheduling of major truck trips and deliveries to avoid peak traffic hours, detour signs if required, lane closure procedures, signs, cones for drivers, and designated construction access routes.
- Notification procedures for adjacent property owners and public safety personnel regarding when major deliveries, detours, and lane closures will occur.
- Location of construction staging areas for materials, equipment, and vehicles at an approved location.

- A process for responding to, and tracking, complaints pertaining to construction activity, including identification of an onsite complaint manager. The manager should determine the cause of the complaints and should take prompt action to correct the problem. The Lead Agency should be informed who the Manager is prior to the issuance of the first permit.
- Provision for accommodation of pedestrian flow.
- As necessary, provision for parking management and spaces for all construction workers to ensure that construction workers do not park in on street spaces.
- Any damage to the street caused by heavy equipment, or as a result of this construction, should be repaired, at the project sponsor's expense, within one week of the occurrence of the damage (or excessive wear), unless further damage/excessive wear may continue; in such case, repair should occur prior to issuance of a final inspection of the building permit. All damage that is a threat to public health or safety should be repaired immediately. The street should be restored to its condition prior to the new construction as established by the Lead Agency (or other appropriate government agency) and/or photo documentation, at the sponsor's expense, before the issuance of a Certificate of Occupancy.
- Any heavy equipment brought to the construction site should be transported by truck, where feasible.
- No materials or equipment should be stored on the traveled roadway at any time.
- Prior to construction, a portable toilet facility and a debris box should be installed on the site, and properly maintained through project completion.
- All equipment should be equipped with mufflers.
- Prior to the end of each work-day during construction, the contractor or contractors should pick up and properly dispose of all litter resulting from or related to the project, whether located on the property, within the public rights-of-way, or properties of adjacent or nearby neighbors.

As a single purpose public agency responsible for adopting and enforcing air quality rules and regulations, the SCAQMD's authority to implement mitigation measures for traffic impacts is limited. CEQA is intended to be implemented in conjunction with discretionary powers granted to public agencies by other laws (CEQA Guidelines §14040(a)). Further, the CEQA Guidelines (§15040(b)) specifically state, "CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws." Thus, it is not

feasible for the SCAQMD to identify appropriate project-specific mitigation measures for traffic and transportation impacts in this [Final](#) Program EIR.

Identification and adoption of mitigation of traffic and transportation impacts would primarily be the responsibility of the local general purpose public agency (e.g., city or county) or other agency that would typically serve as the lead agency on any given future project. Thus, appropriate project-specific mitigation measures would have to be identified by the applicable lead agency, such as SCAG's MM-TR29, in the CEQA document prepared for each future project that is proposed. Since MM-TR29 is currently an adopted mitigation measure from SCAG's 2012 – 2035 RTP/SCS, the SCAQMD recommends that it be implemented for all projects that have the potential to affect roadways, including 2012 AQMP Control Measures ONRD-05, ADV-01, and ADV-02.

In conclusion, the SCAQMD cannot predict how a future lead agency might choose to mitigate a particular significant traffic and transportation impact. Because the catenary lines are expected to be utilized in areas where truck traffic is concentrated and could occur in heavy traffic areas (e.g., Alameda Corridor and downtown Los Angeles) the potential exists for future traffic and transportation impacts to be significant and unavoidable (e.g., significant even after feasible mitigation measures are identified and imposed).

REMAINING IMPACTS – USE OF CATALYSTS: The impacts of the proposed project on traffic and transportation are expected to be significant prior to mitigation. While generally mitigation measures could help minimize some of the impacts, SCAQMD cannot predict how a future lead agency might choose to mitigate a particular significant traffic and transportation. Thus, the potential exists for future traffic and transportation impacts to be significant even after feasible mitigation measures are identified and imposed. Therefore, traffic and transportation impacts that may occur as a result of implementing the 2012 AQMP are expected to remain significant.

4.9.5 Summary of Traffic Impacts

The following is the summary of the conclusions of the analysis of the traffic impacts associated with implementation of the 2012 AQMP.

- Construction impacts, though temporary in nature, could be significant.
- Operational impacts could be significant.
- Any proposed modification to an existing rail or truck traffic route/corridor will require a separate CEQA evaluation to identify specific traffic impacts and mitigation measures for that project.

Summary of PM_{2.5} Control Measure Impacts: PM_{2.5} Control Measures were evaluated in the NOP/IS and it was determined that the PM_{2.5} Control Measures would not generate any potentially significant traffic impacts. Since no significant traffic impacts were identified for any of the PM_{2.5} Control Measures, no mitigation measures are required.

Summary of Ozone Control Measure Impacts: Three Ozone Control Measures (e.g., ONRD-05, ADV-01, and ADV-02) could result in traffic impacts due to construction and operation. The potential traffic impacts of these Ozone Control Measures were determined to be significant and mitigation measures would be required. However, it is not feasible to identify appropriate project-specific mitigation measures for traffic and transportation impacts in this [Final](#) Program EIR. Instead, appropriate project-specific mitigation measures will have to be identified in the CEQA document prepared for each future project that is proposed. The analysis concluded that the potential exists for future traffic and transportation impacts to be significant and unavoidable (e.g., significant even after feasible mitigation measures are identified and imposed).

SUBCHAPTER 4.10

OTHER CEQA TOPICS

Growth-Inducing Impacts

Significant Environmental Effects Which Cannot Be Avoided

Relationship Between Short-Term Uses and Long-Term Productivity

Environmental Effects Not Found to Be Significant

4.10 OTHER CEQA TOPICS

4.10.1 Growth-Inducing Impacts

CEQA defines growth-inducing impacts as those impacts of a proposed project that “could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects, which would remove obstacles to population growth” (CEQA Guidelines §15126.2 (d)).

To address this issue, potential growth-inducing effects are examined through the following considerations:

- Facilitation of economic effects that could result in other activities that could significantly affect the environment;
- Expansion requirements for one or more public services to maintain desired levels of service as a result of the proposed project;
- Removal of obstacles to growth through the construction or extension of major infrastructure facilities that do not presently exist in the project area or through changes in existing regulations pertaining to land development;
- Adding development or encroachment into open space; and/or
- Setting a precedent that could encourage and facilitate other activities that could significantly affect the environment.

4.10.1.1 Economic and Population Growth, and Related Public Services

The proposed project would not directly foster economic or population growth or the construction of new housing in the southern California area. The control measures contained in the 2012 AQMP accommodate the projected growth for the region while still resulting in compliance with the federal 24-hour PM_{2.5} ambient air quality standards and making expeditious progress towards attaining the federal one-hour and eight-hour ozone standards. However, the 2012 AQMP would not be the cause of residential, commercial, industrial, and infrastructure development.

A project would directly induce growth if it would directly foster economic or population growth or the construction of new housing in the surrounding environment (e.g., if it would remove an obstacle to growth by expanding existing infrastructure such as new roads or wastewater treatment plants). The 2012 AQMP would not remove barriers to population growth, as it involves no changes to a General Plan, zoning ordinance, or a related land use policy. Alternatively, the 2012 AQMP would not create barriers to projected population growth because it would result in avoiding sanctions or implementation of a Federal Implementation Plan, which could increase the New Source Review emission offset ratio or result in highway funding sanctions.

The 2012 AQMP does not include policies that would encourage the development of new housing or population-generating uses or infrastructure that would directly encourage such uses. The 2012 AQMP may indirectly increase the efficiency of the region's urban form through encouraging more air quality efficient development patterns. The 2012 AQMP does not change jurisdictional authority or responsibility concerning land use or property issues. Land use authority falls solely under the purview of the local governments. The SCAQMD is specifically excluded from infringing on existing city or county land use authority (California Health & Safety Code §40414). Therefore, the 2012 AQMP would not directly trigger new residential development in the area.

The 2012 AQMP may result in construction activities associated with implementation of certain control measures (e.g., control equipment at existing stationary sources or electrification along existing roadways). However, the [2012 AQMP](#) would not directly or indirectly stimulate substantial population growth, remove obstacles to population growth, or necessitate the construction of new community facilities that would lead to additional growth in the Basin. It is expected that construction workers will be largely drawn from the existing workforce pool in southern California.

Considering the existing workforce in the region and current unemployment rates, it is expected that a sufficient number of workers are available locally and that few or no workers would relocate for construction jobs potentially created by the 2012 AQMP as construction activities would be spread over a period of about 10 years. Further, the 2012 AQMP would not be expected to result in an increase in local population, housing, or associated public services (e.g., fire, police, schools, recreation, and library facilities) since no increase in population or the permanent number of workers is expected. Likewise, the proposed project would not create new demand for secondary services, including regional or specialty retail, restaurant or food delivery, recreation, or entertainment uses. As such, the 2012 AQMP would not foster economic or population growth in the surrounding area in a manner that would be growth-inducing.

4.10.1.2 Removal of Obstacles to Growth

The 2012 AQMP is located within an existing urbanized area where adequate infrastructure is already in place to serve the existing surrounding population. The proposed project would not employ activities or uses that would result in growth inducement, such as the development of new infrastructure (e.g., new roadway access or utilities) that would directly or indirectly cause the growth of new populations, communities, or currently undeveloped areas. The 2012 AQMP would require additional energy (electricity and potentially natural gas) but the increased energy requirements are expected to be within those projected for existing population growth of the region. The 2012 AQMP also encourages energy efficiency to minimize energy use. The 2012 AQMP may also result in the construction of overhead catenary lines to electrify existing roadways and transportation corridors. These transportation measures are expected to use existing roadways and are not expected to require the development of new roads or freeways. Likewise, the proposed project would not result in an expansion of existing public service facilities (e.g., police, fire, libraries, and schools) or the development of public service facilities that do not already exist.

4.10.1.3 Development or Encroachments into Open Space

Development can be considered growth-inducing when it is not contiguous to existing urban development and introduces development into open space areas. The proposed project is situated within the existing South Coast Air Basin, which is urbanized. The areas of the Basin where construction activities may occur would be at existing stationary sources and along transportation corridors. Stationary sources are generally located within commercial and industrial (urbanized) areas. Any related construction activities would be expected to be within the confines of the existing facilities and would not encroach into open space. The 2012 AQMP may also result in the construction of overhead catenary lines to electrify roadways and transportation corridors. These transportation measures are expected to use existing roadways and are not expected to require the development of new roads or freeways. Therefore, the 2012 AQMP would not result in development within or encroachment into an open space area.

4.10.1.4 Precedent Setting Action

The 2012 AQMP demonstrates attainment of the federal 24-hour PM_{2.5} standard by 2014 in the Basin through the adoption of all feasible control measures, and also provides updates to the 8-hour ozone control plan. The federal Clean Air Act requires a 24-hour PM_{2.5} non-attainment area to prepare a State Implementation Plan which must be submitted to the U.S. EPA. Therefore, the 2012 AQMP is being prepared to comply with state and federal air quality planning regulations and requirements. These required approvals are routine compliance actions and would not result in precedent-setting actions that might cause other significant environmental impacts (other than those evaluated in other sections of this [Final Program EIR](#)).

4.10.1.5 Conclusion

The 2012 AQMP was developed to comply with state and federal air quality planning requirements. The 2012 AQMP is not expected to foster economic or population growth or result in the construction of additional housing or other infrastructure, either directly or indirectly, that would further encourage growth. The 2012 AQMP could result in construction projects at existing stationary sources and along existing transportation corridors. However, the proposed project would not be considered growth-inducing, because it would not result in an increase in production of resources or cause a progression of growth that could significantly affect the environment either individually or cumulatively.

4.10.2 Significant Environmental Effects Which Cannot Be Avoided

Section 15126.2 (b) of the CEQA Guidelines requires that an EIR describe significant environmental impacts that cannot be avoided, including those effects that can be mitigated but not reduced to a less than significant level. Irreversible changes include a large commitment of nonrenewable resources, committing future generations to specific uses of the environment (e.g., converting undeveloped land to urban uses), or enduring environmental damage due to an accident. The following is a summary of impacts associated with the 2012 AQMP that this [Draft-Final Program EIR](#) concluded are significant

and unavoidable. These impacts are also described in detail in the preceding portions of Chapter 4.0 of this [Final Program EIR](#).

- Air quality impacts associated with construction activities due to the implementation of the control measures in the 2012 AQMP were considered to be potentially significant for CO and PM10 emissions.
- The increased demand for electricity and natural gas associated with the 2012 [AQMP](#) control measures is considered to be significant.
- Water demand associated with the manufacture and use of waterborne coatings, solvents and other consumer products, and add-on air pollution control technologies are potentially significant. While mitigation measures are available, they can vary from jurisdiction to jurisdiction, and may remain significant.
- The potential hazards associated with LNG transport are considered significant.
- Noise and vibration impacts will be temporary in nature and related solely to construction activities, but could be significant.
- Traffic impacts associated with the construction and operation of catenary overhead electrical lines and fixed guideway systems are potentially significant.

Feasible mitigation measures have been developed for the identified adverse significant impacts; however, those mitigation measures may not reduce the impacts to less than significant. The 2012 AQMP would place only an incremental demand on nonrenewable and limited resources, such as energy and water supplies relative to the rate of use of these resources due to population growth and increased consumer demand. The largely irretrievable conversion of undeveloped/agricultural land to urban uses is a function of the growing population and local land use authority, not the 2012 AQMP. The 2012 AQMP is expected to result in long-term benefits associated with achieving ambient air quality standards and a reduction in the use of petroleum-based fuels (e.g., increased use of alternative fuels).

Conversely, positive environmental changes are expected to result from implementation of the 2012 AQMP. The project will result in significantly reduced emissions of air pollutants, thereby improving air quality and related public health. Emission reductions will also directly improve the vitality of crops and other plants. The health of livestock, domestic animals and other wildlife will be indirectly enhanced by the positive effects on plant life, as well as by any direct benefits attributable to less air pollution. The damage to buildings and other structures attributable to air pollution also will be diminished, as well as an improvement in aesthetics and visibility.

4.10.3 Relationship Between Short-Term Uses and Long-Term Productivity

An important consideration when analyzing the effects of a proposed project is whether it will result in short-term environmental benefits to the detriment of achieving long-term

goals or maximizing productivity of these resources. Implementing the 2012 AQMP is not expected to achieve short-term goals at the expense of long-term environmental productivity or goal achievement. The purpose of the 2012 AQMP is to set forth a comprehensive control program that will lead the Basin into compliance with the federal 24-hour PM_{2.5} air quality standards and achieving additional reductions in ozone precursors. By attaining federal and state air quality standards, the 2012 AQMP is expected to enhance short and long-term environmental productivity in the region.

Implementing the 2012 AQMP does not narrow the range of beneficial uses of the environment. Of the potential environmental impacts discussed in Chapter 4, only those related to air quality impacts associated with construction activities, water demand, noise impacts associated with construction activities and traffic impacts associated with construction activities, are considered potentially significant. Implementation of the recommended mitigation measures will ensure such impacts are mitigated to the greatest degree feasible.

Because no short-term environmental benefits are expected at the expense of long-term environmental goals being achieved, there is no justification for delaying the proposed action. This project must be implemented now as the SCAQMD is required by the Federal and state Clean Air Acts to formally review the [2012 AQMP](#) and adopt relevant plan revisions which will achieve the state and federal ambient air quality standards by the established deadline. The SCAQMD is proceeding with the 2012 AQMP pursuant to this mandate.

4.10.4 Environmental Effects Not Found to Be Significant

The environmental effects of the 2012 AQMP are identified and discussed in detail in the preceding portions of Chapter 4 of this [Final Program](#) EIR and in the Initial Study (see Appendix A) per the requirements of the CEQA Guidelines §15128. The following topics of analysis in this [Final Program](#) EIR were found to have no potentially significant adverse effects, after mitigation:

- Aesthetic impacts associated with implementation of the control measures in the 2012 AQMP.
- Air quality impacts associated with implementation (operation) of the control measures in the 2012 AQMP.
- Energy impacts associated with implementation of the control measures in the 2012 AQMP.
- Hazards and hazardous materials impacts associated with implementation of the control measures in the 2012 AQMP.
- Hydrology and water quality impacts associated with implementation of the control measures in the 2012 AQMP (other than water demand).

- Land use impacts associated with implementation of the control measures in the 2012 AQMP.
- Noise impacts associated with implementation of the control measures in the 2012 AQMP (other than construction activities).
- Traffic impacts associated with implementation of the control measures in the 2012 AQMP (other than construction activities).
- Solid and hazardous waste impacts associated with implementation of the control measures in the 2012 AQMP.

While all the environmental topics required to be analyzed under CEQA were reviewed to determine if the proposed amendments would create significant impacts, the screening analysis (see Appendix A for the NOP/IS) concluded that the following environmental areas would not be significantly adversely affected by 2012 AQMP: agriculture and forest resources, biological resources, cultural resources, geology and soils, mineral resources, population and housing, public services, and recreation. These topics were not analyzed in further detail in this environmental assessment, however, a brief discussion of each is provided below.

4.10.4.1 Agricultural and Forest Resources Impacts

In general, the 2012 AQMP control measures typically affect existing commercial or industrial facilities, establish specifications for fuels or mobile source exhaust emissions, or accelerate the replacement of high-emitting mobile sources with low emitting mobile sources so they are not expected to generate any new construction of buildings or other structures that would require conversion of farmland to non-agricultural use or conflict with zoning for agricultural uses or a Williamson Act contract. Further, the 2012 AQMP control measures typically affect existing facilities that are located in appropriately zoned areas. Any new facilities that may be affected by the 2012 AQMP control measures would be constructed and operated for reasons other than complying with the 2012 AQMP control measures. For these same reasons, it is not expected that implementing 2012 AQMP control measures will conflict with any forest land zoning codes or convert forest land to non-forest uses. No control measures were identified in the proposed 2012 AQMP that would affect or conflict with existing land use plans, policies, or regulations or require conversion of farmland to non-agricultural uses or forest land to non-forest uses.

Land use, including agricultural- and forest-related uses, and other planning considerations are determined by local governments and no agricultural land use or planning requirements will be altered by the proposed project, except as noted above. The 2012 AQMP control measures, including control measures related to mobile sources, would have no direct or indirect effects on agricultural or forest land resources because these types of control measures typically involve reduction in combustion and fugitive VOC emissions, as well as establishing emission

Based upon the above considerations, significant adverse impacts to agricultural and forestland resources are not expected due to implementation of the 2012 AQMP.

4.10.4.2 Biological Resources Impacts

The effects of implementing [the 2012 AQMP](#) control measures typically include reducing mobile source exhaust emissions; modifying fuel specifications; or modifications at existing commercial or industrial facilities to control or further control emissions, which may require some type of construction equipment and activities. Any affected existing commercial or industrial facilities are generally located in appropriately zoned commercial or industrial areas, which typically do not support candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service. Typically, existing industrial or commercial facilities are already devoid of plant life or plant life supporting wildlife species for fire safety reasons. Any new industrial or commercial facilities that may be affected by [the 2012 AQMP](#) control measures and that have the potential to adversely affect biological resources would be constructed and operated for reasons unrelated to complying with [the 2012 AQMP](#) control measures.

Similarly, modifications at existing facilities would not interfere substantially with the movement of any native resident or migratory fish or wildlife species or with native or resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites because implementing [the 2012 AQMP](#) control measures typically occurs within the boundaries of the affected facilities and, therefore, would not require disturbing wildlife habitat. For these same reasons, since the proposed 2012 AQMP primarily regulates stationary emission sources at existing commercial or industrial facilities, it does not directly or indirectly affect land use policy that may adversely affect riparian habitat or other sensitive natural communities identified in local or regional plans, policies, or regulations, or identified by the California Department of Fish and Game or U.S. Fish and Wildlife Service. It is expected that industrial or commercial facilities that may be affected by 2012 AQMP control measures are already located in appropriately zoned areas or would be located in appropriately zoned areas. [The 2012 AQMP](#) control measures do not include any provisions that would allow affected facility operators to violate existing zoning ordinances or regional plans, policies, or regulations. Improving air quality is expected to provide health benefits to plant and animal species in the district. Similarly, the 2012 AQMP contains control measures that establish emission standards for mobile sources or accelerated penetration of low emission vehicles, which could result in additional control of emissions from mobile sources or revision to existing fuel specifications. As a result, the proposed project would not affect land use policies or designations. There are no control measures contained in the 2012 AQMP that would alter this determination.

Implementing some [of the 2012 AQMP](#) control measures (e.g., coatings and solvent control measures) could change or increase a facility's potential to generate waste water. Past SCAQMD staff experience with analyzing modifications at industrial or commercial facilities is that they are considered "point sources" and must release wastewater into publicly owned treatment works (POTWs) (e.g., local sewer systems), and, therefore, are subject to National Pollutant Discharge Elimination System (NPDES) permit program

administered by the Regional Water Quality Control Board (RWQCB). Direct discharge into federally protected wetlands as defined by §404 of the Clean Water Act would be prohibited under federal law (Clean Water Act) and state law (Porter-Cologne Act) and, therefore, is not expected to occur. Some of the 2012 AQMP control measures have the potential to require air pollution controls at port facilities, which are located on the coast. Port facilities are considered to be heavy industrial facilities (point sources) and the installation of additional controls would be consistent with this land use. Further, any facilities that release wastewater into California's ocean waters are subject to water quality standards established in the California Ocean Plan and are also subject to NPDES requirements, enforced by the local RWQCBs. For all of the above reasons the proposed project will not adversely affect protected wetlands as defined by §404 of the Clean Water Act, including, but not limited to marshes, vernal pools, coastal wetlands, etc., through direct removal, filling, hydrological interruption or other means.

Implementing the proposed 2012 AQMP is not expected to affect land use plans, local policies or ordinances, or regulations protecting biological resources such as a tree preservation policy or ordinance for the reasons given in discussions above, i.e. control measures promulgated as rules or regulations primarily affect existing commercial and industrial facilities through installation of air pollution control equipment, which are typically located in appropriately zoned areas or activities that would accelerate the penetration of low emission vehicles into the regional vehicle fleet. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Neither SCAQMD nor CARB has legal authority over land use decisions except to impose certain air pollution control requirements, which do not drive the land use approval process, and, therefore, cannot alter or interfere with land use zoning ordinance or designations and cannot approve new land use projects or modifications to existing land use projects. Similarly, the proposed 2012 AQMP is not expected to affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities for the reasons discussed above.

Based upon the above considerations, significant adverse impacts to biological resources are not expected due to implementation of the 2012 AQMP.

4.10.4.3 Cultural Resource Impacts

Implementing the proposed 2012 AQMP control measures is primarily expected to result in controlling stationary source emissions at existing commercial or industrial facilities or accelerate the penetration of low emission vehicles into the regional vehicle fleet. Affected facilities where physical modifications may occur are typically located in appropriately zoned commercial or industrial areas that have previously been disturbed and are not typically considered to be historically significant. It is unlikely that construction activities, including heavy construction activities, such as cut-and-fill activities or excavation, at potentially affected existing facilities would uncover cultural resources as these existing facilities are located in previously disturbed areas. Some affected facilities (e.g., refineries) may have equipment older than 50 years that may need to be modified to comply with 2012 AQMP control measures. However, such equipment does not typically meet the criteria

identified in CEQA Guidelines §15064.5 [\(a\)\(3\)](#). Based on these considerations, it is unlikely that implementing control measures in the proposed 2012 AQMP would: adversely affect historical or archaeological resources as defined in CEQA Guidelines §15064.5, destroy unique paleontological resources or unique geologic features, or disturb human remains interred outside formal cemeteries.

In spite of the fact that most facilities that would be affected by 2012 AQMP control measures are located on previously disturbed sites where there is little likelihood of any remaining identifiable artifacts, it is possible, that implementing control measures could result in construction activities to install pollution control equipment at affected existing facilities that uncover cultural or archaeological resources. Even if this circumstance were to occur, significant adverse cultural resources impacts are not anticipated because there are existing laws in place that are designed to protect and mitigate potential adverse impacts to cultural resources. As with any construction activity, should archaeological resources be found during construction that results from implementing the proposed [2012 AQMP](#) control measures, the activity would cease until a thorough archaeological assessment is conducted as required by state or federal law.

The proposed 2012 AQMP is, therefore, not anticipated to result in any construction activity or promote any programs that could have a significant adverse impact on cultural resources in the district.

4.10.4.4 Geology and Soils Impacts

The proposed 2012 AQMP control measures would not directly or indirectly expose people or structures to earthquake faults, seismic shaking, seismic-related ground failure including liquefaction, landslides, mudslides or substantial soil erosion for the following reasons. In general, [the 2012 AQMP](#) control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets, would not affect geology or soils because for on-road vehicles, they would continue to operate on existing roadways (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.). Although some [of the 2012 AQMP](#) control measures would accelerate the penetration of zero or low emission off-road equipment, replacing one type of off-road engine with a lower emitting off-road engine would not be expected to affect construction activities. Further, construction activities occur for reasons other than complying with [the 2012 AQMP](#) control measures.

When implemented as rules or regulations, [the 2012 AQMP](#) control measures regulating stationary sources do not directly or indirectly promote new land use projects that could be located on earthquake faults, seismic zones, etc. Any seismic-related activities in areas where facilities that may be subject to [the 2012 AQMP](#) control [measures](#) are located would be part of the existing setting. Some minor structural modifications, however, at existing affected facilities may occur as a result of installing control equipment or making process modifications. Such modifications would not likely require large heavy-duty construction equipment or substantial site modifications. In any event, existing affected facilities or modifications to existing facilities would be required to comply with relevant California

Building Code (formerly referred to as the Uniform Building Code) requirements in effect at the time of initial construction or modification of a structure.

Southern California is an area of known seismic activity. Structures must be designed to comply with the California Building Code requirements if they are located in a seismically active area. The local city or county is responsible for ensuring that a proposed project complies with current California Building Code requirements as part of the issuance of the building permits and can conduct inspections to ensure compliance. The California Building Code is considered to be a standard safeguard against major structural failures and loss of life. The goal of the code is to provide structures that will: 1) resist minor earthquakes without damage; 2) resist moderate earthquakes without structural damage but with some non-structural damage; and 3) resist major earthquakes without collapse but with some structural and non-structural damage.

The California Building Code bases seismic design on minimum lateral seismic forces (“ground shaking”). The California Building Code requirements operate on the principle that providing appropriate foundations, among other aspects, helps to protect buildings from failure during earthquakes. The basic formulas used for the California Building Code seismic design require determination of the seismic zone and site coefficient, which represent the foundation conditions at the site. Accordingly, buildings and equipment at existing affected facilities are likely to conform to the California Building Code and all other applicable state codes in effect at the time they were constructed.

Any potentially affected facilities that are located in areas where there has been historic occurrence of liquefaction (e.g., coastal zones) or existing conditions indicate a potential for liquefaction, including expansive or unconsolidated granular soils and a high water table, may have the potential for liquefaction-induced impacts at the project sites. The California Building Code requirements consider liquefaction potential and establish more stringent requirements for building foundations in areas potentially subject to liquefaction. Compliance with the California Building Code requirements is expected to minimize the potential impacts associated with liquefaction. The issuance of building permits from the local cities or counties will assure compliance with the California Building Code requirements. Finally, [none of the 2012](#) AQMP control measures require the location of new, or relocation of existing facilities in areas prone to liquefaction. Land use decisions are under the authority of the local jurisdictions, typically cities or counties. Neither the SCAQMD nor CARB has authority over land use decisions except to impose specific air pollution control requirements, which do not drive the land use approval process, and CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws (CEQA Guidelines §15040 (b)).

Because facilities affected by any [of the 2012](#) AQMP control measures are typically located in appropriately zoned areas such as industrial or commercial areas, which are not typically located near known geological hazards (e.g., landslide, mudflow, seiche, tsunami or volcanic hazards), no significant adverse geological impacts are expected. Even if potentially affected facilities are located near such geological hazards, the hazards are part of the existing setting and are not made worse by installing control equipment or other activities to comply with emission control rules and regulations. For example, tsunamis at

the Port of Los Angeles and Port of Long Beach, are not expected because the ports are surrounded by breakwaters that protect the area from wave action. In any event, [the 2012 AQMP](#) control measures would not increase potential exposures to tsunamis.

Although the proposed 2012 AQMP control measures may require minor modifications at existing industrial or commercial facilities, such modifications are not expected to require substantial grading or construction activities. Typically, existing facilities have already been graded and soil stabilization is already in place (e.g., through the placement of buildings, paving, or other soil stabilization measures currently required pursuant to SCAQMD Rule 403 – Fugitive Dust). In other cases, potentially affected areas may have already been graded or displaced in some way for other reasons (e.g., leveling the site, stabilization of slopes, etc.). Accelerating the penetration of low emission vehicles into the regional vehicle fleet, (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles, etc.), does not require modifications requiring construction activities at existing facilities. Therefore, significant adverse soil erosion impacts are not anticipated from implementing the 2012 AQMP.

Septic tanks or other similar alternative waste water disposal systems are typically associated with small residential projects in remote areas. The proposed 2012 AQMP does not contain any control measures that generate construction of residential or other types of land use projects in remote areas. Neither the SCAQMD nor CARB has land use approval authority. Consequently, construction of small residential land uses with septic systems would occur for reasons other than complying with [the 2012 AQMP](#) control measures. Further, [the 2012 AQMP](#) control measures typically affect existing industrial or commercial facilities that are already hooked up to appropriate sewerage facilities and are subject to wastewater control requirements, typically through NPDES permits.

Based on these considerations, implementation of the 2012 AQMP is not expected to generate significant adverse geology and soils impacts.

4.10.4.5 Mineral Resources Impacts

There are no provisions of the proposed 2012 AQMP that would directly result in the loss of availability of a known mineral resource of value to the region and the residents of the state, such as aggregate, coal, clay, shale, etc., or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan. Moreover, the 2012 AQMP is not expected to deplete non-renewable mineral resources in a wasteful manner.

Based upon the above considerations, significant adverse impacts to mineral resources are not expected due to implementation of the 2012 AQMP.

4.10.4.6 Population and Housing Impacts

According to SCAG, current population in the SCAG region (which includes all of the district, the non-district portions of Los Angeles and San Bernardino counties, and all of Ventura and Imperial counties) is approximately 18 million people and is expected to

increase by another four million people by 2035. The proposed 2012 AQMP generally affects existing commercial or industrial facilities located in predominantly industrial or commercial urbanized areas throughout the district and, as such, is not anticipated to generate any significant effects, either directly or indirectly, on the district's population or population distribution.

Consistent with past experience, it is expected that the existing labor pool within the southern California area would accommodate the labor requirements for any modifications requiring construction at affected facilities. This is especially true in the current recession. For example, California has a seasonally adjusted unemployment rate of 10.9 percent. Unemployment rates (not seasonally adjusted) in each of the four district counties are as follows: Los Angeles County, 11.5 percent; Orange County, 8.1 percent; Riverside County, 12.8 percent, and San Bernardino County, 12.1 percent.

It is expected that few or no new employees would need to be hired at affected facilities to operate and maintain new control equipment on site because air pollution control equipment is typically not labor intensive equipment. In the event that new employees are hired, it is expected that the existing local labor pool in the district can accommodate any increase in demand for workers that might occur as a result of adopting the proposed 2012 AQMP. Based on the above, it is not expected that the 2012 AQMP would induce population growth resulting in the need for new housing, roads or other infrastructure. As such, adopting the proposed 2012 AQMP is not expected to result in changes in population densities or induce significant growth in population.

In general, [the 2012 AQMP](#) control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles, etc.), would not induce population growth because there is a finite number of drivers in the region at any one time, so drivers who purchase low or zero emission vehicles would not be driving the old high emitting vehicles at the same time they are driving the new low emitting vehicles. Although projected increases in population in the region may result in the continued use of the replaced high emitting vehicles, as already noted, future population growth in the region would occur for reasons other than complying with [the 2012 AQMP](#) control measures.

There are no provisions in any [of the 2012 AQMP](#) control measures that would cause displacement of substantial numbers of people or housing necessitating construction of replacement housing elsewhere. As noted in the discussions under "Land Use and Planning, the proposed 2012 AQMP contains control measures that may result in installing control equipment on stationary sources at existing commercial or institutional facilities and establishing emission exhaust specifications for mobile sources. Construction of new structures affecting land use planning would occur for reasons other than complying with [the 2012 AQMP](#) control measures. As a result, the proposed 2012 AQMP would not be expected to affect the location of people or housing in any areas of the district.

Based upon the above considerations, significant adverse population and housing impacts are not expected to occur due to implementation of the 2012 AQMP.

4.10.4.7 Public Services Impacts

There is little potential for significant adverse public service impacts as a result of adopting the proposed 2012 AQMP. The 2003 AQMP EIR analyzed potential adverse impacts to public services as a result of implementing [the 2003 AQMP](#) control measures and concluded that existing resources at services such as fire departments, police departments and local governments would not be significantly adversely affected as a result of implementing [the 2003 AQMP](#) control measures even if there are slight increases in potential flammability impacts from implementing [the 2003 AQMP](#) control measures. Similarly, the 2007 NOP/IS concluded that implementing [the 2007 AQMP](#) control measures would not significantly adversely affect fire departments, police departments and local governments for the same reasons as identified in the 2003 Program EIR, which include the following considerations. Although implementing [the 2012 AQMP](#) control measures may increase the use of alternative clean fuels, for example, there would be a commensurate reduction in currently used petroleum fuels. As first responders to emergency situations, police and fire departments may assist local hazmat teams with containing hazardous materials, putting out fires, and crowd control to reduce public exposures to hazardous materials releases. In many situations, implementing [the 2012 AQMP](#) control measures may reduce hazardous materials use (e.g., formulating coatings with less hazardous aqueous formulations). Some [of the 2012 AQMP](#) control measures may increase the use of air pollution control equipment that uses hazardous materials. In spite of this, there are no components of any control measures that would result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times or other performance objectives. Further, most large industrial facilities have on-site security that controls public access to facilities so no increase in the need for police services are expected. Many large industrial facilities also have on-site fire protection personnel and/or have agreements for fire protection services with local fire departments. Even in the absence of onsite police or fire protection services, implementing [the 2012 AQMP](#) control measures in no way hinders service ratios or response times and is not expected to require physical modifications to existing government facilities to a greater extent than is currently the case. Finally, pursuant to the Health and Safety Code, emergency or rescue vehicles operated by local, state, and federal law enforcement agencies, police and sheriff departments, fire department, hospital, medical or paramedic facility, and used for responding to situations where potential threats to life or property exist, including, but not limited to fire, ambulance calls, or life-saving calls are specifically exempt from regulations requiring alternative clean fueled vehicles. For these reasons, implementing the 2012 AQMP is not expected to require additional fire protection services to an extent that it would cause a need for construction of new facilities.

As indicated in the discussions under Population and Housing, the 2012 AQMP is not anticipated to affect population growth in the district, which would not be expected to adversely affect existing public services or facilities or physically alter, require new public service facilities, or alter the demand for schools. Anticipated development to accommodate future population growth would occur for reasons other than complying with [the 2012 AQMP](#) control measures. To address future growth it is the responsibility of local land

public agencies with general land use authority, typically cities or counties, over fire departments, police departments and other public services to address potential impacts to public services that may require new or physically altered facilities or affect service ratios, response times, or other performance objectives. Consequently, no significant adverse impacts to schools or parks are foreseen as a result of adopting the proposed 2012 AQMP.

Based upon the above considerations, significant adverse project-specific public services impacts are not expected to occur due to implementation of the 2012 AQMP.

4.10.4.8 Recreation Impacts

As discussed under “Land Use and Planning” and “Population and Housing” above, there are no provisions in the proposed 2012 AQMP that would affect land use plans, policies, ordinances, or regulations. Land use and other planning considerations are determined by local governments. No land use or planning requirements, including those related to recreational facilities, will be altered by the proposal. The proposed project does not have the potential to directly or indirectly induce population growth or redistribution that could adversely affect recreational resources. As a result, the proposed project would not increase the use of, or demand for existing neighborhood and/or regional parks or other recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment.

Based upon the above considerations, no significant adverse project-specific impacts to population and housing are expected to occur due to implementation of the 2012 AQMP.

5.0 CUMULATIVE IMPACTS

CEQA Guidelines §15130 (a) requires an EIR to discuss cumulative impacts of a project when the project's incremental effect is cumulatively considerable, as defined in [CEQA Guidelines](#) §15065 (a)(3). The 2012 AQMP is a regional plan that includes broad policy criteria and as such, the 2012 AQMP [Final](#) Program EIR evaluates the environmental impacts associated with implementing the 2012 AQMP stationary and mobile source control measures to determine whether or not the impacts of the project are cumulatively considerable when combined with potential impacts associated with other similar regional projects involving regulatory activities or other projects with similar impacts.

5.1 INTRODUCTION

The cumulative impacts analysis for the 2012 AQMP [Final](#) Program EIR includes the analyses of the SCAQMD's stationary and mobile source control measures and the regulatory activities associated with other measures that could also generate impacts within the Basin. The traffic control measures (TCMs) in the 2012 AQMP (see Appendix IV-C of the [Revised Draft](#) 2012 AQMP and Appendix E of this [Final](#) Program EIR) were developed and adopted by SCAG as part of the 2012-2035 RTP/SCS¹ and the 2011 Federal Transportation Improvement Program (FTIP) (SCAG 2012).

SCAG's Regional Council approved the TCMs and strategies included in the 2012-2035 RTP/SCS Program EIR and the investment commitments contained in the 2008 RTIP and its subsequent amendments. These measures and recommendations have accordingly been moved forward for inclusion in the region's air quality plans and are included as part of the 2012 AQMP. The impacts of implementation of these TCMs were evaluated in the 2012-2035 RTP/SCS Program EIR (SCAG, 2012). The cumulative analysis in this section of the Final Program EIR for the 2012 AQMP relies primarily on the environmental analyses in the SCAG 2012-2035 RTP/SCS Program EIR for the evaluation of the environmental impacts of implementing the TCMs.

Because the TCMs, their associated mitigation measures², and their emissions reductions are included along with the 2012 AQMP in the PM_{2.5} SIP submittal for the Basin and because the TCMs and other projects in the 2012-2035 RTP/SCS have the potential to generate similar impacts, the 2012-2035 RTP/SCS is considered to be a cumulatively related project. In general, the long-term transportation planning requirements for emission reductions from on-road mobile sources within the district are met by SCAG's RTP/SCS, whereas the short-term implementation requirements of the Transportation Conformity Rule are met by SCAG's biennial Regional Transportation Improvement Program (RTIP) (SCAG 2010).

¹ Under SB 375, SCAG addresses GHG reduction in a Sustainable Communities Strategy (SCS) as part of the Regional Transportation Plan. SB 375 was established to implement the state's GHG emissions reduction goals, as set forth by AB 32, in the sector of cars and light trucks. SCS is intended to provide a vision for future growth in Southern California that would decrease per capita GHG emissions from passenger vehicles.

² [In addition to summarizing impacts from the 2012-2035 RTP/SCS, this document includes a list of all measures identified in the 2012-2035 RTP/SCS Program EIR to mitigate environmental impacts from that project for informational purposes only. The PEIR for the 2012-2035 RTP/SCS, which includes all of the mitigation measures in Appendix F, was previously certified in April 2012.](#)

In general, TCMs are those control measures that provide emission reductions from on-road mobile sources, based on changes in the patterns and modes by which the regional transportation system is used. Strategies that have a particular bearing on the environment can be grouped into the following components:

- **Active Transportation:** This strategy integrates land use and transportation by working with sub-regions and local communities to increase development densities and improve the jobs/housing balance. Implementing this strategy encourages walking, biking, and transit use, thereby reducing vehicular demand and environmental impacts.
- **Transportation Demand Management (TDM):** This strategy reduces vehicular demand and thereby congestion, particularly during peak periods. TDM measures are designed to influence travel behavior and include use of transit, bicycling, and walking, carpools and telecommuting, strategies that allow travelers to easily connect to and from transit service at their origin and destination, vanpool services for larger employers, and rideshare matching services.
- **Transportation Systems Management (TSM):** This strategy increases the productivity of the existing multi-modal transportation system and relies in part on intelligent transportation system (ITS) technologies such as automated vehicle location (AVL) and advanced monitoring systems, which assist in achieving system efficiencies in ports and intermodal operations, reduce delays and wait times at gates and destinations, and allow for more flexible dispatching, thereby reducing emissions.
- **Congestion Management Process (CMP):** This strategy manages congestion by requiring that highway capacity projects that significantly increase the capacity for single occupancy vehicles be developed in a comprehensive context that considers all possible alternatives, including transit, TDM and TSM strategies.
- **High Occupancy Vehicle (HOV) Gap Closures and Connectors:** This strategy builds upon the previous HOV strategy by including additional investments to extend the HOV network, strategically close gaps in the HOV network, convert certain limited access HOV lanes to allow for continuous access, and construct additional direct freeway-to-freeway HOV connectors to maximize the overall system performance by minimizing weaving conflicts and maintaining travel speeds.

The following sections summarize the project-specific and cumulative impacts analyses from the Final Program EIR for the 2012-2035 RTP/SCS. The discussions also summarize project-specific impacts from the 2012 AQMP. The discussions also include an evaluation regarding whether or not impacts from the 2012 AQMP contribute to cumulative impacts from the 2012-2035 RTP/SCS, which have already been evaluated in a Program EIR certified by SCAG.

5.2 AESTHETICS

5.2.1 Cumulative Aesthetic Impacts

Implementation of the 2012 AQMP is not expected to result in potentially significant adverse aesthetic impacts because [the 2012 AQMP](#) control measures relate primarily to emission reductions through the incorporation of electrically powered trucks and locomotives. Although, to power this equipment, catenary lines (overhead power lines) could be needed, areas where catenary lines may be constructed would be limited to commercial, industrial areas, along existing transportation corridors, and at existing railyards. The 2012 AQMP [Final Program EIR](#) determined that construction and operation of such lines would not substantially degrade the existing visual character of a site or its surroundings, impact existing scenic vistas, or impact any scenic resources, including scenic highways.

According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS would adversely affect aesthetics and views. Expected significant impacts would include the obstruction of scenic views and vista points due to the construction of highways, flyovers, interchanges, goods movement roadway facilities, and sound walls for anticipated RTP/SCS transportation projects, which would potentially block or impede views of mountains, oceans, or rivers. In addition, implementation of the 2012-2035 RTP/SCS would alter areas along state designated scenic highways and vista points, in particular along SR-91 through Riverside and Orange Counties and along SR-14 as part of the High Desert Corridor, connecting Palmdale and the Antelope Valley to Santa Clarita.

Implementing the 2012-2035 RTP/SCS is expected to create significant contrasts with the overall visual character of the existing landscape setting and possibly add urban visual elements to an existing natural, rural, and open space area. In particular, the Gold and Crenshaw Light Rail Lines would travel through urban neighborhoods with distinct character and may be located adjacent to historic resources depending on the final alignments. The wires, structures and other elements associated with light rail would change the character of these areas. Increased urbanization through taller buildings or more compact development could have a similar effect by changing the low-scale nature of a particular neighborhood. Transit centers and park-n-ride lots, constructed primarily within the heavily urbanized portions of the SCAG region, could also affect a large number of viewers.

Implementing the 2012-2035 RTP/SCS would create shade and shadow or light and glare impacts when tall newly constructed elevated transportation infrastructure projects cast a shadow on nearby shadow sensitive areas, such as eating or playing areas. Population growth in the region would also potentially create contrasts with the overall visual character of the existing landscape because some urban land would have increased intensity of use and because currently vacant and undeveloped land would be developed into urban uses.

Because implementation of the 2012-2035 RTP/SCS would include the extension of transportation and related infrastructure to areas outside the region and, as such, would indirectly result in changes to the visual character or to scenic areas outside of the SCAG

region, the 2012-2035 RTP/SCS would contribute to a cumulatively considerable loss of scenic resources.

The analysis of potential aesthetics impacts from implementing the 2012 AQMP in Subchapter 4.1 of this Program EIR concluded that the 2012 AQMP would not in itself generate significant adverse aesthetic impacts. Further, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with transportation projects projected in the 2012-2035 RTP/SCS, would not contribute to cumulatively considerable impacts to aesthetic resources identified in the 2012-2035 RTP/SCS because potential aesthetic resources impacts identified in the 2012-2035 RTP/SCS Program EIR are different than the potential aesthetics impacts that could be generated by the 2012 AQMP and, geographically, there is no overlap between the 2012 AQMP projects that may affect aesthetics resources and aesthetic resources impacts created by the 2012-2035 RTP/SCS.

5.2.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse aesthetic impacts. However, because implementation of the 2012-2035 RTP/SCS is expected to generate significant adverse impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.2.3 Level of Impact After Mitigation Measures

Potential aesthetics resources impacts from the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation as the population growth projected by 2035 in combination with projects identified in the 2012-2035 RTP/SCS would consume currently vacant land that would create significant contrasts with the overall visual character of the existing landscape setting. Moreover, the 2012 AQMP would not contribute to that impact as noted in Subsection 5.2.1, so adverse cumulative operational aesthetics resources impacts are concluded to be less than significant.

5.3 AGRICULTURAL RESOURCES

5.3.1 Cumulative Agricultural Resources Impacts

Impacts to agricultural resources were considered and fully evaluated in the August 2, 2012 Notice of Preparation/Initial Study (8/2/12 NOP/IS) prepared for the 2012 AQMP. As concluded in the 8/2/12 NOP/IS, implementation of the 2012 AQMP is not expected to result in significant adverse impacts to the agriculture resource because [the 2012](#) AQMP control measures typically affect existing commercial or industrial facilities or establish specifications for fuels or mobile source exhaust emissions and as such are not expected to generate new construction of buildings or other structures that would require conversion of farmland to non-agricultural use or conflict with zoning for agricultural uses. No comment

letters were received by the SCAQMD during the 8/2/12 NOP/IS comment period disputing this conclusion.

Agricultural resources were considered under the combined category of Land Use and Agricultural Resources section in the 2012-2035 RTP/SCS Program EIR³. According to the 2012-2035 RTP/SCS Program EIR, implementing the proposed 2012-2035 RTP/SCS transportation projects would result in substantial disturbance and/or loss of prime farmlands or grazing lands throughout southern California. Furthermore, development of highway, arterial, and transit projects proposed under the 2012-2035 RTP/SCS would result in the disturbance and/or loss of a substantial portion of these designated agricultural areas. The 2012-2035 RTP/SCS specifically calls out highway expansion and potential connector projects such as the High Desert Corridor project, the mixed flow Express/High Occupancy Toll (HOT) lane project along SR-395, as well as roadway improvements, toll road improvements and connections, grade separated facilities for bus ways, goods movement roadway facilities, and HOV/HOT connectors as projects which could result in significant impacts to agricultural lands.

In total, the 2012 RTP/SCS would result in approximately 74,300 total new lane miles by 2035, some of which would potentially disturb or consume agricultural lands in the region. The loss and disturbance of agricultural land was concluded to be a significant impact of the 2012-2035 RTP/SCS Program EIR.

Impacts to agricultural resources were determined to be below the level of significance in the 8/2/12 NOP/IS. Furthermore, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, the 2012-2035 RTP/SCS would not contribute to a cumulatively considerable impact to agricultural resources requiring mitigation.

5.3.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse agricultural impacts and does not contribute to the impacts identified in the 2012-2035 RTP/SCS Final Program EIR. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.3.3 Level of Impact After Mitigation Measures

Potential agricultural resources impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would contribute to significant loss and disturbance of agricultural lands. Moreover, the 2012 AQMP would not

³ The topic of forestry resources was not evaluated in the Final Program EIR for the 2012-2035 RTP/SCS.

contribute to these impacts as noted in Subsection 5.3.1, so adverse cumulative operational agricultural resources impacts are concluded to be less than significant.

5.4 AIR QUALITY

5.4.1 Cumulative Air Quality Impacts

Construction Impacts: Implementation of the 2012 AQMP is expected to result in potentially significant adverse air quality impacts associated with: 1) additional infrastructure to support electric and alternative fuel vehicles; 2) additional infrastructure for stationary source controls; and, 3) additional infrastructure to support electrification of new sources.

According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS transportation projects would result in substantial construction activities. The construction activities would create short-term temporary emissions from the following activities: 1) demolition; 2) site preparation operations (e.g., grading/excavation); 3) fuel combustion from the operation of construction equipment; 4) delivery and hauling of construction materials and supplies to and from sites; 5) the use of asphalt or other oil based substances during the final construction phases of projects; and, 6) travel by construction workers to and from sites.

Construction activities associated with the 2012 AQMP would result in significant impacts to the air quality resource and any concurrent emissions-generating activities from reasonably foreseeable construction activities would add an additional air emission burden to these significant levels. Therefore, construction air quality impacts from the 2012 AQMP are considered to be cumulatively considerable prior to mitigation and would contribute to significant adverse cumulative impacts from the 2012-2035 RTP/SCS.

Operational Impacts - Criteria Pollutants: The 2012 AQMP is expected to result in an emission reduction in NO_x, VOC, SO_x, and PM emissions, providing an air quality benefit. As shown in Figure 4.2-3, the 2012 AQMP is expected to attain the 24-hour federal PM_{2.5} standard by 2014. The 2012 AQMP also is expected to: 1) implement specific measures to implement Clean Air Action Section 182 (e)(5) to assist in attaining the eight-hour ozone standard by 2023; 2) maintain compliance with state and federal NO₂ standards (even considering the increase in population growth); 3) maintain compliance with state and federal SO₂ standards (even considering the increase in population growth); and, 4) maintain compliance with the federal 24-hour average PM₁₀ standard.

Control measures from the 2012 AQMP are expected to increase the demand for electrical energy associated with operation of add-on control equipment, electrical support facilities for on-road vehicles and off-road vehicles, and shore-side electricity associated with “cold ironing” of marine vessels. While these control measures may cause an increase in emissions from power plants used in electricity production, overall emissions in the Basin would be reduced because combustion emissions from natural gas, used to produce electricity, are lower than combustion emissions from gasoline or diesel engines. The 2012 AQMP [Final](#) Program EIR concluded that overall the net emissions effects from

implementing 2012 AQMP control measures would be a reduction and that no significant adverse impacts to air quality are expected from 2012 AQMP control measures requiring increased demand for electricity or natural gas.

The 2012 AQMP control measures associated with control of stationary sources are expected to result in a small increase in CO and NO_x emissions. However, the 2012 AQMP would achieve enough NO_x reductions overall to maintain ambient air quality standards. Also, although a potential exists for secondary particulate formation from ammonia slip, in selective catalytic reduction (SCR) applications used to control NO_x emissions from stationary sources, the 2012 AQMP [Final](#) Program EIR concluded that no new or substantially more severe significant air quality impacts related to ammonia emissions and secondary particulate formation from the increased use of SCR systems is expected.

Several 2012 AQMP control measures would reduce VOC emissions by reformulating or specifying utilization of certain VOC-containing products. The 2012 AQMP [Final](#) Program EIR concluded that air quality impacts from implementing future coatings rules would result in an overall reduction of VOC emissions and would be beneficial to air quality.

Control measures in the 2012 AQMP would also reduce emissions from mobile sources by accelerating the penetration of partial zero-emission and zero emission vehicles and off-road equipment, accelerating the replacement of old locomotive engines, increasing the amount of shore-side marine power, accelerating the replacement of aircraft engines with cleaner burning engines, increasing the use of alternative fuels, and increasing the use of add-on control devices. The 2012 AQMP [Final](#) Program EIR concluded that estimated VOC, CO, NO_x, SO_x, PM₁₀, and PM_{2.5} emissions associated with on-road mobile sources in the district are expected to be reduced and that the overall impact of mobile source control measures is expected to be a beneficial impact on air quality. Finally, several 2012 AQMP control measures would regulate a variety of different types of emissions sources including both area and point sources. These control measures are expected to reduce VOC, criteria pollutant, and precursor emissions.

Under the 2012-2035 RTP/SCS, mobile source criteria pollutant emissions would stay approximately the same or decrease, providing an air quality benefit. However, the increase of re-entrained roadway dust would increase proportionately to vehicle miles traveled (VMT) and as such was considered a significant impact in the 2012-2035 RTP/SCS Program EIR.

Implementation of the 2012 AQMP would not in itself result in significant air quality impacts associated with operational activities. For this reason, the 2012 AQMP would not be expected to contribute to significant adverse cumulative impacts from transportation projects projected in the 2012-2035 RTP/SCS.

Operational Impacts - Non-Criteria Pollutants: Several 2012 AQMP control measures may result in the increased use of ammonia in SCRs. However, because ammonia slip from SCR units is restricted to 5.0 ppm or less, which has been shown through source-specific permit modeling to have no significant impact on surrounding communities, the impact from the use of ammonia as proposed in the 2012 AQMP is expected to be less than significant.

The 2012 AQMP is expected to result in a reduction of toxic air contaminant (TAC) emissions. The basis for this conclusion is that many TACs are also classified as criteria pollutants (e.g., PM and VOCs). To the extent that [the 2012 AQMP](#) control measures reduce PM and VOC emissions, associated TAC emission reductions could occur as well. The overall impacts associated with implementation of the 2012 AQMP are an overall reduction in non-criteria pollutants (e.g., toxic air contaminants). Therefore, no significant impacts on non-criteria pollutants have been identified.

Under the 2012-2035 RTP/SCS, as a result of on-going emission controls, cancer and other health risks within any given distance of mobile sources in the region would decline, although the health risks adjacent to transportation facilities would remain higher than regional averages and above desirable levels. As a result of 2012-2035 RTP/SCS policies anticipated growth patterns would concentrate population adjacent to transit and other transportation facilities in High Quality Transit Areas (HQTAs) that could result in more people being exposed to elevated cancer risk as compared to areas of the region more distant from such facilities. Therefore under the 2012-2035 RTP/SCS more sensitive receptors would be located adjacent to transportation facilities and would therefore be exposed to transportation-related air toxics. In addition, although non-carcinogenic health impacts due to VMT-related re-entrained dust would increase, these health impacts would be at least partially offset by the decrease in health impacts related to the decrease of air toxics and criteria pollutants from vehicle exhaust.

Implementation of the 2012 AQMP would not in itself result in significant air quality impacts associated with non-criteria pollutants. Moreover, the 2012 AQMP would not contribute to impacts associated with transportation projects projected in the 2012-2035 RTP/SCS and, therefore, would not be expected to contribute to a cumulatively considerable impact requiring mitigation.

Greenhouse Gas Impacts: The 2012 AQMP is expected to result in a reduction of GHGs. This conclusion is based on the fact that mobile source control measures would reduce GHG emissions through accelerated penetration of partial zero-emission and zero emission vehicles, the use of alternative fuels such as natural gas, the combustion of which generates less GHG emissions than diesel fuel.

The proposed 2012 AQMP control measures and the recommended state and federal control measures that promote fuel and energy efficiency and pollution prevention would also reduce GHG emissions. Measures that stimulate the development and use of new technologies would also be beneficial. In general, strategies that conserve energy, promote clean technologies, and result in a reduction in vehicle miles traveled would reduce GHG emissions. Therefore, the cumulative impacts are expected to result in an overall reduction in GHGs.

According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS projects would result in a significant increase of greenhouse gas emissions from residential and commercial building construction, operational energy demand, and total mobile source emissions. The 2012-2035 RTP/SCS Program EIR concludes that implementation of 2012-2035 RTP/SCS projects would meet the applicable AB 32 reduction

targets (identified in SB 375) with respect to light duty vehicles. However, without technical details as to how each sector of the economy would comply with AB 32, growth anticipated to occur under the 2012-2035 RTP/SCS could result in a significant impact related to AB 32 and the Scoping Plan.

The 2012-2035 RTP/SCS Program EIR concluded that because per capita carbon dioxide emissions from light duty trucks and autos would meet ARB targets by 2020 and would achieve even greater emission reductions in 2035, the 2012-2035 RTP/SCS would result in a less-than-significant impact related to per capita emissions and SB 375.

5.4.2 Mitigation Measures

The 2012 AQMP is expected to result in significant adverse air quality impacts associated with construction activities. Mitigation measures AQ-1 through AQ-8 would serve to reduce those impacts, but significant impacts would remain for CO and PM10.

The 2012 AQMP [Final](#) Program EIR concluded that implementation of 2012 AQMP control measures would not generate significant adverse secondary operational air quality impacts from increased electricity and natural gas demand or from control of stationary sources. The 2012 AQMP [Final](#) Program EIR also concluded that the implementation of 2012 AQMP control measures would result in beneficial air quality impacts associated with coating or consumer product regulations, with mobile sources, and with miscellaneous source control measures, by providing emission reductions. Therefore, no significant adverse air quality impacts associated with operational control measures are expected and no mitigation measures are required.

It was also concluded that the 2012 AQMP would not generate significant adverse secondary air quality impacts from non-criteria pollutants. The 2012 AQMP also concluded that implementation of 2012 AQMP control measures would not result in significant air quality impacts from GHG emissions. Therefore, no mitigation is required.

Because implementation of the 2012-2035 RTP/SCS would result in significant air quality impacts associated with construction, health impacts associated with re-entrained roadway dust due to VMT increase, health impacts associated with the location of a potentially greater number of people adjacent to transportation facilities, and an increase in GHG emissions, mitigation measures were imposed in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures would also reduce impacts associated with the 2012 AQMP and are included in Appendix F of the 2012 AQMP [Final](#) Program EIR.

5.4.3 Level of Significance After Mitigation Measures

The air quality impacts associated with 2012 AQMP control measures were determined to be significant for construction activities and less than significant for secondary emissions from increased electricity demand, control of stationary sources, change in use of lower VOC materials, mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone. Although

mitigation measures identified in the 2012 AQMP [Final](#) Program EIR would reduce construction air quality impacts associated with construction activities, impacts would remain significant and as such would continue to contribute to considerable impacts following mitigation.

Similarly, although mitigation measures identified in the 2012-2035 RTP/SCS Program EIR would reduce air quality and associated health impacts, impacts for construction, operation, TACs, and GHG impacts would continue to contribute to cumulatively considerable impacts following mitigation. Moreover, the 2012 AQMP would not contribute to these impacts as noted in Subsection 5.4.1, so adverse cumulative operational air quality impacts are concluded to be less than significant.

5.5 BIOLOGICAL RESOURCES

5.5.1 Cumulative Biological Resources and Open Space Impacts

Impacts to biological resources were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP would not adversely affect plant and/or animal species in the Basin because [the 2012 AQMP](#) control measures typically affect existing commercial or industrial facilities or establish specifications for fuels or mobile source exhaust emissions. Such existing commercial or industrial facilities are generally located in appropriately zoned commercial or industrial areas, which typically do not support candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service. No comment letters were received during the 8/2/12 NOP/IS that disputed this conclusion.

According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS would adversely affect biological resources and open space. Expected significant adverse impacts would include disturbance and removal of natural vegetation that may be utilized by sensitive species, habitat fragmentation and the associated decrease in habitat quality, litter, smoke, light pollution and road noise in previously undisturbed natural areas, trampling of natural vegetation, displacement of riparian and wetland habitat, as well as long-term impacts such as stream siltation of streams and other water bodies during construction and operation.

The amount of new urbanized acreage (consuming previously vacant land) would be on the order of hundreds of thousands of acres. Despite the inability to predict the acreage of each habitat type that may be affected, it is reasonable to expect that this future urban development would contribute to the same types of impacts detailed previously above. These indirect impacts on biological resources are associated with population, employment, and household growth forecasted by SCAG. Transportation projects included in the 2012-2035 RTP/SCS on previously undisturbed land would potentially displace natural vegetation and, thus, habitat, some of which is utilized by sensitive species in the region. In particular, the 2012-2035 RTP/SCS Program EIR states that the Mixed Flow Improvement along Highway 395 and the High Quality Transit Area (HQTA) along the I-15 in Riverside County would be located in sensitive and listed animal species habitat could result in a direct

loss of habitat. In addition, because implementation of 2012-2035 RTP/SCS projects would cause loss of habitat as well as habitat fragmentation in habitat corridors that cross the SCAG region's boundaries, thereby limiting the movement of wildlife species beyond the SCAG region, the 2012-2035 RTP/SCS Program EIR determined that implementation of the 2012-2035 RTP/SCS would contribute to a cumulative biological resources impact.

Implementation of the 2012 AQMP would not in itself result in significant biological impacts. Moreover, the 2012 AQMP would not contribute to impacts associated with transportation projects projected in the 2012-2035 RTP/SCS and, therefore, would not be expected to contribute to a cumulatively considerable impact requiring mitigation.

5.5.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse biological impacts. However, because implementation of the 2012-2035 RTP/SCS would result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.5.3 Level of Impact After Mitigation Measures

2012-2035 RTP/SCS impacts associated with biological and open space resources would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation due to significant disturbance and removal of natural vegetation that may be utilized by sensitive species, habitat fragmentation and the associated decrease in habitat quality, litter, trampling, light pollution and road noise in previously undisturbed natural areas, displacement of riparian and wetland habitat, siltation of streams and other water bodies during construction, and the loss of prime farmlands, grazing lands, open space and recreation lands. The increased urban development anticipated by the 2012-2035 RTP/SCS would also result in similar impacts. However, since the 2012 AQMP was not identified as creating any adverse biological resources impacts, it would not create cumulatively considerable impacts, so adverse cumulative biological resources impacts from the 2012 AQMP are concluded to be less than significant.

5.6 CULTURAL RESOURCES

5.6.1 Cumulative Cultural Resources Impacts

Impacts to cultural resources were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP would not adversely affect cultural resources because [the 2012](#) AQMP control measures typically affect existing commercial or industrial facilities or establish specifications for fuels or mobile source exhaust emissions. Potentially affected facilities would not require extensive cut-and-fill activities or excavation at undeveloped sites, and implementation of the 2012 AQMP would therefore not adversely affect historical or archaeological resources as defined in CEQA Guidelines §15064.5, destroy unique

paleontological resources or unique geologic features, or disturb human remains interred outside formal cemeteries. No comment letters were received by the SCAQMD during the 8/2/12 NOP/IS comment period disputing this conclusion.

In a small number of cases, implementation of the 2012 AQMP may require minor site preparation and grading at an affected facility. Under this circumstance, it is possible that archaeological or paleontological resources could be uncovered. Even if this circumstance were to occur, significant adverse cultural resources impacts are not anticipated because construction activities would occur at previously disturbed industrial or commercial locations and there are existing laws in place that are designed to protect and mitigate potential adverse impacts to cultural resources. As with any construction activity, should archaeological resources be found during construction that result from implementation of the 2012 AQMP, the activity would cease until a thorough archaeological assessment is conducted and the Native American Heritage Commission (NAHC) is contacted, if necessary.

According to the 2012-2035 RTP/SCS Program EIR, as of August 2011, over 68,000 archaeological and over 1,200 historic locations have been identified in the SCAG region. Each of these sites is documented at the Office of Historic Preservation, which holds location information on archaeological sites for each region in California. Paleontological sites are also numerous in southern California. The development of new transportation facilities as part of the 2012-2035 RTP/SCS may affect historical resources because many HQTAs would be located in older urban centers where structures of architectural or historical significance are likely to be located. In addition, 2012-2035 RTP/SCS transportation projects would significantly affect archaeological and paleontological resources because the projects could be located in previously undisturbed areas.

Furthermore, since it is not always possible to predict where human remains may occur outside of formal burials, it is possible that excavation and construction activities associated with 2012-2035 RTP/SCS projects may disturb previously undiscovered human remains not interred in marked, formal burials, resulting in significant impacts.

Finally, the 2012-2035 RTP/SCS's influence on growth would contribute to regional impacts on existing and previously undisturbed and undiscovered cultural resources; impacts would combine with impacts in other areas of Southern California to contribute to a cumulative loss of cultural resources in California.

Implementation of the 2012 AQMP would not in itself result in significant impacts to cultural resources. However, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with increased urbanization, projected in the 2012-2035 RTP/SCS, would not be expected to contribute to cumulatively considerable impacts to existing historic resources and previously undisturbed and undiscovered archeological and paleontological resources requiring mitigation.

5.6.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to cultural resources. However, because implementation of the 2012-2035 RTP/SCS would result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.6.3 Level of Impact After Mitigation Measures

Potential impacts from the 2012-2035 RTP/SCS associated with cultural resources would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts to cultural resources would remain significant following mitigation because the 2012-2035 RTP/SCS is expected to affect a potentially large number of historic properties, archaeological resources, and paleontological resources. Moreover, the 2012 AQMP would not contribute to impacts associated with transportation projects projected in the 2012-2035 RTP/SCS and, therefore, would not be expected to contribute to a cumulatively considerable impact requiring mitigation. As a result, adverse cumulative cultural resources impacts from the 2012 AQMP are concluded to be less than significant.

5.7 ENERGY

5.7.1 Cumulative Energy Impacts

Implementation of the 2012 AQMP is expected to result in an overall increase in electricity demand. While this increase is expected to be within the electric generating capacity of the region, an increase in electricity of greater than one percent represents a substantial increase in electricity use. Similarly, the increased demand for natural gas for both stationary source and mobile source control measures were concluded to be significant, even though since sufficient natural gas resources are available. Thus, the energy impacts associated with electricity and natural gas demand from the implementation of the 2012 AQMP are considered to be significant.

Implementation of the 2012 AQMP is expected to result in less than significant energy impacts for use of petroleum fuels, use of alternative fuels (e.g., hydrogen), and on renewable energy sources. Furthermore, implementation of the 2012 AQMP control measures would result in a demand reduction of petroleum fuels. Finally, although implementation of the 2012 AQMP control measures would increase hydrogen demand as a transportation fuel, this increase is not expected to be significant since hydrogen is not widely available, its use is currently limited, and future demand is expected to be met through increased production. The energy impacts associated with the future use of hydrogen is expected to be less than the current strategy that uses predominately petroleum based fuels such that no significant hydrogen demand impacts are expected. Further, control measures may have a renewable energy benefit from the use of solar energy.

Energy resources are considered as part of the 2012-2035 RTP/SCS Program EIR Public Services and Utilities section. According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS may uncover and potentially sever underground utility lines during construction activities, prior to mitigation.

The 2012-2035 RTP/SCS Program EIR concluded that implementation of the 2012-2035 RTP/SCS would increase energy demand associated with construction of regional transportation system and anticipated development. The RTP/SCS Program EIR also concluded that the 2012-2035 RTP/SCS would result in less transportation fuel consumption due to RTP/SCS' emphasis on compact land use and growth patterns that facilitate transit and non-motorized transportation. The 2012-2035 RTP/SCS Program EIR also identified that overall population growth, accommodated by the transportation investments, would require an increase in energy resources and as such would result in significant impacts to non-renewable energy resources. Finally, the 2012-2035 RTP/SCS Program EIR concluded that the anticipated demand for energy would contribute to depleting energy reserves and as such would contribute to a cumulatively significant impact.

Implementation of the 2012 AQMP was concluded to generate significant impacts to electricity and natural gas energy supplies. The 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with construction activities and accommodated population growth demands predicted by the 2012-2035 RTP/SCS Program EIR, may contribute to cumulatively considerable impacts electricity and natural gas energy impacts. Moreover, the 2012 AQMP would not contribute to impacts associated with demand for petroleum fuels, alternative fuels or non-renewable energy supplies requiring mitigation.

5.7.2 Mitigation Measures

The 2012 AQMP is expected to result in significant electricity demand impacts associated with electrification of stationary and mobile sources. Mitigation measures E-1 through E-7 would serve to reduce impacts from increased electricity demand and mitigation measures E-8 through E-12 would reduce impacts from increased demand for natural gas. In spite of implementing these mitigation measures, significant adverse energy impacts would remain.

The 2012 AQMP [Final](#) Program EIR also concluded that impacts would be less than significant for use of petroleum fuels, use of alternative fuels (e.g., hydrogen), and use of renewable energy sources.

Implementation of the 2012-2035 RTP/SCS would result in significant impacts from construction projects associated with urban development and growth accommodated by the 2012-2035 RTP/SCS transportation projects, therefore, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. Energy resources were addressed as part of the Public Services and Utilities section of the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.7.3 Level of Impact after Mitigation Measures

Electricity and natural gas demand impacts associated with the 2012 AQMP control measures were concluded to be significant, while energy impacts associated with use of petroleum fuels, use of alternative fuels and renewable energy sources were considered to be less than significant. Although mitigation measures identified in the 2012 AQMP [Final Program EIR](#) would reduce energy impacts associated with electricity demand, impacts would remain significant and as such would continue to contribute to considerable impacts following mitigation.

2012-2035 RTP/SCS impacts associated with energy resources would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because energy consumed during construction and expansion of the transportation system, as well as growth that would be accommodated by the 2012-2035 RTP/SCS, would contribute to considerable impacts following mitigation. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would contribute to a cumulatively considerable electricity and natural gas demand impacts following mitigation.

5.8 GEOLOGY AND SOILS

5.8.1 Cumulative Geology and Soils Impacts

Impacts to geologic resources were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP would not directly or indirectly expose people or structures to earthquake faults, seismic shaking, seismic-related ground failure including liquefaction, landslides, mudslides or substantial soil erosion; no new structures would be constructed as the result of implementing the 2012 AQMP. Although some structural modifications at existing affected facilities may occur as a result of installing control equipment or making process modifications, existing affected facilities or modifications to existing facilities would be required to comply with relevant California Building Code requirements in effect at the time of initial construction or modification of a structure which are expected to mitigate geology and soils impacts to less than significant. No comment letters were received disputing these conclusions.

Geology and soils were considered in the 2012-2035 RTP/SCS Program EIR as part of the Geology, Soils and Mineral Resources section. All of southern California is susceptible to impacts from seismic activity and numerous active faults are known to exist in the region that could potentially generate seismic events capable of significantly affecting transportation facilities proposed in the 2012-2035 RTP/SCS. According to the 2012-2035 RTP/SCS Program EIR, seismic events could damage transportation infrastructure through surface rupture, ground shaking, liquefaction, and landsliding. Specifically, implementation of the new light rail transit (LRT) routes/extension in Los Angeles and San Bernardino Counties, new highways, arterials, bus rapid transit routes, goods movement (freight), heavy and light rail routes, high-speed trains, and other capacity enhancements proposed under the

2012-2035 RTP/SCS would be susceptible to impacts from seismic activity. Although seismic activity could cause damage to existing substandard construction, new designs taking account of current engineering knowledge can significantly reduce potential damage and harm. Earthquake-resistant designs employed on new structures minimize the impact to public safety from seismic events. The 2012-2035 RTP/SCS Program EIR also determined that seismically induced tsunami and seiche waves could damage transportation infrastructure proximate to coastal areas, but that the potential for these impacts would be remote and was not considered significant.

The 2012-2035 RTP/SCS Program EIR concluded that earthwork associated with implementation of the 2012-2035 RTP/SCS could result in soil erosion and/or loss of topsoil and in some cases could result in slope failure. The 2012-2035 RTP/SCS Program EIR further determined that location of 2012-2035 RTP/SCS projects on expansive soils and unstable geologic units could have potentially significant impacts to property and public safety due to on- or off-site landslides, lateral spreading, subsidence, liquefaction or collapse. Finally, the 2012-2035 RTP/SCS Program EIR concluded that implementation of the 2012-2035 RTP/SCS would occur within the SCAG region, would be site-specific in nature and as such would not contribute to a cumulatively considerable increase in risk associated with geologic hazards.

Impacts under geologic and soil resources were determined to be below the level of significance in the 8/2/12 NOP/IS, therefore, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, would not be expected to contribute to a cumulatively considerable geologic and soil resources impacts prior to mitigations.

5.8.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts under geologic and soil resources. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.8.3 Level of Impact After Mitigation Measures

Potential geologic and soil resources impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS is expected to result in potential damage to transportation infrastructure through surface rupture, ground shaking, liquefaction, and landsliding, as well as long term soil erosion and/or loss of top soil, subsidence, and slope failure. Moreover, the 2012 AQMP would not contribute to geologic and soil resources impacts associated with transportation projects projected in the 2012-2035 RTP/SCS and, therefore, would not be expected to contribute to a cumulatively considerable impact requiring mitigation.

5.9 HAZARDS AND HAZARDOUS MATERIALS

5.9.1 Cumulative Hazards and Hazardous Materials Impacts

Implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts from hazards and hazardous materials associated with the use of alternative fuels or the use of fuel additives. Fire hazards associated with reformulated coatings, adhesives, solvents, lubricants, mold release products, and other consumer products are potentially significant. The hazard impacts associated with alternative fuels, except for the transport of LNG are considered less than significant. Hazard impacts associated with the transport of LNG are considered potentially significant. In addition, the hazards associated with a spill of ammonia (used as a catalyst in SCR systems) were determined to be potentially significant. Finally, the hazard impacts associated with facility shutdown and start up operations and associated with the use of catalysts were considered less than significant.

According to the 2012-2035 RTP/SCS Program EIR, proposed freight rail enhancements and other goods movement capacity enhancements could result in increased or new transport of hazardous materials or wastes. In addition, construction and maintenance of such projects would result in use of equipment that contains or uses routine hazardous materials (e.g., diesel-fuel, paint and cleaning solutions), and the transportation of excavated soil and/or groundwater containing contaminants from previously contaminated areas. The 2012-2035 RTP/SCS Program EIR concludes that although individual projects would be required to comply with all existing regulations, due to the volume of projects (transportation and development) contained within the RTP/SCS it is possible that significant impacts could occur.

Because implementing the 2012-2035 RTP/SCS would facilitate the movement of goods, including hazardous materials, through the region, transportation of goods, in general, and hazardous materials in particular, is expected to increase substantially with implementation of the 2012-2035 RTP/SCS. The 2012-2035 RTP/SCS Program EIR estimated that daily regional heavy duty truck VMT within the SCAG region would increase from 41 million in 2011 to 65 million in 2035, a 58 percent increase. The 2012-2035 RTP/SCS Program EIR concluded that there would be a potential to create a hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment during transportation. The 2012-2035 RTP/SCS Program EIR also concluded that approximately 541 existing kindergarten through 12th grade schools would be located within a one-quarter mile buffer of the 2012-2035 RTP/SCS projects and as such could be impacted by an accidental release of hazardous materials.

Furthermore, according to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS would potentially disturb contaminated property during the construction of new transportation or expansion of existing transportation facilities and disturb contaminated sites as a result of population, housing and employment growth in the region. Finally, the 2012-2035 RTP/SCS Program EIR concluded that the forecasted urban development and growth that would occur under the 2012-2035 RTP/SCS and the increased mobility provided by the 2012-2035 RTP/SCS would result in increased hazardous materials

transport outside of the SCAG region and as such would contribute to cumulatively considerable impacts.

Implementation of the 2012 AQMP would result in significant impacts from fire hazards associated with reformulated products, the possibility of ammonia tank failures, and from transport of LNG. The 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with transportation projects projected in the 2012-2035 RTP/SCS, would contribute to cumulatively considerable impacts prior to mitigation.

5.9.2 Mitigation Measures

In the 2012 AQMP, mitigation measures HZ1 and HZ2 were developed to minimize fire impacts associated with reformulated products. HZ3 through HZ6 were developed to minimize impacts associated with LNG transport, and HZ7 through HZ10 were development to minimize impacts associated with ammonia storage. Implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.9.3 Level of Impact After Mitigation Measures

It was concluded in the 2012 Program EIR that potentially significant adverse fire hazard impacts associated with reformulated products and the on-site ammonia storage hazards would be less than significant after mitigation. In spite of implementing mitigation measures, it was concluded that hazards associated with LNG transport would remain significant.

It was concluded in the 2012-2035 RTP/SCS that impacts associated with hazards and hazardous materials would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, impacts from the implementation of the 2012-2035 RTP/SCS, associated with upset and accident conditions, hazardous emissions in vicinity of schools, and disturbance of contaminated property during construction activities would remain significant following mitigation. When combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, the 2012 AQMP has the potential to contribute to a cumulatively considerable hazards and hazardous materials impacts following mitigation for the risks associated with the transport of LNG.

5.10 HYDROLOGY AND WATER QUALITY

5.10.1 Cumulative Hydrology and Water Quality Impacts

Implementation of 2012 AQMP control measures may result in impacts to water quality and increased wastewater discharge associated with the use of alternative fuels, increased use of batteries, increased water demand, use and application of sodium bisulfate for livestock operations, and use of ammonia in SCR applications.

The 2012 AQMP [Final](#) Program EIR concluded that wastewater treatment facilities would have sufficient capacity to handle the estimated increase in wastewater that could be generated from reformulation of products and use of air pollution control equipment. The 2012 AQMP [Final](#) Program EIR also concluded that the use of alternative fuels would not result in greater adverse water quality impacts than the use of conventional fuels. In addition, the 2012 AQMP [Final](#) Program EIR concluded that the recycling of EV and hybrid batteries would be greater than lead-acid batteries in conventional vehicles, reducing the potential for illegal disposal and potential water quality impacts. Furthermore, the 2012 AQMP [Final](#) Program EIR concluded that the use and application of sodium bisulfate in livestock operations would be controlled and monitored to prevent water quality runoff and related water quality impacts. The 2012 AQMP [Final](#) Program EIR also concluded that potential spills associated with ammonia would be contained on-site via required secondary spill containment devices and berms. Finally, the 2012 AQMP [Final](#) Program EIR concluded that water demand associated with the manufacture and use of waterborne and add-on air pollution control technologies would be potentially significant.

According to the 2012-2035 RTP/SCS Program EIR, project-specific studies would be necessary to determine the actual potential for significant impacts on water resources resulting from implementation of the 2012-2035 RTP/SCS. However, general program-level impacts from new transportation projects proposed in the 2012-2035 RTP/SCS would degrade local surface water quality by increased roadway and urban runoff, potentially violating water quality standards associated with wastewater and stormwater permits. In addition, the 2012-2035 RTP/SCS could alter the existing drainage patterns in ways that would result in substantial erosion or siltation.

Implementation of the 2012-2035 RTP/SCS would also increase impervious surfaces due to additional miles of roadway, in addition to urban development associated with the population distribution by 2035, and as such would increase runoff and potentially affect groundwater recharge rates. Furthermore, the 2012-2035 RTP/SCS would potentially increase flooding hazards by placing structures such as transportation investments on alluvial fans and within 100-year flood hazard areas and increase the rate or amount of surface runoff in a manner that would result in flooding or produce or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems.

The 2012-2035 RTP/SCS Program EIR concluded that although wastewater rates are expected to increase 21 percent by 2035, population growth would be dispersed throughout the SCAG region and, especially given aggressive water conservation strategies, the SCAG region would not outgrow its wastewater treatment capacity by the year 2035.

The 2012-2035 RTP/SCS Program EIR also concluded that increased mobility and inclusion of land-use-transportation measures would influence the pattern of urbanization in southern California and although most water agencies have plans in place to respond to future growth, the existing water supplies and infrastructure would not be sufficient to meet the expected demand in 2035. Finally, the 2012-2035 RTP/SCS Program EIR concluded that any increase in water demand in the SCAG regions would affect areas outside the region by consuming water that could be used in other areas and that due to uncertainties associated with water

supply management, this would contribute to a cumulatively considerable impact prior to mitigation.

Implementation of the 2012 AQMP would result in significant adverse water demand impacts associated with the manufacture and use of waterborne and add-on air pollution control technologies. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS would contribute to cumulatively considerable impacts prior to mitigation.

5.10.2 Mitigation Measures

The 2012 AQMP [Final](#) Program EIR identifies possible mitigation measures to reduce water demand associated with the manufacture and use of waterborne and add-on air pollution control technologies. The 2012 AQMP [Final](#) Program EIR concludes that while mitigation measures are available, they can vary from jurisdiction to jurisdiction, and impacts may remain significant. In addition, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.10.3 Level of Impact After Mitigation Measures

Although 2012 AQMP impacts associated with water demand would be reduced following the implementation measures, the effectiveness of mitigation measures can vary between jurisdictions, therefore, water demand impacts may remain significant.

2012-2035 RTP/SCS impacts associated with hydrology and water quality would be reduced following the implementation of the 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation for water quality, wastewater, riparian habitats and waters of the U.S. runoff/drainage, groundwater, flooding, and water supply. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would contribute to cumulatively considerable impacts following mitigation to water demand impacts. The cumulative impacts of other hydrology and water quality impacts associated with the 2012 AQMP are less than significant.

5.11 LAND USE AND PLANNING

5.11.1 Cumulative Land Use and Planning Impacts

Implementation of the 2012 AQMP is not expected to result in potentially significant adverse land use impacts because the 2012 AQMP would for the most part impose control requirements on stationary sources at existing commercial or institutional facilities, establish emission exhaust specifications for mobile sources, and control emissions from mobile sources. Although some 2012 AQMP control measures may require the construction of battery charging or fueling infrastructure as well as construction of catenary lines, the 2012

AQMP [Final](#) Program EIR concluded that impacts associated with these activities would not generate significant adverse land use impacts because they would be developed within or adjacent to existing roadways and transportation corridors.

It should be noted that there are no provisions of the 2012 AQMP that would directly affect land use plans, policies, or regulations. The SCAQMD is specifically precluded from infringing on existing city or county land use authority (California Health & Safety Code §40414). Land use and other planning considerations are determined by local governments and no present or planned land uses in the region or planning requirements would be altered by the 2012 AQMP.

Land use and planning were considered under the combined category of Land Use and Agricultural Resources section in the 2012-2035 RTP/SCS Program EIR. According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS would result in inconsistencies with general plans, disruption or division of established communities, changes to land uses by changing concentrations of development throughout SCAG, change patterns of growth and urbanization beyond the SCAG region, and cumulatively considerable changes to land use and the intensity of land use. Short-term construction related impacts and long-term or permanent displacement or offsite impacts from new facilities would potentially occur as a result of implementation of the 2012-2035 RTP/SCS.

Implementation of the 2012 AQMP control measures would not conflict with applicable land use plan, policy, or regulation of an agency with jurisdiction over the project, or physically divide an established community. Therefore, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, it would not contribute to cumulatively considerable impacts requiring mitigation.

5.11.2 Mitigation Measures

Land use and planning mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to land use and planning. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. Land use and planning resources were combined with agricultural resources in the 2012-2035 RTP/SCS. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.11.3 Level of Impact After Mitigation Measures

Potential land use and planning impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would contribute to inconsistencies with general plans, disruption or division of established communities,

changes to land uses by changing concentrations of development throughout SCAG, change patterns of growth and urbanization beyond the SCAG region, and cumulatively considerable changes to land use and the intensity of land use. Short-term construction related impacts and long-term or permanent displacement or offsite impacts from new facilities would also potentially occur as a result of implementation of the 2012-2035 RTP/SCS. Moreover, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable land use and planning impacts requiring mitigation.

5.12 MINERAL RESOURCES

5.12.1 Cumulative Mineral Resources Impacts

Impacts to mineral resources were considered and fully evaluated in the 8/2/12 NOP/IS, prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP would not directly or indirectly impact mineral resources. No comment letters were received by the SCAQMD during the 8/2/12 NOP/IS disputed this conclusion.

Mineral resources were considered under the combined category of Geology, Soils and Mineral Resources in the 2012-2035 RTP/SCS Program EIR. According to the 2012-2035 RTP/SCS Program EIR, implementing the proposed 2012-2035 RTP/SCS transportation projects would result in the loss of availability of known aggregate and mineral resources that would be of value to the region.

Since potential impacts to mineral resources were determined to be below the level of significance in the 8/2/12 NOP/IS, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, the 2012 AQMP is not expected to contribute to cumulatively considerable impacts to mineral resources prior to mitigation.

5.12.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to mineral resources. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. Mineral resources were combined in the 2012-2035 RTP/SCS with geology and soil resources. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.12.3 Level of Impact After Mitigation Measures

Potential impacts from the 2012-2035 RTP/SCS associated with mineral resources would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of 2012-2035 RTP/SCS would result in increased

demand driven by growth and the large number of projects anticipated in the 2012-2035 RTP/SCS. Moreover, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable mineral resources impacts requiring mitigation.

5.13 NOISE

5.13.1 Cumulative Noise Impacts

Construction Impacts: Implementation of the 2012 AQMP control measures associated with air pollution control technologies and exhaust standards would not result in noise and vibration impacts because construction activities would occur within appropriately zoned industrial and commercial areas, impacts would be temporary and limited to construction activities, and construction noise/vibration impacts to sensitive receptors would not be expected. However, implementation of the 2012 AQMP control measures associated with construction of overhead catenary lines could result in significant noise and vibration impacts due to the geographic proximity of sensitive receptors.

According to the 2012-2035 RTP/SCS Program EIR, grading and construction activities associated with the proposed freeway, arterial, transit, and rail projects, as well as anticipated development would intermittently and temporarily generate noise and vibration levels above ambient background levels. Noise and vibration levels in the immediate vicinity of the construction sites would increase substantially sometimes for extended duration, resulting in temporary noise increases at nearby sensitive receptors, creating potentially significant adverse noise impacts.

Operational Impacts: Implementation of the 2012 AQMP control measures is not expected to result in significant adverse operational noise impacts because [the 2012 AQMP](#) control measures typically affect existing commercial or industrial facilities typically located in appropriately zoned industrial or commercial areas. It is not expected that modifications to install air pollution control equipment would substantially increase ambient noise levels in the area, either permanently or intermittently, or expose people to excessive noise levels that would be noticeable above and beyond existing ambient levels. Although overhead catenary lines could be installed to comply with certain control measures, these lines would be installed along existing roadways and transportation corridors and as such would not result in the construction of new roadways or corridors.

According to the 2012-2035 RTP/SCS Program EIR, noise-sensitive land uses could be exposed to operational noise in excess of normally acceptable noise levels and could experience substantial increases in noise as a result of:

- The operation of expanded or new transportation facilities (e.g., increased traffic resulting from new highways, addition of highway lanes, roadways, ramps, and use of new transit facilities as well as increased use of existing transit facilities, etc.).
- Increased vehicle activity (e.g., autos, trucks, buses, planes, trains, etc.) associated with development and resulting in increased ambient noise next to transportation facilities.

Implementation of 2012 AQMP control measures could result in significance noise and vibration impacts during construction activities. Therefore, when combined with past, present, and reasonably foreseeable activities, and in particular with the increased development projected in the 2012-2035 RTP/SCS, the 2012 AQMP would contribute to cumulatively considerable noise impacts prior to mitigation.

5.13.2 Mitigation Measures

Mitigation measures NO-1 through NO-9 [in the 2012 AQMP Final Program EIR](#) would reduce noise impacts associated with construction of overhead catenary lines. Furthermore, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final Program EIR](#).

5.13.3 Level of Impact After Mitigation Measures

Although impacts would be reduced following implementation of noise mitigation measures identified in the 2012 AQMP [Final Program EIR](#), noise and vibration impacts associated with the construction of catenary lines would remain significant in areas where sensitive receptors are located near transportation corridors.

2012-2035 RTP/SCS impacts associated with noise would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation for noise and vibration during construction activities and operational activities. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would contribute to cumulatively considerable noise and vibration impacts following mitigation.

5.14 POPULATION AND HOUSING

5.14.1 Cumulative Population, Housing and Employment Impacts

Impacts to population and housing were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP is not expected to result in significant adverse population and housing impacts because [the 2012 AQMP](#) control measures typically affect existing commercial or industrial facilities located in predominantly industrial or commercial urbanized areas. It is expected that the existing labor pool within the areas surrounding any affected facilities would accommodate the labor requirements for any facility or equipment modifications. In addition, it is not expected that affected facilities would be required to hire additional personnel to operate and maintain new control equipment on site because air pollution control equipment is typically not labor intensive equipment. In the event that new employees are hired, it is expected that the existing local labor pool in the district can accommodate any increase in demand for workers that might occur as a result of adopting the proposed 2012 AQMP. Therefore, implementing 2012

AQMP control measures is not expected to result in changes in population densities or induce significant growth in population. No comment letters were received by the SCAQMD during the 8/2/12 NOP/IS comment period disputing this conclusion.

According to the 2012-2035 RTP/SCS Program EIR, implementing the 2012-2035 RTP/SCS would induce population growth in some areas of the SCAG region, displace existing homes and businesses, and influence the pattern of growth in the regions through transportation investments and land use strategies.

Since population, housing and employment impacts were concluded to be below the level of significance in the 8/2/12 NOP/IS, when combined with past, present, and reasonably foreseeable activities, and in particular with the anticipated impacts in the 2012-2035 RTP/SCS, the 2012 AQMP would not be expected to contribute to cumulatively considerable impacts to population and housing prior to mitigation.

5.14.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to population, housing, and employment. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F of the 2012 AQMP [Final](#) Program EIR.

5.14.3 Level of Impact After Mitigation Measures

Potential population, housing, and employment impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, although the policies included in the 2012-2035 RTP/SCS seek to direct growth in a way that is efficient for both mobility and land consumption, 2012-2035 RTP/SCS population, housing, and employment impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would continue to induce growth to certain areas of the region. In addition, although 2012-2035 RTP/SCS Program EIR mitigation measures would serve to reduce potential impacts related to displacement of residences and businesses, a substantial number of businesses and residences would likely be displaced due to development associated with 2012-2035 RTP/SCS projects. The accessibility afforded by the 2012-2035 RTP/SCS and the expected shifts in population, households, and employment associated with the mobility benefits would change the growth patterns in the region, generating potentially significant adverse cumulative population and housing impacts in spite of implementing mitigation measures. Moreover, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, would not be expected to produce cumulatively considerable impacts requiring mitigation.

5.15 PUBLIC SERVICES

5.15.1 Cumulative Public Services Impacts

Impacts to public services were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As determined in the 8/2/12 NOP/IS, implementation of the 2012 AQMP would not result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times or other performance objectives. Most industrial facilities have on-site security that control public access to facilities and therefore, an increase in the need for police services is not expected. Furthermore, most industrial facilities have on-site fire protection personnel and/or have agreements for fire protection services with local fire departments. For these reasons, implementing the 2012 AQMP is not expected to require additional fire or police protection services. In addition, implementation of the 2012 AQMP is not expected to induce population growth and as such would not increase or otherwise alter the demand for schools and parks in the district. Therefore, no significant adverse impacts to schools or parks are foreseen as a result of adopting the proposed 2012 AQMP. No comment letters were received that disputed this conclusion.

According to the 2012-2035 RTP/SCS Program EIR, implementing the 2012-2035 RTP/SCS would adversely affect public services and utilities. Expected significant impacts would include demand for more police, fire, and emergency personnel and facilities, demand for more school facilities and teachers, and increase in the number of houses in areas subject to wildfires. The 2012-2035 RTP/SCS concluded that impacts to fire services would contribute to regionally cumulatively considerable impacts to staffing levels and response times of police, fire and emergency services.

Construction necessary to implement the 2012-2035 RTP/SCS could potentially uncover and sever underground utility lines (electric and natural gas), as could any groundbreaking in the SCAG region. For this reason, the project implementation agency is normally required to incorporate the locations of existing utility lines into the construction schedule prior to construction. Per the 2012-2035 RTP/SCS Program EIR, prior knowledge and avoidance during construction of existing utility lines would reduce this impact.

Because impacts to public services and utilities were determined to be below the level of significance in the 8/2/12 NOP/IS, when combined with past, present, and reasonably foreseeable activities, and in particular with the anticipated impacts in the 2012-2035 RTP/SCS, the 2012 AQMP is not expected to contribute to cumulatively considerable impacts to public services requiring mitigation.

5.15.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to public services and utilities. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-

2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F of the 2012 AQMP [Final](#) Program EIR.

5.15.3 Level of Impact After Mitigation Measures

Potential adverse impacts to public services and utilities from the 2012-2035 RTP/SCS would be reduced following the implementation of the 2012-2035 RTP/SCS Program EIR mitigation measures. However, public service impacts from the 2012-2035 RTP/SCS associated with police, fire, and emergency response were concluded to be significant in spite of implementing mitigation measures. Impacts to wildfire threats would also remain significant because development would occur in areas that have a high threat of fire.

The region's demand to accommodate an additional 453,000 school children would remain a significant impact on public services following implementation of 2012-2035 RTP/SCS mitigation measures. The 2012-2035 RTP/SCS Program EIR also concluded that impacts to underground utility lines would be reduced to below the level of significance following mitigation.

Based on the above information, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, is not expected to produce cumulatively considerable impacts to public services and utilities requiring mitigation.

5.16 RECREATION

5.16.1 Cumulative Recreational Resources Impacts

Impacts to recreational resources were considered and fully evaluated in the 8/2/12 NOP/IS prepared for the 2012 AQMP. As discussed in the 8/2/12 NOP/IS, and similar to the conclusions regarding potential land use and planning impacts, there are no provisions in the proposed 2012 AQMP that would affect land use plans, policies, ordinances, or regulations related to recreation facilities or services. Recreation-related land use and other planning considerations are determined by local governments and no land use or planning requirements, including those related to recreational facilities, would be altered by the proposal. The proposed project would not have the potential to directly or indirectly induce population growth or redistribution that could adversely affect recreational resources. As a result, the proposed project would not increase the use of, or demand for existing neighborhood and/or regional parks or other recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment. No comment letters were received by the SCAQMD during the 8/2/12 NOP/IS comment period disputing this conclusion.

Impacts to recreational resources were considered under the combined category of Public Services and Utilities section in the 2012-2035 RTP/SCS Program EIR. According to the 2012-2035 RTP/SCS Program EIR, implementing the proposed 2012-2035 RTP/SCS projects would result in a substantial loss or disturbance of existing open space and recreational lands, as well as a potential to increase the use of existing neighborhood and

regional parks or other recreational facilities, such that substantial deterioration of the facilities would occur. The 2012-2035 RTP/SCS Program EIR concluded that implementation of 2012-2035 RTP/SCS projects would result in significant impacts prior to mitigation.

Because potential impacts to recreational resources were determined to be below the level of significance in the 8/2/12 NOP/IS, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, the 2012 AQMP would not be expected to contribute to a cumulatively considerable impact to recreational resources requiring mitigation.

5.16.2 Mitigation Measures

Recreation mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts to recreational resources. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. Recreational resources were considered as part of the Public Services and Utilities section of the 2012-2035 RTP/SCS. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.16.3 Level of Impact After Mitigation Measures

Potential impacts associated with recreational resources from the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would contribute to loss and disturbance of open space and recreational lands. Based on the information above, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable recreation impacts following mitigation.

5.17 SOLID AND HAZARDOUS WASTE

5.17.1 Cumulative Solid and Hazardous Waste Impacts

Implementation 2012 AQMP control measures would not significantly increase disposal of spent batteries, activated carbon, filters, and catalysts, and the early retirement of older equipment and replacement with newer and lower emission technology equipment, would not generate significant additional waste.

The 2012 AQMP [Final](#) Program EIR concluded that because spent batteries are required to be and are largely recycled, the increased use of EVs and hybrid vehicles would not result in a significant increase in the illegal disposal of batteries. In addition, solid waste impacts due to 2012 AQMP air pollution control technologies would not be significant because spent

carbon and catalysts are usually recycled and reused rather than disposed in landfills and filter waste would be small because the amount of material collected is small. The 2012 AQMP [Final](#) Program EIR concludes that control measures that would require new equipment can require that retirement occurs as the life of the old equipment is exhausted and new equipment is put into service. For equipment that may be retired before the end of its useful life, that equipment may be reused in areas outside the district. Equipment with no remaining useful life is expected to be recycled for metal content. Therefore, no significant solid/hazardous waste impacts were identified due to implementation of the control measures.

Impacts from solid waste were considered under the combined category of Public Services and Utilities section in the 2012-2035 RTP/SCS Program EIR, whereas impacts from hazardous waste were considered under the Hazardous Materials section in the 2012-2035 RTP/SCS Program EIR. According to the 2012-2035 RTP/SCS Program EIR, implementing the proposed 2012-2035 RTP/SCS projects would result in a significant amount of solid waste generated during construction of new transit lines, truck lanes, HOV connectors, and HOT projects through grading and excavation activities, as well as debris resulting from removal of structures. Construction of urban development would be expected to generate similar debris. Construction debris would be recycled or used as fill at other projects or transported to the nearest landfill site and disposed of appropriately. The 2012-2035 RTP/SCS Program EIR concluded that implementation of 2012-2035 RTP/SCS projects would result in significant impacts prior to mitigation. Impacts associated with hazardous waste, as identified by the 2012-2035 RTP/SCS Program EIR, are consistent with and are presented in Section 5.9, Hazards and Hazardous Materials of that document.

The 2012-2035 RTP/SCS Program EIR also concluded that because 2012-2035 RTP/SCS projects may require transport of waste to less urban areas of the region or outside of the region, to landfills that are less impacted than local landfills, implementation of 2012-2035 RTP/SCS projects would result in a cumulatively considerable demand on solid waste facilities that exceeds regional capacity.

5.17.2 Mitigation Measures

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse impacts due to solid and hazardous wastes. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.17.3 Level of Impact After Mitigation Measures

Potential impacts associated with solid and hazardous waste from the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because the demand for solid waste services in the SCAG region and the resulting need to move solid waste large distances, potentially out of the region, would

remain. Based on the above information, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable solid or hazardous waste impacts requiring mitigation.

5.18 TRANSPORTATION AND TRAFFIC

5.18.1 Cumulative Transportation and Traffic Impacts

Implementation of the 2012 AQMP is not expected to result in potentially significant adverse transportation and traffic impacts because [the 2012 AQMP](#) control measures typically affect existing commercial or industrial facilities or establish specifications for fuels or mobile source exhaust emissions and as such are not expected to generate new construction or substantially increase vehicle trips or vehicle miles traveled in the district. However, some 2012 AQMP control measures could necessitate the construction of overhead catenary lines, within or adjacent to existing roadways, streets, freeways, and/or transportation corridors. Such construction activities would generate traffic associated with construction worker vehicles and trucks delivering equipment, materials and supplies to the project site during the duration of the construction activities. Construction activities, including potential lane closures, were considered to be significant.

Similarly, transportation infrastructure improvements pertaining to overhead catenary electrical lines could require the dedication of an existing lane exclusive to vehicles using the overhead catenary electrical lines or fixed guideway systems. The dedication of an existing lane would mean that other vehicles would have reduced access to available driving lanes. Thus, a reduction in the number of available lanes on a roadway to accommodate vehicles using the overhead catenary electrical lines could adversely affect traffic and congestion for all other vehicles on the road, significant adverse operational traffic impacts are anticipated to be generated by the 2012 AQMP because no new streets, roads, freeways, or rail lines would be required and the 2012 AQMP control measures would apply to existing transportation corridors.

The 2012 AQMP relies on transportation and related control measures developed by SCAG in the 2012-2035 RTP/SCS. These transportation control measures include strategies to enhance mobility by reducing congestion through transportation infrastructure improvements, mass transit improvements, increasing telecommunications products and services, enhanced bicycle and pedestrian facilities, etc. Specific strategies that serve to reduce vehicle trips and vehicle miles traveled, such as strategies resulting in greater reliance on mass transit, ridesharing, telecommunications, etc., are expected to result in reducing traffic congestion. Although population in the district would continue to increase, implementing the transportation control measures (in conjunction with the RTP) would ultimately result in greater percentages of the population using transportation modes other than single occupant vehicles. As a result, relative to population growth, existing traffic loads and the level of service designation for intersections district-wide would not be expected to decline at current rates due to implementing the [2012 AQMP](#). Implementing the 2012 AQMP would not hinder population growth in the district, however, could hinder

transportation/traffic improvements and congestion reduction benefits of the 2012-2035 RTP/SCS.

According to the 2012-2035 RTP/SCS Program EIR, implementation of the 2012-2035 RTP/SCS would result in several significant and several less than significant impacts as follows:

- **Vehicle Miles Traveled (VMT)** - Substantial growth and development is anticipated to occur within the region between 2011 and 2035. Based on SCAG's modeling results, average daily VMT are expected to grow from 448 million miles in 2011 to 517 million miles per day in 2035; constituting a 13 percent increase over this period and includes light-, medium- and heavy-duty vehicle VMT in all six counties. While the 2012-2035 RTP/SCS's multimodal strategies aim to reduce per capita VMT over the next 25 years, total demand to move people and goods would continue to grow due to the region's population increase. The 2012-2035 RTP/SCS, therefore, targets transportation systems that have room to grow, including transit, high-speed rail, active transportation, express lanes, and goods movement. Although per capita VMT would decrease, the environment would experience an overall increase in VMT and would be significant prior to mitigation.
- **Vehicle Hours of Delay (VHD)** - Average vehicle hours of delay would be reduced from 3,277,000 vehicle-hours in 2011 to 3,115,000 vehicle-hours in 2035, and as such would constitute a less than significant impact.
- **Vehicle Hours of Delay for Heavy-Duty Trucks** - The transportation system is heavily influenced by goods movement, particularly by heavy-duty trucks. Despite regional planning efforts to improve the efficiency of goods movement, increased demand for goods would lead to an increase from 117,000 to 158,000 average daily heavy-duty truck vehicle hours of delay by 2035 and as such would constitute a significant impact.
- **Peak Period Work Trips** - In 2035, with the implementation of the 2012-2035 RTP/SCS, 82 percent of the evening peak period work trips would take 45 minutes or less by single occupancy vehicle, 77 percent of the evening peak period work trips would take 45 minutes or less by high occupancy vehicle, and 21 percent would occur within 45 minutes by transit. There would be an increase in the percent of work opportunities within 45 minutes travel time by personal vehicle as compared to the current condition. The transit percentage would remain approximately the same. This result is considered to be a regional benefit; the 2012-2035 RTP/SCS would result in a less-than-significant impact related to work commute.
- **System-Wide Fatality and Injury** - Implementation of the 2012-2035 RTP/SCS would contribute to a lower system-wide fatality accident rate and injury rate for all travel modes in 2035 compared to the existing condition. The system-wide daily fatality rate would be 0.17 fatalities per million persons for all travel modes, a decrease of 0.03 daily fatalities per million persons when compared to the existing rate of 0.20. The system-wide daily injury rate would be 12.92 injuries per million persons for all travel modes, a decrease of 5.34 daily injuries per million persons when compared to the existing rate of 18.27. The reductions in fatality and injury rates would be beneficial and would constitute less than significant impacts.

- 2012-2035 RTP/SCS Program EIR Cumulative Impact - Implementation of the 2012-2035 RTP/SCS would contribute to a cumulatively considerable amount of transportation impacts, such as VMT and all-vehicle vehicle hours in delay, to counties outside of the SCAG region. As the population increases through 2035, the number of trips originating and ending in Santa Barbara, San Diego and Kern counties to and from the SCAG region would increase. The transportation demand from growth, in combination with the projects in the 2012-2035 RTP/SCS would contribute to a cumulatively considerable transportation impact in these other counties.

Implementation of the 2012 AQMP would significantly adversely affect traffic and circulation during construction of overhead catenary lines and during operation if the roadways are dedicated to low or zero emission trucks. The 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with projects identified as part of the 2012-2035 RTP/SCS, would contribute to cumulatively considerable impacts prior to mitigation.

5.18.2 Mitigation Measures

Mitigation measure TT-1 in the 2012 AQMP would reduce traffic and circulation impacts associated with construction of catenary lines. No mitigation measures were identified that could reduce potentially significant adverse impacts from operating roadways with catenary lines. Since implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP [Final](#) Program EIR.

5.18.3 Level of Impact After Mitigation Measures

Potential construction traffic and circulation impacts from the 2012 AQMP would be reduced following the implementation of TT-1, however because it may not be possible to reduce construction traffic impacts to less than significant under all conditions, the 2012 AQMP [Final](#) Program EIR concluded that construction impacts on traffic would remain significant.

Impacts to transportation and traffic would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, the 2035 VMT and 2035 heavy-duty truck VHD would be substantially greater than the existing conditions and as such would result in a significant impact in spite of implementing mitigation measures. In addition, as population increases through 2035, the number of trips originating and ending in Santa Barbara, San Diego and Kern counties to and from the SCAG region would increase. The transportation demand from growth, in combination with the accommodating projects in the 2012-2035 RTP/SCS would contribute to a cumulatively considerable transportation impact in these counties. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, would contribute to cumulatively considerable construction impacts following mitigation and, since no mitigation measures were identified that reduce potential operation-related traffic impacts, these remain significant.

CHAPTER 6

ALTERNATIVES

Introduction

Methodology for Developing Project Alternatives

Alternatives Rejected as Infeasible

Alternatives to the 2012 AQMP

Alternatives Analysis

Comparison of the Project Alternatives to the 2012 AQMP

Environmentally Superior and Lowest Toxic Alternative

Conclusion

6.1 INTRODUCTION

This [Final](#) Program EIR provides a discussion of alternatives to the proposed project as required by CEQA. Pursuant to the CEQA Guidelines, alternatives should include realistic measures to attain the basic objectives of the proposed project but would avoid or substantially lessen any of the significant effects of the project, and provide means for evaluating the comparative merits of each alternative (CEQA Guidelines §15126.6 (a)). In addition, though the range of alternatives must be sufficient to permit a reasoned choice, they need not include every conceivable project alternative (CEQA Guidelines §15126.6 (a)). The key issue is whether the selection and discussion of alternatives fosters informed decision making and public participation. An EIR need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative (CEQA Guidelines §15126.6 (f)(3)).

6.2 METHODOLOGY FOR DEVELOPING PROJECT ALTERNATIVES

The alternatives typically included in CEQA documents for proposed SCAQMD rules, regulations, or plans are developed by breaking down the project into distinct components (e.g., emission limits, compliance dates, applicability, exemptions, pollutant control strategies, etc.) and varying the specifics of one or more of the components. Different compliance approaches that generally achieve the objectives of the project may also be considered as project alternatives.

The overall control strategy for the 2012 AQMP is designed to meet applicable federal and state requirements, including attainment of ambient air quality standards. The focus of the 2012 AQMP is to demonstrate attainment of the 2006 24-hour PM_{2.5} national ambient air quality standard by the 2014 attainment date, as well as provide an update regarding ozone to ensure further implementation of measures [Clean Air Act §182 (e)(5)] to meet the federal and state 8-hour ozone standards. Therefore, 2012 AQMP serves as the official SIP submittal for the federal 2006 24-hour PM_{2.5} standard, for which U.S. EPA has established a due date of December 14, 2012. The 2012 AQMP includes a number of short-term stationary source control measures and §182 (e)(5) stationary and mobile sources, both on-road and off-road, control measures. The attainment demonstration for the new 8-hour ozone standard (75 ppb) will be addressed in a 2015 ozone plan.

The possible alternatives to the proposed 2012 AQMP are limited by the nature of the project. For example, the SCAQMD is required to prepare a PM_{2.5} AQMP that demonstrates attainment of the federal PM_{2.5} federal ambient air quality standard by 2014. To achieve the 2006 24-hour PM_{2.5} ambient air quality standard by 2014, the 2012 AQMP relies on a comprehensive and integrated control approach. Further, 2012 AQMP control measures are developed to achieve the maximum emission reduction potential that is technically feasible and cost-effective. Because, the 2012 AQMP includes all feasible control measures identified as part of the AQMP development process and control measures reflect the maximum emission reduction potential, it is difficult to develop alternatives that would still achieve the project objectives, including attaining the federal 24-hour PM_{2.5} standard, but are substantially different than the 2012 AQMP.

In spite of the limitations identified above with regard to developing project alternatives, similar to previous AQMP Program EIRs, alternatives to the 2012 AQMP focus on emphasizing different pollutant control strategies. For example, alternatives could rely more heavily on emission reductions from short-term stationary source control measures versus greater reliance on future §182 (e)(5) mobile source control measures. Ultimately, all project alternatives must demonstrate attainment of the federal 24-hour PM_{2.5} standard.

The shortest routes for attaining the federal 24-hour PM_{2.5} typically rely on controlling directly emitted PM_{2.5} or controlling PM_{2.5} precursor pollutants, especially NO_x because it also contributes to the SCAQMD's efforts to attain the federal ozone standards. Some combination of strategies to control both PM_{2.5} and NO_x is necessary because neither a PM_{2.5}-heavy control approach nor a NO_x-heavy control approach can attain the standards alone.

Development of the PM_{2.5} attainment control strategy relies on baseline emissions specified by the emissions inventory of all emissions sources in the district. As indicated in Subchapter 3-1 of this [Final](#) Program EIR, the federal CAA §172 (c)(3) requires all plan (AQMP) submittals to include a comprehensive, accurate, and current inventory of actual emissions from all sources of the relevant pollutant(s). To fulfill the intent of this requirement, the year 2008 was selected as the baseline year for analyzing the effectiveness of 2012 AQMP control measures in attaining the PM_{2.5} standard. Consistent with CAA §172 (c)(3) requirements, the baseline year for alternatives to the 2012 AQMP will also be [year](#) 2008.

Typically, the existing setting is established at the time the NOP/IS is circulated for public review, which was June 2012. This baseline is used for all environmental topics analyzed in this [Final](#) Program EIR except air quality. However, CEQA Guidelines §15125 (a) recognizes that a baseline may be established at times other than when the NOP/IS is circulated to the public by stating (emphasis added), “This environmental setting *will normally* constitute the baseline physical conditions by which a lead agency determines whether an impact is significant.” Therefore, consistent with CAA §172 (c)(3) requirements, the air quality baseline for the 2012 AQMP is the year 2008.

6.3 ALTERNATIVES REJECTED AS INFEASIBLE

In accordance with CEQA Guidelines §15126.6 (c), a CEQA document should identify any alternatives that were considered by the lead agency, but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination. Section 15126.6 (c) also states that among the factors that may be used to eliminate alternatives from detailed consideration in an EIR are: 1) failure to meet most of the basic project objectives; 2) infeasibility; or, 3) inability to avoid significant environmental impacts.

As noted in Section 6.2, the range of feasible alternatives to the 2012 AQMP is limited by the nature of the proposed project and associated legal requirements. Similarly, the range of alternatives considered, but rejected as infeasible is also relatively limited. The following

subsections identify two potential alternatives to the 2012 AQMP, but were rejected for the reasons explained in each subsection.

6.3.1 No Project Alternative – No Further Action

CEQA documents typically assume that the adoption of a no project alternative would result in no further action on the part of the project proponent or lead agency. For example, in the case of a proposed land use project such as a housing development, adopting the No Project Alternative terminates further consideration of that housing development or any housing development alternative identified in the associated CEQA document. In that case, the existing setting would typically remain unchanged.

The concept of taking no further action (and thereby leaving the existing setting intact) by adopting a No Project Alternative does not readily apply to an update of an already adopted and legally mandated plan such as the AQMP. Adopting a no project alternative for an update to the AQMP does not imply that no further action will be taken (e.g., halting implementation of the existing AQMP). The federal and state Clean Air Acts require the SCAQMD to revise and implement the AQMP in order to attain all state and national ambient air quality standards. A no further action no project alternative in the case of the AQMP is not a legally viable alternative. Consequently, the No Project Alternative presented in this [Final Program](#) EIR is the continued implementation of the 2007 AQMP. Although it is unclear whether or not continued implementation of the 2007 AQMP is a feasible alternative because the SCAQMD is required to submit to U.S. EPA a PM_{2.5} AQMP that demonstrates attainment of the 2006 24-hour PM_{2.5} national ambient air quality standard by December 14, 2012, as explained above. However, continued implementation of the 2007 AQMP as the No Project Alternative is consistent with CEQA Guidelines §15126.6 (e)(2) (*italics added*):

“The ‘no project’ analysis shall discuss the existing conditions at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, *as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services...*”

It should be noted that, except for air quality, there would be no further incremental impacts on the existing environment if no further action is taken. Although there are existing rules that may have future compliance dates, potential adverse impacts from these rules have already been evaluated in the Final Program EIR for the 2007 AQMP and subsequent rule-specific CEQA documents. Air quality would continue to improve to a certain extent, but it is unlikely that all state or federal ozone standards would be achieved as required by the federal and California CAAs. It is possible that the federal 24-hour PM_{2.5} standard may be achieved; however, it is unlikely that further progress would be made towards achieving the state PM_{2.5} standard as required by the California CAA.

6.3.2 More NO_x Reductions Through Accelerated Penetration of Alternative Fuel Mobile Sources

This NO_x heavy emission reduction alternative would have relied on accelerated penetration of alternative fuel on-road and off-road mobile sources. Specifically, this alternative would have required 50 percent of all heavy-duty on-road mobile sources subject to CARB's adopted Truck and Bus Regulation to meet the requirement of replacing heavy-duty on-road trucks and buses with trucks and buses that comply with the 2010 model year or newer final requirements by the year 2014. Similarly, this alternative would have required 50 percent of all off-road mobile sources subject to CARB's adopted off-road mobile sources regulations to meet the requirement of replacing heavy-duty off-road mobile sources that comply with Tier 4 or equivalent requirements by the year 2014.

Converting heavy-duty on-road mobile sources to year 2010 model year engines or off-road mobile sources to Tier 4 or equivalent standards has typically required incentive funding to offset the typically higher costs of the cleaner vehicles. Incentive funding sources include Carl Moyer or Proposition 1B funds. This NO_x heavy emission reduction alternative is considered to be economically infeasible because insufficient funding would be available to meet the 50 percent penetration rate in the 2012 to 2014 timeframe.

6.3.3 Alternative Location

CEQA requires consideration of an alternative location alternative if significant effects of the project would be avoided or substantially lessened by putting the project in another location. Pursuant to CEQA Guidelines §15126.6 (f)(2)(B), if the lead agency concludes that no feasible alternative locations exist, it must disclose the reasons for this conclusion, and should include the reasons in the EIR. For example, in some cases there may be no feasible alternative locations for a geothermal plant or mining project which must be in close proximity to natural resources at a given location. The 2012 AQMP applies to the entire area of the SCAQMD's jurisdiction. The SCAQMD has no authority to adopt and enforce 2012 AQMP control measures in areas outside its jurisdiction. CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws (CEQA Guidelines §15040 (b)). Therefore, an alternative locations alternative is not considered to be a feasible alternative

6.4 ALTERNATIVES TO THE 2012 AQMP

Because of the substantial emission reductions necessary to bring the region into attainment with the federal 24-hour PM_{2.5} standard, as well as the eight-hour ozone, the SCAQMD is relatively limited with regard to the number of potential alternatives to the 2012 AQMP. As a result, with the exception of the No Project Alternative, all project alternatives include the same short-term control measures to attain the federal 24-hour standard because of the requirement to attain the standard by 2014 and these measures would regulate or further regulate PM emission sources where emission reductions are feasible.

Although most of the project alternatives also include long-term measures, the primary difference between the various alternatives is the pollutant control strategies being

employed. The alternatives rely to a greater or lesser extent on PM control to attain the federal 24-hour PM_{2.5} standard or NO_x control to, not only attain the federal 24-hour PM_{2.5} standard, but to demonstrate progress in attaining the federal ozone standards as well. Similarly, the pollutant control strategy of the alternative may determine the extent to which the SCAQMD and CARB will rely on specific emission source categories to obtain future emission reductions. This means that the SCAQMD and CARB may rely to a greater or lesser extent on emission reductions from some source categories (e.g., on- and off-road mobile sources), compared to other source categories. The following subsections provide a brief description of the alternatives.

6.4.1 Alternative 1 – No Project Alternative (Continued Implementation of the 2007 AQMP)

CEQA requires the specific alternative of no project to be evaluated. A No Project Alternative consists of what would occur if the proposed project was not approved; in this case, not adopting the 2012 AQMP. The net effect of not adopting the 2012 AQMP would be a continuation of the 2007 AQMP. This approach is consistent with CEQA Guidelines §15126.6 (e)(3)(A), which states: "When no project is the revision on an existing land use or regulatory plan, policy or ongoing operation, the 'no project' alternative will be the continuation of the existing plan, policy, or operation into the future. Typically this is a situation where other projects initiated under the existing plan will continue while the new plan is developed. Thus, the projected impacts of the proposed plan or alternative plans would be compared to the impacts that would occur under the existing plan."

Between 2008 and 2011, twelve short-term control measures from the 2007 AQMP have been promulgated as rules or rule amendments by the SCAQMD. Promulgation of these 12 control measures has allowed the SCAQMD to achieve its stationary source emission reduction targets (see Table 1-2 in Chapter 1 of the 2012 AQMP). Similarly, since the 2007 AQMP was adopted, 2007 AQMP control measure commitments were adopted (either entirely or partially) by CARB (see Table 1-2 in Chapter 1 of the 2012 AQMP).

Based on the above information, it is assumed for this alternative that both the SCAQMD and CARB have achieved their 2007 AQMP short-term emission reduction targets. Therefore, the 2007 AQMP does not contain any remaining short-term stationary source or mobile source control measures (Table 6-1). Although there were a couple of short-term control measures remaining (e.g., BCM-05 - Emission Reductions from Under-fired Charbroilers, MCS-06 - Improved Start-up and Shutdown, and Turnaround Procedures, etc.), there are no emission reductions associated with them or they are, or will be under evaluation to determine the feasibility of potential emission reductions in the future. As a result, all remaining necessary emission reductions from continuing to implement the 2007 AQMP would be obtained through implementing CAA §182 (e)(5) ("black box") measures. Table 6-1 summarizes the components of Alternative 1 and associated assumptions.

TABLE 6-1 (Concluded)
2012 AQMP and Alternatives

PLAN TYPE	ATTAINMENT YEAR	STATIONARY SOURCE CMS	ON-ROAD MOBILE SOURCE CMS	OFF-ROAD MOBILE SOURCE CMS	COMMENT
Alternative 4 – PM2.5 Emissions Reduction Strategies Only					
PM2.5 Control Measures Only, No Ozone Control Measures	PM2.5 – 2014	Same as 2012 AQMP 5 categories: 1) PM Sources (4 CMs); 2) Combustion (1 CM); 3) Multiple Component (1 CM); 4) Indirect (1 CM); 5) Educational (1 CM)	None	None	<p>1. Does not include CAA §182 (e)(5) “black box” measures.</p> <p>2. Includes implementing all remaining 2007 AQMP ozone control measures.</p>

Table 6-2 shows the black box measure strategies from the 2007 AQMP. Because all control measures in Table 6-2 regulate mobile sources or the VOC content in consumer products, they are all considered to be ozone reduction control measures. The only exceptions to this assumption are the renewable energy and AB32 implementation control measures, which primarily address GHG emissions. Otherwise, there are no control measures in Alternative 1 that specifically address reducing PM_{2.5} emissions.

Although Table 6-2 shows the 2007 AQMP black box measures and also shows the §182 (e)(5) control measures from the 2012 AQMP that affect the same emissions sources, this does not imply that the 2007 AQMP measures analyzed in this [Final](#) Program EIR will be updated to conform to the 2012 AQMP control measures. The descriptions of the black box control measures from the 2007 AQMP analyzed here are exactly the same as their descriptions in the 2007 AQMP.

TABLE 6-2

Long-Term (Black Box) Control Measures from the 2007 AQMP

SOURCE CATEGORY	METHOD OF EMISSIONS CONTROL	2012 AQMP CONTROL MEASURES AFFECTING SAME SOURCE
Light Duty Vehicles (SCLTM-01A)	Extensive retirement of high-emitting vehicles and accelerated penetration of ATPZEVs and ZEVs	ONRD-01 & ADV-01
On-Road Heavy Duty Vehicles (SCLTM-01B)	<ul style="list-style-type: none"> • Expanded modernization and retrofit of heavy-duty trucks and buses • Expanded inspection and maintenance program • Advanced near-zero and zero-emitting cargo transportation technologies 	ONRD-03, ONRD-05 & ADV-06
Off-Road Vehicles (SCLTM-02)	Expanded modernization and retrofit of off-road equipment	OFFRD-01 & ADV-06
Consumer Products (SCLTM-03)	Ultra Low-VOC formulations; Reactivity-based controls	CTS-04
Fuels	More stringent gasoline and diesel specifications; Extensive use of diesel alternatives	No update ^a
Marine Vessels	More stringent emission standards and programs for new and existing ocean-going vessels and harbor craft	IND-01, OFFRD-05 & ADV-05
Locomotives	Advanced near-zero and zero emitting cargo transportation technologies	OFFRD-02 & ADV-02

TABLE 6-2 (CONCLUDED)

Long-Term (Black Box) Control Measures from the 2007 AQMP

SOURCE CATEGORY	METHOD OF EMISSIONS CONTROL	2012 AQMP CONTROL MEASURES AFFECTING SAME SOURCE
Pleasure Craft	Accelerated replacement and retrofit of high-emitting engines	No update ^a
Aircraft	More stringent emission standards for jet aircraft (engine standards, clean fuels, retrofit controls); Airport bubble	ADV-07
Renewable Energy	Accelerated use of renewable energy and development of hydrogen technology and infrastructure	No update ^a
AB32 Implementation	Concurrent criteria pollutant reduction technologies	No update ^a

^a No update means that the control measures have not been updated as part of the 2012 AQMP, which primarily addresses attaining the federal 24-hour PM_{2.5} standard, [but also includes a federal one-hour ozone attainment demonstration](#).

The No Project Alternative analyzed here will take into account the most current air quality setting (2008) and will include updated and refined control measures, but no new control measures (Table 6-2).

6.4.2 Alternative 2 – PM_{2.5} Attainment Plan Localized PM Control in Mira Loma Area

Alternative 2 is the 2012 AQMP project that was included in the 8/24/12 NOP/IS. This alternative is similar to the currently proposed 2012 AQMP with the following exceptions. Alternative 2 does not include Control Measure BCM-02 – Further Emission reductions from open burning because this measure was not included as part of the 2012 AQMP project description in the 8/24/12 NOP/IS. Alternative 2 includes the same episodic control measures that would apply only to the Mira Loma area and described in the June 28, 2012 NOP/IS. The episodic control measures for the Mira Loma area, shown in Figure 6-1, are described in the following paragraphs.

Control Measure MCS-04 contains three sub-control measures, two PM_{2.5} control measures and one ozone control measure, targeting specific sources around Mira Loma (approximately within a 10-mile radial), including mobile sources serving warehouse and distribution centers, residential wood burning devices (e.g., fireplaces and wood stoves), and livestock waste. Air quality data through 2011 show that the Mira Loma monitoring station in western Riverside County is the only monitoring station violating the federal 24-hour PM_{2.5} standard. Emissions sources in the Mira Loma area that contribute to violations of the federal 24-hour PM_{2.5} standard include: 1) local PM emissions from the large concentration of warehouses that attract heavy-duty diesel haul trucks; and 2) transport of

ammonia, a PM precursor, from dairies located downwind of the Mira Loma area (Figure 6-1). Therefore, the purpose of the sub-control measures under MCS-04 is to achieve a 1.0 $\mu\text{g}/\text{m}^3$ PM_{2.5} air quality improvement (based on the 24-hour design value) at the Mira Loma station through targeted reductions of direct PM and NO_x emissions from various sources in the areas around the monitoring station.

FIGURE 6-1

PM_{2.5} Emission Sources in the Mira Loma Area
(Numbers Represent Source Receptor Areas)

These control measures would be implemented sequentially and as needed to meet the 24-hour PM_{2.5} standard at the Mira Loma monitoring station. The mobile source control measure would be implemented initially, followed by the wood burning devices control measure. In the event ambient data indicate the 24-hour PM_{2.5} standard continues to be exceeded in Mira Loma in 2014 (single year, 98th percentile), the livestock measure would then be implemented in 2015 specifically applicable to dairies. If the 24-hour PM_{2.5} standard is not exceeded, each subsequent year would then be similarly assessed. U.S. EPA has suggested that such localized, and in some cases episodic or seasonal controls can be a very cost effective strategy for achieving the NAAQSs.

The specific sub-control measures identified in the 6/28/12 NOP/IS under MCS-04 were labeled as Control Measures MCS-04A, MCS-04B, and MCS-04C. They are relabeled to avoid confusion with the 2012 AQMP and are summarized in the following paragraphs.

CMALT-2A (formerly MCS-04A and merged into ONRD-04 of the 2012 AQMP) Further Emission Reductions From Mobile Sources Serving Warehouse And Distribution Centers Located Around The Mira Loma Region [NO_x, PM]: Over the past decade, warehouse and distribution centers have been steadily increasing in size and number throughout the region. The greatest growth in warehouses/distribution centers has been in the Riverside area, especially the Mira Loma area (Figure 6-1), and San Bernardino areas. According to SCAG, by 2035 over one billion square feet of warehousing will be needed in the southern California area to support goods movement activities (SCAG, 2010).

Distribution centers and/or warehouses are facilities that serve as a distribution point for the transfer of goods. Such facilities include cold storage warehouses, goods transfer facilities, and transloading facilities, where imported goods are sorted, tagged, repackaged and prepared for retail distributions. These operations involve trucks, trailers, shipping containers, and other equipment with diesel engines. A warehouse/distribution center can be comprised of multiple centers or warehouse/distribution centers within an area. The size can range from 100,000 square feet to well over one million square feet. Depending on the size and type, a warehouse/distribution center may have hundreds of diesel trucks per day that deliver, load, and/or unload goods, generally operating seven days per week. To the extent that these trucks are transporting perishable goods, they are equipped with diesel-powered transport refrigeration units (TRUs) or TRU generator sets. The activities associated with delivering, storing, and loading freight produces NO_x and PM emissions, including diesel particulate matter (DPM).

This sub-control would be a voluntary incentive program with the intent of reducing emission from older, pre-2010 heavy-duty vehicles beyond the emission reductions targeted in CARB's Truck and Bus Regulation. In addition, the proposed action would direct a portion of available public funding to assist in replacing older diesel trucks serving warehouse and distribution centers to a truck with an engine meeting on-road heavy-duty exhaust emission standards by 2015. The incentive program would place the highest priority on on-road vehicles that provide at least 75 percent of their service to warehouse and distribution centers in the Mira Loma region and have gross vehicle weight ratings of 26,001 lbs or greater.

Sub-Control Measure MCS-04 would only implemented if the federal 24-hour PM_{2.5} standard is exceeded. If needed to demonstrate attainment of the 24-hour PM_{2.5} standard at the Mira Loma monitoring station, Sub-Control Measure MCS-04 would be implemented first of the three sub-control measures. If the 24-hour PM_{2.5} standard is not exceeded in the Mira Loma area in 2014 (single year, 98th percentile), PM_{2.5} concentrations in each subsequent year would then be similarly assessed for any exceedances of the federal 24-hour PM_{2.5} standard.

CMALT-2B (formerly 2007 AQMP Control Measure BCM-03; MCS-04B in the 6/28/12 NOP/IS; and is BCM-01 in the 2012 AQMP) Further Reductions from Residential Wood Burning Devices in Mira Loma Region [PM2.5] SCAQMD Rule 445 – Wood Burning Devices, was adopted in 2008 and prohibits the burning of any product not intended for use as a fuel (e.g., trash) in a wood burning device and requires commercial firewood facilities to only sell seasoned firewood (20 percent or less moisture content) from July through February. Rule 445 also establishes a mandatory wood burning curtailment program that extends from November 1 through the end of February each winter season. During a wood burning curtailment period, the public is required to refrain from both indoor and outdoor solid fuel burning in specific areas where PM2.5 air quality is forecast to exceed $35 \mu\text{g}/\text{m}^3$ (federal 24-hour standard).

Under Sub-Control Measure CMALT-2B the current mandatory wood burning curtailment threshold would be lowered from $35 \mu\text{g}/\text{m}^3$ to a more conservative $30 \mu\text{g}/\text{m}^3$. This means that a mandatory wood burning curtailment would be implemented in the Mira Loma area when a PM2.5 level of greater than $30 \mu\text{g}/\text{m}^3$ is forecast at monitoring stations in the Mira Loma area at any monitoring station at which the design value has exceeded the current PM2.5 24-hour standard of $35 \mu\text{g}/\text{m}^3$ for either of the two previous years. The design value is the three-year average of the annual 98th percentile of monitored ambient PM2.5 data.

It is expected that, initially, the wood burning curtailment program would continue to target winter season emissions. In addition, the feasibility of an enhanced program to incentivize the purchase of gaseous fueled devices would be explored relative to areas in Mira Loma that are affected by high PM2.5 concentrations. For example, an enhanced incentive program for the Mira Loma community could result in the installation of as many as 2,000 units in existing residential homes.

It is expected that this sub-control measure would be implemented only if the federal PM2.5 standard continues to be exceeded in the Mira Loma area. In this situation, Sub-Control Measure CMALT-2A would be implemented first to address exceedances of the federal PM2.5 standard. If, after implementing Sub-Control Measure CMALT-2A, exceedances continue and data indicate the 24-hour PM2.5 standard is exceeded in Mira Loma in 2014 (single year, 98th percentile), only then would Sub-Control Measure CMALT-2B be implemented. If the 24-hour PM2.5 standard is not exceeded in the Mira Loma area in 2014 (single year, 98th percentile), PM2.5 concentrations in each subsequent year would then be similarly assessed for any exceedances of the federal 24-hour PM2.5 standard.

CMALT-2C (formerly 2007 AQMP Control Measure MCS-05; MCS-04C in the 6/28/12 NOP/IS and BCM-04 in the 2012 AQMP) Further Ammonia Reductions from Livestock Waste in Mira Loma Region [Ammonia] Ammonia contributes to formation of PM2.5 and mixes with transport emissions, particularly to form aerosol ammonium nitrate and ammonium sulfate. Livestock waste produces appreciable amounts of ammonia emissions. With the approval of Proposition 2 (known as cage-free proposition that passed in 2008), economic, and product demand climate, the livestock industry in the South Coast jurisdiction is not considered a growth industry

into the future. Currently, however, there continues to be large concentrations of dairies downwind of the Mira Loma area (Figure 6-1), which contributes to exceedances of the federal PM_{2.5} standard.

Like 2012 AQMP Control Measure BCM-04, the purpose of the sub-control measure is to reduce ammonia emissions from livestock operations with emphasis on dairies in the Mira Loma area. This control measure would reduce the pH level in manure through the application of acidulant additives (acidifier) as mitigation for ammonia. The acidifier sodium bisulfate (SBS) is being considered for use in animal housing areas where high concentrations of fresh manure are. Research indicates best results with the use of SBS on localized “hot spots.” SBS can also be applied to manure stock piles, high manure concentrations at fence lines, and when scraping manure to reduce ammonia spiking from the leftover remnants of manure and urine. Implementing this measure would become effective in the event ambient data indicates the 24-hour PM_{2.5} standard is exceeded in Mira Loma in 2014 (single year, 98th percentile). Before implementing Sub-Control Measure CMALT-2C, Sub-Control Measures CMALT-2A and MCS-04 B would be implemented. The livestock measure would then be implemented in 2015, specifically applicable to dairies. If not exceeded, each subsequent year would then be similarly assessed. In the interim, a pilot program will be conducted to further evaluate the application of SBS at local dairies so as to evaluate the direct technical and economic feasibility of application.

6.4.3 Alternative 3 – Greater Reliance on NO_x Emissions Reductions

Alternative 3 would rely to a greater extent on NO_x emission reductions, primarily from on- and off-road mobile sources as described in the following paragraphs, to achieve the federal 24-hour PM_{2.5} standard. Greater reliance on NO_x emission reductions is considered a viable alternative because NO_x is not only a PM_{2.5} precursor, it is also an ozone precursor, so this alternative would also be consistent with the SCAQMD’s efforts to continue making expeditious progress in attaining the federal one-hour and eight-hour ozone standards.

Because this alternative relies more heavily on NO_x emission reductions to attain the federal 24-hour PM_{2.5} standard, it does not include Control Measure BCM-01 - Further Emissions Reductions from Wood Burning Devices. Although direct PM_{2.5} emission reductions are more effective than NO_x in reducing PM_{2.5} concentrations, early and greater reliance on Basin-wide NO_x emission reductions from on- and off-road mobile sources would not only assist with attaining the PM_{2.5} standard, they would also contribute to making greater progress in attaining the one-hour and eight-hour ozone standards than might otherwise be the case. Otherwise Alternative 3 includes all of the same PM_{2.5} control measures as the 2012 AQMP.

Generally, Alternative 3 includes all of the same ozone control measures as the 2012 AQMP, which includes stationary source control measures and CAA §182 (e)(5) stationary source, on-road mobile source, off-road mobile source, and advanced . Two ozone Control Measures, ONRD-03 and OFFRD-01, would be modified under Alternative 3 as explained in the following paragraphs.

Control Measure ONRD-03 would be modified to accelerate implementation of CARB's on-road truck and bus regulation, which was originally adopted December 12, 2008. The regulation requires diesel trucks and buses that operate in California to be upgraded to reduce emissions. Heavier trucks must be retrofitted with PM filters beginning January 1, 2012, and older trucks must be replaced starting January 1, 2015. By January 1, 2023, nearly all trucks and buses will need to have 2010 model year engines or equivalent. The CARB regulation applies to nearly all privately- and federally-owned diesel fueled trucks and buses and privately and publicly owned school buses with a gross vehicle weight rating (GVWR) greater than 14,000 pounds. Small fleets with three or fewer diesel trucks can delay compliance and there are a number of extensions for low-mileage construction trucks, early PM filter retrofits, adding cleaner vehicles, and other situations. Privately and publicly owned school buses have different requirements.

Under Alternative 3 and ozone Control Measure ONRD-03, the rate of compliance with the statewide on-road truck and bus regulation would double by the year 2017 compared to the estimated compliance provided by CARB in the existing regulation for year 2017. Compliance with the increased penetration rate would be with engines that meet 2010 exhaust emission standards. Because there is more than one engine type that complies with the year 2010 engine exhaust requirements, it is unknown what the exact breakdown of compliant engine types will be in operation. Therefore, under this alternative it is assumed that 25 percent of the additional vehicles complying with the year 2010 engine exhaust standards would comply using CNG engines and the remainder would comply using diesel engines.

SCAQMD staff estimates that Alternative 3 could result in approximately 5,000 additional medium-heavy-duty trucks (14,000 to 26,000 pounds gross vehicle weight) complying with the year 2010 engine exhaust requirements for the years 2013 through 2017. This means that over the five years 2013 through 2017, 1,000 additional medium-heavy-duty trucks would comply with the year 2012 engine exhaust requirements. Consistent with the above assumption, approximately 250 of these medium-heavy-duty trucks would comply using CNG engines, while the remaining 750 would be compliant diesel or diesel hybrid trucks.

Finally, Alternative 3 ozone Control Measure OFFRD-01 would require accelerated implementation of CARB's off-road diesel vehicle regulation, which was originally adopted July 26, 2007. The overall purpose of the off-road regulation is to reduce NOx and PM emission from off-road diesel vehicles operating within California through increased turnover of older higher emitting vehicles to newer cleaner ones. The regulation applies to self-propelled diesel-fueled vehicles in California (except for agricultural or personal use, or for use at ports or intermodal railyards) with engines with a maximum rating of 25 horsepower or greater. The requirements and compliance dates of the Off-Road regulation vary by fleet size. To determine the size of their fleets, fleet operators must add up all of the off-road horsepower (hp) under common ownership or control in the fleet. For example, a small fleet would be comprised of a fleet with a total horsepower rating of less than or equal to 2,500 hp; a medium fleet would be comprised of a fleet with a total horsepower rating of 2,501 to 5,000 hp; and a large fleet would be comprised of a fleet with a total horsepower rating of over 5,000 hp (all state and federal fleets would be classified as large fleets

regardless of hp rating). Large, medium and small fleets must begin complying with regulation requirements by the beginning of 2014, 2017, and 2019 respectively.

Alternative 3 ozone Control Measure OFFRD-01 would require CARB to amend the off-road vehicle regulation to require doubling the implementation rate of the regulation such that the emission reductions expected by 2021 (the 8th year of compliance) would be realized by the year 2017. SCAQMD staff estimates that doubling the implementation rate of CARB's off-road vehicle regulation would result in approximately 19,344 additional off-road engine repowers or vehicle replacements over the years 2014 to 2017 (Table 6-3). The reason that the accelerated regulation affects more than three times the number of vehicles, instead of simply doubling the number is that the regulation was designed to regulate more vehicles in the later years (the vehicle turnover percentage rises from 8 percent to 10 percent in 2018 and the small fleets need to comply beginning in 2019).

TABLE 6-3

Number of Additional Off-Road Vehicles Affected by Alternative 3

YEAR	CURRENT RULE	ACCELERATED RULE	# OF ADDITIONAL VEHICLES
2014	2,447	5,500	3,053
2015	3,186	5,164	1,978
2016	1,982	10,087	8,105
2017	3,536	9,742	6,206
Total	11,150	30,494	19,344

6.4.4 Alternative 4 – PM2.5 Emissions Reduction Strategies Only

As requested by the public during the public comment period for the June 28, 2012 NOP/IS, the SCAQMD has incorporated a PM2.5 reduction strategies only alternative. Alternative 4 is considered to be a legally viable alternative because the SCAQMD is only required to submit PM2.5 plan demonstrating attainment of the 2006 24-hour PM2.5 National Ambient Air Quality Standard no later than three years from the effective date of designation of nonattainment of the federal 24-hour PM2.5 standard, December 14, 2012. However, there is no federal requirement to submit an ozone plan by the same date as the PM2.5 plan, December 14, 2012.

Alternative 4 would only include the control measures in Table 6-4. None of the remaining CAA §182 (e)(5) control measures, which include all remaining stationary source control measures (see Table 4-3, 2012 AQMP) and all on-road, off-road, and ADV control measures (see Table 4-6, 2012 AQMP) would be included in Alternative 4.

Creating a PM2.5 reduction strategies only alternative means that the Ozone SIP portion of the 2007 AQMP would remain in effect. This means that the CAA §182 (e)(5) black box measures shown in Table 6-2 would continue to be considered for promulgation into rules or

regulations in the future. Consequently the environmental analysis for this alternative would include potentially significant adverse environmental impacts from the measures listed in Tables 6-2 and 6-4.

TABLE 6-4

List of SCAQMD's Adoption/Implementation Dates and Estimated Emission Reductions from Short-Term PM_{2.5} Control Measures

NUMBER	TITLE	ADOPTION	IMPLEMENTATION PERIOD	REDUCTION (TPD)
CMB-01	Further NO _x Reductions from RECLAIM [NO _x] –Phase I	2013	2014	2-3
BCM-01	Further Reductions from Residential Wood Burning Devices [PM _{2.5}]	2013	2013-2014	7.1 ^a
BCM-02	Further Reductions from Open Burning [PM _{2.5}]	2013	2013-2014	4.6 ^b
BCM-03 (formerly BCM-05)	Emission Reductions from Under-Fired Charbroilers [PM _{2.5}]	Phase I – 2013 (Tech Assessment) Phase II - TBD	TBD	1 ^c
BCM-04	Further Ammonia Reductions from Livestock Waste [NH ₃]	Phase I – 2013-2014 (Tech Assessment) Phase II - TBD	TBD	TBD ^d
IND -01 (formerly MOB-03)	Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources [NO _x , SO _x , PM _{2.5}]	2013	12 months after trigger	N/A ^e
EDU-01 (formerly MCS-02, MCS-03)	Further Criteria Pollutant Reductions from Education, Outreach and Incentives [All Pollutants]	Ongoing	Ongoing	N/A ^e
MCS-01 (formerly MCS-07)	Application of All Feasible Measures Assessment [All Pollutants]	Ongoing	Ongoing	TBD ^d

Source: Table 4-2, 2012 Air Quality Management Plan

- Winter average day reductions based on episodic conditions and 75 percent compliance rate.
- Reductions based on episodic day conditions.
- Will submit into SIP once technically feasible and cost effective options are confirmed.
- TBD means reductions to be determined once the technical assessment is complete, and inventory and control approach are identified.
- N/A means reductions that cannot be quantified due to the nature of the measure (e.g., outreach, incentive programs) or if the measure is designed to ensure reductions that have been assumed to occur will in fact occur.

6.5 ALTERNATIVES ANALYSIS

The following subsections include the same environmental topic areas evaluated for the proposed 2012 AQMP. Under each environmental topic area, impacts and significance conclusions are summarized for the proposed 2012 AQMP. In addition, potential impacts generated by each alternative to that environmental topic are described, a significance determination is made for the alternative, and environmental impacts from each alternative are compared to the environmental impacts identified for the proposed project.

6.5.1 Aesthetics

The potential direct and indirect aesthetics impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect aesthetics impacts from each alternative relative to the 2012 AQMP.

6.5.1.1 Proposed Project

Potential direct and indirect aesthetics impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis of potential aesthetics impacts from implementing the 2012 AQMP, refer to Subchapter 4.1 – Aesthetics.

6.5.1.1.1 *PM2.5 Control Measures*

The analysis in Subchapter 4.1 indicated that no 2012 AQMP PM2.5 control measures were identified that have the potential to significantly adversely affect aesthetics resources. Therefore, potential impacts to aesthetics resources are concluded to be less than significant.

6.5.1.1.2 *Ozone Control Measures*

The analysis in Subchapter 4.1 identified the following 2012 AQMP ozone control measures as having the potential to create significant adverse aesthetics impacts, including visual impacts and impacts to scenic highways, ozone Control Measures ONRD-05, ADV-01, and ADV-2. These control measures identify “wayside” power (such as electricity from overhead wires) as one of the zero emission technologies that could be used to reduce emissions from heavy-duty trucks and locomotives. Wayside power technologies include overhead catenary lines, where power is delivered from the electrical grid through the overhead wire to a pantograph on the vehicle itself. Catenary systems are well-established and efficient in light-rail applications, trolley cars and buses, and even mining trucks.

Control Measure ADV-01 indicates that the I-710 corridor was selected as high priority for introduction of zero-emission technology¹. The 2012-2035 RTP/SCS also designates a route

¹ Los Angeles County Metropolitan Transportation Authority, *Alternative Goods Movement Technology Analysis-Initial Feasibility Study Report, Final Report: I-710 Corridor Project EIR/EIS*. Prepared by URS. January 6, 2009.

along the State Route 60 freeway as an east-west freight corridor². Both of these corridors are currently heavily used freight corridors. In addition, there is currently a pilot project under consideration to install catenary lines at one of two sites, a site along the Terminal Island Freeway and on Navy Way at the Port of Los Angeles. Further, the most likely areas affected by these control measures are likely to be within five miles of the San Pedro Bay Ports complex because the heavy-duty truck measures affect near-dock truck transport. Finally, the I-710 freeway, State Route 60, and the roadways that may be chosen for the pilot project are not identified as scenic highways or eligible to be classified as scenic roadways nor are there any scenic highways or highways eligible for state scenic highway status.

6.5.1.1.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, it was concluded in Subchapter 4.1 that the construction and operation of the catenary or overhead power lines that could be used to power Zero and Near Zero vehicles and locomotives are not expected to be visible to any Scenic Highway or any roadway eligible as a Scenic Highway. Therefore, project-specific aesthetics impacts associated with the 2012 AQMP are less than significant.

Since, anticipated project-specific aesthetics impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific aesthetics impacts from the 2012 AQMP were evaluated in connection with aesthetic impacts from SCAG's 2012-2035 RTP/SCS. Further, it was concluded that aesthetics impacts from the 2012 AQMP would not contribute to significant adverse cumulative aesthetics impacts from the 2012-2035 RTP/SCS. Since aesthetics impacts from the 2012 AQMP are not cumulatively considerable and don't contribute to cumulative impacts generated by the 2012-2035 RTP/SCS, cumulative aesthetics impacts from the 2012 AQMP are not significant.

6.5.1.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR for the 2012 AQMP, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, the aesthetics impacts analysis for Alternative 1 will focus only on potential aesthetics impacts identified for the black box measures. Potential aesthetics impacts from implementing Alternative 1 are described in the Subsections 6.5.1.2.2 and 6.5.1.2.3.

² Los Angeles County Metropolitan Transportation Authority, *Alternative Goods Movement Technology Analysis-Initial Feasibility Study Report, Final Report: I-710 Corridor Project EIR/EIS*. Prepared by URS. January 6, 2009.

6.5.1.2.1 *Alternative 1 Analysis Assumptions*

If 2007 AQMP black box control measures contributed to impacts in any environmental topic areas that were concluded to be less than significant, it is assumed that they would continue to contribute impacts to those environmental topic areas, but impacts would be less than significant. Conversely, if 2007 AQMP black box control measures contributed to impacts to any environmental topic areas that were concluded to be significant, it is assumed for this analysis that they would continue to contribute to significant adverse impacts to those environmental topic areas. If 2007 AQMP black box control measures were not identified as contributing to impacts to an environmental topic area, for this analysis it was also assumed that they would not contribute to impacts to those environmental topic areas. For example, if it was concluded in the 2007 AQMP that the overall significance determination for an environmental topic area would be significant, but no black box control measures contributed to that significant adverse impact, it is assumed here that black box control measures that are part of Alternative 1 would also not contribute to significant adverse impacts to that environmental topic area. These same assumptions will be used for all subsequent environmental topics analyzed under Alternative 1.

6.5.1.2.2 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason and the fact that aesthetics was not an environmental topic identified in the NOP/IS for the 2007 AQMP that could be adversely affected by that AQMP, Alternative 1 is not expected to create any impacts to aesthetics resources from PM2.5 control measures.

6.5.1.2.3 *Ozone Control Measures*

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. As shown in Table 6-2, 2012 AQMP Control Measure ONRD-05 would regulate the same emissions sources as 2007 AQMP Control Measure Off-Road Vehicles (SCLTM-02) (e.g., heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies). However, catenary systems were not identified as a possible method of reducing heavy-duty truck emissions. In fact, it was concluded in the NOP/IS for the 2007 AQMP that some control measures may have beneficial effects on scenic resources by improving visibility as well as improving air quality, preventing smoke, limiting opening burning and wood burning; and minimizing fugitive dust emissions. Therefore, it is concluded that Alternative 1 does not have the potential to generate significant adverse aesthetics impacts.

6.5.1.2.4 *Project-specific and Cumulative Impacts Conclusion*

The NOP/IS for the 2007 AQMP concluded that the 2007 AQMP ozone control measures would not generate any aesthetics impacts. Therefore, consistent with the assumptions in

Subsection 6.5.1.2.1, it is presumed that, overall, Alternative 1 would not generate significant adverse project-specific aesthetics impacts.

Since, anticipated project-specific aesthetics impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project specific aesthetics impacts would be approximately equivalent to those generated by the 2012 AQMP, Alternative 1 would also not contribute to significant adverse cumulative impacts generated by the 2012-2035 RTP/SCS. Since aesthetics impacts from Alternative 1 are not cumulatively considerable, cumulative aesthetics impacts from Alternative 1 are not significant.

6.5.1.3 Alternative 2 – PM2.5 Attainment Plan Localized PM Control in Mira Loma Area

As explained in Subsection 6.4.2, with the exception of the two episodic PM2.5 control measures for Mira Loma³, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone Control Measure CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM2.5 and ozone control measures as the 2012 AQMP, except for PM2.5 Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential aesthetics impacts from implementing Alternative 2 would be the same as potential aesthetics impacts from implementing the 2012 AQMP. For the complete analysis of aesthetics impacts from the 2012 AQMP, refer to Subchapter 4.1 – Aesthetics. Potential aesthetics impacts from implementing Alternative 2 are described in the following subsections.

6.5.1.3.1 PM2.5 Control Measures

Similar to the analysis of aesthetics impacts for the 2012 AQMP in Subchapter 4.1, no PM2.5 control measures were identified from implementing Alternative 2 that have the potential to significantly adversely affect aesthetics resources. The two episodic control measures in this alternative that would apply only to the Mira Loma area do not contain any provisions for reducing heavy-duty truck emissions using wayside electricity such as catenary electric lines. None of the two PM2.5 control measures in the 2012 AQMP that regulates the same sources as the episodic control measures in Alternative 2 was identified as contributing to aesthetics impacts. Therefore, potential impacts to aesthetics resources from implementing the 2012 AQMP were concluded to be less than significant. This same conclusion applies to Alternative 2.

6.5.1.3.2 Ozone Control Measures

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone control measures CMALT-2A (similar to 2012 [AQMP](#) Control Measure ONRD-04) applies only to the Mira Loma area, aesthetics impacts from implementing Alternative 2

³ As indicated in Subsection 6.4.2, Alternative 2 control measures CMALT-2C, which would reduce ammonia emissions from livestock waste in the Mira Loma area, is identical to 2012 control measure BCM-04.

ozone control measures would be the same as the aesthetics impacts from implementing the 2012 AQMP ozone control measures. As shown in the analysis of aesthetics impacts for the 2012 AQMP in Subchapter 4.1, implementing ozone control measures from Alternative 2 (e.g., ozone Control Measures ONRD-05, ADV-01, and ADV-2) has the potential to generate adverse impacts to aesthetics resources, scenic highways in particular. No other 2012 AQMP ozone control measures were identified that could affect aesthetic resources. Such impacts associated with implementing the 2012 AQMP ozone control measures would be less than significant, as no scenic highways or highways eligible for scenic highway status would be adversely affected as a result of installing catenary lines in the future. This same conclusion applies to Alternative 2 because it contains the same three ozone control measures that have the potential to affect aesthetics resources.

6.5.1.3.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential project-specific adverse aesthetics impacts from Alternative 2 would be the same as potential project-specific aesthetics impacts from the 2012 AQMP and less than significant, because construction and operation of the catenary or overhead power lines that could be used to power Zero and Near Zero vehicles and locomotives are not expected to be visible to any Scenic Highway or any roadway eligible as a Scenic Highway.

Since, anticipated project-specific aesthetics impacts from Alternative 2 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project specific aesthetics impacts would be equivalent to those generated by the 2012 AQMP, Alternative 2 would also not contribute to significant adverse cumulative impacts generated by the 2012-2035 RTP/SCS. Since aesthetics impacts from Alternative 2 are not cumulatively considerable, cumulative aesthetics impacts from Alternative 2 are not significant and equivalent to the 2012 AQMP.

6.5.1.4 Alternative 3 – Greater Reliance on NOx Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential aesthetics impacts from implementing Alternative 3 would be the same as potential aesthetics impacts from implementing the 2012 AQMP. For the complete analysis of aesthetics impacts from the 2012 AQMP, refer to Subchapter 4.1 – Aesthetics.

6.5.1.4.1 *PM2.5 Control Measures*

Similar to the analysis of aesthetics impacts for the 2012 AQMP in Subchapter 4.1, no PM2.5 control measures were identified from implementing Alternative 3 that have the potential to significantly adversely affect aesthetics resources. Potential impacts to aesthetics resources from implementing the 2012 AQMP were concluded to be less than significant (see Subchapter 4.1 of this [Final](#) Program EIR). This same conclusion applies to Alternative 3.

6.5.1.4.2 *Ozone Control Measures*

Similar to the analysis of aesthetics impacts for the 2012 AQMP in Subchapter 4.1, implementing ozone control measures from Alternative 3 (e.g., ozone Control Measures ONRD-05, ADV-01, and ADV-02) has the potential to generate adverse impacts to aesthetics resources, scenic highways in particular. No other 2012 AQMP ozone control measures were identified that could affect aesthetic resources. Such impacts associated with implementing 2012 AQMP ozone control measures would be less than significant, as no scenic highways or highways eligible for scenic highway status would be adversely affected as a result of installing catenary lines in the future. This same conclusion applies to Alternative 3 because it contains the same three ozone control measures that have the potential to affect aesthetics resources.

6.5.1.4.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential project-specific adverse aesthetics impacts from Alternative 3 would be the same as potential project-specific aesthetics impacts from the 2012 AQMP and less than significant, because construction and operation of the catenary or overhead power lines that could be used to power Zero and Near Zero vehicles and locomotives are not expected to be visible to any Scenic Highway or any roadway eligible as a Scenic Highway.

Since, anticipated project-specific aesthetics impacts from Alternative 3 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project specific aesthetics impacts would be approximately equivalent to those generated by the 2012 AQMP, Alternative 3 would also not contribute to significant adverse cumulative impacts generated by the 2012-2035 RTP/SCS. Since aesthetics impacts from Alternative 3 are not cumulatively considerable, cumulative aesthetics impacts from Alternative 3 are not significant and equivalent to the 2012 AQMP.

6.5.1.5 *Alternative 4 – PM2.5 Reduction Strategies Only*

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of aesthetics impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.1 – Aesthetics. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential aesthetics impacts from implementing Alternative 4 are described in the following subsections.

6.5.1.5.1 *PM2.5 Control Measures*

Similar to the analysis of aesthetics impacts for the 2012 AQMP in Subchapter 4.1, no PM2.5 control measures were identified from implementing Alternative 4 that have the potential to significantly adversely affect aesthetics resources. Potential impacts to aesthetics resources from implementing the 2012 AQMP were concluded to be less than

significant (see Subchapter 4.1 of this [Final Program EIR](#)). This same conclusion applies to Alternative 4.

6.5.1.5.2 Ozone Control Measures

Adopting Alternative 4 means that the ozone SIP portion of the 2007 AQMP would remain in effect. As shown in Table 6-2 and discussed in subsection 6.5.1.2.3, 2012 AQMP Control Measure ONRD-05 would regulate the same emissions sources as 2007 AQMP Control Measure On-road Heavy-duty Vehicles (SCLTM-01B) (e.g., heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies). However, catenary systems were not identified as a possible method of reducing heavy-duty truck emissions. In fact, it was concluded in the NOP/IS for the 2007 AQMP that some control measures may have beneficial effects on scenic resources by improving visibility as well as improving air quality, preventing smoke, limiting opening burning and wood burning; and minimizing fugitive dust emissions. Therefore, it is concluded that Alternative 4 does not have the potential to generate significant adverse aesthetics impacts and impacts would be less than aesthetics impacts from the 2012 AQMP.

6.5.1.5.3 Project-specific and Cumulative Impacts Conclusion

Based upon the above conclusions, when considering overall aesthetics impacts from implementing Alternative 4, no significant adverse aesthetics impacts were identified from implementing PM_{2.5} or ozone control measures. Therefore, it is presumed that Alternative 4 would not generate significant adverse aesthetics impacts. Finally, it is concluded that potential adverse aesthetics impacts from implementing Alternative 4 would be less than for the 2012 AQMP because unlike the 2012 AQMP, Alternative 4 does not contain any control measures that adversely affect aesthetics resources.

Since, anticipated project-specific aesthetics impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project specific aesthetics impacts would be less than those generated by the 2012 AQMP, Alternative 4 would also not contribute to significant adverse cumulative impacts generated by the 2012-2035 RTP/SCS. Since aesthetics impacts from Alternative 4 are not cumulatively considerable, cumulative aesthetics impacts from Alternative 4 are not significant and less than the 2012 AQMP.

6.5.2 Air Quality

The potential direct air quality effects of implementing the proposed project and the project alternatives were modeled to determine their effectiveness in attaining the federal 24-hour PM_{2.5} standard. Modeling was also conducted to evaluate the effectiveness of the proposed project and project alternatives with regard to continued progress in achieving the one-hour and eight-hour ozone standards by 2023. Potential adverse secondary air quality impacts for the proposed project and project alternatives were also evaluated. The following subsections

provide brief discussions of direct and indirect air quality impacts from each alternative relative to the 2012 AQMP.

6.5.2.1 Methodology

The same models and methodology used to evaluate the effects of 2012 AQMP control measures were used to evaluate direct air quality impacts from the project alternatives. The methodology and assumptions used to analyze direct air quality impacts are summarized in the following paragraphs. For more complete discussions of the models and assumptions, the reader is referred to Chapter 5 of the 2012 AQMP and 2012 AQMP Appendix [V5](#) – Modeling and Attainment Demonstrations.

PM_{2.5} is either directly emitted into the atmosphere (primary particles) or is formed through atmospheric chemical reactions from precursor gases (secondary particles). While the primary particles include road dust, diesel soot, combustion products, and other sources of fine particles, the secondary particles, such as sulfates, nitrates, and complex carbon compounds are formed from reactions with precursor pollutants, such as SO_x, NO_x, VOCs, and ammonia. These secondary particles make up most of the fine particle pollution in the Basin. Accordingly, reductions of the precursor pollutants contribute to lower ambient PM_{2.5} concentration levels so various combinations of reductions of these pollutants could all provide different paths to attaining the 24-hour PM_{2.5} standard.

The full extent of PM_{2.5} chemistry is extremely complex and can be calculated only with a very comprehensive numerical model that incorporates various mechanisms of chemical reactions, mixing, dispersion, removal process, and so on.

The Final 2007 AQMP established a set of factors relating regional per ton precursor emissions reductions to microgram per cubic meter improvements of ambient PM_{2.5} for the annual average concentration. The current CMAQ model simulations provide a similar set of factors, but this time related to 24-hour average PM_{2.5}. For 24-hour average PM_{2.5}, the simulations determined that VOC emissions reductions have the lowest benefit in terms of micrograms per cubic meter ambient PM_{2.5} reduced per ton of emissions reduction, half of NO_x's effectiveness. The analysis further indicated that SO_x emissions were about six times more effective than NO_x, and that directly emitted PM_{2.5} is approximately 14 times more effective than NO_x. It is important to note that the contribution of ammonia emissions is embedded as a component of the SO_x and NO_x factors, since ammonium nitrate and ammonium sulfate are the resultant particulate compounds formed in the ambient chemical process.

The 2012 AQMP PM_{2.5} attainment demonstration has been developed using the U.S. EPA supported Community Multiscale Air Quality (CMAQ) modeling platform, and the Weather Research and Forecasting Model (WRF) meteorological fields. The WRF meteorological simulations were initialized from National Centers for Environmental Prediction (NCEP) analyses and run for four-day increments with the option for four dimensional data assimilation (FDDA).

The emission inventory was prepared with a series of processes to retrieve stationary, mobile, area and biogenic emissions sources. Day-specific point source emissions were extracted from the SCAQMD's stationary source and RECLAIM inventories. Mobile source emissions include weekday, Saturday, and Sunday emission profiles based on CARB's on-road mobile source 2011 Emission Factors model (EMFAC 2011); Caltrans weigh-in-motion profiles; vehicle population and miles traveled; and transportation analysis zone (TAZ) data provided by SCAG. The mobile source data and selected area source data were subjected to daily temperature corrections to account for enhanced evaporative emissions on warmer days. Gridded daily biogenic VOC emissions were provided by CARB using the Model of Emissions of Gases and Aerosols from Nature (MEGAN). Once the emissions inventories for the modeling base year (year 2008 in the 2012 AQMP) were established, future years' inventories for each of the project alternatives were developed based on control measures already adopted through previous AQMPs, inventory projections to future milestone years, and the proposed emission control strategies for each project alternative. This same methodology was applied to the project alternatives, except that the control strategies were modified to account for the different pollutant control strategies embodied in each alternative.

In addition to the numerical modeling, the 2012 AQMP approach to demonstrate attainment of the air quality standards relies heavily on the use of design values and relative response factors (RRF) to translate regional modeling simulation output to the form of the air quality standard. The design value is derived from three consecutive years of monitored data, averaged according to the form of the standard. The 24-hour PM_{2.5} design value is determined from the three-year average of the 98th percentile of all 24-hour concentrations sampled at a monitoring site. The annual PM_{2.5} design value is based on quarterly average PM_{2.5} concentrations, averaged by year, for a three-year period. The Relative Response Factor (RRF) is simply a ratio of future year predicted air quality with the control strategy fully implemented to the simulated air quality in the base year. From these two, the future year design value is estimated by multiplying the non-dimensional RRF by the base year design value and then compared with the standard to determine future year compliance.

Subsequent to the release of the Draft Program EIR, control measures with associated emission reduction values were re-evaluated for the 2012 AQMP and all alternatives resulting in minor modifications to the pollutant emissions inventories, NO_x equivalent values, and PM_{2.5} concentrations derived from the NO_x equivalent values. These minor revisions do not change any of the conclusions for air quality for the 2012 AQMP or any of the project alternatives.

6.5.2.2 Proposed Project

Potential direct and indirect air quality impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.2 – Air Quality.

6.5.2.2.1 *Direct Air Quality Impacts – PM_{2.5} Control Measures*

The 2012 AQMP demonstrated that the federal 24-hour and annual PM_{2.5} standards are predicted to be met in 2014 with implementation of the 2012 AQMP PM_{2.5} control strategy.

The highest 24-hour and annual PM_{2.5} in the Basin were predicted to be 34.2 µg/m³ and 13.8 µg/m³, respectively, which are lower than the federal standards. The 2012 AQMP control strategy targets directly emitted PM_{2.5}, as is evident in the 58 tons per day (tpd) of PM_{2.5} emissions in the 2012 AQMP.

TABLE 6-5
2012 AQMP – PM_{2.5} Remaining Inventory ^a (Tons/Day)

SOURCE CATEGORY	POLLUTANT				
	VOC	NO _x	CO	SO _x	PM _{2.5}
Baseline Year 2008 Average Annual Day (tpd)					
Total Stationary Sources	257	92	137	14	48
Total Mobile Sources	336	666	2,744	40	32
Total	593	758	2,881	54	80
Year 2014 – 2012 AQMP Average Annual Day (tpd) ^b

Year 2019 – 2012 AQMP Average Annual Day ^c (tpd)					
Total Stationary Sources	239	6 72	165	11	40
Total Mobile Sources	170	331 0	1,151	7	18
Total	409	403397	1,716	18	58

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Demonstrate attainment of the federal 24-hour PM_{2.5} standard.

^c Continues to demonstrate attainment of the federal 24-hour PM_{2.5} standard.

6.5.2.2.2 Direct Air Quality Impacts – Ozone Control Measures

~~Because~~ The 2012 AQMP is primarily a PM_{2.5} AQMP as required by the CAA, ~~all~~ primarily emission reductions are based on PM_{2.5} control measures. The 2012 AQMP also includes control measures for making expeditious progress in attaining the federal one-hour (revoked) and eight-hour ozone standards by the years 2022 – 2023, respectively. Table 6-6 shows that implementing the 2012 AQMP would continue to make progress towards attaining the federal one-hour and eight-hour ozone standards, but it would not attain either of the federal ~~one-hour or eight-hour ozone standards~~, as shown in Table 6-6. ~~However, is not technically an ozone attainment AQMP.~~ An ~~ozone attainment~~ AQMP specifically

[addressing the eight-hour ozone standard](#) will be prepared and submitted to U.S. EPA in 2015 as required by federal law.

[As indicated in Chapter 2, the U.S. EPA’s September 19, 2012 proposed “SIP call” and proposed withdrawing its approval/disapproval of the TCM demonstrations, also referred to as VMT emissions offset demonstrations, in the 2003 one-hour ozone plan and the 2007 eight-hour ozone plan. In response to U.S. EPA’s disapproval of the VMT emissions offset demonstrations, has resulted in the preparation of the *One-hour Ozone Attainment Demonstration* \(see 2012 AQMP Appendix VII\) and *VMT Offset Requirement Demonstration* \(2012 AQMP Appendix VIII\). These documents were reviewed by SCAQMD staff to determine any CEQA implications.](#)

[Because the federal one-hour ozone SIP includes all of the same ozone control measures already in the 2012 AQMP and the VMT offset demonstration showed that no new TCMs are required for the one-hour ozone SIP, this Final Program EIR for the 2012 AQMP also serves as the CEQA document for the one-hour ozone SIP. Further, *One-hour Ozone Attainment Demonstration* includes seven mobile source control measures from the 2007 AQMP. Because a CEQA document was prepared and certified for the 2007 AQMP and because the 2007 AQMP control measures do not require any changes, no further environmental analysis of the 2007 AQMP control measures is required.](#)

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Inventory necessary to achieve 80 ppb to attain the federal eight-hour ozone standard by 2023.

6.5.2.2.3 *Secondary Air Quality Impacts – PM2.5 Control Measures*

Construction: Construction air quality impacts associated with a number of 2012 AQMP PM2.5 control measures were identified and evaluated. It was assumed that the following types of construction activities to implement 2012 AQMP PM2.5 control measures contribute to construction activities emission inventories: 1) additional infrastructure to support electric and alternative fuel vehicles; 2) additional infrastructure for stationary source controls; and, 3) additional infrastructure to support electrification of new sources. It was concluded that these PM2.5 control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4). Because future construction air quality impacts were concluded to be significant, seven mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts would remain significant.

Operation: Secondary air quality impacts associated with approximately seven 2012 AQMP PM2.5 control measures were also identified and evaluated. For example, several PM2.5 control measures have the potential to generate secondary criteria pollutant, toxic air contaminant, and GHG emissions from and electricity generation. Additional emission controls could result in increased electricity use and an associated increase in criteria pollutant and GHG combustion emissions. Further, increased use of alternative fuels could generate criteria pollutant and GHG emissions associated with the increased production. Installation of emission control technologies on some sources has the potential reduce engine efficiency resulting in combustion of more fuel and an increase in criteria pollutant and GHG emissions. Potential air toxic impacts could occur as a result of formulating coatings and solvents with more toxic materials than are currently used. The analysis concluded, however, that secondary operational emissions from increased electricity demand, control of stationary sources, coatings and solvents formulated with low VOC materials, use of alternative fuels in mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion would be less than significant.

6.5.2.2.4 *Secondary Air Quality Impacts – Ozone Control Measures*

Construction: Construction air quality impacts associated with approximately 14 2012 AQMP ozone control measures were identified and evaluated. It was assumed that the following types of construction activities to implement 2012 AQMP ozone control measures contribute to construction activities emission inventories: 1) additional infrastructure to support electric and alternative fuel vehicles; 2) additional infrastructure for stationary source controls; and, 3) additional infrastructure to support electrification of new sources. It was concluded that these ozone control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of

550 and 150 pounds per day, respectively (refer to Table 4.2-4). Because future construction air quality impacts were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts would remain significant.

Operation: Secondary air quality impacts associated with a number of 2012 AQMP ozone control measures were also identified and evaluated. The following bullet points show potential impacts from implementing ozone control measures and the significance determination.

- **Secondary Emissions from Increased Electricity Demand:** While there may be an increase in electricity, the existing air quality rules and regulations are expected to minimize emissions associated with increased generation of electricity. The impacts associated with secondary emissions from increased electricity demand are expected to be less than significant.
- **Secondary Emissions from the Control of Stationary Sources:** No significant secondary air quality impacts from control of stationary sources were identified associated with implementation of the 2012 AQMP.
- **Secondary Emissions from Change in Use of Lower VOC Materials:** The secondary air quality impacts associated with reformulated products are expected to be less than significant.
- **Secondary Emissions from Mobile Sources:** The overall impact of mobile sources due implementation of the control measures has been considered less than significant for all pollutants.
- **Secondary Emissions from Increased Use of Fuels due to Reduction in Fuel Economy:** The reduction in fuel economy is expected to be about one percent for the affected sources so a potential increase in fuel use could occur. However, the overall focus of the 2012 AQMP is to reduce PM2.5 and ozone emissions, which is primarily driven by increasing use of cleaner fuels. Therefore, the impact of fuel economy is expected to be less than significant.
- **Secondary Emissions from Miscellaneous Sources:** The impacts of the control measures on secondary emissions from miscellaneous sources were determined to be less than significant.
- **Non-Criteria Pollutants:** Electrification may cause greater emissions of benzene, aldehydes, metals, and polynuclear aromatic hydrocarbons from fuel-based power generating facilities. However, if the process being electrified was previously powered by direct combustion of fossil fuels, then electrification may result in an overall decrease in toxic emissions. No significant secondary air quality impacts were identified from non-criteria pollutants, so no mitigation measures are required.
- **Global Warming and Ozone Depletion:** The 2012 AQMP is expected to have a net effect of reducing emissions of compounds that contribute to global warming and ozone depletion so that no significant adverse impacts are expected.

The air quality impacts associated with approximately 23 ozone control measures (see Table 4.2-1 in this [Final](#) Program EIR) were evaluated and determined to be less than significant for secondary emissions from increased electricity demand, control of stationary sources, change in use of lower VOC materials, mobile sources, increase in use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion.

6.5.2.2.5 *Project-specific and Cumulative Impacts Conclusion*

Based upon the above conclusions, the 2012 AQMP PM_{2.5} and ozone control measures have the potential to generate significant adverse project-specific construction CO and PM₁₀ air quality impacts. In spite of identifying eight construction air quality mitigation measures, project-specific construction CO and PM₁₀ air quality impacts would remain significant.

With regard to project-specific secondary operational air quality impacts, a number of different types of operational air quality impacts from both 2012 AQMP PM_{2.5} and ozone control measures were identified and analyzed. Based on the analysis of operational air quality impacts in Subchapter 4.2, operational air quality impacts were concluded to be less than significant. Since, anticipated project-specific construction CO and PM₁₀ impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific air quality impacts from the 2012 AQMP were evaluated in connection with air quality impacts from SCAG's 2012-2035 RTP/SCS. Further, it was concluded that construction CO and PM₁₀ impacts from the 2012 AQMP would not contribute to significant adverse cumulative air quality impacts from the 2012-2035 RTP/SCS. Since construction CO and PM₁₀ impacts from the 2012 AQMP are cumulatively considerable and contribute to cumulative air quality impacts generated by the 2012-2035 RTP/SCS, cumulative construction air quality impacts from the 2012 AQMP are concluded to be significant.

Alternatively, since anticipated project-specific operational air quality impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project specific operational air quality impacts would be less than those generated by the 2012 AQMP, the 2012 AQMP would also not contribute to significant adverse cumulative operational air quality impacts generated by the 2012-2035 RTP/SCS. Since project-specific operational air quality impacts from the 2012 AQMP are not cumulatively considerable, cumulative operational air quality impacts from the 2012 AQMP are not significant.

6.5.2.3 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since

the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures. The following subsections analyze potential direct air quality impacts from Alternative 1 and compare them to direct air quality impacts from the 2012 AQMP. After the direct air quality analysis, subsections include an analysis of potential secondary air quality impacts from implementing Alternative 1 are described and impacts are compared to the 2012 AQMP. For the complete analysis of direct and secondary air quality impacts from the 2012 AQMP, refer to Subchapter 4.2 – Air Quality.

6.5.2.3.1 Direct Air Quality Impacts – PM2.5 Control Measures

It is expected that air quality will continue to improve under Alternative 1 because of the adoption and implementation by the SCAQMD and CARB of short- and mid-term control measures with future compliance dates. As shown in Table 6-7, which shows the average annual day inventories for demonstrating attainment of the federal 24-hour PM2.5 standard, Alternative 1 would not achieve the federal 24-hour PM2.5 standard until 2019, whereas it is expected that the 2012 AQMP would achieve the federal 24-hour PM2.5 standard by the year 2014, as required by federal law.

The 2012 AQMP control strategy targets directly emitted PM2.5, as is evident in the remaining 58 tons per day PM2.5 emissions inventory in the attainment year 2014 compared to the 70 tons per day PM2.5 emissions inventory in the attainment year 2019 for Alternative 1. Although the remaining PM2.5 emissions inventory for the 2012 AQMP appear to be substantially less than the remaining PM2.5 emissions inventory for Alternative 1, both inventories attain the federal 24-hour PM2.5 standard. To understand how such different results could both demonstrate attainment it is necessary to view pollutant emissions in NOx equivalents.

Total Mobile Sources	170	331 0	1,151	7	18
Total	409	403397	1,716	18	58

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Does **not** demonstrate attainment of the federal 24-hour PM_{2.5} standard.

^c Demonstrates attainment of the federal 24-hour PM_{2.5} standard.

PM_{2.5} has five major precursors that contribute to the development of the ambient aerosol including ammonia, NO_x, SO_x, VOC, and directly emitted PM_{2.5}. For this reason it is useful to weigh the value of the precursor emissions reductions (on a per ton basis) to microgram per cubic meter improvements in ambient PM_{2.5} levels. The 2012 AQMP CMAQ simulations determined that VOC emissions reductions have the lowest return in terms of micrograms reduced per ton reduction, one-half of the benefit of NO_x reductions. SO_x emissions were shown to be about six times more effective than NO_x reductions, while directly emitted PM_{2.5} reductions were shown to be approximately 14 times more effective than NO_x reductions. Applying these weighting factors to the VOC, NO_x, SO_x, and directly emitted PM_{2.5} inventory emissions provides NO_x equivalents, which can then be converted to concentrations in micrograms per cubic meter (µg/m³).

Table 6-8 shows NO_x equivalent emissions for each pollutant and total NO_x equivalent emissions from Alternative 1 compared to the 2012 AQMP for the 24-hour PM_{2.5} attainment years, 2019 and 2014, respectively. Table 6-8 also shows the corresponding PM_{2.5} concentrations. As can be seen in the table, the PM_{2.5} concentration in the 2019 attainment year for Alternative 1 is close to the PM_{2.5} concentration in 2014 attainment year for the 2012 AQMP and both demonstrate attainment of the federal 24-hour PM_{2.5} standard.

The 2012 AQMP control strategy targets directly emitted PM_{2.5}, as is evident in the 58 tons per day of remaining PM_{2.5} emissions from the 2012 AQMP in the year 2014 compared with 70 tons per day of remaining PM_{2.5} emissions in the year 2019 for Alternative 1. Attainment of the federal 24-hour PM_{2.5} standard by the year 2019 is primarily due to reductions in precursor pollutant emissions that form secondary particles rather than directly emitted PM. It is important to note that a greater portion of fine particles is produced

through a series of chemical reaction that involves precursor such as NO_x, VOCs, SO_x and ammonia.

TABLE 6-8
NO_x Equivalent Emissions ^a Comparison Between
Alternative 1 and the 2012 AQMP (Tons/Day)

	POLLUTANT					PM2.5 CONCENTRATION
	VOC	NO _x	CO ^b	SO _x	PM2.5	
Year 2019 – Alternative 1 Attainment (tpd) ^c						
Total Remaining Inventory	415	405 0	1,716	18	70	
NO _x Equivalents	195	405 0	--	100	998	1,698 3 35.4 µg/m ³
Year 2014 – 2012 AQMP Attainment (tpd) ^c						
Total Remaining Inventory	451	491 500	2,095	18 9	58	
NO _x Equivalents	212	491 500	--	108 6	827	1,638 45 34.2 µg/m ³

^a This table shows remaining emissions, not emission reductions.

^b CO does not contribute to PM2.5 formation, so it does not have a NO_x equivalent value.

^c Only emissions representing NO_x equivalents are added together because these are all ratios relative to NO_x emissions.

6.5.2.3.2 Direct Air Quality Impacts – Ozone Control Measures

Because the 2012 AQMP is a PM2.5 AQMP as required by the CAA, all emission reductions are based on PM2.5 control measures. The 2012 AQMP also includes ozone control measures to continue making expeditious progress towards achieving the federal one-hour and eight-hour ozone standards, but any emission reductions from these measures were not included in the analysis of direct air quality impacts.

Because most of the remaining “black box” control measures in the 2007 AQMP would regulate mobile sources, both on-road and off-road, in the future it is assumed that, similar to the CAA §182 (e)(5) mobile source measures in the 2012 AQMP, their primary objective is to make expeditious progress in attaining the federal one-hour and eight-hour ozone standards. However, the black box control measures in the 2007 consisted of general concepts and no emissions reductions were associated with them. The analysis of direct air quality impacts from Alternative 1 in Subsection 6.5.2.3.2 does not include any emission reductions from ozone control measures. As shown in Table 6-9, Alternative 1 would continue to make progress towards attaining the federal one-hour and eight-hour ozone standards, however, progress would not be as great as it would be under the 2012 AQMP.

6.5.2.3.3 Secondary Air Quality Impacts – PM_{2.5} Control Measures

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM_{2.5} control measures. For this reason, Alternative 1 is not expected to create any secondary construction or operational air quality impacts from PM_{2.5} control measures.

6.5.2.3.4 Secondary Air Quality Impacts – Ozone Control Measures

Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of secondary air quality impacts from all control measures, including black box control measures. As noted in Subsection 6.4.1, both SCAQMD and CARB have achieved their 2007 AQMP short-term emission reduction targets, so the 2007 AQMP does not contain any remaining short-term stationary source or mobile source control measures the previously were identified as contributing to secondary air quality impacts. As a result, consistent with the assumption that significance determinations from the 2007 Program EIR continue to apply, it is concluded that Alternative 1 has the potential to generate potential secondary air quality impacts as shown in Table 6-10 and described in the following paragraphs.

TABLE 6-10^a

Environmental Impacts Identified for 2007 AQMP Black Box Measures

CONTROL MEASURE SOURCE CATEGORY	AIR QUALITY	ENERGY	HAZARDS AND HAZARDOUS MATERIALS	HYDROLOGY AND WATER QUALITY	SOLID AND HAZARDOUS MATERIALS WASTE
Light Duty Vehicles (SCLTM-01A)	None identified.	1. Potential increase in electricity demand. (NS)	None identified.	None identified.	None identified.
On-Road Heavy Duty Vehicles (SCLTM-01B)	None identified.	1. Potential increase in electricity demand. (NS)	None identified.	None identified.	1. Potential increase in solid waste due to accelerated vehicle replacement. (NS)
Off-Road Vehicles (SCLTM-02)	1. Decreased engine efficiency could reduce fuel economy and increase emissions. (NS) 2. Potential for passive filters to emit higher levels of NO ₂ . (NS)	1. Potential increase in electricity demand. (NS)	1. SCR to control NO _x could result in ammonia hazard impacts. (NS)	1. Potential impact on water demand and water quality. (NS) 2. Alternative formulations and additives can readily dissolve in water and impact ground and surface water. (NS)	1. Potential increase in solid waste due to accelerated vehicle replacement. (NS)
Consumer Products (SCLTM-03)	1. Increased air toxics emissions from products formulated with hazardous materials. (NS)	None identified.	1. Potential exposure to toxic air contaminant; flammability of reformulated material. (NS)	1. Potential increased use of water based formulations. (NS)	None identified.

^a The topics of aesthetics, land use and planning, noise, and transportation and traffic were concluded to be less than significant in the NOP/IS for the 2007 AQMP and, therefore, were not further analyzed in the 2007 Program EIR.

TABLE 6-10^a (Concluded)

Environmental Impacts Identified for 2007 AQMP Black Box Measures

SOURCE CATEGORY	AIR QUALITY	ENERGY	HAZARDS AND HAZARDOUS MATERIALS	HYDROLOGY AND WATER QUALITY	SOLID AND HAZARDOUS MATERIALS <u>WASTE</u>
Fuels	1. Construction impacts at refineries. (S) 2. Increase emissions at refineries to produce alt fuels. (NS)	None identified.	1. The use of alternative fuels and fuel additives can result in hazard impacts. (NS) 2. Production of alternative fuels could increase hazards at refineries. (S)	None identified.	None identified.
Marine Vessels	None identified.	None identified.	None identified.	None identified.	None identified.
Locomotives	None identified.	None identified.	1. SCR to control NOx could result in ammonia hazard impacts. (NS)	None identified.	None identified.
Pleasure Craft	None identified.	None identified.	None identified.	None identified.	None identified.

Renewable Energy	None identified.	None identified.	None identified.	None identified.	None identified.
AB32 Implementation	None identified.	None identified.	None identified.	None identified.	None identified.

^a The topics of aesthetics, land use and planning, noise, and transportation and traffic were concluded to be less than significant in the NOP/IS for the 2007 AQMP and, therefore, were not further analyzed in the 2007 Program EIR.

Construction: Of the remaining black box measures, the Fuels control measure was identified as having the potential to generate significant adverse construction emissions from modifications at local refineries to produce reformulated gasoline. Phase 3 reformulated gasoline requirements were adopted by CARB in 2008, so potential construction air quality impacts from the Fuels control measure from the 2007 AQMP have already occurred. No other black box control measures were identified as having the potential to generate construction air quality impacts. Therefore, this impact is concluded to be less than significant.

Operation: Potential operational impacts (reduced engine efficiency resulting in higher emissions and passive filters increasing NOx emissions) from Alternative 1 black box measure SCLTM-02 were identified, but concluded to be less than significant. Similarly, black box Control Measure SCLTM-03 impacts (potential toxic emissions from reformulating consumer products) were identified and also concluded to be less than significant. Finally, the Fuels control measure impacts, potential emissions from refineries produce phase 3 reformulated gasoline were identified and concluded to be less than significant.

6.5.4.3.5 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, implementing Alternative 1 has no PM2.5 control measures that could generate project-specific construction or operational air quality impacts. The black box ozone control measures have the potential to generate project-specific operational air quality impacts, but these were concluded to be less than significant. Overall, Alternative 1 would not generate any significant adverse project-specific air quality impacts. Potential project-specific impacts from Alternative 1 are less than project-specific air quality impacts from the 2012 AQMP, but it would achieve the 24-hour federal PM2.5 standard in 2019 instead of 2014.

Since, anticipated project-specific air impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific air quality impacts would be less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative air quality impacts generated by the 2012-2035 RTP/SCS. Since air quality impacts from Alternative 1 are not cumulatively considerable, air quality impacts from Alternative 1 are not significant.

6.5.2.4 Alternative 2 – PM2.5 Attainment Plan Localized PM Control in Mira Loma Area

As explained in Subsection 6.4.2, with the exception of the two episodic PM2.5 control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone Control Measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM2.5 and ozone control measures as the 2012 AQMP, except for PM2.5 Control Measure BCM-02 – Open Burning. The following subsections analyze potential direct air quality impacts from Alternative 2 and compare them to direct air quality impacts from the 2012 AQMP. After the direct air quality analysis, subsections describing potential

secondary air quality impacts from implementing Alternative 2 are described and compared to the 2012 AQMP. For the complete analysis of direct and secondary air quality impacts from the 2012 AQMP, refer to Subchapter 4.2 – Air Quality.

6.5.2.4.1 Direct Air Quality Impacts – PM2.5 Control Measures

The 2012 AQMP control strategy targets directly emitted PM2.5, as is evident in the 58 tons per day of remaining PM2.5 emissions from the 2012 AQMP in the attainment year 2014 compared with 64 tons per day of remaining PM2.5 emissions for Alternative 2 in the attainment year 2017 (Table 6-10). Attainment of the federal 24-hour PM2.5 standard by the year 2017 is primarily due to reductions in precursor pollutant emissions that form secondary particles rather than directly emitted PM. It is important to note that a greater portion of fine particles is produced through a series of chemical reaction that involves precursor such as NOx, VOCs, SOx and ammonia.

Table 6-12 shows NOx equivalent emissions for each pollutant and total NOx equivalent emissions from Alternative 2 compared to the 2012 AQMP for the 24-hour PM2.5 attainment years, 2017 and 2014, respectively. Table 6-12 also shows the corresponding PM2.5 concentrations. As can be seen in the table, the PM2.5 concentration in the 2017 attainment year for Alternative 2 is close to the PM2.5 concentration in 2014 attainment year for the 2012 AQMP and both demonstrate attainment of the federal 24-hour PM2.5 standard.

^a This table shows remaining emissions, not emission reductions.

^b CO does not contribute to PM_{2.5} formation, so it does not have a NO_x equivalent value.

^c Only emissions representing NO_x equivalents are added together because these are all ratios relative to NO_x emissions.

6.5.2.4.2 Direct Air Quality Impacts – Ozone Control Measures

Because the 2012 AQMP also includes control measures for making expeditious progress in attaining the federal one-hour and eight-hour ozone standards by the year 2023, a comparison of the summer planning inventories for ozone was also performed. As shown in Table 6-13, Alternative 2 would continue to make progress towards attaining the federal one-hour and eight-hour ozone standards to the same extent as the 2012 AQMP because

Alternative 2 contains all of the same control measures pertaining to reducing ozone concentrations as the 2012 AQMP.

6.5.2.4.3 Secondary Air Quality Impacts – PM2.5 Control Measures

Construction: The Alternative 2 PM2.5 control measures were evaluated and it was concluded that they would not contribute to construction air quality impacts. However, because all remaining PM2.5 control measures in Alternative 2 are identical to those in the 2012 AQMP, the same construction activities and associated construction emissions would occur. It was concluded that the 2012 AQMP PM2.5 control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4).

The same PM2.5 control measure construction air quality conclusion from the 2012 AQMP applies to Alternative 2. Similarly, because future construction air quality impacts from Alternative 2 were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts from Alternative 2 would remain significant and equivalent to the 2012 AQMP.

Total	431	293.87
Year 2023 – Ozone Attainment Inventory (tpd)		
Total Carrying Capacity: 8-Hr standard ^b	420	114

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Inventory necessary to achieve 80 ppb to attain the federal eight-hour ozone standard by 2023.

Operation: Alternative 2 PM2.5 measures CMALT-2B (similar to 2012 AQMP PM2.5 Control Measure BCM-01) and CMALT-2C (the same as 2012 AQMP PM2.5 Control Measure BCM-04) were evaluated and it was concluded that they have the potential to generate criteria pollutant and GHG emissions from combustion sources. Because all remaining PM2.5 control measures in Alternative 2 are identical to those in the 2012 AQMP, the same operation activities and associated operation emissions would occur. The analysis concluded, however, that secondary operational emissions from increased electricity demand, control of stationary sources, coatings and solvents formulated with low VOC materials, use of alternative fuels in mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion as a result of implementing the 2012 AQMP would be less than significant. Because Alternative 2 Control Measure CMALT-2B (similar to 2012 AQMP PM2.5 Control Measure BCM-01) would only apply to the Mira Loma area, the magnitude of the criteria pollutant and GHG emissions would be less than the operation impacts from 2012 AQMP Control Measure BCM-01. Consequently, operational air quality impacts from Alternative 2 would be less than significant and slightly less than operational air quality impacts from the 2012 AQMP.

6.5.2.4.4 Secondary Air Quality Impacts – Ozone Control Measures

Construction: Alternative 2 Control Measure CMALT-2A (similar to 2012 AQMP Control Measure ONRD-04) was evaluated and it was concluded that it would not contribute to construction air quality impacts. Because all remaining ozone control measures in Alternative 2 are identical to those in the 2012 AQMP, the same construction activities and associated construction emissions would occur. It was concluded that the 2012 AQMP ozone control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4). This same conclusion applies to Alternative 2. Similarly, because future construction air quality impacts from Alternative 2 were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts from Alternative 2 would remain significant and equivalent to the 2012 AQMP.

Operation: Alternative 2 Control Measure CMALT-2A (similar to 2012 AQMP Control Measure ONRD-04) was evaluated and it could potentially generate criteria pollutant, toxic air pollutant and GHG emissions from and electricity generation. Further, it has the potential generate emissions from demolition of retired vehicles. Because all remaining ozone control measures in Alternative 2 are identical to those in the 2012 AQMP, the same operation activities and associated construction emissions would occur. The analysis concluded, however, that secondary operational emissions from increased electricity demand, control of stationary sources, coatings and solvents formulated with low VOC materials, use of alternative fuels in mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion as a result of implementing the 2012 AQMP would be less

than significant. Because Alternative 2 Control Measure CMALT-2B (similar to 2012 AQMP PM2.5 Control Measure BCM-01) would only apply to the Mira Loma area, the magnitude of the criteria pollutant and GHG emissions would be less than the operation impacts from 2012 AQMP Control Measure BCM-01.

6.5.2.4.3 *Project-specific and Cumulative Impacts Conclusion*

Although the three episodic control measures for the Mira Loma area do not contribute to construction air quality impacts, all other control measures in Alternative 2 are identical to the control measures in the [2012 AQMP](#). Consequently, like the 2012 AQMP, Alternative 2 PM2.5 and ozone control measures have the potential to generate significant adverse project-specific construction CO and PM10 air quality impacts. In spite of identifying eight construction air quality mitigation measures, project-specific construction CO and PM10 air quality impacts would remain significant.

With regard to project-specific secondary operational air quality impacts, it was concluded that the three episodic control measures for the Mira Loma area contribute to operational air quality impacts. As already noted, all remaining PM2.5 and ozone control measures in Alternative 2 are identical to the 2012 AQMP PM2.5 and ozone control measures. As a result, operational air quality impacts from Alternative 2 were concluded to be less than significant. Because Alternative 2 Control Measures CMALT-2A (similar to 2012 AQMP PM2.5 control measure ONRD-04) and CMALT-2B (similar to 2012 AQMP PM2.5 Control Measure BCM-01) would only apply to the Mira Loma area, the magnitude of the criteria pollutant and GHG emissions would be less than the operation impacts from 2012 AQMP Control Measures ONRD-04 and BCM-01, respectively.

Since anticipated project-specific construction CO and PM10 air quality impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Since project-specific construction CO and PM10 air quality impacts from Alternative 2 are cumulatively considerable, cumulative project-specific construction CO and PM10 air quality impacts from Alternative 2 are concluded to be significant. Further, since project-specific construction air quality impacts would be significant and equivalent to those generated by the 2012 AQMP, Alternative 2 would also contribute to significant adverse cumulative air quality impacts generated by the 2012-2035 RTP/SCS. No other construction air quality mitigation measures were identified that reduce cumulative construction CO and PM10 air quality impacts to less than significant.

Alternatively, since anticipated project-specific operational air quality impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Since project-specific operational air quality impacts would be approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would also not contribute to significant adverse cumulative operational air quality impacts generated by the 2012-2035 RTP/SCS. Since project-specific construction CO and PM10 air quality impacts from the 2012 AQMP are not cumulatively considerable, cumulative operational air quality impacts from the 2012 AQMP are not significant.

6.5.2.5 Alternative 3 – Greater Reliance on NOx Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except for 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. The following subsections analyze potential direct air quality impacts from Alternative 3 and compare them to direct air quality impacts from the 2012 AQMP. After the direct air quality analysis, subsections describing potential secondary air quality impacts from implementing Alternative 3 are described and compared to the 2012 AQMP. For the complete analysis of direct and secondary air quality impacts from the 2012 AQMP, refer to Subchapter 4.2 – Air Quality.

6.5.2.5.1 Direct Air Quality Impacts – PM2.5 Control Measures

The 2012 AQMP control strategy targets directly emitted PM2.5, as is evident in the 58 tons per day of remaining PM2.5 emissions from the 2012 AQMP in the attainment year 2014 compared with 65 tons per day of remaining PM2.5 emissions for Alternative 3 in the attainment year 2017 (Table 6-14). Attainment of the federal 24-hour PM2.5 standard by the year 2017 is primarily due to reductions in precursor pollutant emissions that form secondary particles rather than directly emitted PM. It is important to note that a greater portion of fine particles is produced through a series of chemical reaction that involves precursor such as NOx, VOCs, SOx and ammonia.

TABLE 6-14

Total	409 25	403 45	1,716 867	18	58

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Does **not** demonstrate attainment of the federal 24-hour PM_{2.5} standard.

^c Demonstrates attainment of the federal 24-hour PM_{2.5} standard.

^d Continues to demonstrate attainment of the federal 24-hour PM_{2.5} standard.

Table 6-15 shows NO_x equivalent emissions for each pollutant and total NO_x equivalent emissions from Alternative 3 compared to the 2012 AQMP for the 24-hour PM_{2.5} attainment years, 2017 and 2014, respectively. Table 6-15 also shows the corresponding PM_{2.5} concentrations. As can be seen in the table, the PM_{2.5} concentration in the 2017 attainment year for Alternative 3 is close to the PM_{2.5} concentration in 2014 attainment year for the 2012 AQMP and both demonstrate attainment of the federal 24-hour PM_{2.5} standard.

6.5.2.5.2 Direct Air Quality Impacts – Ozone Control Measures

Because the 2012 AQMP also includes control measures for making expeditious progress in attaining the federal one-hour and eight-hour ozone standards by the year 2023, a comparison of the summer planning inventories for ozone was also performed. As shown in Table 6-16, Alternative 3 would continue to make progress towards attaining the federal one-hour and eight-hour ozone standards to the same extent as the 2012 AQMP because Alternative 3 contains all of the same control measures pertaining to reducing ozone concentrations as the 2012 AQMP. Even though Alternative 3 would generate NO_x emission reductions sooner, by 2023 NO_x emission reductions from Alternative are expected to be equivalent to NO_x emission reductions from the 2012 AQMP.

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Inventory necessary to achieve 80 ppb to attain the federal eight-hour ozone standard by 2023.

6.5.2.5.3 *Secondary Air Quality Impacts – PM2.5 Control Measures*

Construction: All PM2.5 control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 does not include BCM-01. PM2.5 Control Measure BCM-01 was not identified as a control measure that contributed to construction air quality impacts. Consequently, the same construction activities and associated construction emissions would occur under Alternative 3 as would occur under the 2012 AQMP. It was concluded that the 2012 AQMP PM2.5 control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4). This same conclusion applies to Alternative 3. Similarly, because future construction air quality impacts from Alternative 3 were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts from Alternative 2 would remain significant and equivalent to the 2012 AQMP.

Operation: With the exception of Control Measure BCM-01, Alternative 3 includes all of the same control measures as the 2012 AQMP, so the same operation activities and associated operation emissions would occur. The analysis concluded, however, that secondary operational emissions from increased electricity demand, control of stationary sources, coatings and solvents formulated with low VOC materials, use of alternative fuels in mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion as a result of implementing the 2012 AQMP would be less than significant. Because PM2.5 Control Measure BCM-01 has the potential to generate GHG emissions, but it is not included in as part of the operation impacts from Alternative 3, operational air quality impacts from Alternative 3 would be less than significant and slightly less than operation impacts from the 2012 AQMP.

6.5.2.5.4 *Secondary Air Quality Impacts – Ozone Control Measures*

Construction: All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered or replaced vehicles from the year 2014 through 2017. However, neither of these control measures was identified as contributing to construction air quality impacts. In spite of this conclusion, since all remaining ozone control measures in Alternative 3 are also included in the 2012 AQMP, Alternative 3 has the potential to contribute to significant adverse secondary air quality impacts from increased construction emission inventories for CO and PM10 from the baseline to the year 2023 in amounts that would exceed the applicable

construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4). This same conclusion applies to Alternative 3. Similarly, because future construction air quality impacts from Alternative 3 were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts from Alternative 3 would remain significant and equivalent to the 2012 AQMP.

Operation: All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (1,000 trucks per year, 250 trucks per would comply with the 2010 on-road vehicle exhaust requirements using CNG engines and the rest would be diesel or diesel hybrid). The analysis of Alternative 3 ozone Control Measure ONRD-03 indicated that it has the potential to generate additional criteria pollutant, toxic air pollutant and GHG emissions from and electricity generation beyond those that would occur under the 2012 AQMP.

The increase in electricity demand from ozone Control Measure ONRD-03 would be twice that of the 2012 AQMP (see Table 4.2-5 of this [Final](#) Program EIR). However, this increase would not result in exceedances of any of the applicable regional significance thresholds.

Power generating facilities are subject to AB-32 and would be required to reduce GHG emissions by 2020. Therefore, the additional energy demand from Alternative 3 Control Measure ONRD-03 would be expected to increase, but is not expected to generate significant emission impacts.

Although Alternative 3 Control Measure ONRD-01 could increase demand for electricity, thus, potentially increasing GHG emissions from electric utilities, increased GHG emissions would be offset by reductions in GHG emissions from less polluting trucks. Because alternative 3 ozone Control Measure ONRD-03 would result in twice as many cleaner, less polluting heavy-duty trucks as the 2012 AQMP, GHG reduction benefits would be greater.

Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered or replaced vehicles from the year 2014 through 2017. Alternative 3 ozone Control Measure ONRD-03 has the potential double the increase in the demand for alternative fuels compared to the 2012 AQMP. The reduction in fuel economy associated with use of alternative fuels expected to be greater than the 2012 AQMP, which is one percent for the affected sources so a potential increase in fuel use could occur. However, the overall focus of the 2012 AQMP is to reduce PM2.5 and ozone emissions, which is primarily driven by increasing use of cleaner fuels. Therefore, the impact of fuel economy is expected to be less than significant, but greater than the 2012 AQMP.

6.5.2.5.5 Project-specific and Cumulative Impacts Conclusion

Based upon the above conclusions, Alternative 3 PM2.5 and ozone control measures have the potential to generate significant adverse project-specific construction CO and PM10 air

quality impacts equivalent to those from the 2012 AQMP. In spite of identifying eight construction air quality mitigation measures, project-specific construction CO and PM10 air quality impacts would remain significant.

Since anticipated project-specific construction CO and PM10 air quality impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific construction air quality impacts would be approximately equivalent to those generated by the 2012 AQMP, Alternative 3 would also contribute to significant adverse cumulative construction air quality impacts generated by the 2012-2035 RTP/SCS. Since project-specific construction CO and PM10 air quality impacts from the 2012 AQMP are cumulatively considerable, cumulative project-specific construction CO and PM10 air quality impacts from the 2012 AQMP are concluded to be significant. No other construction air quality mitigation measures were identified that reduce cumulative construction CO and PM10 air quality impacts to less than significant.

With regard to project-specific secondary operational air quality impacts, a number of different types of operational air quality impacts from Alternative 3 PM2.5 and ozone control measures were identified and analyzed. Since project-specific operational air quality impacts would be significant and greater than those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative operational air quality impacts generated by the 2012-2035 RTP/SCS. Based on the analysis of operational air quality impacts, overall operational air quality impacts were concluded to be significant and greater than the 2012 AQMP.

Since anticipated project-specific operational air quality impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Since project-specific construction operational air quality impacts from the 2012 AQMP are cumulatively considerable, cumulative operational air quality impacts from the Alternative 3 are concluded to be significant and greater than the 2012 AQMP.

6.5.2.6 Alternative 4 – PM2.5 Reduction Strategies Only

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. The following subsections analyze potential direct air quality impacts from Alternative 4 and compare them to direct air quality impacts from the 2012 AQMP. After the direct air quality analysis, subsections include an analysis of potential secondary air quality impacts from implementing Alternative 4 are described and impacts are compared to the 2012 AQMP. For the complete analysis of direct and secondary air quality impacts from the 2012 AQMP, refer to Subchapter 4.2 – Air Quality.

6.5.2.6.1 Direct Air Quality Impacts – PM2.5 Control Measures

The 2012 AQMP control strategy targets directly emitted PM2.5, as is evident in the 58 tons per day of remaining PM2.5 emissions from the 2012 AQMP in the attainment year 2014 which is the same as the remaining PM2.5 emissions for Alternative 4 in the attainment year 2014 (Table 6-17). The reason for this result is that Alternative 4 contains the same PM2.5 reduction control measures as the 2012 AQMP, so the same strategy, reducing directly emitted PM2.5, is expected to produce the same results in the year 2014 for both Alternative 4 and the 2012 AQMP.

^a This table shows remaining emissions, not emission reductions.

^b CO does not contribute to PM2.5 formation, so it does not have a NOx equivalent value.

^c Only emissions representing NOx equivalents are added together because these are all ratios relative to NOx emissions.

6.5.2.6.2 Direct Air Quality Impacts – Ozone Control Measures

Because the 2012 AQMP also includes control measures for making expeditious progress in attaining the federal one-hour and eight-hour ozone standards by the year 2023, a comparison of the summer planning inventories for ozone was also performed. As shown in Table 6-19, Alternative 4 would continue to make progress towards attaining the federal one-hour and eight-hour ozone standards, but not to the same extent as the 2012 AQMP, because Alternative 4 contains all of the same control measures pertaining to reducing ozone concentrations as the 2012 AQMP. Even though Alternative 4 would generate NOx emission reductions sooner, by 2023 NOx emission reductions from Alternative are expected to be equivalent to NOx emission reductions from the 2012 AQMP.

6.5.2.6.3 Secondary Air Quality Impacts – PM2.5 Control Measures

Construction: Because Alternative 4 includes all of the same PM2.5 control measures as the 2012 AQMP, construction impacts from Alternative 4 PM2.5 control measures would be the same as for the 2012 AQMP, as explained here. Construction air quality impacts associated with approximately seven 2012 AQMP PM2.5 control measures were identified and evaluated. It was assumed that the following types of construction activities to implement 2012 AQMP PM2.5 control measures contribute to construction activities emission inventories: 1) additional infrastructure to support electric and alternative fuel vehicles; 2) additional infrastructure for stationary source controls; and, 3) additional infrastructure to support electrification of new sources. It was concluded that these PM2.5 control measures have the potential to contribute to significant adverse secondary air quality impacts as the increase in the construction emission inventories for CO and PM10 from the

baseline to the year 2023 would increase in an amount that would exceed the applicable construction air quality significance thresholds of 550 and 150 pounds per day, respectively (refer to Table 4.2-4). Because future construction air quality impacts were concluded to be significant, eight mitigation measures were identified to reduce potentially significant CO and PM10 construction air quality impacts. In spite of implementing these eight construction air quality mitigation measures, CO and PM10 construction air quality impacts would remain significant. This conclusion applies to Alternative 4.

TABLE 6-19

Total Carrying Capacity: 8-Hr standard ^b	420	114

^a This table shows remaining emissions, not emission reductions. Remaining emission take into account emission reductions achieved or projected to be achieved from AQMP control measures and subtracted from the 2008 baseline.

^b Inventory necessary to achieve 80 ppb to attain the federal eight-hour ozone standard by 2023.

Operation: Because Alternative 4 PM_{2.5} measures are identical to those in the 2007 AQMP, the same operation activities and associated operation emissions would occur. The analysis concluded, however, that secondary operational emissions from increased electricity demand, control of stationary sources, coatings and solvents formulated with low VOC materials, use of alternative fuels in mobile sources, increase use of fuels due to reduction in fuel economy, miscellaneous sources, non-criteria pollutants, and global warming and ozone depletion as a result of implementing the 2012 AQMP would be less than significant. Consequently, operational air quality impacts from Alternative 4 would be significant and equivalent to the operational air quality impacts from the 2012 AQMP.

6.5.2.2.4 Secondary Air Quality Impacts – Ozone Control Measures

Construction: Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2 of this [Final](#) Program EIR. As a result, construction air impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1, less than significant and, therefore, less than the 2012 AQMP.

Operation: As noted above, Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2 of this [Final](#) Program EIR. As a result, operation air impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1, less than significant.

6.5.2.6.3 Project-specific and Cumulative Impacts Conclusion

Based upon the above conclusions, implementing PM_{2.5} control measures have the potential to generate significant project-specific construction air quality impacts, while operational impacts would be less than significant. Overall air quality impacts from implementing Alternative 4 PM_{2.5} control measures would be identical to the 2012 AQMP. No project-specific construction or operational air quality impacts were identified from implementing Alternative 4 ozone control measures. Therefore, it is presumed that Alternative 4 has the potential to generate significant adverse project-specific construction air quality impacts, which would be equivalent to the 2012 AQMP and less than significant project-specific operational air quality impacts, which would be less than project-specific impacts from the 2012 AQMP.

Since, anticipated project-specific construction air quality impacts from Alternative 4 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific construction impacts would be significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 4 would contribute to significant adverse cumulative air quality impacts generated by the 2012-2035 RTP/SCS. Since construction air quality impacts from Alternative 4 are cumulatively considerable, cumulative construction air quality impacts from Alternative 4 are significant and equivalent to the 2012 AQMP.

Alternatively, since anticipated project-specific operational air quality impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific operational air quality impacts would be less significant and less than those generated by the 2012 AQMP, Alternative 4 would also not contribute to significant adverse cumulative operational air quality impacts generated by the 2012-2035 RTP/SCS. Since operation air quality impacts from Alternative 4 are not cumulatively considerable, cumulative operational air quality impacts from Alternative 4 are significant, but less than the 2012 AQMP.

6.5.3 Energy

The potential direct and indirect energy impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide a brief summary of potential direct and indirect energy impacts from the 2012 and evaluate potential direct and indirect energy impacts from each alternative relative to the 2012 AQMP.

6.5.3.1 Proposed Project

Potential direct and indirect energy impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis of potential energy impacts from implementing the 2012 AQMP, refer to Subchapter 4.3 - Energy.

6.5.3.1.1 *PM2.5 Control Measures*

As shown in Table 4.3-1, there are a number of 2012 AQMP PM2.5 control measures that have the potential to generate adverse energy impacts associated with implementing the 2012 AQMP PM2.5 control measures. Potential energy impacts from increased demand for electricity natural gas, petroleum fuels, and alternative fuels as a result of implementing 2012 PM2.5 control measures, are summarized in the following paragraph.

The potential increase in electricity and natural gas use due to implementation of 2012 AQMP PM2.5 control measures is partially associated with the potential installation of add-on control equipment. The energy impacts associated with 2012 AQMP PM2.5 control measures (see Table 4.3-1) were evaluated and determined to be less than significant for electricity, natural gas, petroleum fuels, and alternative fuels impacts.

6.5.3.1.2 *Ozone Control Measures*

As shown in Table 4.3-1 of this [Final](#) Program EIR, there are a number of 2012 AQMP ozone control measures that have the potential to generate adverse energy impacts associated with implementing the 2012 AQMP ozone control measures. Potential energy impacts from increased demand for electricity natural gas, petroleum fuels, and alternative fuels as a result of implementing 2012 PM2.5 control measures, are summarized in the following paragraphs.

A number of ozone control measures in the 2012 AQMP, in particular mobile source control measures, are expected to increase the demand for electricity and natural gas to fuel both on-road and off-road mobile sources as a means of complying with 2012 AQMP ozone control measures. Any increases in the use of electricity or natural gas as a combustion fuel would likely result in a concurrent decrease in tradition petroleum fuels such as gasoline and diesel. The increase in demand for electricity and natural gas associated with the ozone control measures and strategies in the 2012 AQMP is considered to be significant.

Subchapter 4.3 also included an analysis of 2012 AQMP ozone control measures that may have the potential to increase demand for alternative fuels such as hydrogen, methanol, ethanol, etc. Demand for alternative fuels could increase primarily as a result of

implementing ~~3023~~ 2012 AQMP ozone control measures, especially those affecting mobile sources. However, the analysis concluded that increased demand for alternative fuels as transportation fuels is not expected to be significant since they are not widely available and their use is currently limited. Therefore, energy impacts associated with the 2012 AQMP ozone control measures (see Table 4.3-1) were evaluated and determined to be less than significant for petroleum fuels and alternative fuels.

6.5.3.1.3 *Project-specific and Cumulative Impacts Conclusion*

It was concluded in Subchapter 4.1 that 2012 AQMP control measures, both PM2.5 and ozone control measures, could generate potential adverse impacts related to increased demand for electricity, natural gas, petroleum fuels, and alternative fuels. When considering overall electricity, natural gas, petroleum fuels, and alternative fuels impacts from the 2012 AQMP PM2.5 and ozone control measures, although potential adverse energy impacts were identified, none exceeded any of the energy significance thresholds identified in Subsection 4.3.3. Therefore, project-specific aesthetics impacts associated with the 2012 AQMP are less than significant.

Since, anticipated project-specific energy impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific energy impacts from the 2012 AQMP were evaluated in connection with energy impacts from SCAG's 2012-2035 RTP/SCS. Since project-specific energy impacts would be significant, the 2012 AQMP would contribute to significant adverse cumulative energy impacts generated by the 2012-2035 RTP/SCS. Since energy impacts from the 2012 AQMP are cumulatively considerable, cumulative energy impacts from the 2012 AQMP are significant.

6.5.3.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. Since the 2007 AQMP now includes only black box measures, energy impacts analysis for Alternative 1 will focus only on potential impacts identified for the black box measures. Potential energy impacts from implementing Alternative 1 are described in the following subsections.

6.5.3.2.1 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason, Alternative 1 is not expected to create any energy impacts from PM2.5 control measures.

6.5.3.2.2 *Ozone Control Measures*

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of

energy impacts from all control measures, including black box control measures. As a result, consistent with the assumption in Subsection 6.5.1.2 that significance determinations from the 2007 Program EIR continue to apply, it is concluded that Alternative 1 does not have the potential to generate potentially significant adverse energy impacts as shown in Table 6-10 and described in the following paragraphs.

It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-01 regulating on-road light-duty vehicles and heavy-duty vehicles could generate potentially significant adverse energy impacts because of potential increases in demand primarily for electricity, natural gas, and other alternative fuels, displacing and potentially reducing demand for gasoline and diesel fuels. Potential energy demand impacts in the future from on-road light-duty vehicles and heavy-duty vehicles were concluded to be less than significant because total demand for energy in the on-road light- and heavy-duty vehicle mobile source sectors was expected to be a small percentage of future energy demand in the district.

Similarly, it was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-02 regulating off-road heavy duty vehicles could also generate potentially significant adverse energy impacts because of potential increases in demand primarily for electricity, natural gas, and other alternative fuels, displacing and potentially reducing demand for diesel fuels. Potential energy demand impacts were concluded to be less than significant because total demand for energy in the off-road heavy duty vehicle sector was expected to be a small percentage of future energy demand in the district.

6.5.3.2.3 *Project-specific and Cumulative Impacts Conclusion*

As indicated in Subsection 6.4.1, the SCAQMD and CARB have adopted all short-term control measures within their authority, so that only black box control measures remain. Since Alternative 1 does not include short-term control measures, potential energy impacts would be even less compared to the 2007 AQMP when it was originally adopted. It was concluded in the 2007 Program EIR that the 2007 AQMP ozone control measures would not generate significant adverse energy impacts. Consequently, overall energy impacts from Alternative 1 are concluded to be less than significant.

Since, anticipated project-specific energy impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific energy impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative energy impacts generated by the 2012-2035 RTP/SCS. Since energy impacts from Alternative 1 are not cumulatively considerable, cumulative energy impacts from Alternative 1 are not significant.

6.5.3.3 *Alternative 2 – Localized PM Emissions Control*

As explained in Subsection 6.4.2, with the CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS), CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone

control measures as the 2012 AQMP, except for PM2.5 Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential energy impacts from implementing Alternative 2 would be the same as potential energy impacts from implementing the 2012 AQMP. For the complete analysis of energy impacts from the 2012 AQMP, refer to Subchapter 4.3 – Energy. Potential energy impacts from implementing Alternative 2 are described in the following subsections.

6.5.3.3.1 *PM2.5 Control Measures*

As shown in Table 4.3-1, there are a number of 2012 AQMP PM2.5 control measures that have the potential to generate adverse energy impacts associated with implementing the 2012 AQMP PM2.5 control measures. Of the two Alternative 2 PM2.5 episodic control measures affecting the Mira Loma area, only one, CMALT-2C (2012 AQMP PM2.5 Control Measure BCM-04), was identified as contributing to potential adverse energy impacts. However, 2012 AQMP PM2.5 Control Measure BCM-04 only regulates affected livestock facilities in the Mira Loma area, so it is the same as Alternative 2 PM2.5 Control Measure CMALT-2C. Consequently, energy impacts from implementing 2012 AQMP ~~or~~ Alternative 2 PM2.5 control measures would be the same and less than significant.

6.5.3.3.2 *Ozone Control Measures*

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 [AQMP](#) Control Measure ONRD-04) applies only to the Mira Loma area, energy impacts from implementing Alternative 2 ozone control measures would be the same as the energy impacts from implementing the 2012 AQMP ozone control measures. As shown in Table 4.3-1 in Subchapter 4.3, the analysis of electricity, natural gas, petroleum fuels, and alternative fuels impacts from implementing the 2012 AQMP ozone control measures indicated that they have the potential to generate adverse energy impacts. The analysis concluded that electricity and natural gas impacts associated with implementing the 2012 AQMP ozone control measures would be significant, while impacts to petroleum fuels, alternative fuels, and renewable fuels were concluded to be less than significant. This same conclusion also applies to Alternative 2 because it contains the same ozone control measures that have the potential to affect energy resources as the 2012 AQMP. Measures to mitigate significant adverse electricity and natural gas impacts were identified and would apply to Alternative 2. The analysis concluded, however, that in spite of implementing the electricity and natural gas mitigation measures, impacts would remain significant.

6.5.3.3.3 *Project-specific and Cumulative Impacts Conclusion*

As explained above, overall, potential project-specific adverse energy impacts from Alternative 2 would be the same as potential project-specific energy impacts from the 2012 AQMP and both would be significant.

Since, anticipated project-specific energy impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific energy impacts would be

significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would contribute to significant adverse cumulative energy impacts generated by the 2012-2035 RTP/SCS. Since energy impacts from Alternative 2 are cumulatively considerable, cumulative energy impacts from Alternative 2 are significant and equivalent to the 2012 AQMP.

6.5.3.4 Alternative 3 – Greater Reliance on NO_x Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM_{2.5} control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential energy impacts from implementing Alternative 3 would be the same as potential energy impacts from implementing the 2012 AQMP. For the complete analysis of energy impacts from the 2012 AQMP, refer to Subchapter 4.3 – Energy.

6.5.3.4.1 *PM_{2.5} Control Measures*

As shown in Table 4.3-1, there are a number of 2012 AQMP PM_{2.5} control measures that have the potential to generate adverse energy impacts associated with implementing the 2012 AQMP PM_{2.5} control measures. Alternative 3 includes all of the same PM_{2.5} control measures as the 2012 AQMP, except for BCM-01. PM_{2.5} Control Measure [BCM-01](#) was evaluated for the potential to generate adverse energy impacts, but it was concluded that this control measure did not have the potential to generate any energy impacts. It was concluded in the analysis of potential adverse energy impacts from implementing 2012 AQMP PM_{2.5} control measures that natural gas, petroleum fuels, and alternative fuels impacts would be less than significant. As with the 2012 AQMP, electricity impacts would be significant for the same reasons. Since Alternative 3 contains the same PM_{2.5} control measures as the 2012 AQMP, potential electricity, natural gas, petroleum fuels, and alternative fuels impacts would be same as energy impacts from implementing 2012 AQMP. Since all remaining PM_{2.5} control measures in Alternative 3 are the same as those in the 2012 AQMP, energy impacts from implementing Alternative 3 PM_{2.5} control measures would be significant and equivalent to energy impacts from the 2012 AQMP.

6.5.3.4.2 *Ozone Control Measures*

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered vehicles from the year 2014 through 2017. Energy impacts for the 2012 AQMP were analyzed by type of energy source and, since Alternative 3 Ozone Control Measures ONRD-03 and OFF-01 may

contribute adverse impacts to each type of energy source, the same approach will be used here.

Electricity: Mobile source control measures in the 2012 AQMP are expected to increase the electricity demand in the district. A number of control measures would result in an increase in electricity demand associated with the electrification of mobile sources, including Control Measure ONRD-03. (Control Measure OFFRD-03 is not expected to increase demand for electricity since electric motors are not generally available for repowering off-road vehicles.) Although it is not expected that this category of heavy-duty on-road trucks would use electricity, consistent with the analysis of the 2012 AQMP electricity impacts, a worst-case assumption was made that mobile sources could switch to battery electric or hybrid vehicles. Table 6-20 shows the anticipated energy demand from Alternative 3 compared to the 2012 AQMP for those control measures where sufficient information is available to quantify electricity impacts.

TABLE 6-20

Electricity Impacts for Los Angeles, Orange, Riverside, and San Bernardino Counties (gigawatt-hours)

Control Measure	2010	2012 AQMP 2023 ^a	ALT. 3 2023

Source: CEC, 2012a

^a Projections based on CEC, 2012j

^b Based on 12,600 miles/year and 0.34 kWh/mile.

^c Based on 16,600 miles/year and 1 kWh/mile.

^d Based on 18,000 miles/year and 2.75 kWh/mile.

Because electricity information is not available for all ozone control measures, increased electricity demand could be greater than shown in Table 6-20. Therefore, electricity demand

impacts are concluded to be significant and greater than the 2012 AQMP. Because the primary effect of Alternative 3 would be to increase electricity demand for mobile sources, no mitigation measures were identified to reduce electricity demand impacts from this alternative. Because electricity demand impacts are concluded to be significant for Alternative 3, the same mitigation measures identified for the 2012 AQMP also apply to this alternative.

Natural Gas: A number of control measures in the 2012 AQMP may result in an increase in demand for natural gas associated with stationary sources due to the need for additional emission controls. Other control measures are expected to encourage the use of natural gas as a fuel to offset the use of petroleum fuels including ONRD-03. In addition, increased demand for electricity will require additional natural gas, as most of the power plants in California are operated using natural gas.

According to the CEC, there were about 24,819 light-duty natural gas and about 11,500 heavy-duty natural gas vehicles in California in 2009 (CEC, 2011). The CEC expects a steady increase in natural gas consumption used as an alternative fuel (see Table 4.3-4 of this [Final](#) Program EIR). As indicated in Subchapter 4.3 of this [Final](#) Program EIR, some of the control measures in the 2012 AQMP could result in an increase in the use of natural gas in medium- and heavy-duty on road vehicles. It is expected that Alternative 3 Control Measure ONRD-03 has the potential to expand the use of natural gas fuels in on-road medium-duty and heavy-duty trucks using more efficient, advanced natural gas engine technologies by approximately 750 vehicles. Although Alternative 3 Control Measure OFFRD-01 has the potential to accelerate the penetration of heavy-duty off-road vehicles by as much as 19,344 it is unknown and, therefore, speculative regarding how many of these vehicles would repower using natural gas engines. Otherwise, natural gas impacts from other Alternative 3 ozone control measures are expected to be significant and slightly greater than the 2012 AQMP. Because natural gas demand impacts are concluded to be significant, mitigation measures were identified required and would apply to Alternative 3. The analysis concluded, however, that in spite of implementing the electricity and natural gas mitigation measures, impacts would remain significant.

Petroleum Fuels: Similar to the effects of the 2012 AQMP, implementing Alternative 3 is expected to result in a decrease in the future increased demand for petroleum fuels (e.g., diesel, distillate, residual oil, and gasoline) due to mobile source control measures, as well as a potential increase in engine efficiency associated with the retrofit of new engines. Ozone control measures that are expected to result in a reduction in the demand for petroleum fuels include Control Measure ONRD-03. Table 6-21 shows the reduction in demand for petroleum fuels for Alternative 3 compared to the 2012 AQMP.

TABLE 6-21

^b Based on 16,600 miles/year and 11 miles/gallon.

^c Based on 18,000 miles/year and 6 miles/gallon.

^d Control measure ONRD-4 starts in 2015.

Construction activities that could be required to implement control measures in the 2012 AQMP would also increase the use of gasoline and diesel, including ozone Control Measure OFFRD-01. Construction activities could be required under a number of the control measures to develop transportation infrastructure (e.g., overhead catenary lines), install air pollution control equipment, and further develop electricity to support electrification of sources. OFFRD-01 has the potential to accelerate the turnover of up to 19,344 off-road mobile source vehicles. Currently, there are adequate fuel supplies in California. In fiscal year 2011, 14,728,734,063 gallons of gasoline and 2,564,017,901 gallons of diesel were sold in California⁴. Construction activities are temporary and all construction equipment will cease once construction activities are finished. As the use of petroleum fuels in other mobile sources decreases, there is likely to be an excess availability of gasoline and diesel. Even if all off-road mobile sources affected by Control Measure OFFRD-01 use diesel engines, it is unlikely that demand for diesel for these vehicles would offset the reduction in demand for diesel shown in Table 6-21. Petroleum fuel impacts from Alternative 3 for other control measures would be equivalent to the 2012 AQMP. Therefore, demand for petroleum fuels is expected to be less than significant for Alternative 3, but greater than similar impacts from the 2012 AQMP.

⁴ State Board of Equalization, Fuel Taxes Statistics & Reports, <http://www.boe.ca.gov/sptaxprog/spftrpts.htm>.

Alternative Fuels: Electricity, natural gas (including forms such as CNG, etc.), and diesel (which would include biodiesel) have already been evaluated in the above paragraphs. As noted in Subchapter 4.3, potential alternative fuel M85 is no longer sold in California. Although ethanol is used as a fuel additive, this primarily for gasoline powered on-road passenger cars and light-duty trucks and would not likely be used in vehicles affected by Alternative 3 ozone Control Measures ONRD-03 or OFFRD-01. While hydrogen fuel cell technology is promising, its use in the future is dependent on many things (cost-effectiveness of the technology, availability of hydrogen, etc.), so that the extent to which it may be used in the future to displace petroleum fuels is currently unknown and, therefore, speculative.

Potential energy impacts associated with the Alternative 3 ozone control measures (21 control measures, see Table 4.4-1) were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products. Implementing ozone control measures that result in the use of ammonia in emission control systems could generate significant adverse energy impacts from exposure to ammonia in the event of an accidental release. Mitigation measures were identified that could reduce ammonia energy impacts to less than significant. Finally, ozone control measures that increase demand for alternative fuels (LNG) have the potential to generate significant adverse energy impacts. No mitigation measures were identified that could reduce energy impacts from alternative fuels to less than significant. Since Alternative 3 ozone Control Measures ONRD-03 and OFFRD-01 have the potential to increase demand for alternative fuels to a greater extent for on-road heavy-duty vehicles and a much greater extent for off-road vehicles compared to the 2012 AQMP, energy impacts from Alternative 3 are significant and greater than significant energy impacts from the 2012 AQMP.

In general, energy demand impacts from Alternative 3 would be greater than energy demand impacts from the 2012 AQMP. The energy impacts associated with the Alternative 3 ozone control measures were evaluated and determined to be less than significant for natural gas, petroleum fuels, and alternative fuels impacts. Impacts from increased demand for electricity were concluded to be significant for Alternative 3 and for the 2012 AQMP.

6.5.3.4.3 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, potential project-specific adverse energy impacts from Alternative 3 for natural gas, petroleum fuels, and alternative fuels would be greater than potential project-specific natural gas, petroleum fuels, and alternative fuels impacts from the 2012 AQMP, but for both projects natural gas, petroleum fuels, and alternative fuels impacts would be less than significant. Potential project-specific adverse energy impacts from Alternative 3 for electricity would be greater than potential project-specific electricity impacts from the 2012 AQMP and for both projects electricity impacts would be significant.

Since, anticipated project-specific petroleum fuels, alternative fuels, and renewable fuels impacts from Alternative 3 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Since, anticipated project-specific electricity and natural gas demand impacts from Alternative 3 are concluded to be significant, they are considered to be cumulatively considerable as

defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific energy impacts would be significant and greater than those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative energy impacts generated by the 2012-2035 RTP/SCS. Therefore, since energy impacts (electricity and natural gas demand impacts from Alternative 3 are cumulatively considerable, cumulative energy impacts from Alternative 3 are significant and greater than the 2012 AQMP.

6.5.3.5 Alternative 4 – PM2.5 Reduction Strategies Only

As explained in Subsection 6.4.3, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of energy impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.3 – Energy. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2 of this [Final](#) Program EIR. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential energy impacts from implementing Alternative 4 are described in the following subsections.

6.5.3.5.1 *PM2.5 Control Measures*

As shown in Table 4.3-1 of this [Final](#) Program EIR, there are a number of 2012 AQMP PM2.5 control measures that have the potential to generate adverse energy impacts associated with implementing the 2012 AQMP PM2.5 control measures. It was concluded in the analysis of potential adverse energy impacts from implementing 2012 AQMP PM2.5 control measures that electricity, natural gas, petroleum fuels, and alternative fuels impacts would be less than significant. Since Alternative 4 contains the same PM2.5 control measures as the 2012 AQMP, potential electricity, natural gas, petroleum fuels, and alternative fuels impacts would be same as energy impacts from implementing 2012 AQMP. Consequently, energy impacts from implementing Alternative 4 PM2.5 control measures would also be less than significant.

6.5.3.5.2 *Ozone Control Measures*

Adopting Alternative 4 ozone control measures would result in the same potential adverse energy impacts as would occur under Alternative 1. It was concluded in the analysis of impacts from Alternative 1 that all remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of energy impacts from all control measures, including black box control measures. As a result, consistent with the assumption in Subsection 6.5.1.2 that significance determinations from the 2007 Program EIR continue to apply, it is concluded that Alternative 1 does not have the potential to generate potentially significant adverse energy impacts as shown in Table 6-10 and described in the following paragraphs.

It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-01 regulating on-road light-duty vehicles and heavy-duty vehicles could

generate potentially significant adverse energy impacts because of potential increases in demand primarily for electricity, natural gas, and other alternative fuels, displacing and potentially reducing demand for gasoline and diesel fuels. Potential energy demand impacts in the future from on-road light-duty vehicles and heavy-duty vehicles were concluded to be less than significant because total demand for energy in the on-road light- and heavy-duty vehicle mobile source sectors was expected to be a small percentage of future energy demand in the district.

Similarly, it was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-02 regulating off-road heavy duty vehicles could also generate potentially significant adverse energy impacts because of potential increases in demand primarily for electricity, natural gas, and other alternative fuels, displacing and potentially reducing demand for diesel fuels. Potential energy demand impacts were concluded to be less than significant because total demand for energy in the off-road heavy duty vehicle sector was expected to be a small percentage of future energy demand in the district.

6.5.3.5.3 *Project-specific and Cumulative Impacts Conclusion*

Based upon the above conclusions, when considering overall energy impacts from implementing Alternative 4, adverse energy impacts were identified from implementing ozone control measures, but these impacts were concluded to be less than significant. Potentially significant adverse electricity and natural gas impacts were identified from implementing the PM_{2.5} control measures, but would be less than similar impacts from the 2012 AQMP. Therefore, it is concluded that potential adverse energy impacts from implementing Alternative 4 would be significant, but less than those for the 2012 AQMP because Alternative 4 contains fewer control measures that could adversely affect electricity, natural gas, petroleum fuels, and alternative fuels resources.

Since anticipated project-specific energy impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific energy impacts would be significant, although less than those generated by the 2012 AQMP, Alternative 4 would contribute to significant adverse cumulative energy impacts generated by the 2012-2035 RTP/SCS. Since energy impacts from Alternative 4 are cumulatively considerable, cumulative energy impacts from Alternative 4 are significant.

6.5.4 Hazards and Hazardous Materials

The potential direct and indirect hazards and hazardous materials impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect hazards and hazardous materials impacts from each alternative relative to the 2012 AQMP.

6.5.4.1 Proposed Project

Potential direct and indirect hazards and hazardous materials impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.4 – Hazards and Hazardous Materials.

6.5.4.1.1 *PM2.5 Control Measures*

The analysis in Subchapter 4.4 identified three 2012 AQMP PM2.5 control measures, CMB-01, IND-01, and MCS-01 that have the potential to generate the following adverse hazards and hazardous materials impacts. Use of alternative fuels and fuel additives can result in hazard impacts for some fuels (e.g., LNG and CNG) in the event of an accidental release during transport. Potential exposure to a toxic air contaminant, ammonia, used as a NOx reducing agent for SCRs and SNCR in the event of an onsite accidental release during use or storage could also occur as a result of implementing 2012 AQMP PM2.5 control measures. Reformulating coatings with more toxic or flammable solvents could cause fire, accidental release, and offsite/onsite exposure and worker risk. Hazard impacts from transport of alternative fuels (LNG) were concluded to be significant. Hazard impacts from exposure to ammonia vapor were concluded to be significant, but could be reduced to less than significant.

6.5.4.1.2 *Ozone Control Measures*

The analysis in Subchapter 4.7 identified a number of 2012 AQMP ozone control measures as having the potential to create the following adverse hazards and hazardous materials impacts.

- Low VOC coatings could be formulated with more toxic or flammable solvents could cause fire, accidental release, and offsite/onsite exposure and worker risk. This potential impact is considered to be significant. Mitigation measures were identified to reduce this potential hazards and hazardous materials impact to less than significant.
- Receptors could be exposed to hazardous waste that may be generated from spent carbon, use of ammonia to operate condensers, hazardous waste from operating scrubbers, and hazardous waste of spent catalyst from operating thermal oxidizers. This impact was concluded to be less than significant.
- Use of alternative fuels and fuel additives can result in hazard impacts during transport. This impact was concluded to be significant and no mitigation measures were identified that could potentially reduce hazard impacts from and accidental release of alternative fuels during transport.
- Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release. Hazard impacts from exposure to accidental releases of ammonia were concluded to be less than significant, except for potential onsite releases, which were concluded to be significant, but could be reduced to less than significant.

The hazard impacts associated with the ozone control measures control measures, see Table 4.4-1, were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products; and all alternative fuels except LNG.

6.5.4.1.3 *Project-specific and Cumulative Impacts Conclusion*

It was concluded in Subchapter 4.4 that potential hazards and hazardous materials impacts from implementing 2012 AQMP PM_{2.5} and ozone control measures would be less than significant for most control measures. In the case of exposure to accidental releases onsite at a commercial or industrial facility, impacts were concluded to be significant, but could be reduced to less than significant through implementing mitigation measures. Finally, hazard impacts from transporting LNG were concluded to be significant and no mitigation measures were identified that could reduce these potential hazard impacts to less than significant. Therefore, project-specific hazards and hazardous materials impacts associated with the 2012 AQMP are concluded to be significant.

Since, anticipated project-specific hazards and hazardous materials impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific hazard and hazardous materials impacts from the 2012 AQMP were evaluated in connection with hazardous materials impacts from SCAG's 2012-2035 RTP/SCS. Since project-specific hazards and hazardous materials impacts generated by the 2012 AQMP would be significant, the 2012 AQMP would contribute to significant adverse cumulative hazard and hazardous materials impacts generated by the 2012-2035 RTP/SCS. Since hazards and hazardous materials impacts from the 2012 AQMP are cumulatively considerable, cumulative hazards and hazardous materials impacts from the 2012 AQMP are significant.

6.5.4.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final Program EIR](#), all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures.

6.5.4.2.1 *PM_{2.5} Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM_{2.5} control measures. For this reason, Alternative 1 is not expected to create any impacts to hazards and hazardous materials resources from PM_{2.5} control measures.

6.5.4.2.2 *Ozone Control Measures*

Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of hazards and hazardous materials impacts from all control measures, including black box control measures. As a result, consistent with the assumptions in Subsection 6.5.1.2 regarding the applicability of the significance determinations from the 2007 Program EIR, it is concluded that Alternative 1 does not have the potential to generate potentially significant hazard and hazardous materials impacts as shown in Table 6-10 and described in the following paragraphs.

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-01 regulating on-road light-duty vehicles and heavy-duty vehicles could generate potentially significant adverse hazards and hazardous materials impacts. In particular, one of the NOx pollution control technologies that could be used for heavy-duty on-road vehicles could consist of SCR equipment. SCR uses ammonia as a reducing agent to convert NOx to nitrogen and water. Potential hazard and hazardous materials impacts from the use of SCR on heavy-duty vehicles were concluded to be less than significant because aqueous ammonia in concentrations less than 20 percent by volume would be used. No significant adverse hazards or hazardous materials impacts were identified using aqueous ammonia in concentrations less than 20 percent by volume.

Similarly, it was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-02 regulating off-road heavy duty vehicles could also generate potentially significant adverse hazards and hazardous materials impacts for the same reason identified for SCLTM-01 (e.g., installation of SCRs on off-road mobile sources that use ammonia as a reducing agent). Potential hazards and hazardous materials impacts were concluded to be less than significant for the same reason as above, aqueous ammonia in concentrations less than 20 percent by volume would be used.

Finally, it was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-03 regulating the VOC content of consumer products could generate potentially significant adverse hazards and hazardous materials impacts. The reason for this conclusion is that future rules regulating consumer products could result in formulations that are more flammable or toxic than current formulations. This impact, however, was concluded to be less than significant if water-based formulations are used. Further, solvents are currently available such as Texanol, propylene glycol, etc., that would not generate significant adverse flammability or hazard impacts.

6.5.4.2.3 *Project-specific and Cumulative Impacts Conclusion*

It was concluded in the 2007 Program EIR that all 2007 AQMP that, even with the implementation of mitigation measure HZ1, the 2007 AQMP had the potential to generate significant adverse hazards and hazardous materials impacts. Potential hazards and hazardous materials impacts could occur primarily from implementing Control Measure ARB-ONRD-03⁵/SCFUEL-01 – California Phase 3 Reformulated Gasoline Modifications. Other control measures that have the potential of affecting motor vehicle fuel formulations include: SC-ONRD-01, SCFUEL-02, ARB-ONRD-4/SCONRD-03, and ARB-OFFRD-1. As indicated in Subsection 6.4.1, the SCAQMD and CARB have adopted all short-term control measures within their authority, so that only black box control measures remain. Since Alternative 1 does not include short-term control measures, potential hazard and hazardous materials impacts would be even less compared to the 2007 AQMP when it was

⁵ Short-term control measures adopted by CARB were revised and renamed, so it is not possible to identify a CARB measure identified as ARB-ONRD-03, for example.

originally adopted. Consequently, overall hazards and hazardous materials impacts from Alternative 1 are concluded to be less than significant.

Since, anticipated project-specific hazards and hazardous materials impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hazards and hazardous materials impacts would be less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative hazards and hazardous materials impacts generated by the 2012-2035 RTP/SCS. Since hazards and hazardous materials impacts from Alternative 1 are not cumulatively considerable, cumulative hazards and hazardous materials impacts from Alternative 1 are not significant.

6.5.4.3 Alternative 2 – Localized PM Emissions Control

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential hazards and hazardous materials impacts from implementing Alternative 2 would be the same as potential hazards and hazardous materials impacts from implementing the 2012 AQMP. For the complete analysis hazards and hazardous materials impacts from the 2012 AQMP, refer to Subchapter 4.4 – Hazards and Hazardous Materials. Potential noise impacts from implementing Alternative 2 are described in the following subsections.

6.5.4.3.1 *PM_{2.5} Control Measures*

Similar to the analysis of hazards and hazardous materials impacts for the 2012 AQMP in Subchapter 4.4, none of the two PM_{2.5} control measures in Alternative 2 that regulates the same sources as the episodic control measures in the 2012 AQMP was identified as contributing to construction hazards and hazardous materials impacts. However, because all other 2012 AQMP PM_{2.5} control measures, including those contributing to significant adverse hazards and hazardous materials impacts, are also included in Alternative 2, it has the potential to generate the same hazards and hazardous materials impacts as implementing the 2012 AQMP, which were concluded to be significant. This same conclusion applies to Alternative 2.

6.5.4.3.2 *Ozone Control Measures*

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 control measure ONRD-04) applies only to the Mira Loma area, potential hazards and hazardous materials impacts from implementing Alternative 2 ozone control measures would be similar to the hazards and hazardous materials impacts from implementing the 2012 AQMP ozone control measures: VOC coatings could be formulated with more toxic or flammable solvents (not significant); exposure to hazardous waste from spent carbon, use of ammonia, and spent

catalyst from operating thermal oxidizers, etc., (not significant); and exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release (mitigated to less than significant). Potential hazard and hazardous materials impacts from catastrophic releases of alternative fuels during transport (significant and unavoidable), would be slightly less because it is expected that fewer vehicles would be affected. Similar to the significance determination for potential hazards and hazardous materials impacts of the ozone control measures from the 2012 AQMP, hazards and hazardous materials impacts under Alternative 2 would also be significant, but would be slightly less compared to the 2012 AQMP. The mitigation measures (see Subchapter 4.4) identified to reduce potential hazards and hazardous materials impacts from the 2012 control measures would continue to apply to Alternative 2.

6.5.4.3.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential hazards and hazardous materials impacts from implementing Alternative 2 PM2.5 and ozone control measures could generate significant adverse hazards and hazardous materials impacts. Mitigation measures were identified that could reduce hazard impacts from exposure to onsite releases of ammonia to less than significant. No mitigation measures were identified that could reduce hazard impacts from catastrophic releases of alternative fuels during transport. Therefore, project-specific hazards and hazardous materials impacts associated with Alternative 2 are concluded to be significant and less than the 2012 AQMP.

Since, anticipated project-specific hazards and hazardous materials impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hazards and hazardous materials impacts would be significant, less than those generated by the 2012 AQMP, Alternative 2 would contribute to significant adverse cumulative hazards and hazardous materials impacts generated by the 2012-2035 RTP/SCS. Since hazards and hazardous materials impacts from the Alternative 2 are cumulatively considerable, cumulative hazards and hazardous materials impacts from the Alternative 2 are significant and less than the 2012 AQMP.

6.5.4.4 Alternative 3 – Greater Reliance on NOx Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential hazards and hazardous materials impacts from implementing Alternative 3 would be the same as potential hazards and hazardous materials impacts from implementing the 2012 AQMP. For the complete analysis of hazards and hazardous materials impacts from the 2012 AQMP, refer to Subchapter 4.4 – Hazards and Hazardous Materials.

6.5.4.4.1 *PM2.5 Control Measures*

Alternative 3 includes all of the same 2012 AQMP PM2.5 control measures, except BCM-01, so it has the potential to generate similar hazards and hazardous materials impacts as implementing the 2012 AQMP. PM2.5 control measures were identified as having the potential to generate significant adverse exposure impacts to a toxic air contaminant (ammonia) associated with SCRs and SNCR during storage, transport, use and accidental release. Mitigation measures were identified that could reduce this impact to less than significant. Use of alternative fuels and fuel additives could also result in hazard impacts, which were concluded to be significant. No mitigation measures were identified that could reduce hazard impacts from alternative fuels to less than significant. The hazard impacts associated with PM2.5 control measures (CMB-01, IND-01, and MCS-01) were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products; alternative fuels; ammonia use in SCRs, and fuel additives. Since BCM-01 was not identified as a PM2.5 control measure that could generate hazards or hazardous materials impacts, hazards and hazardous materials impacts from Alternative 3 PM2.5 control measures would be equivalent to those from the 2012 AQMP.

6.5.4.4.2 *Ozone Control Measures*

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered vehicles from the year 2014 through 2017.

Potential hazard impacts associated with the Alternative 3 ozone control measures (21 control measures, see Table 4.4-1) were evaluated and determined to be less than significant for reformulated coatings, adhesives, solvents, lubricants, mold release, and consumer products. Implementing ozone control measures that result in the use of ammonia in emission control systems could generate significant adverse hazard impacts from exposure to ammonia in the event of an accidental release. Mitigation measures were identified that could reduce ammonia hazard impacts to less than significant. Finally, ozone control measures that increase demand for alternative fuels (LNG) have the potential to generate significant adverse hazard impacts. No mitigation measures were identified that could reduce hazard impacts from alternative fuels to less than significant. Since Alternative 3 ozone Control Measures ONRD-03 and OFFRD-01 have the potential to increase demand for alternative fuels to a greater extent for on-road heavy-duty vehicles and a much greater extent for off-road vehicles compared to the 2012 AQMP, hazard and hazardous materials impacts from Alternative 3 are significant and greater than significant hazards and hazardous materials impacts from the 2012 AQMP.

6.5.4.4.3 *Project-specific and Cumulative Impacts Conclusion*

Since, anticipated project-specific hazards and hazardous materials impacts from Alternative 3 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hazards and hazardous materials impacts would be significant and greater than those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative hazards and hazardous materials impacts generated by the 2012-2035 RTP/SCS. Since hazards and hazardous materials impacts from Alternative 3 are cumulatively considerable, cumulative hazards and hazardous materials impacts from Alternative 3 are significant and greater than cumulative hazards and hazardous materials impacts from the 2012 AQMP.

6.5.4.5 *Alternative 4 – PM2.5 Reduction Strategies Only*

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter, which are the same as those in the 2012 AQMP. For the complete analysis of hazards and hazardous materials impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.4 – Hazards and Hazardous Materials. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential hazards and hazardous materials impacts from implementing Alternative 4 are described in the following subsections.

6.5.4.5.1 *PM2.5 Control Measures*

Similar to the analysis of hazards and hazardous materials impacts for the 2012 AQMP in Subchapter 4.4, because Alternative 4 includes all of the same 2012 AQMP PM2.5 control measures, including those contributing to significant adverse hazards and hazardous materials impacts, it has the potential to generate the same hazards and hazardous materials impacts as implementing the 2012 AQMP, which were concluded to be significant. This same conclusion applies to Alternative 4.

6.5.4.5.2 *Ozone Control Measures*

Adopting Alternative 4 ozone control measures would result in the same potential adverse hazards and hazardous materials impacts as would occur under Alternative 1. It was concluded in the analysis of impacts from Alternative 1 that all remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of hazards and hazardous materials impacts from all control measures, including black box control measures. The 2007 AQMP Program EIR included analyses of the following types of hazards and hazardous materials impacts.

- Low VOC coatings could be formulating with more toxic or flammable solvents could cause fire, accidental release, and offsite/onsite exposure and worker risk. This potential impact is considered to be less than significant.
- Use of alternative fuels and fuel additives can result in hazard impacts during transport, handling and storage. This impact was concluded to be less than significant.
- Potential exposure to toxic air contaminant (ammonia) associated with SCRs during storage, transport, use and accidental release. Hazard impacts from exposure to accidental releases of ammonia were concluded to be less than significant.

As a result, consistent with the assumption in Subsection 6.5.1.2 that significance determinations from the 2007 Program EIR continue to apply, it is concluded that Alternative 1 does not have the potential to generate potentially significant adverse hazards and hazardous materials impacts as shown in Table 6-10 and described in the following paragraphs.

6.5.4.5.3 *Project-specific and Cumulative Impacts Conclusion*

Because Alternative 4 includes all of the same 2012 AQMP PM2.5 control measures, including those contributing to significant adverse hazards and hazardous materials impacts, it has the potential to generate the same hazards and hazardous materials impacts as implementing the 2012 AQMP, which were concluded to be significant. Potential hazards and hazardous materials impacts from Alternative 4 ozone control measures would be the same as those identified for Alternative 1. Since Alternative 1 does not include short-term control measures, potential hazard and hazardous materials impacts would be even less compared to the 2007 AQMP when it was originally adopted. Consequently, overall hazards and hazardous materials impacts from Alternative 4 are concluded to be significant, less than significant.

Since, anticipated project-specific hazards and hazardous materials impacts from Alternative 4 are concluded to be significant, but less than those generated by the 2012 AQMP, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hazards and hazardous materials impacts would be significant, but less than those generated by the 2012 AQMP, Alternative 4 would contribute to significant adverse cumulative hazards and hazardous materials impacts generated by the 2012-2035 RTP/SCS. Since hazards and hazardous materials impacts from Alternative 4 are cumulatively considerable, cumulative hazards and hazardous materials impacts from Alternative 4 are significant.

6.5.5 Hydrology and Water Quality

The potential direct and indirect hydrology and water quality impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect hydrology and water quality impacts from each alternative relative to the 2012 AQMP.

6.5.5.1 Proposed Project

Potential direct and indirect hydrology and water quality impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.5 – Hydrology and Water Quality.

6.5.5.1.1 *PM2.5 Control Measures*

The hydrology and water quality impacts associated with PM2.5 control measures (e.g., BCM-03, IND-01, MCS-01, etc.) were analyzed and the following impacts were identified: water demand and wastewater discharge from operating wet ESPs or wet scrubbers, water quality impacts from the use of alternative fuels and fuel additives, water demand and water quality impacts from wastewater discharges from increased use of water-based formulations. Of the potential hydrology and water quality impacts analyzed, water demand impacts associated with the manufacture and use of waterborne and add-on air pollution control technologies were concluded to be significant. While mitigation measures were identified, water demand impacts are expected to remain significant. The hydrology and water quality impacts associated with wastewater generation and related wastewater quality are less than significant. Further, the use and application of SBS (BCM-04) on water quality is also expected to be less than significant.

6.5.5.1.2 *Ozone Control Measures*

Hydrology and water quality impacts associated with Ozone Control Measures are potentially significant for water demand (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01). The water quality impacts associated with wastewater generation and related wastewater quality from 2012 AQMP ozone control measures (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01) are less than significant. No significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels (IND-01, MSC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07). No significant adverse water quality impacts associated with increase battery use in EV and hybrid vehicles are expected (ONRD-01, ONRD-03, ONRD-04, ONRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-06, and ADV-07). Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills are expected to be less than significant.

6.5.5.1.3 *Project-specific and Cumulative Impacts Conclusion*

Water demand impacts from some types of air pollution control equipment (wet ESPs) and reformulating coatings with water-based coatings associated with 2012 AQMP PM2.5 and ozone control measures are potentially significant as indicated in the subsections above. No other hydrology or water quality impacts from 2012 AQMP PM2.5 or ozone control measures were identified. Further, it was concluded in Subchapter 4.5 that in spite of identifying water demand mitigation measures, implementing 2012 AQMP PM2.5 and ozone control measures has the potential to generate significant adverse water demand

impacts. Therefore, project-specific water demand impacts from implementing 2012 AQMP PM2.5 and ozone control measures are concluded to be significant and unavoidable.

Since, anticipated project-specific water demand impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific hydrology or water quality impacts from the 2012 AQMP were evaluated in connection with hydrology or water quality impacts from SCAG's 2012-2035 RTP/SCS. Further, since project-specific hydrology or water quality impacts (water demand impacts) generated by the 2012 AQMP would be significant, the 2012 AQMP would contribute to significant adverse cumulative hydrology or water quality impacts generated by the 2012-2035 RTP/SCS. Other hydrology or water quality impacts from implementing 2012 AQMP PM2.5 and ozone control measures were identified, but concluded to be less than significant. Since water demand impacts from the 2012 AQMP are cumulatively considerable, cumulative water demand impacts from the 2012 AQMP are significant. No measures beyond those identified in Subchapter 4.5 were identified to mitigate significant adverse cumulative water demand impacts.

6.5.5.2 Alternative 1 – No Project Alternative

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures.

6.5.5.2.1 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason, Alternative 1 is not expected to create any hydrology and water quality impacts from PM2.5 control measures.

6.5.5.2.2 *Ozone Control Measures*

Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of hydrology and water quality impacts from all control measures, including black box control measures. As a result, consistent with the assumptions in Subsection 6.5.1.2 regarding the applicability of the significance determinations from the 2007 Program EIR, it is concluded that Alternative 1 does not have the potential to generate potentially significant hydrology and water quality impacts as shown in Table 6-10 and described in the following paragraphs.

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-01B regulating on-road heavy duty vehicles could generate potentially significant water quality impacts because potential emission reduction technologies such as alternative fuels or fuel additives, if accidentally

released could readily dissolve in water and create adverse groundwater and surface water impacts. As indicated in the 2007 AQMP Program EIR, potential water quality impacts were concluded to be less than significant because alternative fuels and fuel additives would not generate greater water quality impacts in the event of an accidental release than accidental releases of gasoline and diesel fuels.

It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-03 regulating the VOC content of consumer products could generate potentially significant adverse water demand impacts. The reason for this conclusion is that future rules regulating consumer products could result in greater use of water-based formulation, thus, increasing water demand to supply these types of products. This impact, however, was concluded to be less than significant because the projected future increase in water demand from implementing 2007 AQMP control measures did not exceed the SCAQMD's water demand significance threshold in effect at that time.

6.5.5.2.3 *Project-specific and Cumulative Impacts Conclusion*

It was concluded in the 2007 Program EIR that water quality impacts from implementing all 2007 AQMP control measures would not be significant. However, the following three mitigation measures were identified to ensure that water quality impacts would remain less than significant.

HWQ-1: To ensure that users of reformulated solvents are aware of the proper disposal methods for reformulated solvents, the SCAQMD will provide an outreach and education program for affected parties. The SCAQMD will coordinate the outreach program with POTWs, the DTSC, and other appropriate agencies.

HWQ-2: The Sanitation Districts and other sewage agencies must increase their surveillance programs to quantify measurable effects resulting from this control measure and take appropriate action as necessary.

HWQ-3: CARB will monitor the use and limit or prohibit the use of toxic air contaminants, including perchloroethylene and methylene chloride, in reformulated consumer products.

Because Control Measure SCLTM-03 contributed to water quality impacts identified in the 2007 AQMP, the above mitigation measures would continue to be applicable under Alternative 1.

Potentially significant water quality impacts from illegal disposal of spent batteries resulting in battery acid leaking into the environment were also identified in the 2007 AQMP. As a result, mitigation measures HWQ-4 and HWQ-5 were identified to mitigate this type of potential water quality impact. It was concluded that implementing these two mitigation measures would reduce potential water quality impacts from illegal disposal of spent batteries to less than significant. However, because no 2007 AQMP black box control measures contributed to this water quality impact, the mitigation measures are no longer applicable. As indicated in Chapter 2 of this [Final](#) Program EIR, the SCAQMD and CARB have adopted all short-term control measures within their authority, so that only black box

control measures remain. Since Alternative 1 does not include short-term control measures, potential hydrology and water quality materials impacts would be even less compared to the 2007 AQMP when it was originally adopted. Consequently, overall hydrology and water quality impacts from Alternative 1 are concluded to be less than significant and less than hydrology and water quality impacts from the 2012 AQMP.

Since, anticipated project-specific hydrology and water quality impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hydrology or water quality impacts would be less significant and less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative hydrology or water quality impacts generated by the 2012-2035 RTP/SCS. Since hydrology and water quality impacts from Alternative 1 are not cumulatively considerable, cumulative hydrology and water quality impacts from Alternative 1 are not significant and are less than cumulative hydrology and water quality impacts from the 2012 AQMP.

6.5.5.3 Alternative 2 – Localized PM Emissions Control

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, hydrology and water quality impacts from implementing Alternative 2 would be the same as potential hydrology and water quality impacts from implementing the 2012 AQMP. For the complete analysis of hydrology and water quality impacts from the 2012 AQMP, refer to Subchapter 4.5 – Hydrology and Water Quality. Potential hydrology and water quality impacts from implementing Alternative 2 are described in the following subsections.

6.5.5.3.1 *PM_{2.5} Control Measures*

Because Alternative 2 contains most of the same PM_{2.5} control measures as the 2012 AQMP, it has the potential generate the same hydrology and water quality impacts. Potential hydrology and water quality impacts associated with Alternative 2 PM_{2.5} control measures (e.g., BCM-03, IND-01, MCS-01, etc.) were analyzed and the following impacts were identified: water demand and wastewater discharge from operating wet ESPs or wet scrubbers, water quality impacts from the use of alternative fuels and fuel additives, water demand and water quality impacts from wastewater discharges from increased use of water-based formulations. Of the potential hydrology and water quality impacts analyzed, water demand impacts associated with the manufacture and use of waterborne and add-on air pollution control technologies were concluded to be significant. While mitigation measures are available, they can vary from jurisdiction to jurisdiction, and may remain significant. The hydrology and water quality impacts associated with wastewater generation and related wastewater quality are less than significant. Further, the use and application of SBS (BCM-04) on water quality is also expected to be less than significant. Consequently, water

demand impacts from Alternative 2 PM_{2.5} control measures are the same as water demand impacts from 2012 AQMP PM_{2.5} controls and are concluded to be significant.

6.5.5.3.2 *Ozone Control Measures*

Water demand impacts associated with Alternative 2 ozone control measures (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01) are potentially significant for water demand. Under Alternative 2, water quality impacts associated with wastewater generation and related wastewater quality from the same 2012 AQMP ozone control measures (see Subsection 6.5.5.1.2) are less than significant. Similarly, under Alternative 2 no significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels (see Subsection 6.5.5.1.2). No significant adverse water quality impacts associated with increase battery use in EV and hybrid vehicles are expected (see Subsection 6.5.5.1.2). Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills are expected to be less than significant. Overall, water demand impacts from Alternative 2 are concluded to be significant and equivalent to the 2012 AQMP. Water quality impacts from Alternative 2 are concluded to be less than significant and equivalent to the 2012 AQMP.

6.5.5.3.3 *Project-specific and Cumulative Impacts Conclusion*

Under Alternative 2, water demand impacts from some types of air pollution control equipment (wet ESPs) and reformulating coatings with water-based coatings would be the same as water demand impacts from the 2012 AQMP PM_{2.5} and ozone control measures and are potentially significant. As a result, the water demand mitigation measures identified in Subchapter 4.5 of [this Final Program EIR](#) would be applicable to Alternative 2. Similarly, in spite of applying the 2012 AQMP water demand mitigation measures, implementing Alternative 2 PM_{2.5} and ozone control measures has the potential to generate significant adverse water demand impacts. No other hydrology or water quality impacts from Alternative 2 PM_{2.5} or ozone control measures were identified. Therefore, project-specific water demand impacts from implementing Alternative 2 PM_{2.5} and ozone control measures are equivalent to water demand impacts from the 2012 AQMP and are concluded to be significant and unavoidable.

Since, anticipated project-specific water demand impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Other hydrology or water quality impacts from implementing Alternative 2 PM_{2.5} and ozone control measures were identified, but concluded to be less than significant. Further, since project-specific hydrology or water quality (water demand) impacts would be significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would contribute to significant adverse cumulative hydrology or water quality (water demand) impacts generated by the 2012-2035 RTP/SCS. Since water demand impacts from Alternative 2 are cumulatively considerable, cumulative water demand impacts from Alternative 2 are significant. No measures beyond those identified in Subchapter 4.5 were identified to mitigate significant adverse cumulative water demand impacts.

6.5.5.4 Alternative 3 – Greater Reliance on NOx Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential hydrology and water quality impacts from implementing Alternative 3 PM2.5 control measures would be the same as potential hydrology and water quality impacts from implementing the 2012 AQMP. It is expected, however, that potential hydrology and water quality impacts from Alternative 3 ozone control measures would be greater than those from the 2012 AQMP.

6.5.5.4.1 *PM2.5 Control Measures*

Alternative 3 contains all of the same PM2.5 control measures as the 2012 AQMP, except BCM-01, however. BCM-01 was evaluated and it was concluded that it does not have the potential to contribute to hydrology and water quality impacts. Consequently Alternative 3 PM2.5 measures would generate hydrology water quality impacts equivalent to the 2012 AQMP. The analysis indicated that the 2012 AQMP has the potential generate potential hydrology and water quality impacts associated with PM2.5 control measures (e.g., BCM-03, IND-01, MCS-01, etc.) which were analyzed and the following impacts were identified: water demand and wastewater discharge from operating wet ESPs or wet scrubbers, water quality impacts from the use of alternative fuels and fuel additives, water demand and water quality impacts from wastewater discharges from increased use of water-based formulations. The hydrology and water quality impacts associated with wastewater generation and related wastewater quality are less than significant. Further, the use and application of SBS (BCM-04) on water quality is also expected to be less than significant. Consequently, water demand impacts from Alternative 3 PM2.5 control measures are the same as water demand impacts from 2012 AQMP PM2.5 controls and are concluded to be significant.

6.5.5.4.2 *Ozone Control Measures*

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered or replaced vehicles from the year 2014 through 2017. Hydrology and water quality impacts associated with Ozone control measures are potentially significant for water demand (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01). The water quality impacts associated with wastewater generation and related wastewater quality from 2012 AQMP control measures (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01) are less than significant. Less than significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels (IND-01, MSC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-

04, ADV-05, ADV-06, and ADV-07). Similarly, less than significant adverse water quality impacts associated with increase battery use in EV and hybrid vehicles are expected (ONRD-01, ONRD-03, ONRD-04, ONRD-05, ADV-01, ADV-02, ADV-03, ADV-04, ADV-06, and ADV-07). Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills are expected to be less than significant.

Although it is expected that ozone Control Measure ONRD-03 would result in double the number of trucks complying with the 2010 engine exhaust standards and OFFRD-01 would likely affect approximately three times as many vehicles, water quality impacts could be greater than for the 2012 AQMP, but they are not expected to be significant because the use of alternative fuels is not expected to result in any greater adverse water quality impacts than the use of conventional fuels like diesel or gasoline. Similarly, since none of the alternative fuels typically require water as part of their manufacturing or distribution processes, any increased use of alternative fuels under Alternative 3 would not likely be greater than under the 2012 AQMP.

Mitigation measures to reduce water demand impacts were identified for the 2012 AQMP and would apply to Alternative 3 as well. In spite of implementing the water demand mitigation measures, water demand impacts from Alternative 3 are expected to remain significant and equivalent to the 2012 AQMP and water quality impacts are expected to be less than significant and equivalent to the 2012 AQMP.

6.5.5.4.3 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, like the 2012 AQMP, Alternative 3 PM_{2.5} and ozone control measures are not expected to create significant adverse project-specific water quality impacts, but would be expected to generate water demand impacts equivalent to the 2012 AQMP. To ensure that water demand impacts remain significant, four mitigation measures were identified. Because Alternative 3 Control Measures ONRD-03 and OFFRD-01 would affect more on- and off-road sources than the comparable measures in the 2012 AQMP, project-specific impacts would be expected to be greater than impacts from the 2012 AQMP, but still less than significant.

Since, anticipated project-specific hydrology and water quality impacts from Alternative 3 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hydrology or water quality impacts would be significant and greater than those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative hydrology or water quality impacts generated by the 2012-2035 RTP/SCS. Since hydrology and water quality impacts from Alternative 3 are cumulatively considerable, cumulative hydrology and water quality impacts from Alternative 3 are significant and greater than cumulative hydrology and water quality impacts from the 2012 AQMP.

6.5.5.5 Alternative 4 – PM2.5 Reduction Strategies Only

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of hydrology and water quality impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.5 – Hydrology and Water Quality. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential hydrology and water quality impacts from implementing Alternative 4 are described in the following subsections.

6.5.5.5.1 *PM2.5 Control Measures*

Because Alternative 4 contains all of the same PM2.5 control measures as the 2012 AQMP, it has the potential generate the same hydrology and water quality impacts. Potential hydrology and water quality impacts associated with Alternative 4 PM2.5 control measures (e.g., BCM-03, IND-01, MCS-01, etc.) were analyzed and the following impacts were identified: water demand and wastewater discharge from operating wet ESPs or wet scrubbers, water quality impacts from the use of alternative fuels and fuel additives, water demand and water quality impacts from wastewater discharges from increased use of water-based formulations. Of the potential hydrology and water quality impacts analyzed, water demand impacts associated with the manufacture and use of waterborne and add-on air pollution control technologies were concluded to be significant. While mitigation measures are available, they can vary from jurisdiction to jurisdiction, and may remain significant. The hydrology and water quality impacts associated with wastewater generation and related wastewater quality are less than significant. Further, the use and application of SBS (BCM-04) on water quality is also expected to be less than significant. Consequently, water demand impacts from Alternative 4 PM2.5 control measures are the same as water demand impacts from 2012 AQMP PM2.5 controls and are concluded to be significant.

6.5.5.5.2 *Ozone Control Measures*

Water demand impacts associated with Alternative 4 ozone control measures (CTS-01, CTS-02, CTS-03, CTS-04, and FUG-01) are potentially significant for water demand. Under Alternative 4, water quality impacts associated with wastewater generation and related wastewater quality from the same 2012 AQMP ozone control measures (see Subsection 6.5.5.1.2) are less than significant. Similarly, under Alternative 4 no significant adverse hydrology and water quality impacts are expected from the increased use of alternative fuels (see Subsection 6.5.5.1.2). No significant adverse water quality impacts associated with increase battery use in EV and hybrid vehicles are expected (see Subsection 6.5.5.1.2). Potential spills associated with ammonia are expected to be contained on-site due to the requirement for secondary spill containment devices and berms. Therefore, potential ammonia spills are expected to be less than significant.

6.5.5.5.3 *Project-specific and Cumulative Impacts Conclusion*

Because Alternative 4 does not specifically include any ozone control measures, like Alternative 1, it relies on the ozone portion of the 2007 AQMP. It was concluded in the 2007 Program EIR that water quality impacts from implementing all 2007 AQMP control measures would not be significant. However, the mitigation measures HWQ1, HWQ2, and HWQ3 were identified to ensure that water quality impacts would remain less than significant (see Subsection 6.5.5.2.3 for a description of these control measures).

Because Control Measure SCLTM-03 contributed to water quality impacts identified in the 2007 AQMP, the same mitigation measures would continue to be applicable under Alternative 4.

Potentially significant water quality impacts from illegal disposal of spent batteries resulting in battery acid leaking into the environment were also identified in the 2007 AQMP. As a result, mitigation measures HWQ4 and HWQ5 were identified to mitigate this type of potential water quality impact. It was concluded that implementing these two mitigation measures would reduce potential water quality impacts from illegal disposal of spent batteries to less than significant. However, because no 2007 AQMP black box control measures contributed to this water quality impact, the mitigation measures are no longer applicable. As indicated in Chapter 2 of this [Final](#) Program EIR, the SCAQMD and CARB have adopted all short-term control measures within their authority, so that only black box control measures remain. Since Alternative 4 does not include short-term control measures, potential hydrology and water quality materials impacts would be even less compared to the 2007 AQMP when it was originally adopted. Consequently, overall hydrology and water quality impacts from Alternative 4 are concluded to be less than significant and less than hydrology and water quality impacts from the 2012 AQMP.

Since, anticipated project-specific hydrology and water quality impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific hydrology or water quality (water demand) impacts would be significant, but less than those generated by the 2012 AQMP, Alternative 4 would contribute to significant adverse cumulative hydrology or water quality impacts generated by the 2012-2035 RTP/SCS. Since hydrology and water quality impacts from Alternative 4 are cumulatively considerable, cumulative hydrology and water quality impacts from Alternative 4 are significant, but are less than significant cumulative hydrology and water quality impacts from the 2012 AQMP.

6.5.6 Land Use and Planning

The potential direct and indirect land use and planning impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect land use and planning impacts from each alternative relative to the 2012 AQMP.

6.5.6.1 Proposed Project

Potential direct and indirect land use and planning impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.6 - Land Use and Planning.

6.5.6.1.1 *PM2.5 Control Measures*

The analysis in Subchapter 4.6 indicated that no 2012 AQMP PM2.5 control measures were identified that have the potential to significantly adversely affect land use and planning decisions by local land use agencies. Therefore, potential impacts to land use and planning are concluded to be less than significant.

6.5.6.1.2 *Ozone Control Measures*

The analysis in Subchapter 4.6 identified the following 2012 AQMP ozone control measures as having the potential to create significant adverse land use and planning impacts, including visual impacts and impacts to scenic highways, ozone Control Measures ONRD-05, ADV-01, and ADV-2. These control measures identify construction of “wayside” power (such as electricity from overhead wires) as one of the zero emission technologies that could be used to reduce emissions from heavy-duty trucks and locomotives. Wayside power technologies include overhead catenary lines, where power is delivered from the electrical grid through the overhead wire to a pantograph on the vehicle itself. Catenary systems are well-established and efficient in light-rail applications, trolley cars and buses, and even mining trucks.

Control Measure ADV-01 indicates that the I-710 corridor was selected as high priority for introduction of zero-emission technology⁶. The 2012-2035 RTP/SCS also designates a route along the State Route 60 freeway as an east-west freight corridor⁷. In addition, there is currently a pilot project under consideration to install catenary lines at one of two sites, a site along the Terminal Island Freeway and on Navy at the Port of Los Angeles. Construction activities to install catenary lines at these locations would be expected to occur along heavily travelled roadways such as those identified above and possibly on other roads near the ports, such as Sepulveda Boulevard, Terminal Island Freeway, and Alameda Street.

Installation of electric and/or magnetic infrastructure will not change the existing condition (i.e., there will be limited opportunities to cross these major transportation corridors); however, the installation of the electric and/or magnetic infrastructure is not expected to create any new barriers or physically divide an established community. Further, the electric and/or magnetic infrastructure would be expected to be construction within or adjacent to the existing rights-of-way of existing streets and freeways, so no conflict with existing land

⁶ Los Angeles County Metropolitan Transportation Authority, *Alternative Goods Movement Technology Analysis-Initial Feasibility Study Report, Final Report: I-710 Corridor Project EIR/EIS*. Prepared by URS. January 6, 2009.

⁷ Los Angeles County Metropolitan Transportation Authority, *Alternative Goods Movement Technology Analysis-Initial Feasibility Study Report, Final Report: I-710 Corridor Project EIR/EIS*. Prepared by URS. January 6, 2009.

uses, general plans, specific plans, local coastal program, zoning ordinance, or other policies would be expected. Therefore, land use and planning impacts from the 2012 AQMP are concluded to be less than significant.

6.5.6.1.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, it was concluded in Subchapter 4.6 that 2012 AQMP control measures are not expected to conflict with applicable land use plans, policies, or regulations or physically divide an established community. Therefore, no significant adverse project-specific land use impacts are expected.

Since, anticipated project-specific land use and planning impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific land use and planning impacts from the 2012 AQMP were evaluated in connection with land use and planning impacts from SCAG's 2012-2035 RTP/SCS. Further, since project-specific land use and planning impacts would be less than significant for the 2012 AQMP, the 2012 AQMP would not contribute to significant adverse cumulative land use and planning impacts generated by the 2012-2035 RTP/SCS. Since aesthetics impacts from the 2012 AQMP are not cumulatively considerable, cumulative aesthetics impacts from the 2012 AQMP are not significant.

6.5.6.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, land use and planning impacts for Alternative 1 will focus only on potential impacts identified for the black box measures. Potential land use and planning impacts from implementing Alternative 1 are described in the subsection.

6.5.6.2.1 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason and the fact that land use and planning was not an environmental topic identified in the NOP/IS for the 2007 AQMP that could be adversely affected by that AQMP, Alternative 1 is not expected to create any land use and planning impacts.

6.5.6.2.2 *Ozone Control Measures*

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. The analysis of potential land use and planning impacts from the 2012 AQMP was not originally identified as a topic that would be adversely affected by the 2012 AQMP. However, public comments received on the 6/28/12 NOP/IS requested that land use and planning be added to the analysis of impacts in the 2012

AQMP [Final](#) Program EIR because it was suggested that construction and operation fixed guideway systems contemplated as part of Control Measure ONRD-05 “may impact established communities.”

As shown in Table 6-4, like Control Measure ONRD-05, 2007 AQMP Control Measure Off-Road Vehicles (SCLTM-02) would also regulate heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies. However, fixed guideway systems were not identified as a possible method of reducing heavy-duty truck emissions. The NOP/IS for the 2007 AQMP concluded that since the 2007 AQMP did not require construction of structures or new land uses in any areas of the district, no land use and planning impacts would be generated and land use and planning impacts would be less than would occur for the 2012 AQMP.

6.5.6.2.3 *Project-specific and Cumulative Impacts Conclusion*

The NOP/IS for the 2007 AQMP concluded that the 2007 AQMP would not generate any land use and planning impacts. Therefore, consistent with the assumptions in Subsection 6.5.1.2.1, it is presumed that Alternative 1 would not generate significant adverse project-specific land use and planning impacts.

Since, anticipated project-specific land use and planning impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific land use and planning impacts would be less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative land use and planning impacts generated by the 2012-2035 RTP/SCS. Since land use and planning impacts from Alternative 1 are not cumulatively considerable, cumulative land use and planning impacts from Alternative 1 are not significant and would be less than cumulative land use and planning impacts from the 2012 AQMP.

6.5.6.3 Alternative 2 – Localized PM Emissions Control

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential land use and planning impacts from implementing Alternative 2 would be the same as potential land use and planning impacts from implementing the 2012 AQMP. For the complete analysis of land use and planning impacts from the 2012 AQMP, refer to Subchapter 4.6 – Land Use and Planning. Potential land use and planning impacts from implementing Alternative 2 are described in the following subsections.

6.5.6.3.1 *PM2.5 Control Measures*

Similar to the analysis of land use and planning impacts for the 2012 AQMP in Subchapter 4.6, no PM2.5 control measures were identified from implementing Alternative 2 that have the potential to significantly adversely affect land use and planning by local land use agencies. The three episodic control measures in this alternative that would apply only to the Mira Loma area do not contain any provisions for constructing wayside electricity such as catenary electric lines. Therefore, potential land use and planning impacts from implementing 2012 AQMP PM2.5 control measures were concluded to be less than significant. This same conclusion applies to Alternative 2.

6.5.6.3.2 *Ozone Control Measures*

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 Control Measure ONRD-04) applies only to the Mira Loma area, land use and planning impacts from implementing Alternative 2 ozone control measures would be the same as the land use and planning impacts from implementing the 2012 AQMP ozone control measures. As shown in the analysis of land use and planning impacts for the 2012 AQMP in Subchapter 4.6, implementing ozone control measures from Alternative 2 (e.g., ozone Control Measures ONRD-05, ADV-01, and ADV-2) has the potential to generate adverse land use and planning impacts, such impacts would be less than significant. No other 2012 AQMP ozone control measures were identified that could affect land use and planning. This same conclusion applies to Alternative 2 because it contains the same three ozone control measures that have the potential to affect aesthetics resources.

6.5.6.3.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential project-specific adverse land use and planning impacts from Alternative 2 would be the same as potential project-specific land use and planning impacts from the 2012 AQMP and less than significant, because construction of the catenary or overhead power lines would not be expected to conflict with applicable land use plans, policies, or regulations or physically divide an established community.

Since, anticipated project-specific land use and planning impacts from Alternative 2 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific land use and planning impacts would be less than those generated by the 2012 AQMP, Alternative 2 would not contribute to significant adverse cumulative land use and planning impacts generated by the 2012-2035 RTP/SCS. Since land use and planning impacts from Alternative 2 are not cumulatively considerable, cumulative land use and planning impacts from Alternative 2 are not significant and equivalent to the 2012 AQMP.

6.5.6.4 *Alternative 3 – Greater Reliance on NOx Emissions Reductions*

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP

Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential land use and planning impacts from implementing Alternative 3 would be the same as potential land use and planning impacts from implementing the 2012 AQMP. For the complete analysis of land use and planning impacts from the 2012 AQMP, refer to Subchapter 4.6 – Land Use and Planning.

6.5.6.4.1 *PM2.5 Control Measures*

Similar to the analysis of land use and planning impacts for the 2012 AQMP in Subchapter 4.6, no PM2.5 control measures were identified from implementing Alternative 3 that have the potential to significantly adversely affect land use and planning by local land use agencies. Potential land use and planning impacts from implementing the 2012 AQMP were concluded to be less than significant (see Subchapter 4.6 of this [Final](#) Program EIR). This same conclusion applies to Alternative 3.

6.5.6.4.2 *Ozone Control Measures*

Similar to the analysis of land use and planning impacts for the 2012 AQMP in Subchapter 4.1, implementing ozone control measures from Alternative 3 (e.g., ozone Control Measures ONRD-05, ADV-01, and ADV-2) has the potential to generate adverse land use and planning impacts. No other 2012 AQMP ozone control measures were identified that could affect land use and planning by local land use agencies. This same conclusion applies to Alternative 3 because it contains the same three ozone control measures that have the potential to generate land use and planning impacts. Consequently, land use and planning impacts from Alternative 3 would be the same as for the 2012 AQMP and both would be less than significant.

6.5.6.4.3 *Project-specific and Cumulative Impacts Conclusion*

As explained above, potential project-specific adverse land use and planning impacts from implementing Alternative 3 PM2.5 and ozone control measures would be the same as potential project-specific land use and planning impacts from implementing 2012 AQMP PM2.5 and ozone control measures and less than significant.

Since, anticipated project-specific land use and planning impacts from Alternative 3 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific land use and planning impacts would be less than those generated by the 2012 AQMP, Alternative 3 would not contribute to significant adverse cumulative land use and planning impacts generated by the 2012-2035 RTP/SCS. Since land use and planning impacts from Alternative 3 are not cumulatively considerable, cumulative land use and planning impacts from Alternative 3 are not significant and equivalent to the 2012 AQMP.

6.5.6.5 *Alternative 4 – PM2.5 Reduction Strategies Only*

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of land use and planning

impacts from 2012 AQMP PM_{2.5} control measures, refer to Subchapter 4.6 – Land Use and Planning. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential land use and planning impacts from implementing Alternative 4 are described in the following subsections.

6.5.6.5.1 PM_{2.5} Control Measures

Similar to the analysis of land use and planning impacts for the 2012 AQMP in Subchapter 4.6, no PM_{2.5} control measures were identified from implementing Alternative 4 that have the potential to significantly adversely affect land use and planning by local land use agencies. Potential land use and planning impacts from implementing the 2012 AQMP were concluded to be less than significant (see Subchapter 4.6 of this [Final](#) Program EIR). This same conclusion applies to Alternative 4.

6.5.6.5.2 Ozone Control Measures

Adopting Alternative 4 means that the ozone SIP portion of the 2007 AQMP would remain in effect. As shown in Table 6-2 and discussed in subsection 6.5.1.2.3, 2012 AQMP Control Measure ONRD-05 would regulate the same emissions sources as 2007 AQMP Control Measure On-road Heavy-duty Vehicles (SCLTM-01B) (e.g., heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies). However, catenary systems were not identified as a possible method of reducing heavy-duty truck emissions. In fact, it was concluded in the NOP/IS for the 2007 AQMP that some control measures may have beneficial effects on scenic resources by improving visibility as well as improving air quality, preventing smoke, limiting opening burning and wood burning; and minimizing fugitive dust emissions. Therefore, it is concluded that Alternative 4 does not have the potential to generate significant adverse aesthetics impacts.

6.5.6.5.3 Project-specific and Cumulative Impacts Conclusion

Based upon the above conclusions, when considering overall land use and planning impacts from implementing Alternative 4, no significant adverse land use and planning impacts were identified from implementing PM_{2.5} or ozone control measures. Therefore, it is presumed that Alternative 4 would not generate significant adverse land use and planning impacts. Finally, it is concluded that potential adverse land use and planning impacts from implementing Alternative 4 would be less than for the 2012 AQMP because unlike the 2012 AQMP, Alternative 4 does not contain any control measures that adversely affect land use and planning.

Since, anticipated project-specific land use and planning impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific

land use and planning impacts would be less than those generated by the 2012 AQMP and less than significant, Alternative 4 would not contribute to significant adverse cumulative land use and planning impacts generated by the 2012-2035 RTP/SCS. Since land use and planning impacts from Alternative 4 are not cumulatively considerable, cumulative land use and planning impacts from Alternative 4 are not significant and less than the 2012 AQMP.

6.5.7 Noise

The potential direct and indirect noise impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect noise impacts from each alternative relative to the 2012 AQMP.

6.5.7.1 Proposed Project

Potential direct and indirect noise impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.7 - Noise.

6.5.7.1.1 PM2.5 Control Measures

The analysis in Subchapter 4.7 identified three 2012 AQMP PM2.5 control measures, BCM-03, IND-01, and MCS-01 that have the potential to generate the adverse construction noise/vibration impacts. The analysis of noise impacts in Subchapter 4.7 indicated that three control measures identified here may result in construction activities associated with air pollution control equipment and other control strategies that could generate construction noise/vibration impacts. However, potential adverse construction noise/vibration impacts from implementing PM2.5 control measures were concluded to be less than significant because construction noise/vibration impacts associated with installing control equipment would occur within appropriately zoned industrial and commercial areas, impacts would be temporary and limited to construction activities, and construction noise/vibration impacts to sensitive receptors would not be expected.

6.5.7.1.2 Ozone Control Measures

The analysis in Subchapter 4.7 identified a number of 2012 AQMP ozone control measures as having the potential to create the following adverse construction noise/vibration impacts. Ozone control measures from the 2012 AQMP have the potential to generate adverse noise impacts as a result of construction activities associated with: installing emission control technologies onto stationary source equipment; installing battery charging or fueling infrastructures, as well as transportation infrastructure, constructing wayside power, catenary lines or other similar technologies. Potential noise/vibration impacts of the ozone control measures during the construction phases were determined to be significant. Nine mitigation measures (see Subchapter 4.7, Section 4.7.5) were identified to reduce potential construction noise/vibration, however, construction noise/vibration impacts could remain significant in areas where sensitive receptors are located near transportation corridors.

6.5.7.1.3 *Project-specific and Cumulative Impacts Conclusion*

It was concluded in Subchapter 4.7 that potential construction noise/vibration impacts from implementing 2012 AQMP PM2.5 control measures would be significant. However, in spite of identifying construction noise/vibration mitigation measures, potential construction noise/vibration impacts were concluded to remain significant. Therefore, project-specific construction noise/vibration impacts associated with the 2012 AQMP are concluded to be significant.

Since, anticipated project-specific construction noise/vibration impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific noise and vibration impacts from the 2012 AQMP were evaluated in connection with noise and vibration impacts from SCAG's 2012-2035 RTP/SCS. Further, since project-specific construction noise and vibration impacts would be significant, the 2012 AQMP would contribute to significant adverse cumulative noise and vibration impacts generated by the 2012-2035 RTP/SCS. Since construction noise/vibration impacts from the 2012 AQMP are cumulatively considerable, cumulative construction noise/vibration impacts from the 2012 AQMP are significant.

6.5.7.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures.

6.5.7.2.1 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason and the fact that noise was not an environmental topic identified in the NOP/IS for the 2007 AQMP that could be adversely affected by that AQMP, Alternative 1 is not expected to create any noise impacts.

6.5.7.2.2 *Ozone Control Measures*

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. The analysis of potential noise impacts from the 2012 AQMP was not originally identified as a topic that would be adversely affected by the 2012 AQMP. However, public comments received on the 6/28/12 NOP/IS requested that noise impacts be added to the analysis of impacts in the 2012 AQMP [Final](#) Program EIR because of the potential for noise impacts "from the construction and operation of control measures in support of the [2012](#) AQMP. In particular it was asserted that construction and operation of Control Measure ONRD-05 could create potential noise impacts to nearby sensitive receptors.

As shown in Table 6-4, most Alternative 1 control measures would regulate mobile sources, although there is one control measure that would regulate consumer products. These control measures do not typically require construction activities and it is unlikely that operation would noticeably affect noise levels because control technologies that control emissions from mobile sources do not typically have movable parts that could generate noise.

Like Control Measure ONRD-05, 2007 AQMP Control Measure Off-Road Vehicles (SCLTM-02) would also regulate heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies. However, fixed guideway systems were not identified as a possible method of reducing heavy-duty truck emissions. The NOP/IS for the 2007 AQMP concluded that installing air pollution control equipment would not substantially increase ambient [operational] noise levels in the area, either permanently or intermittently, or expose people to excessive noise levels that would be noticeable above and beyond existing ambient levels. Further, it was not expected that affected facilities would exceed noise standards established in local general plans, noise elements, or noise ordinances currently in effect. Consequently noise impacts from Alternative 1 would not be significant and would be less than the 2012 AQMP.

6.5.7.2.3 *Project-specific and Cumulative Impacts Conclusion*

As a result, the NOP/IS for the 2007 AQMP concluded that the 2007 AQMP would not generate any noise impacts. Therefore, consistent with the assumptions in Subsection 6.4.1, it is presumed that Alternative 1 would not generate significant adverse noise impacts.

Since, anticipated project-specific noise impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific noise and vibration impacts would be less than those generated by the 2012 AQMP, would be less than significant and less than the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative noise and vibration impacts generated by the 2012-2035 RTP/SCS. Since noise impacts from Alternative 1 are not cumulatively considerable, cumulative noise impacts from Alternative 1 are not significant and less than noise impacts from the 2012 AQMP.

6.5.7.3 *Alternative 2 – Localized PM Emissions Control*

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential noise impacts from implementing Alternative 2 would be the same as potential noise impacts from implementing the 2012 AQMP. For the complete analysis of solid and hazardous waste impacts from the 2012 AQMP, refer to Subchapter 4.7 – Noise. Potential noise impacts from implementing Alternative 2 are described in the following subsections.

6.5.7.3.1 *PM2.5 Control Measures*

Similar to the analysis of construction noise/vibration impacts for the 2012 AQMP in Subchapter 4.7, none of the three PM2.5 control measures in the 2012 AQMP that regulates the same sources as the episodic control measures in Alternative 2 was identified as contributing to construction noise/vibration impacts. However, because all other 2012 AQMP PM2.5 control measures, including those contributing to adverse construction noise/vibration impacts, are also included in Alternative 2, it has the potential to generate the same construction noise/vibration impacts as implementing the 2012 AQMP, which were concluded to be less than significant. This same conclusion applies to Alternative 2.

6.5.7.3.2 *Ozone Control Measures*

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 control measure ONRD-04) applies only to the Mira Loma area, potential construction noise/vibration impacts from implementing Alternative 2 ozone control measures would be the same as the solid and hazardous [waste](#) impacts from implementing the 2012 AQMP ozone control measures (e.g., noise from construction activities associated with: installing emission control technologies onto stationary source equipment; installing battery charging or fueling infrastructures, as well as transportation infrastructure, constructing wayside power, catenary lines or other similar technologies). Similar to the significance determination for potential construction noise/vibration impacts of the ozone control measures from the 2012 AQMP, construction noise/vibration during construction phases under Alternative 2 would also be significant. The nine mitigation measures (see Subchapter 4.7, Section 4.7.5) identified to reduce potential construction noise/vibration impacts from the 2012 ozone control measures would continue to apply to Alternative 2; however, construction noise/vibration impacts could remain significant in areas where sensitive receptors are located near transportation corridors.

6.5.7.3.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential construction noise/vibration impacts from implementing Alternative 2 PM2.5 control measures would be less than significant. However, implementing Alternative 2 ozone control measures could generate significant adverse construction noise/vibration impacts. In spite of applying construction noise/vibration mitigation measures, potential construction noise/vibration impacts were concluded to be significant. Therefore, project-specific construction noise/vibration impacts associated with Alternative 2 are concluded to be significant.

Since, anticipated project-specific construction noise/vibration impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific noise and vibration impacts would be significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would contribute to significant adverse cumulative noise and vibration impacts generated by the 2012-2035 RTP/SCS. Since construction noise/vibration impacts from the Alternative 2 are cumulatively considerable, cumulative construction

noise/vibration impacts from the Alternative 2 are significant and equivalent to the 2012 AQMP.

6.5.7.4 Alternative 3 – Greater Reliance on NOx Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM_{2.5} control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential noise impacts from implementing Alternative 3 would be the same as potential noise impacts from implementing the 2012 AQMP. For the complete analysis of noise impacts from the 2012 AQMP, refer to Subchapter 4.7 – Noise.

6.5.7.4.1 *PM_{2.5} Control Measures*

Similar to the analysis of construction noise/vibration impacts for the 2012 AQMP in Subchapter 4.7, no PM_{2.5} control measures were identified from implementing Alternative 3 that have the potential to generate significant adverse construction noise/vibration impacts. Potential construction noise/vibration impacts from implementing the 2012 AQMP were concluded to be less than significant (see Subchapter 4.7 of this [Final](#) Program EIR). This same conclusion applies to Alternative 3.

6.5.7.4.2 *Ozone Control Measures*

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone control measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Alternative 3 ozone Control Measure OFFRD-01 was evaluated and it was concluded that it did not have the potential to generate noise impacts.

The analysis of the 2012 AQMP ozone control measures, including Control Measure ONRD-03, indicated that the 2012 AQMP has the potential to create adverse noise impacts as a result of construction activities associated with: installing emission control technologies onto stationary source equipment; installing battery charging or fueling infrastructures, as well as transportation infrastructure, constructing wayside power, catenary lines or other similar technologies. Potential noise/vibration impacts of the ozone control measures during the construction phases were determined to be significant. Although Alternative 3 ozone Control Measure ONRD-03 is expected to double the number of trucks complying with the year 2010 engine exhaust standards, they would use the same sources of electricity as trucks under the 2102 AQMP. Consequently, no additional construction noise impacts would occur under Alternative since no additional sources of electricity would need to be constructed. Nine mitigation measures (see Subchapter 4.7, Section 4.7.5) were identified to reduce potential construction noise/vibration, however, construction noise/vibration impacts

from Alternative 3 could remain significant in areas where sensitive receptors are located near transportation corridors and equivalent to the 2012 AQMP.

6.5.7.4.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential construction noise/vibration impacts from implementing Alternative 3 PM2.5 control measures would be less than significant. However, implementing Alternative 3 ozone control measures could generate significant adverse construction noise/vibration impacts. In spite of applying construction noise/vibration mitigation measures, potential construction noise/vibration impacts were concluded to be significant. Therefore, project-specific construction noise/vibration impacts associated with Alternative 3 are concluded to be significant.

Since, anticipated project-specific construction noise/vibration impacts from Alternative 3 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific noise and vibration impacts would be significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative noise and vibration impacts generated by the 2012-2035 RTP/SCS. Since construction noise/vibration impacts from the Alternative 3 are cumulatively considerable, cumulative construction noise/vibration impacts from the Alternative 3 are significant and equivalent to the 2012 AQMP.

6.5.7.5 *Alternative 4 – PM2.5 Reduction Strategies Only*

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of noise impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.7 – Noise. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential noise impacts from implementing Alternative 4 are described in the following subsections.

6.5.7.5.1 *PM2.5 Control Measures*

Similar to the analysis of construction noise/vibration impacts for the 2012 AQMP in Subchapter 4.7, no PM2.5 control measures were identified from implementing Alternative 4 that have the potential to generate significant adverse construction noise/vibration impacts. Potential construction noise/vibration impacts from implementing the 2012 AQMP were concluded to be less than significant (see Subchapter 4.7 of this [Final](#) Program EIR). This same conclusion applies to Alternative 4.

6.5.7.5.2 *Ozone Control Measures*

Adopting Alternative 4 means that the ozone SIP portion of the 2007 AQMP would remain in effect. The NOP/IS for the 2007 AQMP concluded that the 2007 AQMP may require existing commercial or industrial owners/operators of affected facilities to install air

pollution control equipment or modify their operations to reduce stationary source emissions. Potential modifications would occur at facilities typically located in appropriately zoned industrial or commercial areas. Further, ambient noise levels in commercial and industrial areas are typically driven primarily by freeway and/or highway traffic in the area and any heavy-duty equipment used for materials manufacturing or processing at nearby facilities. It was concluded in the 2007 AQMP NOP/IS that, since modifications to install air pollution control equipment would not substantially increase ambient [operational] noise levels in the area, either permanently or intermittently or expose people to excessive noise levels that would be noticeable above and beyond existing ambient levels, noise impacts from the 2007 AQMP would be less than significant. Therefore, consistent with the assumptions in Subsection 6.4.1, it is presumed that implementing Alternative 4 ozone control measures would not generate significant adverse noise impacts and noise impacts would be less than noise impacts from the 2012.

6.5.7.5.3 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, implementing Alternative 4 PM_{2.5} control measures would not generate significant adverse noise impacts. As indicated in the 2007 AQMP NOP IS, the 2007 AQMP would not generate any adverse noise impacts. Therefore, consistent with the assumptions in Subsection 6.4.1, it is presumed that Alternative 4 would not generate significant adverse project-specific noise impacts, which means that noise impacts would be less than for the 2012 AQMP, which were concluded to be significant.

Since, anticipated project-specific noise impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific construction noise and vibration impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 4 would not contribute to significant adverse cumulative noise and vibration impacts generated by the 2012-2035 RTP/SCS. Since noise impacts from Alternative 4 are not cumulatively considerable, cumulative noise impacts from Alternative 4 are not significant and less than noise impacts from the 2012 AQMP.

6.5.8 Solid and Hazardous Waste

The potential direct and indirect solid and hazardous waste impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect aesthetics impacts from each alternative relative to the 2012 AQMP.

6.5.8.1 Proposed Project

Potential direct and indirect solid and hazardous waste impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.8 – Solid and Hazardous Waste.

6.5.8.1.1 *PM2.5 Control Measures*

The analysis in Subchapter 4.8 identified three 2012 AQMP PM2.5 control measures, BCM-03, IND-01, and MCS-01 that have the potential to generate the following adverse solid hazardous waste impacts. PM2.5 Control Measures BCM-01 and MCS-01 have the potential to generate solid waste associated with air pollution control equipment (e.g., filters). PM2.5 Control Measure IND-01 was also identified as having the potential generate solid waste impacts due to early retirement of equipment, solid was associated with air pollution control equipment, and EV battery disposal. However, potential adverse solid and hazardous waste impacts from implementing PM2.5 control measures were concluded to be less than significant.

6.5.8.1.2 *Ozone Control Measures*

The analysis in Subchapter 4.8 identified a number of 2012 AQMP ozone control measures as having the potential to create the following adverse solid and hazardous waste impacts. Potential solid and hazardous waste impacts from ozone control measures could occur due to burner replacement and SCR catalyst disposal. Similarly, potential solid and hazardous waste impacts from implementing ozone control measures from combustion equipment replacement, generation of solid waste from air pollution control equipment (e.g., used filters), and EV battery disposal. Finally, solid and hazardous waste impacts from implementing ozone control measures could potentially result in an increase in solid waste generation from early retirement of vehicles and EV battery disposal. However, potential adverse solid and hazardous waste impacts from implementing ozone control measures were concluded to be less than significant.

6.5.8.1.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, it was concluded in Subchapter 4.8 that potential solid and hazardous waste impacts from implementing the 2012 AQMP would be less than significant. Therefore, project-specific solid and hazardous waste impacts associated with the 2012 AQMP are less than significant.

Since anticipated project-specific solid and hazardous waste impacts from the 2012 AQMP are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific solid and hazardous waste impacts from the 2012 AQMP were evaluated in connection with air quality impacts from SCAG's 2012-2035 RTP/SCS. Further, since project-specific solid and hazardous waste impacts would be less than significant, the 2012 AQMP would not contribute to significant adverse cumulative solid and hazardous waste impacts generated by the 2012-2035 RTP/SCS. Since solid and hazardous waste impacts from the 2012 AQMP are not cumulatively considerable, cumulative solid and hazardous waste impacts from the 2012 AQMP are not significant.

6.5.8.2 *Alternative 1 – No Project Alternative*

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#)

Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures.

6.5.8.2.1 PM2.5 Control Measures

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason, Alternative 1 is not expected to create any solid and hazardous waste impacts from PM2.5 control measures.

6.5.8.2.2 Ozone Control Measures

Potential impacts from adopting the 2007 AQMP were evaluated in the 2007 Program EIR. The 2007 Program EIR included an analysis of solid and hazardous waste impacts from all control measures, including black box control measures. As a result, consistent with the assumptions in Subsection 6.5.1.2 regarding the applicability of the significance determinations from the 2007 Program EIR, it is concluded that Alternative 1 does not have the potential to generate potentially significant solid and hazardous waste impacts as shown in Table 6-10 and described in the following paragraphs.

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. It was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-01 regulating on-road light-duty passenger vehicles and heavy-duty vehicles could generate potentially significant adverse solid and hazardous waste impacts. The reason for this conclusion was that accelerated penetration of low or zero emission vehicles could generate solid waste impacts from disposal of old batteries and replaced vehicles. This impact, however, was concluded to be less than significant.

Similarly, it was concluded in the Program EIR for the 2007 AQMP that the black box Control Measure SCLTM-02 regulating off-road heavy duty vehicles could also generate potentially significant adverse solid and hazardous waste impacts for the same reason identified for SCLTM-01 (e.g., accelerated penetration of low or zero emission vehicles could generate solid waste impacts from disposal of old batteries and replaced vehicles). This impact, however, was concluded to be less than significant. Therefore, solid and hazardous waste impacts from Alternative 1 are less than significant and less than the solid and hazardous waste impacts from the 2012 AQMP.

6.5.8.2.3 Project-specific and Cumulative Impacts Conclusion

It was concluded in the 2007 Program EIR that all 2007 AQMP control measures would not generate significant adverse solid and hazardous waste impacts. As indicated in Subsection 6.4.1, the SCAQMD and CARB have adopted all short-term control measures within their authority, so that only black box control measures remain. Since Alternative 1 does not include short-term control measures, potential solid and hazardous waste impacts would be even less compared to the 2007 AQMP when it was originally adopted. Consequently,

overall solid and hazardous waste impacts from Alternative 1 are concluded to be less than significant.

Since, anticipated project-specific solid and hazardous waste impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific solid and hazardous waste impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative solid and hazardous waste impacts generated by the 2012-2035 RTP/SCS. Since solid and hazardous waste impacts from Alternative 1 are not cumulatively considerable, cumulative solid and hazardous waste impacts from Alternative 1 are not significant and less than the solid and hazardous waste impacts from the 2012 AQMP.

6.5.8.3 Alternative 2 – Localized PM Emissions Control

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, potential solid and hazardous waste impacts from implementing Alternative 2 would be the same as the potential solid and hazardous [waste](#) impacts from implementing the 2012 AQMP. For the complete analysis of the solid and hazardous waste impacts from the 2012 AQMP, refer to Subchapter 4.8 – Solid and Hazardous Waste. Potential solid and hazardous [waste](#) impacts from implementing Alternative 2 are described in the following subsections.

6.5.8.3.1 PM_{2.5} Control Measures

Similar to the analysis of solid and hazardous [waste](#) impacts for the 2012 AQMP in Subchapter 4.8, none of the three PM_{2.5} control measures in the 2012 AQMP that regulates the same sources as the episodic control measures in Alternative 2 was identified as contributing to solid and hazardous waste impacts. However, because all other 2012 AQMP PM_{2.5} control measures, including those contributing to adverse solid and hazardous [waste](#) impacts, are also included in Alternative 2, it has the potential to generate the same solid and hazardous [waste](#) impacts as implementing the 2012 AQMP, which were concluded to be less than significant. This same conclusion applies to Alternative 2.

6.5.8.3.2 Ozone Control Measures

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 Control Measure ONRD-04) applies only to the Mira Loma area, potential solid and hazardous waste impacts from implementing Alternative 2 ozone control measures would be the same as the solid and hazardous [waste](#) impacts from implementing the 2012 AQMP ozone control measures. As shown in the analysis of solid and hazardous [waste](#) impacts for the 2012 AQMP in Subchapter 4.8, implementing ozone control measures from Alternative 2 (CMB-01, CMB-

02, CMB-03, INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07), have the potential to generate adverse impacts to solid and hazardous [waste](#) impacts. No other 2012 AQMP ozone control measures were identified that could affect aesthetic resources. Such impacts associated with implementing the 2012 AQMP ozone control measures were concluded to be less than significant. This same conclusion applies to Alternative 2 because it contains the same ozone control measures identified above that have the potential to affect solid and hazardous [waste](#) resources.

6.5.8.3.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential project-specific adverse solid and hazardous [waste](#) impacts from Alternative 2 would be the same as potential project-specific solid and hazardous [waste](#) impacts from the 2012 AQMP and less than significant, because wastes generated by Alternative 2 (e.g., spent batteries) are required to be, and are largely recycled. For equipment that may be retired before the end of its useful life, that equipment may be reused in areas outside the district.

Since, anticipated project-specific solid and hazardous [waste](#) impacts from Alternative 2 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific solid and hazardous waste impacts would be less than those than significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would not contribute to significant adverse cumulative solid and hazardous waste impacts generated by the 2012-2035 RTP/SCS. Since solid and hazardous [waste](#) impacts from Alternative 2 are not cumulatively considerable, cumulative solid and hazardous [waste](#) impacts from Alternative 2 are not significant and equivalent to the 2012 AQMP.

6.5.8.4 *Alternative 3 – Greater Reliance on NOx Emissions Reductions*

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM2.5 control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential solid and hazardous waste impacts from implementing Alternative 3 would be the same as potential solid and hazardous waste impacts from implementing the 2012 AQMP. For the complete analysis of solid and hazardous waste impacts from the 2012 AQMP, refer to Subchapter 4.8 – Solid and Hazardous Waste.

6.5.8.4.1 *PM2.5 Control Measures*

Similar to the analysis of solid and hazardous waste impacts for the 2012 AQMP in Subchapter 4.8, no PM2.5 control measures were identified from implementing Alternative 3 that have the potential to generate significant adverse solid and hazardous waste impacts. Potential solid and hazardous waste impacts from implementing the 2012 AQMP were

concluded to be less than significant (see Subchapter 4.8 of this [Final](#) Program EIR). This same conclusion applies to Alternative 3.

6.5.8.4.2 *Ozone Control Measures*

Alternative 3 ozone control measures were evaluated for the potential to generate solid or hazardous wastes. The following potential solid or hazardous waste impacts were identified: combustion equipment replacement, generation of solid waste from air pollution control equipment (e.g., used filters), early retirement and replacement of on- and off-road vehicles, and EV battery disposal. The analysis concluded that Alternative 3 ozone control measure would not be expected to generate significant adverse solid and hazardous waste generation from the control measures evaluated (CMB-01, CMB-02, CMB-03, INC-01, ONRD-01, ONRD-02, ONRD-03, ONRD-04, ONRD-05, OFFRD-01, OFFRD-02, OFFRD-03, OFFRD-04, ADV-01, ADV-02, ADV-03, ADV-04, ADV-05, ADV-06, and ADV-07). The analysis indicated that the solid and hazardous waste impacts associated with spent batteries are required to be and are largely recycled. Further, for equipment that may be retired before the end of its useful life, it would likely be reused in areas outside the district. Equipment with no remaining useful life is expected to be recycled for metal content.

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered vehicles from the year 2014 through 2017. Although it is possible that Alternative 3 Control Measures ONRD-03 and OFFRD-01 could generate greater solid waste impacts than the 2012 AQMP, for the same reason identified above for the 2012 AQMP, solid waste impacts from Alternative 3 concluded to be less than significant.

6.5.8.4.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, potential project-specific adverse solid and hazardous [waste](#) impacts from Alternative 3 would be greater than potential project-specific solid and hazardous [waste](#) impacts from the 2012 AQMP, but would still be less than significant, because wastes generated by Alternative 3 (e.g., spent batteries) are required to be, and are largely recycled. For equipment that may be retired before the end of its useful life, that equipment may be reused in areas outside the district.

Since, anticipated project-specific solid and hazardous [waste](#) impacts from Alternative 3 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Although project-specific solid and hazardous waste impacts would be less than significant, but greater than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative solid and hazardous waste impacts generated by the 2012-2035 RTP/SCS. Since solid and hazardous [waste](#) impacts from Alternative 3 are not cumulatively considerable, cumulative

solid and hazardous [waste](#) impacts from Alternative 3 are not significant and greater than those generated by the 2012 AQMP.

6.5.8.5 Alternative 4 – PM2.5 Reduction Strategies Only

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of solid and hazardous waste impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.8 – Solid and Hazardous Waste. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential solid and hazardous waste impacts from implementing Alternative 4 are described in the following subsections.

6.5.8.5.1 *PM2.5 Control Measures*

The analysis of 2012 AQMP PM2.5 control measures identified three 2012 AQMP PM2.5 control measures, BCM-03, IND-01, and MCS-01, that have the potential to generate the following adverse solid hazardous waste impacts. PM2.5 Control Measures BCM-01 and MCS-01 have the potential to generate solid waste associated with air pollution control equipment (e.g., filters). PM2.5 Control Measure IND-01 was also identified as having the potential generate solid waste impacts due to early retirement of equipment, solid was associated with air pollution control equipment, and EV battery disposal. However, potential adverse solid and hazardous waste impacts from implementing PM2.5 control measures were concluded to be less than significant. Because Alternative 4 includes all of the same PM2.5 control measures as the 2012 AQMP, solid and hazardous waste impacts would be the same.

6.5.8.5.2 *Ozone Control Measures*

Adopting Alternative 4 means that the ozone SIP portion of the 2007 AQMP would remain in effect. As shown in Table 6-2, there are a number 2012 AQMP ozone control measures that would regulate similar sources to those regulated by the remaining 2007 AQMP black box measures that have the potential to generate adverse solid and hazardous waste impacts (Table 6-22). However, the same reasons solid and hazardous waste impacts from the 2012 AQMP would be less than significant would apply to Alternative 4. Therefore, it is concluded that Alternative 4 does not have the potential to generate significant adverse solid and hazardous waste impacts and impacts would be less than solid and hazardous waste impacts from the 2012 AQMP because more ozone control measures with the potential to generate adverse solid and hazardous waste impacts were identified.

TABLE 6-22

Long-Term (Black Box) Control Measures from the 2007 AQMP

SOURCE CATEGORY	2012 AQMP CONTROL MEASURES AFFECTING SAME SOURCE
Light Duty Vehicles (SCLTM-01A)	ONRD-01 & ADV-01
On-Road Heavy Duty Vehicles (SCLTM-01B)	ONRD-03, ONRD-05 & ADV-06
Off-Road Vehicles (SCLTM-02)	OFFRD-01 & ADV-06
Marine Vessels	IND-01, OFFRD-05 & ADV-05
Locomotives	OFFRD-02, OFFRD-03 & ADV-02
Aircraft	ADV-07

6.5.8.5.3 *Project-specific and Cumulative Impacts Conclusion*

Based upon the above conclusions, when considering overall solid and hazardous waste impacts from implementing Alternative 4, although some 2007 black box measures have the potential to generate adverse solid and hazardous waste impacts, no significant adverse solid and hazardous waste impacts were identified from implementing PM_{2.5} or ozone control measures. Finally, it is concluded that potential adverse solid and hazardous waste impacts from implementing Alternative 4 would be less than for the 2012 AQMP because more ozone control measures with the potential to generate adverse solid and hazardous waste impacts were identified. As a result, Alternative 4 would not generate significant adverse solid and hazardous waste impacts and solid and hazardous waste impacts would be less than those from the 2012 AQMP.

Since, anticipated project-specific solid and hazardous waste impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific solid and hazardous waste impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 4 would not contribute to significant adverse cumulative solid and hazardous waste impacts generated by the 2012-2035 RTP/SCS. Since solid and hazardous waste impacts from Alternative 4 are not cumulatively considerable, cumulative solid and hazardous waste impacts from Alternative 4 are not significant and less than the 2012 AQMP.

6.5.9 Transportation and Traffic

The potential direct and indirect transportation and traffic impacts from implementing the proposed project and the project alternatives were evaluated. The following subsections provide brief discussions of direct and indirect hazards and hazardous materials impacts from each alternative relative to the 2012 AQMP.

6.5.9.1 Proposed Project

Potential direct and indirect transportation and traffic impacts from the 2012 AQMP are summarized in the following subsections. For the complete analysis, refer to Subchapter 4.9 – Transportation and Traffic.

6.5.9.1.1 *PM2.5 Control Measures*

The analysis in Subchapter 4.9 – Transportation and Traffic, indicated that no 2012 AQMP PM2.5 control measures were identified that have the potential to significantly adversely affect transportation and traffic. Therefore, potential impacts to transportation and traffic are concluded to be less than significant.

6.5.9.1.2 *Ozone Control Measures*

The analysis in Subchapter 4.9 identified the following three 2012 AQMP ozone control measures as having the potential to create significant adverse transportation and traffic impacts: ONRD-05, ADV-01, and ADV-02. It was determined that these three 2012 AQMP ozone control measures could generate potential traffic impacts due to construction and operation of wayside sources of electricity, such as overhead catenary lines; battery charging stations; alternative fuel fueling infrastructure; and magnetic infrastructure. The potential transportation and traffic impacts of these ozone control measures were determined to be significant and mitigation measures would be required. It is not feasible to identify project- and site-specific mitigation measures for future traffic and transportation projects in this [Final](#) Program EIR. Instead, appropriate project-specific mitigation measures would to be identified by the appropriate lead agency⁸ in the CEQA/NEPA document prepared for each future project that may be proposed. However, standard traffic construction mitigation measures, such as a traffic management plan containing mitigation measures such as those identified in transportation traffic Subchapter 4.9 would likely be implemented⁹. The analysis of 2012 AQMP ozone control measures concluded that the potential exists for future traffic and transportation impacts to be significant and unavoidable (i.e., significant even after standard types of roadway construction mitigation measures are identified and imposed).

6.5.9.1.3 *Project-specific and Cumulative Impacts Conclusion*

Overall, it was concluded in Subchapter 4.9 that in spite of identifying a roadway construction mitigation measure, implementing 2012 AQMP ozone control measures has the potential to generate significant adverse traffic impacts from construction future wayside sources of energy. Although temporary in nature, traffic impacts during construction are still considered to be significant. Similarly, traffic impacts during the operation of roadways dedicated as truck lanes for vehicles using the overhead catenary electrical lines or fixed guideway systems are also considered to be significant because traffic patterns and

⁸ The SCAQMD has no jurisdiction over constructing and operating roadways.

⁹ The traffic construction mitigation measure identified in Subchapter 4.9 is from SCAG's 2012 – 2035 RTP/SCS.

congestion may be adversely affected. Therefore, project-specific transportation and traffic impacts from implementing 2012 AQMP ozone control measures are concluded to be significant and unavoidable.

Since, anticipated project-specific transportation and traffic impacts from the 2012 AQMP are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). In Chapter 5 potential project-specific transportation and traffic impacts from the 2012 AQMP were evaluated in connection with transportation and traffic impacts from SCAG's 2012-2035 RTP/SCS. Further, since project-specific transportation and traffic impacts were concluded to be significant, the 2012 AQMP would contribute to significant adverse cumulative transportation and traffic impacts generated by the 2012-2035 RTP/SCS. Since transportation and traffic impacts from the 2012 AQMP are cumulatively considerable, cumulative transportation and traffic impacts from the 2012 AQMP are significant. No measures beyond that identified in Subchapter 4.9 were identified to mitigate significant adverse cumulative transportation and traffic impacts.

6.5.9.2 Alternative 1 – No Project Alternative

The Program EIR for the 2007 AQMP included environmental analyses for all control measures, including the black box control measures. As discussed in Chapter 2 of this [Final](#) Program EIR, all of the SCAQMD's and CARB's short- and mid-term control measures have been adopted. The only remaining control measures are the black box measures. Since the 2007 AQMP now includes only black box measures, environmental impacts for Alternative 1 will focus only on potential impacts identified for the black box measures.

6.5.9.2.1 *PM2.5 Control Measures*

As discussed in Subsection 6.4.1, Alternative 1 has no control measures that are considered to be PM2.5 control measures. For this reason and the fact that transportation and traffic was not an environmental topic identified in the NOP/IS for the 2007 AQMP that could be adversely affected by that AQMP, Alternative 1 is not expected to create any transportation and traffic impacts.

6.5.9.2.2 *Ozone Control Measures*

All remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. The analysis of potential transportation and traffic impacts from the 2012 AQMP was not originally identified as a topic that would be adversely affected by the 2012 AQMP. However, public comments received on the 6/28/12 NOP/IS requested that transportation and traffic impacts be added to the analysis of impacts in the 2012 AQMP [Final](#) Program EIR because of the potential for transportation and traffic impacts on major traffic corridors from the use of catenary systems that could affect heavy-duty truck lane choice by trucks and traffic flow patterns. The only control measures from the 2012 AQMP that include catenary systems as a means of reducing emissions are ONRD-05 and ADV-01.

As shown in Table 6-4, like Control Measures ONRD-05 and ADV-01, 2007 AQMP Control Measure On-road Heavy-duty Vehicles (SCLTM-01B) would also regulate heavy-

duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies. However, fixed guideway systems were not identified as a possible method of reducing heavy-duty truck emissions. Consequently, implementing the black box measures of the 2007 AQMP would not generate any transportation and traffic impacts, so transportation and traffic impacts would be less than those for the 2012 AQMP.

6.5.9.2.3 *Project-specific and Cumulative Impacts Conclusion*

The NOP/IS for the 2007 AQMP concluded that, overall, controlling emissions at existing commercial or industrial facilities and establishing mobile source exhaust and fuel specifications would not impede traffic patterns in any way. Further, the 2007 AQMP included TCMS, which were expected to reduce vehicle trips and vehicle miles traveled and result in greater reliance on mass transit, ridesharing, telecommunications, etc., resulting in reduced traffic congestion, a beneficial effect. As a result, the NOP/IS for the 2007 AQMP concluded that the 2007 AQMP would not generate any transportation and traffic impacts. Therefore, consistent with the assumptions in Subsection 6.4.1, it is presumed that Alternative 1 would not generate significant adverse transportation and traffic impacts, which means that transportation and traffic impacts would be less than for the 2012 AQMP, which were concluded to be significant.

Since, anticipated project-specific transportation and traffic impacts from Alternative 1 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Although project-specific transportation and traffic impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 1 would not contribute to significant adverse cumulative transportation and traffic impacts generated by the 2012-2035 RTP/SCS. Since transportation and traffic impacts from Alternative 1 are not cumulatively considerable, cumulative transportation and traffic impacts from Alternative 1 are not significant.

6.5.9.3 *Alternative 2 – Localized PM Emissions Control*

As explained in Subsection 6.4.2, with the exception of the two episodic PM_{2.5} control measures for Mira Loma, CMALT-2B (formerly MCS-04B in the 6/28/12 NOP/IS) and CMALT-2C (formerly MCS-04C in the 6/28/12 NOP/IS), and one episodic ozone control measure, CMALT-2A (formerly MCS-04A in the 6/28/12 NOP/IS), Alternative 2 includes all of the same PM_{2.5} and ozone control measures as the 2012 AQMP, except for PM_{2.5} Control Measure BCM-02 – Open Burning. As explained in the following subsections, transportation and traffic impacts from implementing Alternative 2 would be the same as potential transportation and traffic impacts from implementing the 2012 AQMP. For the complete analysis of transportation and traffic impacts from the 2012 AQMP, refer to Subchapter 4.9 – Transportation and Traffic. Potential transportation and traffic impacts from implementing Alternative 2 are described in the following subsections.

6.5.9.3.1 *PM2.5 Control Measures*

Similar to the analysis of potential transportation and traffic impacts for the 2012 AQMP in Subchapter 4.9, no PM2.5 control measures were identified from implementing Alternative 2 that have the potential to significantly adversely affect transportation and traffic. The three episodic control measures in this alternative that would apply only to the Mira Loma area do not contain any provisions for constructing wayside electricity such as catenary electric lines. Therefore, potential transportation and traffic impacts from implementing 2012 AQMP PM2.5 control measures were concluded to be less than significant. This same conclusion applies to Alternative 2.

6.5.9.3.2 *Ozone Control Measures*

Because Alternative 2 contains the same ozone control measures as the 2012 AQMP, except that ozone Control Measure CMALT-2A (similar to 2012 Control Measure ONRD-04) applies only to the Mira Loma area, transportation and traffic impacts from implementing Alternative 2 ozone control measures would be the same as the transportation and traffic impacts from implementing the 2012 AQMP ozone control measures. As shown in the analysis of transportation and traffic impacts for the 2012 AQMP in Subchapter 4.9, implementing ozone control measures from Alternative 2 (e.g., ozone Control Measures ONRD-05, ADV-01, and ADV-2), has the potential to generate significant adverse transportation and traffic impacts from the construction and operation of wayside sources of electricity, such as overhead catenary lines; battery charging stations; alternative fuel fueling infrastructure; and magnetic infrastructure. Because implementing the three Alternative 2 ozone control measures identified above has the potential to generate significant adverse transportation and traffic impacts from constructing and operating of wayside sources of electricity, the standard traffic construction mitigation measure (e.g., the traffic management plan measures identified in [the](#) transportation [and](#) traffic Subchapter 4.9) would also apply to Alternative 2.

6.5.9.3.3 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, it is concluded that, in spite of identifying a roadway construction mitigation measure, implementing Alternative 2 ozone control measures has the potential to generate significant adverse traffic impacts from constructing future wayside sources of energy. Although temporary in nature, traffic impacts during construction are still considered to be significant. Similarly, traffic impacts during the operation of roadways dedicated as truck lanes for vehicles using the overhead catenary electrical lines or fixed guideway systems are also considered to be significant because traffic patterns and congestion may be adversely affected. Therefore, project-specific transportation and traffic impacts from implementing Alternative 2 ozone control measures are concluded to be significant and unavoidable and are equivalent to transportation and traffic impacts from the 2012 AQMP.

Since, anticipated project-specific transportation and traffic impacts from Alternative 2 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific transportation and traffic

impacts would be significant and approximately equivalent to those generated by the 2012 AQMP, Alternative 2 would contribute to significant adverse cumulative transportation and traffic impacts generated by the 2012-2035 RTP/SCS. Since project-specific transportation and traffic impacts from Alternative 2 are cumulatively considerable, cumulative transportation and traffic impacts from Alternative 2 are significant and would be equivalent to transportation and traffic impacts from the 2012 AQMP. No measures beyond that identified in Subchapter 4.9 were identified to mitigate significant adverse cumulative transportation and traffic impacts.

6.5.9.4 Alternative 3 – Greater Reliance on NO_x Emissions Reductions

As explained in Subsection 6.4.3, Alternative 3 includes all of the same PM_{2.5} control measures as the 2012 AQMP except it does not include 2012 AQMP Control Measure BCM-01. With regard to ozone control measures, with the exceptions of 2012 AQMP Control Measures ONRD-03 and OFFRD-01, all other ozone control measures are the same as those in the 2012 AQMP. As explained in the following subsections, potential transportation and traffic impacts from implementing Alternative 3 would be the same as potential transportation and traffic impacts from implementing the 2012 AQMP. For the complete analysis of transportation and traffic impacts from the 2012 AQMP, refer to Subchapter 4.9 – Transportation and Traffic.

6.5.9.4.1 *PM_{2.5} Control Measures*

Similar to the analysis of transportation and traffic impacts for the 2012 AQMP in Subchapter 4.9, no PM_{2.5} control measures were identified from implementing Alternative 3 that have the potential to significantly adversely affect transportation and traffic. Therefore, potential transportation and traffic impacts from implementing 2012 AQMP PM_{2.5} control measures were concluded to be less than significant. This same conclusion applies to Alternative 3.

6.5.9.4.2 *Ozone Control Measures*

All ozone control measures in Alternative 3 are identical to those in the 2012 AQMP, except that Alternative 3 ozone Control Measure ONRD-03 could result in approximately 5,000 additional medium-heavy-duty trucks complying with the year 2010 engine exhaust requirements for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year) would comply with the 2010 on-road vehicle exhaust requirements using CNG engines and the rest would be diesel or diesel hybrid). Similarly, Alternative 3 OFFRD-01 could result in a total of 19,344 additional repowered vehicles from the year 2014 through 2017. Because the remaining Alternative 3 ozone control measures are the same as the 2012 AQMP, transportation and traffic impacts from implementing Alternative 3 ozone control measures would be the same as the transportation and traffic impacts from implementing the 2012 AQMP ozone control measures. As shown in the analysis of transportation and traffic impacts for the 2012 AQMP in Subchapter 4.9, implementing ozone control measures from Alternative 3 (e.g., ozone Control Measures ONRD-05 and ADV-01) has the potential to generate significant

adverse transportation and traffic impacts from the construction and operation of wayside sources of electricity, such as overhead catenary lines; battery charging stations; alternative fuel fueling infrastructure; and magnetic infrastructure. Because implementing the two Alternative 3 ozone control measures identified above has the potential to generate significant adverse transportation and traffic impacts from constructing and operating of wayside sources of electricity, the standard traffic construction mitigation measure (e.g., the traffic management plan measures identified in [the transportation and traffic Subchapter 4.9](#)) would also apply to Alternative 3. In spite of implementing these traffic mitigation measures, transportation and traffic impacts from Alternative 3 remain significant and greater than the 2012 AQMP.

6.5.9.4.3 *Project-specific and Cumulative Impacts Conclusion*

Based on the above information, it is concluded that, in spite of identifying a roadway construction mitigation measure, implementing Alternative 3 ozone control measures has the potential to generate significant adverse traffic impacts from constructing future wayside sources of energy. Although temporary in nature, traffic impacts during construction are still considered to be significant. Similarly, traffic impacts during the operation of roadways dedicated as truck lanes for vehicles using the overhead catenary electrical lines or fixed guideway systems are also considered to be significant because traffic patterns and congestion may be adversely affected. Therefore, project-specific transportation and traffic impacts from implementing Alternative 3 ozone control measures are concluded to be significant and unavoidable and are equivalent to transportation and traffic impacts from the 2012 AQMP.

Since, anticipated project-specific transportation and traffic impacts from Alternative 3 are concluded to be significant, they are considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific transportation and traffic impacts would be significant and greater than those generated by the 2012 AQMP, Alternative 3 would contribute to significant adverse cumulative transportation and traffic impacts generated by the 2012-2035 RTP/SCS. Since transportation and traffic impacts from Alternative 3 are cumulatively considerable, cumulative transportation and traffic impacts from Alternative 3 are significant and greater than transportation and traffic impacts from the 2012 AQMP. No measures beyond that identified in Subchapter 4.9 were identified to mitigate significant adverse cumulative transportation and traffic impacts.

6.5.4.5 *Alternative 4 – PM2.5 Reduction Strategies Only*

As explained in Subsection 6.4.4, Alternative 4 would only include the PM2.5 control measures in Table 6-4 of this chapter. For the complete analysis of transportation and traffic impacts from 2012 AQMP PM2.5 control measures, refer to Subchapter 4.9 – Transportation and Traffic. Because Alternative 4 does not address attaining either the federal one-hour or eight-hour ozone standards, the ozone SIP portion of the 2007 AQMP would remain in effect, which includes only the black box measures in Table 6-2. As a result, impacts from implementing 2007 AQMP black box control measures would be the same as for Alternative 1. Potential transportation and traffic impacts from implementing Alternative 4 are described in the following subsections.

6.5.9.4.1 *PM2.5 Control Measures*

Similar to the analysis of transportation and traffic impacts for the 2012 AQMP in Subchapter 4.9, no PM2.5 control measures were identified from implementing Alternative 4 that have the potential to significantly adversely affect transportation and traffic. Therefore, potential transportation and traffic impacts from implementing 2012 AQMP PM2.5 control measures were concluded to be less than significant. This same conclusion applies to Alternative 4.

6.5.9.4.2 *Ozone Control Measures*

As already indicated, all remaining black box measures from the 2007 AQMP that comprise Alternative 1 are assumed to be ozone control measures. This assumption also applies to the ozone control measures of Alternative 4.

As shown in Table 6-4, like Control Measures ONRD-05 and ADV-01, 2007 AQMP Control Measure On-road Heavy-duty Vehicles (SCLTM-01B) would also regulate heavy-duty trucks using control technologies such as: expanded modernization and retrofit of heavy-duty trucks and buses; expanded inspection and maintenance program; and advanced near-zero and zero-emitting cargo transportation technologies. However, fixed guideway systems were not identified as a possible method of reducing heavy-duty truck emissions. Consequently, implementing the black box measures of the 2007 AQMP would not generate any transportation and traffic impacts.

6.5.9.4.3 *Project-specific and Cumulative Impacts Conclusion*

The NOP/IS for the 2007 AQMP concluded that, overall, controlling emissions at existing commercial or industrial facilities and establishing mobile source exhaust and fuel specifications would not impede traffic patterns in any way. Further, the 2007 AQMP included TCMs, which were expected to reduce vehicle trips and vehicle miles traveled and result in greater reliance on mass transit, ridesharing, telecommunications, etc., resulting in reduced traffic congestion, a beneficial effect. As a result, the NOP/IS for the 2007 AQMP concluded that the 2007 AQMP would not generate any transportation and traffic impacts. This conclusion also applies to Alternative 4, which means that transportation and traffic impacts from Alternative 4 would be less than for the 2012 AQMP, which were concluded to be significant.

Since, anticipated project-specific transportation and traffic impacts from Alternative 4 are concluded to be less than significant, they are not considered to be cumulatively considerable as defined in CEQA Guidelines §15064 (h)(1). Further, since project-specific transportation and traffic impacts would be less than significant and less than those generated by the 2012 AQMP, Alternative 4 would not contribute to significant adverse cumulative transportation and traffic impacts generated by the 2012-2035 RTP/SCS. Since transportation and traffic impacts from Alternative 4 are not cumulatively considerable, cumulative transportation and traffic impacts from Alternative 1 are not significant.

6.6 COMPARISON OF THE PROJECT ALTERNATIVES TO THE 2012 AQMP

Pursuant to CEQA Guidelines §15126.6 (d), “The EIR shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project. A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, but in less detail than the significant effects of the project as proposed.” The sections above provide a comprehensive analysis of potential impacts generated by each project alternative and compares impacts to those generated by the 2012 AQMP. Table 6-23 provides a matrix displaying the major characteristics and significant environmental effects of each alternative compared to the 2012 AQMP.

TABLE 6-23

S = Significant

NS = Not Significant

(-) = Potential impacts are less than the proposed project.

(+) = Potential impacts are greater than the proposed project.

(=) = Potential impacts are approximately the same as the proposed project.

6.7 ENVIRONMENTALLY SUPERIOR AND LOWEST TOXIC ALTERNATIVE

Pursuant to CEQA Guidelines §15126.6 (e)(2), if the environmentally superior alternative is the “no project” alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives. Alternative 1 – No Project Alternative, continued implementation of the 2007 AQMP is considered to be the environmentally superior alternative because it is not expected to generate any significant adverse impacts to any environmental topic areas. Alternative 1 (the 2007 AQMP) was originally drafted to demonstrate compliance with the federal eight-hour ozone and PM2.5 standards and does not specifically address attaining the federal 24-hour PM2.5 standard. Although Alternative 1 would ultimately achieve the federal 24-hour PM2.5 standard by the year 2019, it is not clear at this point if it would be approvable by U.S. EPA.

Based on the above, since the No Project Alternative was deemed the environmentally superior alternative, an alternative from the remaining alternatives must be selected. Based on the analysis of potential impacts from each of the project alternatives, it is concluded that Alternative 4 – PM2.5 Emissions Reduction Strategies Only, is the environmentally superior alternative. This conclusion is based on the fact that the ozone portion of Alternative 4 relies on continued implementation of the ozone portion of the 2007 AQMP. The 2007 AQMP has fewer ozone control measures and the ozone control measures are less likely to cause significant adverse impacts because they do not affect as many sources or control technologies do not produce as many secondary impacts.

In accordance with SCAQMD’s policy document Environmental Justice Program Enhancements for FY 2002-03, Enhancement II-1 recommends that all SCAQMD CEQA documents required to include an alternatives analysis, also include and identify a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a

“least harmful” perspective with regard to hazardous or toxic air pollutants. It is expected that potential energy, hazards and hazardous materials, hydrology and water quality, and solid waste impacts associated with earlier penetration of on-road and off-road fleets using alternative fuels, would be less under Alternative 1 – No Project Alternative because it would avoid significant adverse impacts to all environmental topic areas evaluated compared to the remaining alternatives. Thus, from an air toxics perspective, when compared to the proposed project and the other alternatives under consideration, if implemented, Alternative 1 is considered the lowest toxic alternative.

6.8 CONCLUSION

Of the project Alternatives, Alternative 1 would generate the least severe and fewest number of environmental impacts compared to the 2012 AQMP. However, of the project alternatives it would achieve the fewest of the project objectives, namely only project objective 7 – Update planning assumptions and the best available information such as SCAG’s 2012 RTP, CARB’s latest EMFAC2011 for the on-road mobile source emissions inventory, and CARB’s OFF-ROAD 2011 model; 8 – Update emission inventories using 2008 as the base year and incorporate emission reductions achieved from all applicable rules and regulations and the latest demographic forecasts; and 11 – Continue to work closely with businesses and industry groups to identify the most cost-effective and efficient path to meeting clean air goals while being sensitive to their economic concerns; would not attain them as effectively as the 2012 AQMP, project objectives 4 – Continue making expeditious progress towards attaining the federal eight-hour ozone standard and demonstrate attainment of the federal one-hour ozone standard (revoked) by 2022 – 2023; 5 – Reduce population exposure to ozone through continued progress towards attaining the federal one-hour (revoked) and eight-hour ozone standards by 2022 – 2023; and 6 – Reduce nonattainment pollutants at a rate of five percent per year, or include all feasible measures and an expeditious adoption schedule, or would not achieve them at all, project objectives 1 – Reduce PM_{2.5} nonattainment pollutants and their precursors on an expeditious implementation schedule; 2 – Demonstrate attainment of the 24-hour PM_{2.5} national ambient air quality standard at the earliest possible date; 3 – Reduce population exposure to PM_{2.5} achieving the 24-hour PM_{2.5} national ambient air quality standard; 9 – Update any remaining control measures from the 2007 AQMP and incorporated into the 2012 AQMP as appropriate; and 10 – Compliance with federal contingency measure requirements.

Alternative 2 would be expected to generate equivalent impacts to the 2012 AQMP in all environmental topic areas analyzed. It would achieve all of the project objectives, but would not achieve the objectives related to reducing PM_{2.5} emissions as well as the 2012 AQMP because it is projected to achieve the federal 24-hour PM_{2.5} standard in 2017, two years later than the 2012 AQMP.

Alternative 3 has the potential to generate greater impacts than the 2012 AQMP because Alternative 3 ozone Control Measure ONRD-03 could result in accelerated penetration of approximately 5,000 additional medium-heavy-duty trucks for the years 2013 through 2017 (750 trucks per year that would be diesel or diesel-hybrids that comply with the year 2010 exhaust emission standards and 250 trucks per year that would use CNG engines for a total of 1,000 trucks per year). Similarly, Alternative 3 OFFRD-01 could result in a total of

19,344 additional repowered or replaced vehicles from the year 2014 through 2017. To the extent that these ozone control measures contribute to environmental impacts, they would be greater than environmental impacts from the 2012 as shown in Table 6-23. Consequently, Alternative 3 does meet the CEQA requirement to reduce environmental impacts compared to the proposed project.

As shown in Table 6-23, Alternative 4 would generate fewer environmental impacts or less severe impacts than the 2012 AQMP. It would achieve all but three ~~four~~ of the project objectives, objectives 4 – Continue making expeditious progress towards attaining the federal eight-hour ozone standard and demonstrate attainment of the federal one-hour ozone standard (revoked) by 2022 – 2023; 5 – Reduce population exposure to ozone through continued progress towards attaining the federal one-hour (revoked) and eight-hour ozone standards by 2022 – 2023; and 9 – Update any remaining control measures from the 2007 AQMP and incorporated into the 2012 AQMP as appropriate. As shown in the air quality Table 6-19, Alternative 4 would not be as effective as the 2012 AQMP in making expeditious progress toward attaining the federal one-hour ozone standard (revoked) or the federal eight-hour ozone standard. Similarly, because a large amount of emission reductions from the ozone control measures are from stationary sources, in addition to obtaining NOx and VOC emission reductions, they would also obtain PM emission reductions, thus, further enhancing the SCAQMD’s ability, not only to attain the federal 24-hour PM2.5 standard, but to maintain the standard in the future. Similarly, since Alternative 4 focuses primarily on PM2.5 emission reductions, it would not likely be as effective as the 2012 AQMP achieving project objective 6 – Reduce nonattainment pollutants at a rate of five percent per year, or include all feasible measures and an expeditious adoption schedule.

Based on the above information, the 2012 AQMP is the most effective project that achieves the project objectives relative to environmental impacts generated.

7.1 ORGANIZATIONS AND PERSONS CONSULTED

The CEQA statutes and Guidelines require that organizations and persons consulted be provided in the [Final Program EIR](#). A number of organizations, state and local agencies, and private industry have been consulted. The following organizations and persons have provided input into this document.

Marianna Buoni, General Manager
Clean Harbors

Steven Mac
California Energy Commission

[iLanco Environmental LLC, Redondo Beach, California](#)

[Castle Environmental Consulting, Los Angeles, California](#)

7.2 ~~LIST OF FINAL PROGRAM ENVIRONMENTAL IMPACT REPORT PREPARERS~~

Prepared By:

[Environmental Audit, Inc. for the South Coast Air Quality Management District](#)
[Steve Smith, Ph.D., Program Supervisor](#)
[Jeffrey Inabinet, Air Quality Specialist](#)
[James Koizumi, Air Quality Specialist](#)
[Barbara Radlein, Air Quality Specialist](#)

Contributors:

[Richard Carlson, Air Quality Specialist](#)
[Joseph Cassmassi, Planning and Rules Manager](#)
[Dave Coel, Program Supervisor](#)
[Ali Ghasemi, Program Supervisor](#)
[Henry Hogo, Assistant Deputy Executive Officer](#)
[Kathy Hsiao, Program Supervisor](#)
[Sang-Mi Lee, Ph.D., Air Quality Specialist](#)
[Randall Pasek, Ph.D., Planning and Rules Manager](#)
[Dean Saito, Fleet Implementation Manager](#)
[Susan Yan, Air Quality Specialist](#)

Reviewers:

[Barbara Baird, J.D., District Counsel](#)
[Naveen Berry, Planning and Rules Manager](#)
[Philip Fine, Ph.D., Planning and Rules Manager](#)
[Aaron Katzenstein, Ph.D., Program Supervisor](#)

Michael Krause, Program Supervisor
Susan Nakamura, Planning and Rules Manager
Lauren Nevitt, J.D., Deputy District Counsel II
Veera Tyagi, J.D., Senior Deputy District Counsel
William Wong, J.D., Principal Deputy District Counsel

Production:

Angela Kim, Senior Office Assistant
Arlene Martinez, Administrative Secretary
Lori Moore, Secretary

CHAPTER 8

ACRONYMS

Acronyms

8.0 ACRONYMS

ABBREVIATION	DESCRIPTION
AAs	Administering Agencies
AB	Assembly Bill
AB32	California's Global Warming Solutions Act of 2006
AB939	California Integrated Waste Management Act of 1989
AB2588	Air Toxic "Hot Spots" Information and Assessment Act
ACGIH	American Conference of Governmental Industrial Hygienists
af	acre-feet
AFV	Alternative Fuel Vehicles
AIChE	American Institute of Chemical Engineers
ALUC	Airport Land Use Commission
AMP	Alternative Marine Power
ANPR	Advance Notice of Proposed Rulemaking
API	American Petroleum Institute
APS	Alternative Planning Strategy
AQMD	Air Quality Management District
AQMP	Air Quality Management Plan
ARB	Air Resources Board
ASTM	American Society for Testing and Materials
ATCM	Airborne Toxic Control Measure
ATCP	Air Toxics Control Plan
ATPZEVs	Advanced Technology Partial Zero-Emission Vehicles
AVL	automated vehicle location
AVR	Average Vehicle Ridership
AVTA	Advanced Vehicle Testing Activity
BACT	Best Available Control Technology
BACM	Best Available Control Measures
BARCT	Best Available Retrofit Control Technology
BART	Best Available Retrofit Technology
Basin	South Coast Air Basin
BAU	business-as-usual
BLEVE	boiling liquid expanding vapor explosion
BLM	Bureau of Land Management
BMP	Best Management Practices
BNSF	Burlington Northern Santa Fe Railway
BOD	Bio-chemical Oxygen Demand
BPTCP	Bay Protection and Toxic Clean Up Plan
Btu	British Thermal Units
Btu/hr	British Thermal Units per hour
°C	Degrees Centigrade
CAA	Clean Air Act
CAAP	Clean Air Action Plan
CAFE	Corporate Average Fuel Economy
CaH2Net	California Hydrogen Highway Network

CalARP	California Accidental Release Prevention Program
CalEMA	California Emergency Management Agency
CalEPA	California Environmental Protection Agency
CalRecycle	(formerly known as the California Integrated Waste Management Board)
Caltrans	California Department of Transportation
CalOSHA	California Occupational Safety and Health Administration
CARB	California Air Resources Board
CCAA	California Clean Air Act
CCC	California Coastal Commission
CCP	Clean Communities Plan
CCR	California Code of Regulations
CDF	California Department of Forestry and Fire Protection
CDPR	California Department of Parks and Recreation
CEC	California Energy Commission
CE-CERT	College of Engineering Center for Environmental Research and Technology
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CEQA	California Environmental Quality Act
CFCs	Chloroflorocarbons
CFR	Code of Federal Regulations
CH ₄	Methane
CHMIRS	California Hazardous Materials Incident Reporting System
CHP	California Highway Patrol
CIP	Capital Improvement Program
CIWMB	California Integrated Waste Management Board
CIWMP	Countywide Integrated Waste Management Plan
CLEEN	Continuous Lower Energy, Emissions and Noise
CM	Control Measure
CMAAs	Congestion Management Agencies
CMB	Combustion Sources
CMPs	Congestion Management Programs
CMS	Congestion Management System
CMAQ	Community Multiscale Air Quality
CNEL	Community Noise Equivalent Level
CNG	Compressed Natural Gas
CNS	Central nervous system
CO	Carbon Monoxide
CO ₂	Carbon Dioxide
CO ₂ e	CO ₂ equivalents
COHb	Carboxyhemoglobin
CPUC	California Public Utilities Commission
CPSC	Consumer Products Safety Commission
CRA	Colorado River Aqueduct
CSI	California Solar Initiative

CTS	Coatings and Solvents
CUPA	Certified Unified Program Agency
CVRP	Clean Vehicle Rebate Pilot
CVWD	Coachella Valley Water District
CWA	Clean Water Act
CWAP	Clean Water Action Plan
CWM	Chemical Waste Management
CWMI	Chemical Waste Management Inc.
dB	decibels
dBA	decibels (A-weighted)
DC	direct current
Delta	Sacramento-San Joaquin Delta
DHS	Department of Health Services
DMC	dimethyl carbonate
DOT	Department of Transportation
DPF	Diesel Particulate Filters
DPM	Diesel Particulate Matter
DPR	Department of Pesticide Regulation
DRRP	Risk Reduction Plan to Reduce Particulate Matter Emissions from Diesel-Fueled Engines and Vehicles (also known as the Diesel Risk Reduction Plan)
DTSC	California Department of Toxic Substances Control
DTIM	Direct Travel Impact Model
DWR	California Department of Water Resources
EAP	Emergency Action Plan
ECA	Emissions Control Area
EDMS	Emissions and Dispersion Modeling System
EFMP	Enhanced Fleet Modernization Program
EHS	Extremely Hazardous Substances
EIA	Energy Information Administration
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
EISA	Energy Independence and Security Act of 2007
EJ	Environmental Justice
EJAG	Environmental Justice Advisory Group
EMFAC	Emission Factors Model
EMFAC 2011	2011 Emission Factors model
EMWD	Eastern Municipal Water District
EOR	Enhanced Oil Recovery
EPA	Environmental Protection Agency
EPAct	Energy Policy Act
EPCRA	Emergency Planning and Community Right-to-Know Act
ERPG	Emergency Response Planning Guideline
ERPG-2	Emergency Response Planning Guide Level 2
ERPG-3	Emergency Response Planning Guide Level 3
ESP	Electrostatic Precipitators

EVs	Electric Vehicles
EVSE	electric vehicle supply equipment
E85	Ethanol
°F	Degrees Fahrenheit
FAA	Federal Aviation Administration
FCCU	Fluid Catalytic Cracking Unit
FCV	fuel cell vehicles
FDA	Food and Drug Administration
FDDA	four dimensional data assimilation
FEMA	Federal Emergency Management Agency
FEIR	Final Environmental Impact Report
FePo	iron phosphate
FESA	Federal Endangered Species Act
Fe ₂ O ₃	iron oxide
FFVs	Flexible Fuel Vehicles
FHWA	Federal Highway Administration
FIP	Federal Implementation Plan
FMCSA	Federal Motor Carrier Safety Administration
FMVSS	Federal Motor Vehicle Safety Standard
FRA	Federal Railroad Administration
FTA	Federal Transit Administration
FTIP	Federal Transportation Improvement Program
ft ²	square feet
FUA	Fuel Use Act
FUG	Fugitive Emissions
GHG	Greenhouse Gas
GHGRP	Greenhouse Gas Reporting Program
GRAS	Generally Recognized As Safe
GVWR	gross vehicle weight rating
GWh	gigawatt hour
H ₂	Hydrogen
H ₂ S	Hydrogen Sulfide
H ₂ SO ₄	Sulfuric Acid
HAPs	Hazardous Air Pollutants
HCFCs	Hydrochlorofluorocarbons
HDV	Heavy Duty Vehicles
HEPA	High-Efficiency Particulate AirArrestor
HFCs	hydrofluorocarbons
HGS	Harbor Generating Station
HI	Hazard Index
HMTA	Hazardous Materials Transportation Act
HNO ₃	Nitric Acid
HOV	High Occupancy Vehicle
hp	horsepower
HRA	Health Risk Assessment
HOT	High-Occupancy Toll

HQTAs	High Quality Transit Areas
HSC	Health and Safety Code
HUD	Housing and Urban Development
HVIP	Hybrid Vehicle Incentives Project
HWCA	Hazardous Waste Control Act
HWMP	Hazardous Waste Management Plan
IARC	International Agency for Research on Cancer
ICEs	Internal Combustion Engines
ICTA	International Center for Technology Assessment
IDLH	Immediately Dangerous to Life and Health
IGR	Intergovernmental Review
IMO	International Maritime Organization
IM	industrial maintenance
IOUs	Investor Owned Utilities
IRP	Integrated Water Resources Plan
IRWD	Irvine Ranch Water District
ITS	Intelligent Transportation Systems
kW	Kilowatt
kWh	Kilowatt Hour
°K	degrees Kelvin
LAA	Los Angeles Aqueduct
LACDPW	Los Angeles County Department of Public Works
LACFD	Los Angeles County Fire Department
LACSD	Los Angeles County Sanitation Districts
LADPW	Los Angeles Department of Public Works
LADWP	Los Angeles Department of Water and Power
LAER	Lowest Achievable Emission Reduction
LAFCO	Local Agency Formation Commission
LAX	Los Angeles International Airport
LBGOD	Long Beach Gas & Oil Department
lbs	pounds
lbs/day	pounds per day
lbs/gal	pounds per gallon
lbs/hr	pounds per hour
LCFS	Low-Carbon Fuel Standard
LCP	local coastal program
LDAR	Leak Detection and Repair
LEAs	Local Enforcement Agencies
LEL	Lower Explosive Limit
LEPC	Local Emergency Planning Committee
LEV III	Low-Emission Vehicle
Leq	Equivalent Continuous Level
LID	Low Impact Development
Li-ion	lithium ion
Lmax	maximum measured noise level
LNG	Liquefied Natural Gas

LOS	Level of Service
LPG	Liquefied Petroleum Gas
LRP	Local Resources Program
LRT	light rail transit
LTCP	Long-Term Conservation Plan
LUPs	land use plans
LVP-VOC	low vapor pressure volatile organic compounds
MAF	Million acre-feet
MATES	Multiple Air Toxic Exposure Study
MATES II	Multiple Air Toxic Exposure Study II
MATES III	Multiple Air Toxic Exposure Study III
MCLs	Maximum Containment Levels
MDAB	Mojave Desert Air Basin
MECA	Manufacturer's of Emission Controls Association
MEGAN	Model of Emissions of Gases and Aerosols from Nature
MEK	methyl ethyl ketone
MeTHF	methylnetrahydrofuran
Metro	Los Angeles County Metropolitan Transit Authority
mgd	million gallons per day
mg/L	milligrams per liter
mg/m ³	milligrams per cubic meter
MIBK	methyl isobutyl ketone
MIR	Maximum Incremental Reactivity
MMTCO ₂ e	million metric tons of carbon dioxide equivalent
MnO	manganese oxide spinel
MoO ₃	molybdenic anhydride
MTCO ₂ e/year	CO ₂ equivalent emissions per year
MRFs	Material Recovery Facilities
MPO	Metropolitan Planning Organization
m/s	meters per second
MSDS	Material Safety Data Sheet
MSRC	Mobile Source Air Pollution Reduction Review Committee
MS4s	municipal separate storm sewer systems
MTBE	methyl tertiary butyl ether
MW	megawatts
Metropolitan	Metropolitan Water District of Southern California
MWD	Metropolitan Water District
M85	Methanol
NAAQS	National Ambient Air Quality Standards
NAHC	Native American Heritage Commission
NCA	nickel-cobalt- aluminum
NCEP	National Centers for Environmental Prediction
NCM	nickel-cobalt-manganese
NCP	National Contingency Plan
NECPA	National Energy Conservation Policy Act
NEC	National Electric Code

NESHAPS	National Emission Standards for Hazardous Air Pollutants
NPDES	National Pollutant Discharge Elimination System
NFC	National Fire Codes
NFPA	National Fire Protection Association
NHTSA	National Highway Traffic Safety Administration
NiMH	nickel-metal hydride
NIOSH	National Institute of Occupational Safety and Health
N ₂	Nitrogen
N ₂ O	Nitrous Oxide
NO	Nitric Oxide
NO ₂	Nitrogen Dioxide
NOP	Notice of Preparation
NOP/IS	Notice of Preparation/Initial Study
NO _x	Nitrogen Oxide
NPS	National Park Service
NPDES	National Pollutant Discharge Elimination System
NRCS	Natural Resources Conservation Service
NS	No significant impacts
NSPS	New Source Performance Standards
O ₂	Oxygen
O ₃	Ozone
OCA	Off-site Consequences Analyses
OCHCA	Orange County Health Care Agency
OCS	Outer Continental Shelf
OCSD	Orange County Sanitation District
OCTA	Orange County Transportation Authority
OCWD	Orange County Water District
ODS	Ozone Depleting Substances
OEHHA	Office of Environmental Health Hazards Assessment
OES	Office of Emergency Services
OHMS	Office of Hazardous Materials Safety
OPR	Office of Planning and Research
OSHA	Occupational Safety and Health Administration
PAHs	Polynuclear Aromatic Hydrocarbons
Pb	lead
PCBF	Perchlorobenzotrifluoride
PCBTF	p-chlorobenzotrifluoride
PCE	passenger car equivalents
PD	positive displacement
PEIR	Program Environmental Impact Report
PELs	Permissible Exposure Limits
PEVs	plug-in electric vehicles
PFCs	Perfluorocarbons
PG&E	Pacific Gas & Electric
pH	potential hydrogen ion concentration
PM	Particulate Matter

PM10	particulate matter less than 10 microns equivalent aerodynamic diameter
PM2.5	particulate matter less than 2.5 microns equivalent aerodynamic diameter
POTW	Publicly Owned Treatment Works
POUs	publicly owned utilities
ppb	parts per billion
ppm	parts per million
PPV	peak particle velocity
Program EIR	Program Environmental Impact Report
PSD	Prevention of Significant Deterioration
psi	pounds per square inch
psig	pounds per square inch (gauge)
PSM	Process Safety Management
PSU	Primers, Sealers, and Undercoaters
PTFE	Polytetrafluoroethylene
PUC	Public Utilities Commission
PURPA	Public Utility Regulatory Policies Act of 1978
PV	Photovoltaic
PVC	Polyvinyl Chloride
PZEV	Partial Zero Emission Vehicle
PX	Power Exchange
Qfs	qualifying facilities
QSA	Quantified Settlement Agreement
QVT	Qualified Vehicle Testers
RCRA	Resource Conservation and Recovery Act
RCTC	Riverside County Transportation Commission
RECLAIM	Regional Clean Air Incentives Market
RELOOC	Regional Landfill Options for Orange County
RELS	Reference Exposure Levels
RFS	Renewable Fuel Standard
RFS2	2007 Renewable Fuel Standard
RHNA	Regional Housing Needs Assessment
RMP	Risk Management Program
RMS	Root Mean Squared
ROC	Reactive Organic Compound
ROG	Reactive Organic Gas
RPS	Renewable Portfolio Standard
RQs	Reportable Quantities
RRF	Relative Response Factors
RRWG	Reactivity Research Working Group
RSPA	Research and Special Programs Administration
RTAC	Regional Targets Advisory Committee
RTC	RECLAIM Trading Credit
RTIP	Regional Transportation Implementation Plan
RTP	Regional Transportation Plan

RTP/SCS	Regional Transportation Plan/Sustainable Communities Strategy
RWQCB	Regional Water Quality Control Board
SAE	Society of Automotive Engineers
SAFETEA-LU	Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users
SB	Senate Bill
SBS	sodium bisulfate
SCAB	South Coast Air Basin
SCAG	Southern California Association of Governments
SCAQMD	South Coast Air Quality Management District
SCE	Southern California Edison
SCR	Selective Catalytic Reduction
SCRRA	Southern California Regional Rail Authority
SCS	Sustainable Communities Strategy
SCHWMA	Southern California Hazardous Waste Management Authority
SDG&E	San Diego Gas & Electric
SEL	Sound Exposure Level
SF ₆	Sulfur Hexafluoride
SGVEWP	San Gabriel Valley Energy Wise Program
SIP	State Implementation Plan
SNCR	selective non-catalytic reduction
SO ₂	sulfur dioxide
SO ₃	Sulfur Trioxide
SoCalGas	Southern California Gas Company
SOON	Surplus Off-Road Option for NO _x
SO ₂	sulfur dioxide
SO _x	sulfur oxide
SPCC	Spill Prevention, Control and Countermeasure
SRRE	Source Reduction and Recycling Element
SSAB	Salton Sea Air Basin
STE	solar thermal energy
STEL	short-term exposure limits
SWFPs	Solid Waste Facility Permits
SWP	State Water Project
SWMD	Solid Waste Management Division
SWMP	Storm Water Management Plan
SWPPP	Stormwater Pollution Prevention Plan
SWRCB	State Water Resources Control Board
TAC	Toxic Air Contaminant
TAF	Thousand Acre-Feet
TAO	Technology Advancement Office
TAZ	transportation analysis zone
TBA	tert-butyl alcohol
T-BAc	tertiary butyl acetate
TCM	Transportation Control Measure
TDM	Transportation Demand Management

SUBJECT: RECIRCULATED NOTICE OF PREPARATION OF A DRAFT PROGRAM ENVIRONMENTAL IMPACT REPORT

PROJECT TITLE: 2012 AIR QUALITY MANAGEMENT PLAN (AQMP)

In accordance with the California Environmental Quality Act (CEQA), the South Coast Air Quality Management District (SCAQMD) will be the Lead Agency for the project identified above. This Notice of Preparation (NOP) and Initial Study (IS) serve two purposes: 1) to solicit information on the scope of the environmental analysis for the proposed project; and 2) to notify the public that the SCAQMD will prepare a Draft Program Environmental Impact Report (Program EIR) to further assess potential adverse environmental impacts that may result from implementing the proposed project.

The NOP/IS is being recirculated because changes were made to the 2012 AQMP project description subsequent to release of the original NOP/IS on June 27, 2012. Recirculation of the NOP/IS allows the public the full 30 days to review the revised project description and provide comments as necessary on the environmental analysis for the 2012 AQMP.

This cover letter and Revised NOP and the attached IS are not SCAQMD applications or forms requiring a response from you. Their purpose is simply to provide information to you on the above project. If the proposed project has no bearing on you or your organization, no action on your part is necessary.

Comments submitted on the June 27, 2012 NOP/IS will continue to be included in the administrative record for the project and responses to these comments will be prepared and included in the Draft PEIR. Therefore, these comment letters need not be submitted a second time. Please focus your comments on the changes to the project description made subsequent to June 27, 2012. Comments focusing on your area of expertise, your agency's area of jurisdiction, or issues relative to the environmental analysis should be addressed to Mr. Jeffrey J. Inabinet (c/o CEQA) at the address shown above, or sent by FAX to (909) 396-3324 or by e-mail to jinabinet@aqmd.gov. Comments must be received no later than 5:00 PM on August 31, 2012. Please include the name and phone number of the contact person for your agency. Questions relative to the proposed 2012 AQMP should be directed to Mr. Michael Krause at (909) 396-2706.

Two public workshops/CEQA scoping meetings will be held for the proposed project at the following locations and times.

Workshop Date	Time	Locations	Address	County
Thursday 8/9/12	2:00 PM	Coachella Valley Association of Governments	73-710 Fred Waring Drive Palm Desert, CA 92260	Riverside
Thursday 8/23/12	9:00 AM	South Coast Air Quality Management District	21865 Copley Drive, Diamond Bar, CA 91765	Los Angeles

The final Public Hearing is currently scheduled for Friday, November 2, 2012 at 9:00 am at the SCAQMD headquarters, at which time the Governing Board will consider certifying the Program EIR and approving the 2012 AQMP. Please note, the Public Hearing date is subject to change.

Date: August 1, 2012

RECIRCULATED NOTICE OF PREPARATION OF A
DRAFT PROGRAM ENVIRONMENTAL IMPACT REPORT

Project Title:

Draft Program Environmental Impact Report: 2012 Air Quality Management Plan (AQMP)

Project Location:

South Coast Air Quality Management District (SCAQMD) area of jurisdiction consisting of the four-county South Coast Air Basin (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin and the Mojave Desert Air Basin

Description of Nature, Purpose, and Beneficiaries of Project:

The 2012 AQMP identifies control measures to demonstrate that the region will attain the federal 24-hour standard for particulate matter less than 2.5 microns in diameter (PM_{2.5}) by the applicable target dates and provides Clean Air Act §182(e)(5) proposed implementation measures to assist in achieving the one-hour (revoked) and 8-hour ozone standards by the applicable date. The Draft 2012 AQMP control measures consist of three components: 1) the SCAQMD's Stationary and Mobile Source Control Measures; 2) State and Federal Control Measures; and 3) Regional Transportation Strategy and Control Measures provided by SCAG. Overall, the Draft 2012 AQMP includes stationary and mobile source measures. The AQMP also includes the most current air quality setting, updated emissions inventories of stationary and mobile sources, updated growth projections, new modeling techniques, compliance with contingency requirements, and an implementation schedule for adoption of the proposed control measures. Subsequent to the release of the June 27, 2012 NOP/IS, the following changes were made to the 2012 AQMP: control measure MCS-04a has been folded into control measure ONRD-04; control measure MCS-04b is now control measure BCM-01; control measure MCS-04c is now BCM-04; these three CMs would now apply to the entire Basin instead of just the Mira Loma area; and new control BCM-02 – Further Reductions from Open Burning, that would apply to the entire district, has been added to the 2012 AQMP.

1.0 Recirculation of the Notice of Preparation (NOP) / Initial Study (IS) of a Draft Program Environmental Impact Report for the 2012 Air Quality Management Plan (AQMP) and Initial Study (IS)

On June 27, 2012, the South Coast Air Quality Management District (SCAQMD) released a NOP/IS for the 2012 AQMP for a 30-day public review period. Subsequent to release of the NOP/IS, changes were made to the control strategy in the 2012 AQMP. As a result of these changes, the project description in the NOP/IS was not entirely consistent with project described in the 2012 AQMP. Specifically, the following changes were made to the 2012 AQMP: control measure MCS-04a was folded into control measure ONRD-04; control measure MCS-04b is now control measure BCM-01; control measure MCS-04c is now control measure BCM-04; these three CMs would now apply to the entire Basin instead of just the Mira Loma area; and new control BCM-02 – Further Reductions from Open Burning, has been added to the 2012 AQMP and applies to the entire district.

To afford the public the fullest opportunity to review and comment on the preliminary environmental evaluation of the 2012 AQMP, the NOP/IS has been revised to include an updated accurate project description and the NOP/IS is being recirculated for a second 30-day public review period.

Nine comment letters were received on the June 27, 2012 NOP/IS for the 2012 AQMP. As result of these comment letters the following changes have been made to the environmental analysis in Chapter 2 of this NOP/IS. An analysis of potential solid waste impacts has been added for control measure FUG-01. In addition, the environmental topic of potential traffic impacts has been added to the list of environmental topic areas that will be evaluated in the Program EIR.

Responses to comments submitted on the June 27, 2012, will be prepared and included in the Draft PEIR along with responses to comments received on this NOP/IS. Therefore, these comment letters need not be submitted a second time. Please focus your comments on the changes to the project description made subsequent to June 27, 2012.

1.1 Introduction

The SCAQMD was created by the California legislature in 1977¹ as the public agency responsible for developing and enforcing air pollution control regulations in the South Coast Air Basin (Basin) and portions of the Salton Sea Air Basin and Mojave Desert Air Basin referred to herein as the district. The Lewis Air Quality Act (now known as the Lewis-Presley Air Quality Management Act) requires the SCAQMD to prepare and adopt an Air Quality Management Plan (AQMP) consistent with federal planning requirements. In 1977,

¹ The Lewis-Presley Air Quality Management Act, 1976 Cal. State. ch. 324 (codified at H & S Code, Sections 40400 - 40540).

amendments to the federal Clean Air Act (CAA) included requirements for submitting State Implementation Plans (SIPs) for nonattainment areas that fail to meet all federal ambient air quality standards (CAA § 172) and similar requirements exist in state law (Health & Safety Code §40462). The federal CAA was amended in 1990 to specify attainment dates and SIP requirements for ozone, carbon monoxide (CO), nitrogen dioxide (NO₂) and particulate matter with an aerodynamic diameter of less than 10 microns (PM₁₀). In 1997, the United States Environmental Protection Agency (EPA) promulgated ambient air quality standards for a new pollutant, particulate matter with an aerodynamic diameter less than 2.5 microns (PM_{2.5}). The California Clean Air Act (CCAA), adopted in 1988, requires the SCAQMD to endeavor to achieve and maintain state ambient air quality standards for ozone, CO, sulfur dioxide (SO₂), and NO₂ by the earliest practicable date (Health & Safety Code §40910). The CCAA also requires a three-year plan review if necessary, and an update to the AQMP. The EPA is required to periodically update the national ambient air quality standards. The AQMP revision currently under development is primarily triggered by an update to the PM_{2.5} standard, but also provides requirements to attain the (revoked) one-hour ozone standard and measures to continue making progress toward attaining the 8-hour ozone standard.

The South Coast Air Basin (Basin), which includes all of Orange County and the nondesert portions of Los Angeles, San Bernardino and Riverside counties, has one of the worst air quality problems in the nation. Though there have been significant improvements in air quality in the Basin over the last two decades, some ambient air quality standards are still exceeded relatively frequently and by a wide margin. The 2007 AQMP concluded that major reductions in emissions of oxides of sulfur (SO_x), particulate matter less than 2.5 microns (PM_{2.5}) and oxides of nitrogen (NO_x) are necessary to attain the air quality standards for ozone and particulate matter by the dates mandated by federal law. Less emphasis is placed on emission reductions from volatile organic compounds (VOCs) because of the greater emphasis on NO_x emission reductions, which is a precursor to both ozone and PM. Ozone, a criteria pollutant, is formed when VOCs react with NO_x in the atmosphere and has been shown to adversely affect human health. NO_x also contributes to the formation of PM₁₀ and PM_{2.5}.

1.2 Background

The first AQMP was prepared and approved by the SCAQMD in 1979 and has been updated and revised eight times since first adopted. The 2012 AQMP will be the tenth plan, not including certain SIPs for specific pollutants, e.g., PM₁₀ for the Coachella Valley and lead, prepared by the SCAQMD. The following bullets summarize the main components of the past AQMP updates and revisions:

- The 1982 AQMP was revised to reflect better data and modeling tools.

- In 1987, a federal court ordered the U.S. Environmental Protection Agency (U.S. EPA) to disapprove the 1982 AQMP because it did not demonstrate attainment of all national ambient air quality standards (NAAQS) by 1987 as required by the CAA. This, in part, led to the preparation of the 1989 AQMP.
- The 1989 AQMP was adopted on March 17, 1989 and was specifically designed to attain all NAAQS. This plan called for three “tiers” of measures as needed to attain all standards and relied on significant future technology advancement to attain these standards.
- In 1991, the SCAQMD prepared and adopted the 1991 AQMP to comply with the CCAA.
- In 1992, the 1991 AQMP was amended to add a control measure containing market incentive programs.
- In 1994, the SCAQMD prepared and adopted the 1994 AQMP to comply with the CCAA three-year update requirement and to meet the federal CAA requirement for an ozone SIP. The AQMP, as adopted in 1994, included the following:
 - All geographical areas under the jurisdiction of the SCAQMD (referred to here as the district), as opposed to just the South Coast Air Basin;
 - The basic control strategies remained the same although the three-tiered structure of control measures was replaced and measures previously referred to as Tier I, II or III were replaced with short-/intermediate-term or long-term control measures;
 - Updated and refined control measures carried over from 1991;
 - Best Available Control Measure (BACM) PM10 Plan;
 - The ozone attainment demonstration plan;
 - Amendments to the federal Reactive Organic Compound (ROC) Rate-of-Progress Plan (also referred to as the volatile organic compound (VOC) Rate-of-Progress Plan); and
 - Attainment Demonstration Plans for the federal PM10, nitrogen dioxide, and carbon monoxide air quality standards; etc.
- The 1997 AQMP was designed to comply with the three-year update requirements specified in the CCAA as well as to include an attainment demonstration for PM10 as required by the federal CAA. Relative to ozone, the 1997 AQMP contained the following changes to the control strategies compared to the 1994 AQMP:

- ❑ Less reliance on transportation control measures (TCMs);
- ❑ Less reliance on long-term control measures that rely on future technologies as allowed under §182(e)(5) of the CAA; and
- ❑ Removal of other infeasible control measures and indirect source measures.
- In 1999, the ozone plan portion of the 1997 AQMP was amended to address partial disapproval of the 1997 AQMP by the U.S. EPA and a settlement of litigation by environmental groups challenging the 1997 AQMP to provide the following:
 - ❑ Greater emission reductions in the near-term than would occur under the 1997 AQMP;
 - ❑ Early adoption of the measures that would otherwise be contained in the next three-year update of the AQMP; and
 - ❑ Additional flexibility relative to substituting new measures for infeasible measures and recognition of the relevance of cost effectiveness in determining feasibility.
- In April 2000, U.S. EPA approved the 1999 ozone SIP to the 1997 plan. The 1999 Amendment in part addressed the State's requirements for a triennial plan update.
- The 2003 AQMP was approved and adopted by the SCAQMD in August 2003. The 2003 AQMP was never fully approved by the U.S. EPA as part of the SIP. The 2003 AQMP addressed the following control strategies:
 - ❑ Attaining the federal PM10 ambient air quality standard for the South Coast Air Basin and Coachella Valley- these portions were approved by the U.S. EPA ; in both areas, the attainment demonstration was disapproved after the California Air Resources Board (CARB) withdrew its measures;
 - ❑ Attaining the federal one-hour ozone standard;
 - ❑ 1997/1999 control measures not yet implemented;
 - ❑ Revisions to the Post-1996 VOC Rate-of-Progress Plan and SIP for CO; and
 - ❑ Initial analysis of emission reductions necessary to attain the PM2.5 and eight-hour ozone standards; etc.
 - ❑ The 2003 AQMP was partially approved and partially disapproved by EPA,
- The SCAQMD Governing Board approved the 2007 AQMP on June 1, 2007. On September 27, 2007, CARB adopted the State Strategy for the 2007 State

Implementation Plan and the 2007 South Coast Air Quality Management Plan as part of the (SIP). The 2007 SIP was then forwarded to U.S. EPA for approval. The following summarize the major components of the 2007 AQMP:

- ❑ The most current air quality setting (i.e., 2005 data);
- ❑ Updated emission inventories using 2002 as the base year, which also incorporate measures adopted since adopting the 2003 AQMP;
- ❑ Updated emission inventories of stationary and mobile on-road and off-road sources;
- ❑ 2003 AQMP control measures not yet implemented (eight of the control measures originally contained in the 2003 AQMP have been updated or revised for inclusion into the Draft 2007 AQMP);
- ❑ 24 new measures are incorporated into the 2007 AQMP based on replacing the SCAQMD's long-term control measures from the 2003 AQMP with more defined or new control measures and control measure adoption and implementation schedules;
- ❑ SCAQMD's recommended control measures aimed at reducing emissions from sources that are primarily under State and federal jurisdiction, including on-road and off-road mobile sources, and consumer products;
- ❑ SCAG's regional transportation strategy and control measures; and
- ❑ Analysis of emission reductions necessary and attainment demonstrations to achieve the federal eight-hour ozone and PM_{2.5} air quality standards.

On November 22, 2010, U.S. EPA issued a notice of proposed partial approval and partial disapproval of the 2007 South Coast SIP for the 1997 Fine Particulate Matter Standards and the corresponding 2007 State Strategy. Specifically, U.S. EPA proposed approving the SIP's inventory and regional modeling analyses, but it also proposed disapproving the attainment demonstration because it relied too extensively on commitments to emission reductions in lieu of fully adopted, submitted, and SIP-approved rules. The notice also cited deficiencies in the SIP's contingency measures.

- In response to U.S. EPA's proposed partial disapproval of the 2007 SIP, on March 4, 2011, the SCAQMD Governing Board approved Revisions to the 2007 PM_{2.5} and Ozone State Implementation Plan for South Coast Air Basin and Coachella Valley. The revisions to the 2007 PM_{2.5} and Ozone SIP consist of the following:
 - ❑ Updated implementation status of SCAQMD control measures necessary to meet the 2015 PM_{2.5} attainment date;

- Revisions to the control measure adoption schedule;
 - Changes made to the emission inventory resulting from California Air Resources Board's (CARB's) December 2010 revisions to the on-road truck and off-road equipment rules; and
 - An SCAQMD commitment to its "fair share" of additional NO_x emission reductions, if needed, in the event U.S. EPA does not voluntarily accept the "federal assignment."
- In response to the July 14, 2011 U.S. EPA notice of proposed partial approval and partial disapproval of the 2007 South Coast SIP for the 1997 Fine Particulate Matter Standards, at the October 7, 2011 public hearing, the SCAQMD Governing Board approved Further Revisions to PM_{2.5} and Ozone State Implementation Plan for South Coast Air Basin and Coachella Valley. Revisions to the PM_{2.5} SIP included a three-prong approach for identifying contingency measures needed to address U.S. EPA's partial disapproval:
 - Equivalent emissions reductions achieved through improvements in air quality;
 - Relying on committed emissions reductions for the 2007 ozone plan; and
 - Quantifying excess emissions reductions achieved by existing rules and programs that were not originally included in the 2007 PM_{2.5} SIP;
 - U.S. EPA approved the PM_{2.5} SIP except for contingency measures on November 9, 2011. Action is pending on the contingency measures;
 - U.S. EPA fully approved the 2007 SIP for the 8-hour ozone standard on March 1, 2012.

1.2.1 Progress Implementing the 2007 AQMP

The SCAQMD has fulfilled the majority of its emissions reductions commitments specified in the 2007 SIP. Table 1-1 summarizes the progress achieved toward fulfilling SCAQMD's emissions reductions commitments to attain the 1997 PM_{2.5} annual and federal 8-hour ozone standards by the required dates. Through January 31, 2011, the SCAQMD Governing Board has amended and adopted 12 rules. The majority of these rules have been submitted to U.S. EPA and approved as part of the SIP. Several recently adopted SCAQMD rules have been submitted to CARB and have been or are expected to be submitted to and subsequently evaluated by U.S. EPA. As shown in Table 1-1, for the control measures adopted by the District over this period, 22.5 tons per day of VOC reductions, 7.6 tons per day of NO_x reductions, 4.0 tons per day of SO_x reductions, and 1.0 tons per day of PM_{2.5} reductions will be achieved by 2014. Additional reductions from these adopted rules will be achieved by 2023.

TABLE 1-1
Total 2007 AQMP Emission Reductions
from SCAQMD Control Measures (tons per day)

Pollutant	COMMITMENT ^a		ACHIEVED ^a	
	2014	2023	2014	2023
VOC	10.4	19.2	22.5	26.4
NO _x	10.8	9.2	7.6	10.3
PM _{2.5}	2.9	5.4	1.0	1.6
SO _x	2.9	2.9	4.0	5.7

Source: 2012 AQMP, Chapter 1, Table 1-2

^a 2014 reductions estimated in average annual day, 2023 in planning inventory.

Table 1-2 lists the 2007 AQMP's control measure commitments that have been adopted (either entirely or partially) by CARB since the 2007 AQMP was adopted. The emissions are presented in terms of remaining emissions, rather than reductions, due to some significant changes to the inventory that preclude a direct comparison of committed emissions to those achieved. The table is based on SIP revisions submitted to U.S. EPA in 2011, and thus reflect adopted measures through specific dates in 2011 as described in the footnotes. To date, CARB has achieved more than the committed 2014 emissions reductions for all pollutants for these source categories. The same is true for VOC and NO_x emissions in 2023.

- a. The 2014 emissions data reflect the 2014 Emissions Inventory that was included in the March 2011 *Progress Report on Implementation of PM2.5 State Implementation Plans*. The inventory is in the process of being updated, and may change slightly in the final AQMP draft.
- b. The 2023 emissions data tables reflect the 2023 Emissions Inventory that was current as of August 2011. The inventory is in the process of being updated, and may change slightly in the final AQMP draft.
- c. These are remaining emissions. If achieved emissions are lower than the committed emissions, it means the SIP targets are met.
- d. Remaining emissions are included in "other local, state, and federal emissions"
- e. Includes benefits of local emission reductions that were not reflected in the revised RFP estimates.

1.3 Agency Authority – 2012 AQMP

The 2012 AQMP sets forth emission reduction programs which require the cooperation of all levels of government: local, regional, state, and federal, as well as public engagement. Each level is represented in the AQMP by the appropriate agency or jurisdiction that has the authority over specific emissions sources. Accordingly, each agency or jurisdiction commits to specific planning and implementation responsibilities.

At the federal level, the U.S. EPA is charged with establishing emission standards of motor vehicle standards; train, airplane, and ship pollutant exhaust and fuel standards; and regulation of non-road engines less than 175 horsepower. CARB, representing the state level, also oversees development of 2012 AQMP control measures for on-road vehicle emission standards in California; motor vehicle fuel specifications; some off-road source emission standards and fuel standards, including marine vessels; and consumer product standards. At the regional level, the SCAQMD is responsible primarily for non-vehicular sources and has limited authority over mobile sources (e.g., in-use fleet regulations, incentives for accelerated vehicle turnover, reduction in average vehicle ridership, etc.). In addition, the SCAQMD has lead responsibility for developing stationary, some area, and indirect source control measures and coordinating the development and adoption of the 2012 AQMP. Lastly, at the local level, the cities and counties and their various departments (e.g., harbors and airports) have a dual role related to transportation and land use. Their efforts are coordinated through the regional metropolitan planning organization for the South Coast Air Basin, the Southern California Association of Governments (SCAG), which is responsible for preparing the transportation control measure component of the 2012 AQMP. Interagency commitment and cooperation are the keys to success of the 2012 AQMP.

1.4 Agency Authority – CEQA

CEQA, Public Resources Code §21000 *et seq.*, requires that the environmental impacts of proposed projects be evaluated and that feasible methods to reduce, avoid or eliminate significant adverse impacts of these projects be identified and implemented. The lead agency is the “public agency that has the principal responsibility for carrying out or approving a project that may have a significant effect upon the environment” (Public Resources Code Section 21067). Since the SCAQMD has the primary responsibility for supervising or approving the entire project as a whole, it is the most appropriate public agency to act as lead agency (CEQA Guidelines Section 15051(b)).

A Program Environmental Impact Report (Program EIR) for the 2012 AQMP is considered to be the appropriate document pursuant to CEQA Guidelines Section 15168(a)(3), because the 2012 AQMP constitutes a series of actions that can be characterized as one large project and are related in the connection with the issuance or rules, regulations, plans, or other criteria to govern the conduct of a continuing program.

As the lead agency SCAQMD for proposed 2012 AQMP, SCAQMD staff prepared Notice of Preparation/Initial Study (NOP/IS) for the proposed 2012 AQMP Program EIR. The NOP/IS was released for a 30-day public review and comment period. The NOP/IS was

also recirculated for a 30-day public review and comment period from August 2 through August 31, 2012 due to changes in the project description since the original NOP/IS circulation.

1.5 Project Location

The SCAQMD has jurisdiction over an area of approximately 10,743 square miles, consisting of the four-county South Coast Air Basin (Basin) (all of Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin (SSAB) and Mojave Desert Air Basin (MDAB), referred to hereafter as the district. The Basin, which is a subregion of the SCAQMD's jurisdiction, is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. It includes all of Orange County and the nondesert portions of Los Angeles, Riverside, and San Bernardino counties. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley. The federal nonattainment area (known as the Coachella Valley Planning Area) is a subregion of the Riverside County and the SSAB that is bounded by the San Jacinto Mountains to the west and the eastern boundary of the Coachella Valley to the east (Figure 1-1).

1.6 Overall Attainment Strategy

The overall control strategy for the Draft 2012 AQMP is designed to meet applicable federal and state requirements. The focus of the AQMP is to demonstrate attainment of the federal 24-hour PM_{2.5} ambient air quality standard by 2014, while making expeditious progress toward attainment of state standards. In addition, to further implement the existing 8-hour ozone plan, the 2012 AQMP includes section 182(e)(5) implementation measures designed to assist in future attainment of the 8-hour ozone standard (refer to subsection 1.6.1). The proposed control measures in the Draft 2012 AQMP are based on implementing all feasible control measures through the application of available technologies and management practices as well as development and implementation of advanced technologies and control methods. For purposes of the environmental analysis, it is expected that full implementation of all section 182(e)(5) measures for the one-hour ozone standard would have the same environmental effects as implementing the section 182(e)(5) measures for the 8-hour standard that were already analyzed in the EIR for the 2007 AQMP. These measures rely on proposed actions to be taken by several agencies that currently have the statutory authority to implement such measures. Similar to the approaches taken in previous AQMPs, the SIP commitment includes an adoption and implementation schedule for each control measure. Each agency is also committed to achieving a total emission reduction target with the ability to substitute specified control measures for control measures deemed infeasible, as long as equivalent reductions are met by other means. These measures are also designed to satisfy the federal Clean Air Act requirement of reasonably available control technologies [§172(c)], and the California requirement of Best Available Retrofit Control Technologies (BARCT) [Health and Safety Code §40440(b)(1)].

**FIGURE 1-1
Southern California Air Basins**

To ultimately achieve the 24-hour PM_{2.5} ambient air quality standards and demonstrate attainment, PM emissions reductions will be necessary, not only from non-vehicular sources under the jurisdiction of the SCAQMD, but substantial PM reductions will be necessary from sources primarily under the jurisdiction of CARB (e.g., on-road motor vehicles, off-road equipment, and consumer products) and U.S. EPA (e.g., aircraft, ships, trains, and pre-empted off-road equipment). Without an adequate and fair-share level of reductions from all sources, the emissions reduction burden would unfairly be shifted to stationary sources that are already stringently regulated. The SCAQMD will continue to work closely with CARB to further control mobile source emissions where federal or State actions do not meet regional needs.

1.6.1 One-hour Ozone Standard Attainment Strategy

The federal one-hour ozone standard was revoked, effective one year after the eight-hour standard designations were effective (i.e., 2005). U.S. EPA guidance indicated that while certain planning requirements remained in effect, a new SIP would not be required if an area failed to attain the standard by the attainment date. However, recent litigation and court decisions have suggested that there likely will be a need for the SCAQMD to prepare a new one-hour ozone SIP in the near future. If a one-hour ozone SIP is requested by U.S. EPA,

the SIP would be due within 12 months of such a SIP call. The attainment demonstration in the SIP would have to show attainment within five years with a potential five-year extension, which would be a similar timeframe (2022) as is required for the 1997 eight-hour ozone standard (deadline of 2023). However, many new technical issues such as modeling for the attainment demonstration and other CAA requirements would require U.S. EPA's guidance, since the previous preambles/guidelines are no longer directly applicable. Based on previous modeling estimates, the control strategies that are needed to attain the eight-hour ozone standard are nearly identical to those that would be needed to attain the one-hour ozone standard.

Although the primary purpose of the 2012 AQMP Basin is to set forth a comprehensive and integrated program that will lead the Basin into compliance with the federal 24-hour PM_{2.5} air quality standard, it will also provide an update of the Basin's projections in meeting the federal one-hour and eight-hour ozone standards. The AQMP will update specific elements of the previously approved 8-hour ozone SIP: 1) an updated emissions inventory, and 2) new control measures and commitments for emissions reductions to help fulfill the §182(e)(5) portion of the 8-hour ozone SIP and one-hour ozone SIP.

Regardless of whether or not U.S. EPA requests that the SCAQMD prepare a one-hour ozone SIP, the multi-agency effort to identify 2012 AQMP control measures that specifically address the SCAQMD's efforts to continue making progress towards attaining all state and national ambient air quality standards for ozone. For example, there are four coatings and solvent control measures (CTS 01, CTS02, CTS-03, and CTS-04; Table 1-3); two combustion control measures (CMB-01, RECLAIM phase 2, and CMB-02; Table 1-3); and five §182(e)(5) on-road mobile source control measures, five off-road mobile source control measures, and seven advanced control measures (Table 1-4) that all primarily address attaining the ozone standards.

No other control measures to attain the ozone standards were identified during the multi-agency effort to identify 2012 AQMP control measures. As a result, no additional control measures to address progress in attaining the ozone standards would likely be identified. This means that a one-hour ozone SIP would include all of the same ozone-related control measures as the 2012 AQMP. Further, by analyzing the 2012 AQMP ozone-related control measures in this Program EIR, this Program EIR would also serve as the CEQA document for a one-hour ozone SIP.

1.7 Purpose of the 2012 AQMP

The 2012 AQMP will provide an updated air pollution control strategy to attain federal ambient air quality standards and has been developed as an integrated Plan taking into consideration: air quality improvement needs, climate change, transportation, and energy reliability. The 2012 AQMP focuses on PM reductions to attain the federal 24-hour PM_{2.5} standard by 2014. The 2012 AQMP also includes ozone reduction strategies to make expeditious progress in attaining the state one-hour and eight-hour standards and the federal eight-hour ozone standards (80 parts per billion (ppb) by 2023 and 75 ppb by 2032). The 2012 AQMP also provides for meeting requirements applicable under the (revoked) one-

hour federal ozone standard. In particular the ozone strategy approach relies heavily on NOx emission reductions, primarily from mobile sources, and identifies actions that can be taken in the next two to three years. The 2012 AQMP relies upon the most recent planning assumptions and the best available information such as CARB's latest EMFAC2011 for the on-road mobile source emissions inventory, CARB's OFF-ROAD 2011 model for the off-road mobile source emission inventory, the latest point source and improved area source inventories as well as the use of new episodes and air quality modeling analysis, and SCAG's forecast assumptions based on its recent 2012 Regional Transportation Plan. The 2012 AQMP includes the current and future air quality in the Coachella Valley. The 2012 AQMP also includes a discussion of ultra-fine particles, near roadway exposure and energy.

It is expected that implementing the 2012 control measures will provide substantial benefits of improved air quality, which are numerous and far-reaching. From a public health standpoint, air pollution has been linked to long-term health problems affecting the lungs, heart, blood, brain and immune and nervous systems. Therefore, improving air quality is expected to result in improvements to public health. Additional benefits include improved visibility, reduced destruction of materials and buildings, reduced damage to agricultural crops and habitat for wildlife and, more efficient land use patterns and transportation systems. 2012 AQMP control measures have the potential reduce reliance on traditional petroleum fuels, thus, providing reductions in greenhouse gas emissions. The following sections summarize the overall components of the 2012 AQMP and the specific control measures that comprise the 2012 AQMP.

1.8 Project Description

The Draft 2012 AQMP control measures consist of three components: 1) the SCAQMD's Stationary and Mobile Source Control Measures including; 2) SCAQMD, State, and Federal Mobile Source Control Measures; and 3) Regional Transportation Strategy and Control Measures provided by SCAG. Overall, the Draft 2012 AQMP includes stationary and mobile source measures. These measures primarily rely on the traditional command-and-control approach, facilitated by market incentive programs, as well as advanced technologies expected to be implemented by 2015 (for PM2.5). A summary of these measures is provided in the following subsections. The following bullet points summarize the major components of the 2012 AQMP:

- The most current air quality setting (i.e., 2008 data);
- Updated emission inventories using 2008 as the base year, which also incorporate measures adopted since adopting the 2007 AQMP;
- Updated emission inventories of stationary and mobile on-road and off-road sources;
- Consider action on the 2007 AQMP control measures not yet implemented (through January 31, 2011, the SCAQMD Governing Board has amended and adopted 13 rules achieving approximately 96 percent of the SCAQMD's SIP commitment outlined in the 2007 AQMP);

- New measures are to be incorporated into the Draft 2012 AQMP;
- SCAG's 2012 regional transportation strategy and control measures;
- Analysis of emission reductions necessary to achieve the federal 24-hour PM_{2.5} air quality standards, and (revoked) one-hour ozone standard;
- Overview of state and federal planning requirements;
- Implementation schedule for adoption of the proposed control measures;
- Latest information on near-roadway emissions of combustion-related pollutants with particular focus on ultrafine particulates formation, transport, exposure, and health effects and potential control strategies, although there are no ambient air quality standards specifically for ultrafine particulates; and
- Energy Policy Update including: energy consumption, costs, associated emissions for base year 2008 and the future AQMP years, and associated energy impacts and GHG emissions inventory in the Basin.

1.8.1 Stationary Source Control Measures

The stationary source control measures included in the Draft 2012 AQMP would further reduce emissions from both point sources (permitted facilities) and area sources (generally small and non-permitted). The proposed control strategies for stationary sources under the SCAQMD's jurisdiction include implementing the remaining revised and partially implemented measures from the 2007 AQMP and new measures that are deemed feasible, which will provide additional emission reduction opportunities. In light of significant reductions needed for PM_{2.5} attainment demonstrations, the SCAQMD will work closely with CARB to further regulate mobile sources. In addition to PM reduction control measures, the 2012 AQMP also identifies control measures to be implemented by the SCAQMD to make progress towards attaining ambient air quality standards for ozone. These control measures include short-term and Clean Air Act §182(e) implementation, and would regulate stationary and mobile sources.

The basic principles followed in developing the SCAQMD's stationary source control measures included: 1) identify PM_{2.5}, ammonia and NO_x reduction opportunities and maximize reductions by the earliest possible and feasible attainment year, and 2) initiate programs or rulemaking activities for further VOC and NO_x control strategies to maximize ozone reductions by the year 2022-2023 timeframe. Therefore, the proposed control strategy for stationary sources under the SCAQMD's jurisdiction includes some revised and partially implemented measures from the 2007 AQMP and new measures that are deemed feasible to provide additional control opportunities. In addition, to foster further technology advancement, long-term measures are also included to achieve additional reductions from stationary sources based on implementation and accelerated penetration of advanced technologies. For each control measure, the SCAQMD will seek to achieve the maximum reduction potential that is technically feasible and cost-effective. The control measures to be

implemented by the SCAQMD are listed in Table 1-3 summarized in the paragraphs following Table 1-3.

- a. Winter average day reductions based on episodic conditions and 75 percent compliance rate
- b. Reduction based on episodic day conditions
- c. Will submit into SIP once technically feasible and cost effective options are confirmed
- d. TBD are reductions to be determined once the technical assessment is complete, and inventory and control approach are identified
- e. Pending because emission reductions will be provided prior to the Final Draft
- f. N/A are reductions that cannot be quantified due to the nature of the measure (e.g., outreach, incentive programs) or if the measure is designed to ensure reductions that have been assumed to occur will, in fact, occur
- g. Reductions submitted in SIP once emission inventories are included in the SIP
- h. TBD are reductions to be determined once the inventory and control approach are identified.

Summaries of the Stationary Source Control Measures

BCM-01 – Further Reductions from Residential Wood Burning Devices [PM2.5] (*formerly BCM-05 in the 2007 AQMP*) (*formerly control measure MCS-04B in the NOP/IS for the 2012 AQMP*): The purpose of this measure would be to seek further PM2.5 emissions reductions from residential wood burning fireplaces and wood stoves whenever key areas in the South Coast Air Basin are forecast to approach the federal 24-

hour PM_{2.5} standard. A review of other California air district regulations has indicated that the most appropriate amendment to the existing AQMD wood smoke control program would be to decrease the mandatory wood burning curtailment forecast threshold from 35 µg/m³ to a more conservative 30 µg/m³. In addition to the existing sub-regional curtailment program of Rule 445 (based on areas forecast to exceed the existing PM_{2.5} standard), this measure would implement a curtailment that would apply Basin-wide whenever a PM_{2.5} level of greater than 30 µg/m³ is forecast at any monitoring station at which the design value has exceeded the current PM_{2.5} 24-hour standard of 35 µg/m³ for either of the two previous periods. Lowering the wood burning curtailment forecast threshold and applying the curtailment to the entire Basin when triggered could potentially reduce Basin-wide ambient PM_{2.5} concentrations on these episodic no-burn days by about 7.1 tons per winter day (assuming 75% rule effectiveness).

BCM-02 – Further Reductions from Open Burning [PM_{2.5}] (new control measure added after the release of the NOP/IS): Rule 444 outlines the criteria and guidelines for agricultural and prescribed burning, as well as training burns, to minimize PM emissions and smoke in a manner that is consistent with state and federal laws. Agricultural burning is open burning of vegetative materials produced from the growing and harvesting of crops. Prescribed burning is a planned open burning of vegetative materials, usually conducted by a fire protection agency and/or department of forestry, to promote a healthier habitat for plants and animals, to prevent plant disease and pests, and to reduce the risk of wild fires. Training burns are hands-on instructional events conducted by fire protection agencies on methods of preventing and/or suppressing fire. Rule 444 currently contains requirements that a no-burn day may be called under a combination of geographical, meteorological, and air quality conditions. This control measure would potentially increase the number of no-burn days by establishing an additional criteria for no-burn during episodic days as described in control measure BCM-01 by implementing a curtailment that would apply Basin-wide whenever a PM_{2.5} level of greater than 30 µg/m³ is forecast at any monitoring station at which the design value has exceeded the current PM_{2.5} 24-hour standard of 35 µg/m³ for either of the two previous periods. Enhancing the open burning restrictions with this new threshold criteria and applying a curtailment to the entire Basin could potentially reduce Basin-wide ambient PM_{2.5} concentrations on these episodic no-burn days by about 4.6 tons per winter day. Since the burning would likely be shifted to other days, the total annual emissions would remain the same, but would not occur on days where high PM_{2.5} levels are forecast.

BCM-03 – Emission Reductions from Under-Fired Charbroilers (Rule 1138) [PM_{2.5}] (formerly BCM-05 in the 2007 AQMP) (formerly control measure BCM-01 in the NOP/IS for the 2012 AQMP): This proposed measure seeks emission reductions by potentially requiring new and/or existing medium to large volume restaurants with under-fired charbroilers to install control devices meeting a minimum efficiency requirement. Under-fired charbroilers are responsible for the majority of emissions from restaurant operations – 84 percent of PM and 71 percent of VOC emissions. Several control options are currently being evaluated and tested including electrostatic precipitators (ESP), high efficiency particulate arresting (HEPA) filters, wet scrubbers, and thermal oxidizers. Under-fired charbroilers are one of the largest unregulated sources of directly emitted PM. A technical assessment of potential control technologies is currently ongoing at University of

California, Riverside (CE-CERT), to evaluate the efficiency and the cost-effectiveness of various control devices for the capture and control of filterable and/or condensable forms of PM from under-fired charbroilers. The Bay Area AQMD adopted a rule for commercial cooking equipment that controls both chain-driven and under-fired charbroilers. The Bay Area measure will be evaluated to meet the all feasible measures requirement. A rule will be developed if deemed feasible. Technical and economic feasibility, as well as affordability of controls, particularly for existing restaurants relative to retrofit installation and operation/maintenance, will be considered in conjunction with any future rule development to establish requirements for under-fired charbroilers.

BCM-04 – Further Ammonia Reductions from Livestock Waste [Ammonia] (formerly MCS-05 in the 2007 AQMP) (formerly control measure MCS-04C in the NOP/IS for the 2012 AQMP): This measure seeks to reduce ammonia emissions from livestock operations with emphasis on dairies. Existing Rule 1127 – Emission Reductions from Livestock Waste requires best management practices for dairies and specific requirements regarding manure removal, handling, and composting; however, the rule does not focus on fresh manure, which is one of the largest dairy sources of ammonia emissions. An assessment will be conducted to evaluate the use of sodium bisulfate (SBS) at local dairies to evaluate the technical and economic feasibility of its application. Reducing pH level in manure through the application of acidulant additives (acidifier), such as SBS, is one of the potential mitigations for ammonia. SBS is currently being considered for use in animal housing areas where high concentrations of fresh manure are located. Research indicates that best results occur when SBS is used on “hot spots”. SBS can also be applied to manure stock piles and at fencelines, and upon scraping manure to reduce ammonia spiking from the leftover remnants of manure and urine. A rule will be developed if deemed feasible. SBS application may be required seasonally or episodically during times when high ambient PM2.5 levels are forecast.

CMB-01 – Further NO_x Reductions from RECLAIM [NO_x] – Phase I: This proposed control measure will seek further reductions of 2 tpd of NO_x allocations by 2014. In addition, staff would seek to identify appropriate approaches during rulemaking to implement the allocation shaving methodology. The control measure has the ability to produce co-benefits in the reduction of PM2.5 and ozone.

CMB-01 – Further Emission Reductions from NO_x RECLAIM [NO_x] – Phase II: This proposed control measure would seek further reductions in NO_x allocations by the year 2020. This phase of control is to implement periodic BARCT evaluation as required under state law. The control measure has the ability to produce co-benefits in the reduction of PM2.5 and ozone.

CMB-02 – NO_x Reductions from Biogas Flares [NO_x]: There are no source specific rules regulating NO_x emissions from biogas flares. Flare NO_x emissions are regulated through new source review and BACT. This control measure proposes that, consistent with the feasible measures, older biogas flares be gradually replaced with new flares that meet current BACT. Strategies that minimize flaring and associated emissions can also be considered as alternative control options.

CMB-03 – Reductions from Commercial Space Heating [NOx] (Rule 1111): This control measure would apply to space heaters used for comfort heating. SCAQMD Rule 1111 - NOx Emissions from Natural Gas-Fired Fan Type Central Furnaces, regulates natural gas-fired commercial space heaters with input rates less than 175,000 Btu/hr. This control measure is expected to reduce NOx emissions from affected heaters by reducing the NOx emission control limit for new space heaters for commercial applications, which can be achieved through the use of low-NOx burners or other low emitting combustion technologies.

CTS-01 – Further VOC Reductions from Architectural Coatings (Rule 1113) [VOC]: SCAQMD adopted Rule 1113 – Architectural Coatings, in 1977 and it has undergone numerous amendments. This proposed control measure seeks to reduce VOC emissions from large volume coating categories such as flat, non-flat and primer, sealer, undercoaters (PSU) and from phasing out the currently exempt use of high-VOC architectural coatings sold in one liter containers or smaller. Additional VOC emission reductions could be achieved from the application of architectural coatings by use of application techniques with greater transfer efficiency. Such transfer efficiency improvements could be achieved through the use of a laser paint targeting system, which has been shown to improve transfer efficiency on average by 30 percent over equipment not using a targeting system, depending on the size, shape and configuration of the substrate. The proposal is anticipated to be accomplished with a multi-phase adoption and implementation schedule.

CTS-02 – Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants [VOC]: This control measure seeks to reduce VOC emissions from miscellaneous coating, adhesive, solvent and lubricant categories by further limiting the allowable VOC content in formulations. Examples of the miscellaneous categories to be considered include, but are not limited to, coatings used in aerospace and marine applications; adhesives used in a variety of sealing applications; solvents for graffiti abatement activities; and lubricants used as metalworking fluids to reduce heat and friction to prolong the life of the tool, improve product quality, and carry away debris. Reductions would be achieved by lowering the VOC content of the coatings, adhesives and lubricants. For solvents, reductions could be achieved with the use of alternative low-VOC products or non-VOC product/equipment at industrial facilities. The proposal is anticipated to be accomplished with a multi-phase adoption and implementation schedule.

CTS-03 – Further VOC Reductions from Mold Release Products [VOC]: Metal, fiberglass, composite and plastic products are often manufactured using molds which form the part into a particular configuration. Mold release agents are used to ensure that the parts, as they are made, can be released easily and quickly from the molds. These agents are often blended with VOC solvent carriers and may also contain toxic components such as toluene and xylene. Mold release products are also used for concrete stamping operations to keep the mold from adhering to the fresh concrete. Residential and commercial concrete stamping is a rapidly growing industry and overall VOC emissions are estimated to be significant. This control measure would reduce VOC emissions from mold release products on metal, fiberglass, composite and plastic products, as well as concrete stamping operations, by requiring the use of low-VOC content mold release products.

CTS-04 – Further VOC Reductions from Consumer Products [VOC]: This measure seeks to eliminate or revise the exemption for low vapor pressure solvents in CARB’s consumer products regulation, which exempts low vapor pressure volatile organic compounds (LVP-VOC) from counting towards the compliance obligation for consumer product VOC limits. Recent testing conducted by the District on institutional cleaners found that traditionally formulated consumer products may contain significant amounts of LVP-VOC solvents. In some cases, such as certain multipurpose solvents, the products were 100 percent LVP-VOC solvents. Further testing indicated that many of the LVP-VOC solvents evaporate nearly as quickly as the traditional solvents they were meant to replace and have Maximum Incremental Reactivity (MIR) values well above the threshold considered to be non-reactive, currently based on ethane. Therefore, an evaluation of the continued need for use of LVP-VOC solvents in certain categories is warranted

FUG-01 – Further VOC Reductions from Vacuum Trucks [VOC]: This control measure seeks to reduce emissions from the further venting of vacuum trucks. Emissions from such operations can be reduced through the utilization of control technologies, including but not limited to, carbon adsorption systems, internal combustion engines, thermal oxidizers, refrigerated condensers and liquid scrubbers. Additionally, implementation of a leak detection and repair (LDAR) program may further reduce fugitive emissions.

FUG-02 – Emission Reduction from LPG Transfer and Dispensing [VOC]: In June 2012, the SCAQMD adopted phase I Rule 1177 - Liquefied Petroleum Gas (LPG) Transfer and Dispensing. Rule 1177 requires use of low-emission fixed liquid level gauges or equivalent alternatives while filling LPG-containing tanks and cylinders, use of low-emission connectors, routine leak checks and repairs of LPG transfer and dispensing equipment. The purpose of control measure FUG-02 is to further reduce fugitive VOC emissions associated with the transfer and dispensing of LPG by expanding rule applicability to include LPG transfer and dispensing at currently exempted facilities such as refineries, marine terminals, natural gas processing plants and pipeline transfer stations, as well as facilities that conduct fill-by-weight techniques.

FUG-03 – Further VOC Reductions from Fugitive VOC Emissions [VOC]: This control measure would broaden the applicability of improved leak detection and repair (LDAR) programs to remove additional fugitive VOC emissions. Areas for further study may include, but are not limited to, Rule 1142 - Marine Vessel Tank Operations, and wastewater separators. This control measure would explore the opportunity of incorporating a recently developed advanced optical gas imaging technology to detect leaks (Smart LDAR) to more easily identify and repair leaks in a manner that is less time consuming and labor intensive. Additionally, vapor recovery systems are currently required to have a control efficiency of 95 percent. In an effort to further reduce VOC emissions from these types of operations, this control measure would explore opportunities and the feasibility of further improving the collection/control efficiency of existing control systems, resulting in additional VOC reductions.

MCS-01 – Application of All Feasible Measures Assessment [All Pollutants]: This control measure is to address the state law requirement for all feasible measures for ozone. Existing rules and regulations for pollutants such as VOC, NOx, SOx and PM typically

reflect BARCT requirements at the time the rules or regulations were adopted or amended. However, BARCT continually evolves as feasible and cost-effective new technology becomes available or becomes more efficient. Through this proposed control measure, the SCAQMD would commit to the adoption and implementation of the new retrofit control technology standards. Finally, staff would review actions taken by other air districts for applicability in the district.

MCS-02 – Further Emission Reductions from Green Waste Processing (Chipping and Grinding Not Associated with Composting) [VOC]: Chipped or ground greenwaste and/or woodwaste have the potential to emit VOCs when being stockpiled or land-applied for various purposes. Chipping and grinding is a process to mechanically reduce the size of greenwaste and woodwaste pieces. SCAQMD rules have established best management practices (BMPs) for greenwaste composting and related operations under Rule 1133.1 – Chipping and Grinding Activities, and Rule 1133.3 – Greenwaste Composting Operations. During rule development, stakeholders raised the need to develop a holistic approach to identifying and accounting for emissions from all greenwaste streams and reducing potential emissions from greenwaste material handling operations at chipping and grinding facilities and other related facilities, not just the ones associated with composting operations. This control measure would seek to establish additional BMPs for handling processed or unprocessed greenwaste material by greenwaste processors, haulers, and operators who inappropriately stockpile material or directly apply the material to land. The implementation of the control measure would be in two phases. First, the existing database would be reviewed to refine greenwaste material inventory, and second, a rule would potentially be developed to incorporate technically feasible and cost-effective BMPs or controls.

MCS-03 – Improved Start-up, Shutdown and Turnaround Procedures [All Pollutants] (formerly MCS-06 in the 2007 AQMP): This proposed control measure seeks to reduce emissions during equipment startup, shutdown, and turnaround. Opportunities for further reducing emissions from start-up, shut-down and turnaround activities potentially exist at refineries as well as other industries. Examples of possible areas for improvement may include implementing BMPs, promoting better engineering and equipment design, diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability. This measure will be implemented through a two-phase effort to first collect/refine emissions and related data and then, based on the data collected, assess viable controls, if appropriate.

IND-01 - Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources [NO_x, SO_x, PM_{2.5}] (formerly MOB-03 in the 2007 AQMP): This measure would be designed to ensure NO_x, SO_x and PM_{2.5} emissions reductions from port-related sources are sufficient to attain the 24-hour federal PM_{2.5} ambient air quality standard. If emission levels projected to result from the current regulatory requirements and voluntary reduction strategies specified by the Ports are not realized, the 24-hr federal PM_{2.5} ambient air quality standard may not be achieved. This control measure is designed to ensure that the necessary emission reductions from port-related sources projected in the 2012 AQMP milestone years are achieved or if it is later determined through a SIP amendment that additional region-wide reductions are needed due to the change in Basin-

wide carrying capacity for PM_{2.5} attainment. In this case, the ports will be required to further reduce their emissions on a “fair-share” basis.

INC-01: Economic Incentive Programs to Adopt Zero and Near-Zero Technologies [NO_x]: The primary objective of this measure is to develop a program that promotes and encourages adoption and installation of cleaner, more efficient combustion equipment, such as boilers, water heaters and commercial space heating, through economic incentive programs subject to the availability of public funding. Incentives may include grants for new purchases of equipment as well as loan programs in areas where long-term cost savings from increased efficiency are achieved.

INC-02: Expedited Permitting and CEQA Preparation Facilitating the Manufacturing of Zero and Near-Zero Technologies [All Pollutants]: This proposed measure is aimed at providing incentives for companies to manufacture zero and near-zero emission technologies locally, thus, populating the market, potentially lowering the purchase cost, and increasing demand. With availability and usage of such technologies, air quality benefits would be achieved. This proposed measure focuses on two elements: 1) processing the required air permit(s) in an expedited procedure; and 2) prioritizing the preparation, circulation and certification of any applicable CEQA document where the SCAQMD is the lead agency. A stakeholder process will be initiated to design the program and collaborate with other existing AQMD or local programs.

EDU-01: Further Criteria Pollutant Reductions from Education Outreach and Incentives [All Pollutants] (formerly MCS-02, MCS-03): This proposed control measure would provide educational outreach and incentives for consumers to contribute to clean air efforts. Examples include the usage of energy efficient products, new lighting technology, “super compliant” coatings, tree planting, and the use of lighter colored roofing and paving materials which reduce VOC or NO_x by lowering the ambient temperature. In addition, this proposed measure intends to increase the effectiveness of energy conservation programs through public education and awareness as to the environmental effects and benefits from conservation. Finally, educational and incentive tools to be used include social comparison applications (e.g., lifestyle comparisons of personal energy use and efficiency), social media, and public/private partnerships.

1.8.2 Mobile Source Control Measures (Federal, State and/or District)

This subsection describes SCAQMD staff’s proposed control measures to be included in the 2012 AQMP to reduce mobile source emissions to provide progress in attaining the eight-hour ozone and one-hour ozone ambient air quality standards by 2022-2023. The §182(e)(5) proposed implementation measures presented in this subsection are based upon a variety of control technologies that are commercially available and/or technologically feasible to implement in the next several years. The focus of these measures includes accelerated retrofits or replacement of legacy fleets of vehicles or equipment, acceleration of vehicle turnover through voluntary vehicle retirement programs, and greater use of cleaner fuels in the near-term. In the longer-term, in order to attain the federal ozone ambient air quality standard, there is a need to increase the penetration and deployment of near-zero and zero-emissions vehicles such as plug-in hybrids, battery-electric, and fuel cell vehicles;

accelerate the penetration and use of cleaner fuels (either alternative fuels or new formulations of gasoline and diesel fuels); and obtain additional emission reductions from aircraft engines. As set forth in the descriptions of individual control measures in Table 2-4, some of the measures will likely require action by CARB, while some control measures recognize actions being taken by other agencies.

**TABLE 1-4
Mobile Source Control Measures Categorized by Source Type**

§182(e) Proposed Implementation 8-Hour Ozone Measures – On-Road Mobile Sources				
CM Number	Title	Adoption	Implementation Period	Reduction (tpd)
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles [VOC, NOx, PM]	N/A	Ongoing	TBD ^a
ONRD-02	Accelerated Retirement of Older Light-Duty and Medium-Duty Vehicles [VOC, NOx, PM]	N/A	Ongoing	TBD ^a
ONRD-03	Accelerated Penetration of Partial Zero-Emission and Zero Emission Light Heavy-Duty Vehicles [NOx, PM]	N/A	Ongoing	TBD ^a
ONRD-04	Accelerated Retirement of Older Heavy-Duty Vehicles [NOx, PM]	N/A	Ongoing	TBD ^{a,b}
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards [NOx, PM]	2014	2015-2020	0.75 [NOx] 0.025 [PM2.5]
§182(e) Proposed Implementation 8-Hour Ozone Measures – Off-Road Mobile Sources				
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment [NOx]	N/A	Ongoing	7.5
OFFRD-02	Further Emission Reductions from Freight Locomotives [NOx, PM]	Ongoing	2015 -2023	12.7 [NOx] 0.32 [PM2.5]
OFFRD-03	Further Emission Reductions from Passenger Locomotives [NOx, PM]	Ongoing	Beginning 2014	3.0 [NOx] ^c 0.06 [PM2.5] ^c
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels While at Berth [NOx, PM]	N/A	Ongoing	TBD ^a
OFFRD-05	Emission Reductions from Ocean-Going marine Vessels [NOx]	N/A	Ongoing	TBD ^a

**TABLE 1-4 (Concluded)
Mobile Source Control Measures Categorized by Source Type**

§182(e) Proposed Implementation Measures to Deploy Advanced Control Technologies				
ADV-01	§182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles [NOx]	N/A	2012 and on	TBD ^d
ADV-02	§182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives [NOx]	N/A	2012 and on	TBD ^d
ADV-03	§182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment [NOx]	N/A	2012 and on	TBD ^d
ADV-04	§182(e) Proposed Implementation Measures for the Deployment of Cleaner Commercial Harborcraft [NOx]	N/A	2012 and on	TBD ^d
ADV-05	§182(e) Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels [NOx]	N/A	2012 and on	TBD ^d
ADV-06	§182(e) Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment [NOx]	N/A	2012 and on	TBD ^d
ADV-07	§182(e) Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines [NOx]	N/A	2012 and on	TBD ^d

- a. Emission reductions will be determined after projects are identified and implemented
- b. Reductions achieved locally in Mira Loma region
- c. Submitted into the SIP once technically feasible and cost effective options are confirmed
- d. Emission reductions will be quantified after the projects are demonstrated.

Summaries of §182(e)(5) Implementation 8-Hour Ozone Measures – On-Road Mobile Sources

By 2023, it is estimated that about 12 million vehicles will be operating in the Basin. To address emissions from these vehicles, SCAQMD staff is proposing five on-road mobile source control measures. The first two measures focus on on-road light- and medium-duty vehicles operating in the South Coast Air Basin, while the remaining three measures focus on heavy-duty vehicles. Summaries of each of the five on-road mobile source control measures are provided in the following paragraphs.

ONRD-01 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles [NOx]: This measure proposes to continue incentives for the purchase of zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode. The state Clean Vehicle Rebate Pilot (CVRP) program is proposed to continue from 2015 to 2023 with a proposed funding for up to \$5,000 per vehicle. The

proposed measure seeks to provide funding assistance for up to 1,000 zero-emission or partial-zero emission vehicles per year.

ONRD-02 – Accelerated Retirement of Older Light-Duty and Medium-Duty Vehicles [NO_x]: This proposed measure calls for promoting the permanent retirement of older eligible vehicles through financial incentives currently offered through local funding incentive programs and the AB 118 Enhanced Fleet Modernization Program (EFMP). The proposed measure seeks to retire up to 2,000 older light- and medium-duty vehicles (up to 8,500 lbs gross vehicle weight) per year. Funding incentives of up to \$2,500 per vehicle are proposed for the scrapping of the vehicle, which may include a replacement voucher for a newer or new vehicle.

ONRD-03 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium Heavy-Duty Vehicles [NO_x]: The objective of the proposed action is to accelerate the introduction of advanced hybrid and zero-emission technologies for Class 4 through 6 heavy-duty vehicles. The state is currently implementing a Hybrid Vehicle Incentives Project (HVIP) program to promote zero-emission and hybrid heavy-duty vehicles. The proposed measure seeks to continue the program from 2015 to 2023 to deploy up to 1,000 zero- and partial-zero emission vehicles per year with up to \$25,000 funding assistance per vehicle. Zero-emission vehicles and hybrid vehicles with a portion of their operation in an “all electric range” mode would be given the highest priority.

ONRD-04 – Accelerated Retirement of Older Heavy-Duty Vehicles [NO_x]: This proposed measure seeks to replace up to 1,000 heavy-duty vehicles per year with newer or new vehicles that at a minimum, meet the 2010 on-road heavy-duty NO_x exhaust emissions standard of 0.2 g/bhp-hr. Given that exceedances of the 24-hour PM_{2.5} air quality standard occur in the Mira Loma region, priority will be placed on replacing older diesel trucks that operate primarily at the warehouse and distribution centers located in the Mira Loma area. Funding assistance of up to \$35,000 per vehicle is proposed and the level of funding will depend upon the NO_x emissions certification level of the replacement vehicle. In addition, a provision similar to the Surplus Off-Road Option for NO_x (SOON) provision of the statewide In-Use Off-Road Fleet Vehicle Regulation will be sought to ensure that additional NO_x emission reduction benefits are achieved.

ONRD-05 – Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards [NO_x, PM]: This proposed control measure calls for a requirement that any cargo container moved between the Ports of Los Angeles and Long Beach to the nearby railyards (the Intermodal Container Transfer Facility and the proposed Southern California International Gateway) be with zero-emission technologies. The measure would be fully implemented by 2020 through the deployment of zero-emission trucks or any alternative zero-emission container movement system such as a fixed guideway system. The measure calls for CARB to either adopt a new regulation or amend an existing regulation to require such deployment by 2020. To the extent the measure can feasibly be extended beyond near-dock railyards, this would be considered for adoption by CARB.

§182(e)(5) Implementation 8-Hour Ozone Measures – Off-Road Mobile Sources: SCAQMD staff is proposing five control measures that seek further emission reductions from off-road mobile sources and industrial equipment. Off-road mobile sources such as aircraft, locomotives, and marine vessels are principally regulated by federal and state agencies. In addition, several of the off-road mobile source control measures include certain local actions that can result in emission reductions beyond the emissions standard setting authority of the state and EPA. Summaries of each of the five off-road mobile source control measures are provided in the following paragraphs.

OFFRD-01 – Extension of the SOON Provision for Construction/Industrial Equipment [NO_x]: This measure seeks to continue the Surplus Off-Road Option for NO_x (SOON) provision of the statewide In-Use Off-Road Fleet Vehicle Regulation beyond 2014 through the 2023 timeframe. In order to implement the SOON program in this timeframe, funding of up to \$30 million per year would be sought to help fund the repower or replacement of older Tier 0 and Tier 1 equipment, with reductions that are considered surplus to the statewide regulation with Tier 4 or cleaner engines.

OFFRD-02 – Further Emission Reductions from Freight Locomotives [NO_x]: The proposed control measure is to meet the commitment in the 2007 SIP for the accelerated use of Tier 4 locomotives in the South Coast Air Basin. The measure calls for CARB to seek further emission reductions from freight locomotives through enforceable mechanisms within its authority to achieve 95 percent or greater introduction of Tier 4 locomotives by 2023.

OFFRD-03 – Further Emission Reductions from Passenger Locomotives [NO_x]: This measure recognizes the recent actions by the Southern California Regional Rail Authority (SCRRA or Metrolink) to consider replacement of their existing Tier 0 passenger locomotives with Tier 4 locomotives. The SCRRA adopted a plan that contains a schedule to replace their older existing passenger locomotives with Tier 4 locomotives by 2017. More recently, SCRRA released a Request for Quotes on the cost of new or newly manufactured passenger locomotives with locomotive engines that meet Tier 4 emission levels.

OFFRD-04 – Further Emission Reductions from Ocean-Going Marine Vessels While at Berth [NO_x]: This measure seeks additional emission reductions from ocean-going marine vessels while at berth. The actions would affect ocean-going vessels that are not subject to the statewide Shorepower Regulation or vessel calls that are considered surplus to the statewide regulation. The measure seeks at a minimum to have an additional 25 percent of vessel calls beyond the statewide regulation to deploy shorepower technologies or alternative forms of emissions reduction as early as possible. Such actions could be implemented through additional incentives programs or through the San Pedro Bay Ports as part of the implementation of the Ports Clean Air Action Plan.

OFFRD-05 – Emission Reductions from Ocean-Going Marine Vessels [NO_x]: This measure recognizes the recent actions at the Ports of Los Angeles and Long Beach to initiate an incentives program for cleaner ocean-going vessels to call at the ports. The program has been initiated as part of the San Pedro Bay Ports Clean Air Action Plan. The program will

provide financial incentives for cleaner Tier 2 and Tier 3 ocean-going vessels to call at the ports. This measure also recognizes the need to monitor progress under such programs and augment them as necessary to ensure sufficient results. The program will be monitored on annual basis and, if necessary, any adjustments to the program will be made.

§182(e)(5) Implementation to Deploy Advanced Control Technologies

SCAQMD staff is also proposing the following seven additional §182(e) proposed implementation measures to deploy the cleanest control technologies as early as possible and the development, demonstration, and deployment of near-zero and zero-emission technologies. Many of these actions have already begun. However, additional research and development will be needed that will lead to commercial development of control technologies that achieve emission levels below current adopted emission standards. Other near-zero and zero-emission technologies that are commercially available will require infrastructure development to facilitate their deployment.

ADV-01 – §182(e)(5) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles [NOx] This measure would continue the efforts underway to develop zero-emission and near-zero emission technologies for on-road heavy-duty vehicle applications. Such technologies include, but not limited to, fuel cell, battery-electric, hybrid-electric with all electric range, and overhead catenary systems. Hybrid-electric systems incorporate an engine powered by conventional fuels or alternative fuels such as natural gas. The actions provided in the proposed measure are based on the SCAG 2012 Regional Transportation Plan.

ADV-02 – §182(e)(5) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Locomotives [NOx] This measure calls for the development and deployment of zero-emission and near-zero emission technologies for locomotives. Such technologies include overhead catenary systems, hybrid locomotives that have some portion of their operation in an “all electric range” mode, and alternative forms of external power such as a battery tender car. The actions provided in the proposed measure are based on the SCAG 2012 Regional Transportation Plan. The zero-emission technologies could apply to freight and passenger locomotives.

ADV-03 – §182(e)(5) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment [NOx] This measure recognizes the actions underway to develop and deploy zero- and near-zero emission technologies for various cargo handling equipment. The San Pedro Bay Ports are currently demonstrating battery-electric yard tractors. In addition, battery-electric, fuel cell, and hybridized systems could be deployed on smaller cargo handling equipment. In addition, the use of alternative fuels for conventional combustion engines could potentially result in greater emissions benefits.

ADV-04 – §182(e)(5) Proposed Implementation Measures for the Deployment of Cleaner Commercial Harborcraft [NOx] Several commercial harbor craft operators have begun deployment of hybrid systems in their harbor craft to further reduce criteria pollutant emissions and improve fuel efficiency. Other cleaner technologies include the use of alternative fuels, retrofit of existing older marine engines with selective catalytic converters,

and diesel particulate filters. This measure recognizes several efforts between the District and the Ports of Los Angeles and Long Beach to further demonstrate control technologies that could be deployed on commercial harbor craft that could go beyond the statewide Harbor Craft Regulation.

ADV-05 – §182(e)(5) Proposed Implementation Measures for the Deployment of Cleaner Ocean-Going Marine Vessels [NO_x] The Ports of Los Angeles and Long Beach, CARB, and the District have sponsored research and demonstration of various control technologies to further reduce emissions from ocean-going vessels. In addition, the San Pedro Bay Ports Clean Air Action Plan contains a measure to further demonstrate such technologies on ocean-going vessels. This measure recognizes many of these efforts and the need to further demonstrate retrofit technologies on existing ocean-going vessels.

ADV-06 – §182(e)(5) Proposed Implementation Measures for the Deployment of Cleaner Off-Road Equipment [NO_x] The District, Mobile Source Air Pollution Reduction Review Committee (MSRC), and CARB have been conducting an off-road “showcase” program for retrofit technologies to further reduce emissions from older off-road equipment. In addition, several major off-road engine manufacturers are investigating the potential use of hybrid systems to further reduce criteria pollutant and greenhouse gas emissions. Potential advanced technologies include hybrid systems that utilize batteries, fuel cells, or plug-in capabilities, which could result in lower emissions compared to Tier 4 emission levels when combined with future Tier 4 compliant engines. The measure is implemented by the District, CARB and U.S. EPA.

ADV-07 – §182(e)(5) Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines [NO_x] This measure recognizes the efforts of the Federal Aviation Administration’s Continuous Lower Energy, Emissions and Noise (CLEEN) Program. The goal of the CLEEN Program is the development of new aircraft engines that potentially can be up to 60 percent cleaner in NO_x emissions than current aircraft engines. The actions under this measure are to continue the development of cleaner aircraft engines and work with the airlines and local airport authorities to develop mechanisms to route the cleanest aircraft to serve the South Coast Air Basin.

1.8.3 Transportation Control Measures from the Southern California Association of Governments 2012 Regional Transportation Plan and Sustainable Communities Strategy

The Southern California Association of Governments (SCAG), the Metropolitan Planning Organization (MPO) for Southern California, is mandated to comply with federal and state transportation and air quality regulations. Further, pursuant to California Health and Safety Code (HSC) §40460, SCAG has the responsibility of preparing and approving the portions of the AQMP related to regional demographic projections and integrated regional land use, housing, employment, and transportation programs, measures, and strategies. The SCAQMD combines its portion of the AQMP with those portions prepared by SCAG and required by HSC §40460.

The transportation strategy and transportation control measures (TCMs) to be included as part of the 2012 PM2.5 AQMP and SIP for the South Coast Air Basin, as defined in the Health and Safety Code, are based on SCAG's adopted 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) and 2011 Federal Transportation Improvement Program (FTIP), which were developed in consultation with federal, state and local transportation and air quality planning agencies and other stakeholders. A list of the TCMs from the 2012-2035 RTP/SCS can be found in Appendix B of this recirculated NOP/IS.

The Regional Transportation Strategy and Transportation Control Measures portion of the 2012 AQMP/SIP consists of the following three related sections.

- Section I. Linking Regional Transportation Planning to Air Quality Planning: As required by federal and state laws, SCAG is responsible for ensuring that the regional transportation plan, program, and projects are supportive of the goals and objectives of AQMPs/SIPs. SCAG is also required by state law to develop demographic projections and regional transportation strategy and control measures for the AQMPs/SIPs. SCAG prepares the RTP/SCS, which is updated every four years, and the Federal Transportation Improvement Plan biennially.
- Section II. Regional Transportation Strategy and Transportation Control Measures: The 2012-2035 RTP/SCS was formally adopted by the SCAG Regional Council on April 4, 2012. The 2012-2035 RTP/SCS contains a host of improvements to every component of the regional multimodal transportation system including:
 - Active transportation (non-motorized transportation, such as biking and walking)
 - Transportation demand management (TDM)
 - Transportation system management (TSM)
 - Transit
 - Passenger and high-speed rail
 - Goods movement
 - Aviation and airport ground access
 - Highways
 - Arterials
 - Operations and maintenance

Included within these transportation system improvements are projects that reduce vehicle use or change traffic flow or congestion conditions ("TCMs"). TCMs include the following three main categories of transportation improvement projects and programs:

- High occupancy vehicle (HOV) measures,
- Transit and systems management measures, and
- Information-based transportation strategies.

- Section III. Reasonably Available Control Measure Analysis: As required by the CAA, a RACM analysis must be included as part of the overall control strategy in the AQMP/SIP to ensure that all potential control measures are evaluated for implementation and that justification is provided for those measures that are not implemented. Based on this comprehensive review, it is determined that the TCMs being implemented in the South Coast Air Basin are inclusive of all TCM RACM. None of the candidate measures reviewed and determined to be infeasible meets the criteria for RACM implementation.

The 2012-2035 RTP/SCS was formally adopted by the SCAG Regional Council on April 4, 2012. In conjunction with preparing the 2012-2035 RTP/SCS, SCAG also prepared a 2012 Final Program EIR (State Clearinghouse # 2011051018) for the 2012-2035 RTP/SCS to evaluate potential impacts from the project at the program level. Potential adverse impacts from implementing the TCMs were also evaluated in the 2012 Final Program EIR. The Program EIR for the 2012 AQMP will rely on the environmental analyses in SCAG's 2012 Final Program EIR for the 2012-2035 RTP/SCS for the evaluation of the environmental impacts of implementing the TCMs. Environmental impacts from implementing the TCMs will be addressed in the Draft Program EIR for the 2012 AQMP under cumulative impacts.

1.8.3 Coordination with the State's Greenhouse Gas Reduction Efforts

The Basin faces several ozone and PM attainment challenges, as strategies for significant emission reductions become harder to identify and the federal standards continue to become more stringent. California's Greenhouse Gas reductions targets under AB32 add new challenges and timelines that affect many of the same sources that emit criteria pollutants. In finding the most cost-effective and efficient path to meet multiple deadlines for multiple air quality and climate objectives, it is essential that an integrated planning approach is developed. Responsibilities for achieving these goals span all levels of government, and coordinated and consistent planning efforts among multiple government agencies are a key component of an integrated approach.

To this end, and concurrent with the development of the 2012 AQMP, the District, the Air Resources Board, and San Joaquin Valley Air Pollution Control District engaged in a joint effort to take a coordinated and integrated look at strategies needed to meet California's multiple air quality and climate goals, as well as its energy policies. California's success in reducing smog has largely relied on technology and fuel advances, and as health-based air quality standards are tightened, the introduction of cleaner technologies must keep pace. More broadly, a transition to zero- and near-zero emission technologies is necessary to meet 2023 and 2032 air quality standards and 2050 climate goals. Many of the same technologies will address air quality, climate and energy goals. As such, strategies developed for air quality and climate change planning should be coordinated to make the most efficient use of limited resources and the time needed to develop cleaner technologies. The product of this collaborative effort, the draft *Vision for Clean Air: A Framework for Air Quality and Climate Planning*, examines how those technologies can meet both air quality and climate goals over time. A public review draft of this document is now available at <http://www.aqmd.gov/aqmp/2012aqmp/> and serves as context and a resource for the 2012 AQMP.

1.8.4 Ultrafine Particles

The Draft 2012 AQMP also includes a discussion of the emerging issues of ultrafine particle and near-roadway exposures. There is growing concern about the potential health effects as caused by exposure for people living near major roadways to criteria pollutants and air toxics emitted from both gasoline and diesel vehicles (HEI, 2010). Recent toxicological and epidemiological studies have identified living near major roadways as a risk factor for respiratory and cardiovascular problems and other health related issues. These very minute particles (consisting primarily of organic material, soot, and trace elements) have a different chemical composition than the larger PM fractions (PM_{2.5} and PM₁₀). Due to their small size, UFPs can penetrate deeply into the human respiratory tract, into the blood stream, and be transported to other critical organs such as the heart and brain. Furthermore, their large surface area may provide a mechanism for delivering potentially toxic adsorbed material into the lung and other organs.

UFPs are emitted from almost every fuel combustion process, including diesel, gasoline, and jet engines, as well as external combustion processes such as wood burning. Consequently, there is growing concern that people living in close proximity to highly trafficked roadways and other sources of combustion-related pollutants (e.g. airports and rail yards) may be exposed to significant levels of UFPs and other air toxics.

Over the last decade, substantial efforts have been made to better characterize the physical and chemical properties of UFPs and their potential impact on people living in close proximity to roadways and other emissions sources. Two areas of research have received particular attention:

- On-roadways, near-roadways, and in-vehicle measurements
- Effect of UFP reduction technologies

From a regulatory perspective, the U.S. focus has been on reducing the mass of PM emitted in the ambient air. However, UFPs contribute a very small portion of the overall atmospheric particle mass concentration. Thus, there has been growing interest over the last two decades to study, understand, and regulate the size and number of particles found in PM generated from diesel and other combustion engines. Partly because light-duty diesel vehicles are very common in European countries, the European Union has already adopted standards that phase in particle number limits for passenger car and light-duty vehicle emissions. However, there are still concerns related to the health impacts of non-solid organic UFP components that are not addressed by the European solid particle number standard.

Recently, CARB staff prepared a preliminary discussion paper on proposed amendments to California's Low-Emission Vehicle (LEV III) Regulations, to address UFP emissions from light-duty motor vehicles by promoting a solid particle number based PM compliance strategy (CARB, 2010)². CARB staff ultimately decided that the complexity of the issues warranted further study and understanding before proceeding. Although the District has limited authority to regulate mobile source pollution in the near-roadway environment,

² http://www.arb.ca.gov/msprog/levprog/leviii/meetings/051810/pm_disc_paper-v6.pdf

District staff has implemented a variety of measures to assess and reduce the health impacts of near-roadway emissions on local communities. The District continues to demonstrate and incentivize the deployment of zero/near-zero emission technology, has implemented numerous installations of high-efficiency air filtration in schools, and conducts outreach and education on near-roadway health impacts. Furthermore, on July 1, 2012 the District began the next Multiple Air Toxics Exposure Study (MATES IV) to characterize the carcinogenic risk from exposure to air toxics in the Basin. A new focus of MATES IV will be the inclusion of measurements of UFP and BC concentrations across the Basin, and near specific combustion sources (e.g. airports, freeways, rail yards, busy intersections, and warehouse operations) to evaluate the long- and short-term exposures to these pollutants.

Environmental impacts from implementing potential control, mitigation, and policy strategies for limiting exposures to ultrafine particles will be addressed in the Draft Program EIR for the 2012 AQMP under cumulative impacts.

1.9 Project Objectives

CEQA Guidelines §15124(b) requires an EIR to include a statement of objectives, which describes the underlying purpose of the proposed project. The purpose of the statement of objectives is to aid the lead agency in identifying alternatives and the decision-makers in preparing a statement of findings and a statement of overriding considerations, if necessary. The objectives of the proposed 2012 AQMP are summarized in the following bullet points. These objectives may be refined or modified as part of the Program EIR preparation process.

- Reduce PM_{2.5} nonattainment pollutants and their precursors on an expeditious implementation schedule;
- Demonstrate attainment of the 24-hour PM_{2.5} national ambient air quality standard by 2014;
- Continue making expeditious progress towards attaining the federal eight-hour standard and demonstrate attainment of the federal one-hour ozone standard (revoked) by 2022 – 2023 timeframe;
- Reduce population exposure to nonattainment pollutants (i.e., ozone and PM_{2.5} for the Basin) according to a prescribed schedule;
- Rank control measures by cost-effectiveness and implementation priority;
- Update planning assumptions and the best available information such as CARB's latest EMFAC2011 for the on-road mobile source emissions inventory, CARB's OFF-ROAD 2011 model;
- Update emission inventories using 2008 as the base year, which also incorporate measures adopted since adopting the 2007 AQMP; and
- Update any remaining control measures from the 2007 AQMP.

1.10 Project Alternatives

The Program EIR will discuss and compare alternatives to the proposed project as required by CEQA where there are potential significant adverse environmental impacts. Alternatives must include realistic measures for attaining the basic objectives of the proposed project and provide a means for evaluating the comparative merits of each alternative. In addition, the range of alternatives must be sufficient to permit a reasoned choice and it need not include every conceivable project alternative. The key issue is whether the selection and discussion of alternatives fosters informed decision making and public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative.

Alternatives in SCAQMD CEQA documents are typically developed based in part on the major components of the proposed project or different pollutant control strategies. The rationale for selecting alternatives rests on CEQA's requirement to present "realistic" alternatives; that is alternatives that can actually be implemented. CEQA also requires an evaluation of a "No Project Alternative." SCAQMD's policy document Environmental Justice Program Enhancements for fiscal year (FY) 2002-03, Enhancement II-1 recommends that all SCAQMD CEQA assessments include a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a "least harmful" perspective with regard to hazardous air emissions.

Alternatives to the 2012 AQMP are relatively limited because the AQMP currently identifies all feasible control measures. Further, the 2012 AQMP is required to demonstrate attainment of the PM_{2.5} national ambient air quality standard. Project alternatives to the 2012 AQMP currently being developed include the following:

- No Project, continued implementation of the 2007 AQMP);
- Localized PM control in the Mira Loma area (the project described in the June 27, 2012 NOP/IS);
- Greater NO_x control, e.g., accelerated penetration of: heavy-duty on-road vehicles to 2010 engine model or ZEV standards; off-road construction vehicles to Tier 4 standards; and
- A PM_{2.5} only AQMP.

The Governing Board may choose to adopt any portion or all of any alternative presented in the EA with appropriate findings as required by CEQA. The Governing Board is able to adopt any portion or all of any of the alternatives presented because the impacts of each alternative will be fully disclosed to the public and the public will have the opportunity to comment on the alternatives and impacts generated by each alternative.

Written suggestions on potential project alternatives received during the comment period for the Initial Study will be considered when preparing the Program EIR.

CHAPTER 2 - ENVIRONMENTAL CHECKLIST

Introduction

General Information

Potentially Significant Impact Areas

Determination

Environmental Checklist and Discussion

INTRODUCTION

The environmental checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. This checklist identifies and evaluates potential adverse environmental impacts that may be created by the proposed project. Responses to checklist questions provide a sampling of control measures that may create significant adverse impacts to that environmental topic area and do not necessarily represent a comprehensive list of all control measures that could create impacts to that environmental topic area. Table A-1 in Appendix A provides a list of all 2012 AQMP stationary and on-road and off-road mobile source control measures and identifies each environmental topic area that could be adversely affected by those measures.

GENERAL INFORMATION

Project Title:	Proposed 2012 Air Quality Management Plan
Lead Agency Name:	South Coast Air Quality Management District
Lead Agency Address:	21865 Copley Drive, Diamond Bar, CA 91765
CEQA Contact Person:	Jeffrey J. Inabinet, (909) 396-2453
2012 AQMP Contact Person:	Mike Krause (909) 396-2706
Project Sponsor's Name:	South Coast Air Quality Management District
Project Sponsor's Address:	21865 Copley Drive, Diamond Bar, CA 91765
General Plan Designation:	Not applicable
Zoning:	Not applicable
Description of Project:	The 2012 AQMP identifies control measures to demonstrate that the region will attain the 24-hour federal standard for particulate matter less than 2.5 microns in diameter (PM2.5) by the applicable target dates and provides Clean Air Act §182(e)(5) proposed implementation measures to assist in achieving the 8-hour ozone standard. The Draft 2012 AQMP control measures consist of three components: 1) the SCAQMD's Stationary and Mobile Source Control Measures; 2) State and Federal Control Measures; and 3) Regional Transportation Strategy and Control Measures provided by SCAG. Overall, the Draft 2012 AQMP includes stationary and mobile source measures. The AQMP also includes the most current air quality setting, updated emissions inventories of stationary and mobile sources, updated growth projections, new modeling techniques, compliance with contingency requirements, and an implementation schedule for adoption of the proposed control measures.
Surrounding Land Uses and Setting:	Industrial, commercial, and potentially residential
Other Public Agencies Whose Approval is Required:	Not applicable

POTENTIALLY SIGNIFICANT IMPACT AREAS

The following environmental impact areas have been assessed to determine their potential to be affected by the proposed project. As indicated by the checklist on the following pages, environmental topics marked with a "✓" may be adversely affected by the proposed project. An explanation relative to the determination of impacts can be found following the checklist for each area.

- | | | |
|--|---|--|
| <input checked="" type="checkbox"/> Aesthetics | <input type="checkbox"/> Geology and Soils | <input type="checkbox"/> Population and Housing |
| <input type="checkbox"/> Agriculture and Forestry Resources | <input checked="" type="checkbox"/> Hazards and Hazardous Materials | <input type="checkbox"/> Public Services |
| <input checked="" type="checkbox"/> Air Quality and Greenhouse Gas Emissions | <input checked="" type="checkbox"/> Hydrology and Water Quality | <input type="checkbox"/> Recreation |
| <input type="checkbox"/> Biological Resources | <input type="checkbox"/> Land Use and Planning | <input checked="" type="checkbox"/> Solid/Hazardous Waste |
| <input type="checkbox"/> Cultural Resources | <input type="checkbox"/> Mineral Resources | <input checked="" type="checkbox"/> Transportation/Traffic |
| <input checked="" type="checkbox"/> Energy | <input type="checkbox"/> Noise | <input checked="" type="checkbox"/> Mandatory Findings |

DETERMINATION

On the basis of this initial evaluation:

- I find that although the proposed project could have a significant effect on the environment, there will NOT be significant effects in this case because revisions in the project have been made by or agreed to by the project proponent. A NEGATIVE DECLARATION will be prepared.
- I find that although the proposed project could have a significant effect on the environment, there will NOT be significant effects in this case because revisions in the project have been made by or agreed to by the project proponent. A MITIGATED NEGATIVE DECLARATION will be prepared.
- I find that the proposed project MAY have a significant effect(s) on the environment, and a PROGRAM ENVIRONMENTAL IMPACT REPORT will be prepared.
- I find that the proposed project MAY have a "potentially significant impact" on the environment, but at least one effect: 1) has been adequately analyzed in an earlier document pursuant to applicable legal standards, and 2) has been addressed by mitigation measures based on the earlier analysis as described on attached sheets. An ENVIRONMENTAL IMPACT REPORT is required, but it must analyze only the effects that remain to be addressed.
- I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects: (a) have been analyzed adequately in an earlier NEGATIVE DECLARATION or ENVIRONMENTAL IMPACT REPORT pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier NEGATIVE DECLARATION or ENVIRONMENTAL IMPACT REPORT, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

ENVIRONMENTAL CHECKLIST AND DISCUSSION

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
I. AESTHETICS. Would the project:				
a) Have a substantial adverse effect on a scenic vista?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
b) Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Substantially degrade the existing visual character or quality of the site and its surroundings?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
d) Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential aesthetics resources impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse aesthetics resources impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse aesthetics resources impacts.

Significance Criteria

The proposed project impacts on aesthetics will be considered significant if:

- The project will block views from a scenic highway or corridor.
- The project will adversely affect the visual continuity of the surrounding area.
- The impacts on light and glare will be considered significant if the project adds lighting which would add glare to residential areas or sensitive receptors.

Discussion

I. a), b), & c): Most of the proposed control measures in the 2012 AQMP are not expected to adversely affect scenic vistas in the district; damage scenic resources, including but not limited to trees, rock outcroppings, or historic buildings within a scenic highway; or substantially degrade the visual character of a site or its surroundings. As described below, some control measures have the potential to create significant adverse aesthetics impacts, especially to scenic highways.

The reasons that most of the AQMP control measures would not generate significant adverse aesthetics impacts are explained as follows. Most AQMP control measures to be implemented by the SCAQMD typically affect industrial, institutional, or commercial facilities located in appropriately zoned areas (e.g., industrial and commercial areas) that are not usually associated with scenic resources. Construction activities are expected to be limited to industrial and commercial areas. Further, modifications typically occur inside the buildings at the affected facilities, or because of the nature of the business (e.g., commercial or industrial) can easily blend with the facilities with little or no noticeable effect on adjacent areas. Finally, because the purpose of implementing 2012 AQMP control measures is to reduce emissions and improve air quality to attain state and federal ambient air quality standards, improved air quality would provide benefits to scenic vistas and resources in the district.

Generally, control measures that are under the jurisdiction of CARB or the U.S. EPA would accelerate replacement of high emitting on-road and off-road mobile source vehicles with low emitting mobile source vehicles. Accelerating the penetration of low emitting mobile sources would also not be expected to adversely affect scenic resources because these strategies do not require construction or disturbance of any sort to such resources. Although IND-01 [formerly MOB-03 (Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources)] and some of the mobile control measures could result in control devices at port facilities to control ship emissions from ships at berth, these activities would be consistent with activities already being undertaken as part of the San Pedro Bay Ports Clean Air Action Plan 2010 update. Control devices may include hoods or bonnets on ship exhaust stacks to capture emissions and are expected to be as high as 80 feet (PLB, 2006). While these control devices would be visible to surrounding areas, they would be similar to other structures used within the heavily industrialized portions of the ports, which contain terminals, tanks, shiploading structures (including conveyors and cranes), and other similar structures.

Control measures ONRD-05, ADV-01, ADV-02, and ADV-03 have the potential to create significant adverse aesthetics impacts, especially to scenic highways for the following reasons. These control measures promote the use of zero emissions trucks powered by electricity. In addition to electricity stored in batteries or produced onboard through a fuel cell, these control measures contemplate as a source of electricity “wayside” electricity from outside sources such as overhead catenary power lines, as is currently used for transit buses and heavy mining trucks. Catenary lines would need to be constructed on major roadways where such lines do not currently exist, which has the potential to adversely affect scenic highways and vistas, resulting in the degradation of the visual character of affected areas.

I. d): The proposed 2012 AQMP is not expected to create additional demand for new lighting or exposed combustion sources (e.g., flares) that could create glare that could adversely affect day or nighttime views in any areas. Compliance with 2012 AQMP control measures may affect operations at industrial or commercial facilities, but they are not expected to affect hours of operation, that is, complying with 2012 AQMP control measures would not be expected to require changing operations from day time to night time. Further, many types of industrial or commercial facilities are already lighted at night for safety and security reasons. As noted in item I. a) – c) above, facilities affected by AQMP control measures typically make modifications in the interior of an affected facility so any new light sources would typically be inside a building or not noticeable because of the presence of existing outdoor light sources. Further, operators of commercial or industrial facilities who would make physical modifications to facilities and may

require additional lighting would be located in appropriately zoned areas that are not usually located next to residential areas, so new light sources, if any, in addition to existing light sources would not likely be noticeable to residents.

Conclusion

Based upon the above considerations, potentially significant adverse project-specific aesthetic impacts may occur due to implementation of 2012 AQMP control measures and, therefore, will be evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
II. AGRICULTURE AND FOREST RESOURCES. Would the project:				
a) Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland mapping and Monitoring Program of the California Resources Agency, to non- agricultural use?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Conflict with existing zoning for agricultural use, or a Williamson Act contract?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
c) Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code §12220(g)), timberland (as defined by Public Resources Code §4526), or timberland zoned Timberland Production (as defined by Government Code §51104 (g))?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Result in the loss of forest land or conversion of forest land to non-forest use?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential agricultural and forest resources impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse agricultural and forest resources impacts as explained in the following discussions.

Significance Criteria

Project-related impacts on agriculture and forest resources will be considered significant if any of the following conditions are met:

- The proposed project conflicts with existing zoning or agricultural use or Williamson Act contracts.
- The proposed project will convert prime farmland, unique farmland or farmland of statewide importance as shown on the maps prepared pursuant to the farmland mapping and monitoring program of the California Resources Agency, to non-agricultural use.
- The proposed project conflicts with existing zoning for, or causes rezoning of, forest land (as defined in Public Resources Code §12220(g)), timberland (as defined in Public Resources Code §4526), or timberland zoned Timberland Production (as defined by Government Code § 51104 (g)).
- The proposed project would involve changes in the existing environment, which due to their location or nature, could result in conversion of farmland to non-agricultural use or conversion of forest land to non-forest use.

Discussion

II. a), b), c) & d) AQMP control measures typically affect existing commercial or industrial facilities, establish specifications for fuels or mobile source exhaust emissions, or accelerate the replacement of high-emitting mobile sources with low emitting mobile sources so they are not expected to generate any new construction of buildings or other structures that would require conversion of farmland to non-agricultural use or conflict with zoning for agricultural uses or a Williamson Act contract. Further, AQMP control measures typically affect existing facilities that are located in appropriately zoned areas. Any new facilities that may be affected by AQMP control measures would be constructed and operated for reasons other than complying with AQMP control measures. For these same reasons, it is not expected that implementing AQMP control measures will conflict with any forest land zoning codes or convert forest land to non-forest uses. No control measures were identified in the proposed 2012 AQMP that would affect or conflict with existing land use plans, policies, or regulations or require conversion of farmland to non-agricultural uses or forest land to non-forest uses.

One sub-control measure, MCS-04C – Further Ammonia Reductions from Livestock Waste in Mira Loma Region (formerly MCS-05) was identified that could affect agricultural operations. This control measure would call for applying an acidifier, sodium bisulfate, to control ammonia emissions from fresh manure at livestock operations. While this sub-control measure could increase costs, it is not expected that the sub-control measure would be designed in a way that would cause costs high enough to result in conversion of farmland to other uses. Further, this sub-control measure is one of three sub-control measures that would be implemented only in the Mira Loma area (approximately within a 10-mile radial) and would only be implemented if the 24-hour PM2.5 standard is exceeded in the Mira Loma area in 2014 (single year, 98th percentile).

Regardless, land use, including agriculture- and forest-related uses, and other planning considerations are determined by local governments and no agricultural land use or planning requirements will be altered by the proposed project, except as noted above. AQMP control measures, including control measures related to mobile sources, would have no direct or indirect effects on agricultural or forest land resources because these types of control measures typically involve reduction in combustion and fugitive VOC emissions, as well as establishing emission

exhaust requirements or increasing the penetration of low-emitting mobile sources. The 2012 AQMP could provide benefits to agricultural and forest land resources by improving air quality in the region, thus, reducing the adverse oxidation impacts of ozone on plants and animals.

Conclusion

Based upon the above considerations, significant adverse project-specific impacts to agricultural resources or forest land resources are not expected to occur due to implementation of the 2012 AQMP and, therefore, will not be further analyzed in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
III. AIR QUALITY AND GREENHOUSE GAS EMISSIONS.				
Would the project:				
a) Conflict with or obstruct implementation of the applicable air quality plan?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
b) Violate any air quality standard or contribute to an existing or projected air quality violation?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
d) Expose sensitive receptors to substantial pollutant concentrations?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
e) Create objectionable odors affecting a substantial number of people?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
f) Diminish an existing air quality rule or future compliance requirement resulting in a significant increase in air pollutant(s)?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
g) Generate greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
h) Conflict with an applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential air quality impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse air quality impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse air quality impacts.

Significance Criteria

To determine whether or not air quality impacts from the proposed project may be significant, impacts were evaluated and compared to the criteria in Table 2-1. If impacts exceed any of the criteria in Table 2-1, they will be considered further in the Draft EA. As necessary, all feasible mitigation measures will be identified in the Draft EA and implemented to reduce significant impacts to the maximum extent feasible.

**Table 2-1
SCAQMD Air Quality Significance Thresholds**

Mass Daily Thresholds ^a		
Pollutant	Construction ^b	Operation ^c
NOx	100 lbs/day	55 lbs/day
VOC	75 lbs/day	55 lbs/day
PM10	150 lbs/day	150 lbs/day
PM2.5	55 lbs/day	55 lbs/day
SOx	150 lbs/day	150 lbs/day
CO	550 lbs/day	550 lbs/day
Lead	3 lbs/day	3 lbs/day
Toxic Air Contaminants (TACs), Odor, and GHG Thresholds		
TACs (including carcinogens and non-carcinogens)	Maximum Incremental Cancer Risk ≥ 10 in 1 million Cancer Burden > 0.5 excess cancer cases (in areas ≥ 1 in 1 million) Hazard Index ≥ 1.0 (project increment)	
Odor	Project creates an odor nuisance pursuant to SCAQMD Rule 402	
GHG	10,000 MT/yr CO ₂ eq for industrial facilities	
NO₂ 1-hour average annual arithmetic mean	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 0.18 ppm (state) 0.03 ppm (state)	
PM10 24-hour average annual average	10.4 $\mu\text{g}/\text{m}^3$ (construction) ^e & 2.5 $\mu\text{g}/\text{m}^3$ (operation) 1.0 $\mu\text{g}/\text{m}^3$	
PM2.5 24-hour average	10.4 $\mu\text{g}/\text{m}^3$ (construction) ^e & 2.5 $\mu\text{g}/\text{m}^3$ (operation)	
Sulfate 1-hour average	0.075 ppm (federal – 98 th percentile)	

**TABLE 2-1 (Concluded)
SCAQMD Air Quality Significance Thresholds**

Toxic Air Contaminants (TACs), Odor, and GHG Thresholds	
CO 1-hour average 8-hour average	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 20 ppm (state) 9.0 ppm (state/federal)
Lead Rolling 3-month average	0.15 µg/m ³ (federal)

^a Source: SCAQMD CEQA Handbook (SCAQMD, 1993)

^b Construction thresholds apply to both the South Coast Air Basin and Coachella Valley (Salton Sea and Mojave Desert Air Basins).

^c For Coachella Valley, the mass daily thresholds for operation are the same as the construction thresholds.

^d Ambient air quality thresholds for criteria pollutants based on SCAQMD Rule 1303, Table A-2 unless otherwise stated.

^e Ambient air quality threshold based on SCAQMD Rule 403.

KEY: lbs/day = pounds per day ppm = parts per million µg/m³ = microgram per cubic meter ≥ = greater than or equal to
MT/yr CO₂eq = metric tons per year of CO₂ equivalents

To determine whether or not greenhouse gas emissions from the proposed project may be significant, impacts will be evaluated and compared to the 10,000 metric tons of CO₂ equivalent per year (MT CO₂e/year) threshold for industrial sources.

Discussion

III. a) The SCAQMD is required by law to prepare a comprehensive district-wide AQMP which includes strategies (e.g., control measures) to reduce emission levels to achieve and maintain state and federal ambient air quality standards, to ensure that new sources of emissions are planned and operated to be consistent with the SCAQMD’s air quality goals, and to protect sensitive receptors and the public in general from the adverse effects of criteria pollutants which are known to have adverse human health effects. The AQMP’s air pollution reduction strategies include control measures that target stationary, mobile and indirect sources. These control measures are based on feasible methods of attaining ambient air quality standards. Pursuant to the provisions of both the state and federal Clean Air Acts, the SCAQMD is required to attain the state and federal ambient air quality standards for all criteria pollutants.

The proposed project would update the SCAQMD’s 2007 AQMP, as required pursuant to state law. By revising and updating emission inventories and control strategies, the SCAQMD is complying with state law, and furthering development of new AQMP control measures, which along with remaining 2007 AQMP control measures would be expected to reduce emissions and make progress towards attaining and maintaining all state and federal ambient air quality standards in the district. Updating the AQMP, as required by law is not considered to be an obstruction to the implementation of the local air quality plan. Therefore, this topic will not be further evaluated in the Draft Program EIR.

III. b) & d): The anticipated direct air quality effect of implementing the 2012 AQMP is obtaining further emissions reductions from existing emission sources or promoting the lowest achievable emission rates from new emissions sources, both stationary and mobile sources. Implementing some control measures has the potential of generating secondary air quality impacts in several ways as explained in the following paragraphs.

AQMP control measures that may involve retrofitting, replacing, or installing new air pollution control equipment, would likely require physical modifications at affected facilities. Physical modifications may involve the use of construction equipment for demolition, site preparation, site grading, and construction. Exhaust emissions from on-road and off-road equipment during construction phases may be substantial depending on the number, types, and activity levels of the construction equipment used. Similarly, if large areas need to be graded to install equipment foundations or construct buildings, fugitive dust emissions could be substantial. Consequently, construction air quality impacts will be analyzed in the Program EIR for the proposed project.

Implementing AQMP control measures often requires installing air pollution control equipment. Although the primary effect of installing air pollution control equipment is to reduce emissions of a particular pollutant, e.g., VOCs or NO_x, some types of control equipment have the potential to create secondary adverse air quality impacts. For example, combustion equipment, e.g., thermal oxidizers, could be used to control VOC emissions, but they have the potential to generate secondary NO_x emissions.

AQMP control measures that are intended to reduce NO_x emissions from stationary or mobile sources, e.g., CMB-01 – Further NO_x Reductions for RECLAIM; etc., may use ammonia as part of the control process (e.g., selective catalytic reduction). Ammonia use could result in increased ammonia emissions and, since ammonia is a precursor to particulate formation, increased particulate emissions. Similarly, in the event of an accidental release of ammonia, sensitive receptors in the vicinity of the release could be exposed to harmful concentrations of ammonia vapor.

Some control measures are expected to improve air quality overall, but there may be trade-offs. The increase in electrification of sources (e.g., ONRD-01, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles, ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles), etc., would result in the need for additional electricity and potentially result in the construction and operation of new electrical power plants and increased emissions from power plants.

Emissions of one or more pollutants may increase slightly in order to effectively reduce overall emissions and protect public health. Potentially significant air toxics impacts could occur due to reformulation of consumer products, including coatings, use of new fuel or alternative fuel additives, and use of new low VOC replacements for diesel engine lubricating oil additives. As a result, these potential air quality impacts will be evaluated in the Draft Program EIR.

Implementing other types of AQMP control measures, especially the CTS category of control measures, e.g., CTS-01 – Further VOC Reduction from Architectural Coatings; and CTS-02 – Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants; etc., may result in facility operators electing to reduce VOC emissions by replacing high-VOC solvent or coating materials with exempt solvents or other formulations that may contain toxic compounds, such as formaldehyde or glycol ethers, or compounds that have a higher flammability rating. As a result, material replacement or reformulation to reduce the use of high-VOC materials has the potential to result in health risks associated with exposure to both carcinogenic and non-carcinogenic toxic air contaminants. Both secondary air quality impacts

and health impacts from exposure to substantial pollutant concentrations will be analyzed in the Program EIR for the proposed project.

III. c): The intent of implementing AQMP control measures is to reduce criteria pollutants emissions to attain and maintain state and national ambient air quality standards and reduce toxic contaminants and greenhouse gases. However, secondary air quality impacts of some control measures may generate increased emissions. Because the proposed amendments may result in significant adverse secondary air quality effects, the project's incremental contribution to a cumulative effect may be cumulatively considerable. Cumulative air quality impacts from implementing the 2012 AQMP will be evaluated in the Draft Program EIR.

III. e) Implementing some AQMP control measures may require construction activities at affected facilities. Odors are sometimes associated with the exhaust from diesel-fueled equipment. However, odor impacts from construction equipment are not expected to be significant because most diesel-fueled equipment are mobile and do not remain in one location that could continuously affect offsite receptors. In addition, diesel exhaust is generally hot and, therefore, buoyant, which results in dilution of potential odor impacts as the exhaust rises into the atmosphere. As a result, odor impacts from construction activities to implement AQMP control measures are not expected to be significant and will not be further discussed in the Program EIR.

Past projects evaluating promulgation of AQMP control measures into rules or regulations, especially control measures that involve reformulated coatings or solvents, have included assessments of potential odor impacts. Although in some cases reformulated products have noticeable odors, it is typically the case that reformulated products have less noticeable odors than the products they are replacing. Reformulated products tend to have reduced VOC content and reduced emissions and, therefore, lower potential for creating odor impacts. As a result, significant adverse odor impacts have not been associated with reformulated products, especially those relying on water-based formulations, compared to conventional high VOC products. Modifications to industrial facilities to produce reformulated products (e.g., refineries) also have the potential to create odor impacts. However, owners/operators of industries affected by control measures in the proposed 2012 AQMP would still be subject to existing air quality rules and regulations, including SCAQMD's Rule 402 - Nuisance, which prohibits creating odor nuisances. For these reasons, implementing the 2012 AQMP is not expected to create significant adverse odor impacts and, therefore, will not be further addressed in the Draft Program EIR.

III. f): Promulgating AQMP control measures, such as control requirements for stationary sources, mobile sources, market incentive programs, etc., into rules or regulations typically serves to strengthen an existing rule or regulation, not weaken it. Similarly, an AQMP control measure may be promulgated as a new rule or regulation, which typically controls emissions from an unregulated or minimally regulated source. As a result, the proposed project would not diminish an existing air quality rule. This topic will not be further analyzed in the Draft Program EIR.

III. g): Although the 2007 AQMP did not contain control measures that specifically targeted greenhouse gas (GHG) emissions, it was estimated that by 2014 CO₂ emission reductions of 427,849 metric tons per year would be generated and by 2020 CO₂ emission reductions of 1,523,445 metric tons per year by 2020 would occur, primarily as a result of co-benefits from control measures that reduce criteria pollutant combustion emissions.

To specifically address GHG emissions the 2012 AQMP includes two new categories of control measures, incentive (INC) and education (EDU) programs. In addition to GHG reductions generated as co-benefits of implementing other AQMP control measures, INC and EDU measures are expected to reduce GHG primarily through increasing energy efficiency and conservation (INC-01, EDU-01). Improving energy efficiency can be accomplished layering smart grid systems onto the existing electricity distribution system. A smart grid is a digitally enabled electrical grid that gathers, distributes, and acts on information about the behavior of all participants (suppliers and consumers) in order to improve the efficiency, importance, reliability, economics, and sustainability of electricity services³. Establishing a smart grid system does not necessarily require constructing a new grid system; use of smart technologies allows the existing grid system to be used more efficiently.

Some 2012 control measures, however, have the potential to generate combustion emissions that could increase GHG emissions. For example, implementing BCM-01 – Emission Reductions from Under-fired Charbroilers, may result in increased combustion emissions through installation of afterburner technologies. Other control measures, e.g., ONRD-01 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles, ONRD-03 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles, etc., have the potential to increase demand for electricity resulting in increased combustion emissions, GHG emissions in particular, from increased electricity generation. Therefore, potential GHG emission impacts will be analyzed in the Program EIR.

III. h): The only GHG plans that may be affected by the 2012 AQMP are CARB’s Climate Change Scoping Plan and the Regional Transportation Plan and Sustainable Community Strategy (RTP/SCS), which was formally adopted by the Southern California Association of Governments (SCAG) on April 4, 2012. As noted in discussion III. g) above, new INC and EDU control measures in the 2012 AQMP rely primarily on energy efficiency and conservation, which is consistent with the Scoping Plan’s energy efficiency GHG reduction measures. Examples of energy efficiency measures in the Scoping Plan include: zero net energy buildings where a building produces more power over the course of year than it needs; more stringent building codes and appliance efficiency standards; going beyond green building targets mandated by existing codes; whole building retrofits for existing buildings; etc. Similarly, 2012 AQMP control measures that accelerate the penetration of hybrid and/or alternative-fueled vehicles also have the potential to provide GHG emission reduction impacts.

SCAG’s Draft 2012 RTP/SCS was released to the public in December 2011. The SCS in particular focuses GHG reduction efforts through modifying traditional land use development patterns to include more mixed use projects, which eliminates or substantially shortens commute trip lengths compared to traditional land use planning where residential land uses are separate from and potentially long distances from jobs and other commercial land uses. In general, neither SCAQMD nor CARB has authority over land use decisions, so implementing AQMP control measures would not affect land use decisions envisioned in the SCS. Further, because the transportation control measures (TCMs) SCAG provides to the SCAQMD for incorporation into the 2012 AQMP will likely be a subset of the TCMs in the 2012 RTP/SCS, it is not expected

³ http://en.wikipedia.org/wiki/Smart_grid, accessed December 16, 2011.

that the 2012 AQMP would conflict with the RTP/SCS. For these reasons it is not expected that the 2012 AQMP would conflict with the 2012 RTP/SCS.

As indicated in the above discussion, some types of control measures may increase the use of combustion technologies, such as thermal oxidizers, which could also generate GHG emissions. Depending on the magnitude of any GHG emissions generated from combustion devices, some 2012 AQMP control measures may have the potential to create conflicts with the Scoping Plan or the SCS. This topic will be analyzed further in the Program EIR.

Conclusion

The goal of the AQMP is to protect public health by achieving the state and federal ambient air quality standards. However, secondary adverse air quality impacts may occur from implementing the proposed revisions to the AQMP due to increases in criteria pollutant emissions from certain types of air pollution control equipment. Similarly, the 2012 AQMP has the potential to generate significant adverse cumulative air quality impacts, including GHG emission impacts. Therefore, potential adverse air quality impacts resulting from implementing the 2012 AQMP will be evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
IV. BIOLOGICAL RESOURCES.				
Would the project:				
a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
c) Have a substantial adverse effect on federally protected wetlands as defined by §404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e) Conflicting with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
f) Conflict with the provisions of an adopted Habitat Conservation plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential biological resources impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse biological resources impacts as explained in the following discussions.

Significance Criteria

Impacts on biological resources will be considered significant if any of the following criteria apply:

- The project results in a loss of plant communities or animal habitat considered to be rare, threatened or endangered by federal, state or local agencies.
- The project interferes substantially with the movement of any resident or migratory wildlife species.
- The project adversely affects aquatic communities through construction or operation of the project.

Discussion

IV. a), b), & d) The effects of implementing AQMP control measures typically include reducing mobile source exhaust emissions; modifying fuel specifications; or modifications at existing commercial or industrial facilities to control or further control emissions, which may require some type of construction equipment and activities. Any affected existing commercial or industrial facilities are generally located in appropriately zoned commercial or industrial areas, which typically do not support candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service. Typically, existing industrial or commercial facilities are already devoid of plant life or plant life supporting wildlife species for fire safety reasons. Any new industrial or commercial facilities that may be affected by AQMP control measures and that have the potential to adversely affect biological resources would be constructed and operated for reasons unrelated to complying with AQMP control measures.

Similarly, modifications at existing facilities would not interfere substantially with the movement of any native resident or migratory fish or wildlife species or with native or resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites because implementing AQMP control measures typically occurs within the boundaries of the affected facilities and, therefore, would not require disturbing wildlife habitat. For these same reasons, since the proposed 2012 AQMP primarily regulates stationary emission sources at existing commercial or industrial facilities, it does not directly or indirectly affect land use policy that may adversely affect riparian habitat or other sensitive natural communities identified in local or regional plans, policies, or regulations, or identified by the California Department of Fish and Game or U.S. Fish and Wildlife Service. It is expected that industrial or commercial facilities that may be affected by 2012 AQMP control measures are already located in appropriately zoned areas or would be located in appropriately zoned areas. AQMP control measures do not include any provisions that would allow affected facility operators to violate existing zoning ordinances or regional plans, policies, or regulations. Improving air quality is expected to provide health benefits to plant and animal species in the district. Similarly, the 2012 AQMP contains control measures that establish emission standards for mobile sources or accelerated penetration of low emission vehicles, which could result in additional control of emissions from mobile sources or revision to existing fuel specifications. As a result, the proposed project would not affect land use policies or designations. There are no control measures contained in the 2012 AQMP that would alter this determination.

IV. c): Implementing some AQMP control measures, e.g., coatings and solvent control measures could change or increase a facility's potential to generate waste water. Past SCAQMD staff experience with analyzing modifications at industrial or commercial facilities is that they are considered "point sources" and must release wastewater into publicly owned treatment works (POTWs), i.e., local sewer systems, and, therefore, are subject to National Pollutant Discharge Elimination System (NPDES) permit program administered by the Regional Water Quality Control Board (RWQCB). Direct discharge into federally protected wetlands as defined by §404 of the Clean Water Act would be prohibited under federal law (Clean Water Act) and state law (Porter-Cologne Act) and, therefore, is not expected to occur.

Some 2012 AQMP control measures have the potential to require air pollution controls at port facilities, which are located on the coast. Port facilities are considered to be heavy industrial facilities (point sources) and the installation of additional controls would be consistent with this

land use. Further, any facilities that release wastewater into California's ocean waters are subject to water quality standards established in the California Ocean Plan and are also subject to NPDES requirements, enforced by the local RWQCBs. For all of the above reasons the proposed project will not adversely affect protected wetlands as defined by §404 of the Clean Water Act, including, but not limited to marshes, vernal pools, coastal wetlands, etc., through direct removal, filling, hydrological interruption or other means.

IV. e) & f) Implementing the proposed 2012 AQMP is not expected to affect land use plans, local policies or ordinances, or regulations protecting biological resources such as a tree preservation policy or ordinance for the reasons given in discussions above, i.e. control measures promulgated as rules or regulations primarily affect existing commercial and industrial facilities through installation of air pollution control equipment, which are typically located in appropriately zoned areas accelerating the penetration of low emission vehicles into the regional vehicle fleet. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Neither SCAQMD nor CARB has legal authority over land use decisions except to impose certain air pollution control requirements, which do not drive the land use approval process, and, therefore, cannot alter or interfere with land use zoning ordinance or designations and cannot approve new land use projects or modifications to existing land use projects. Similarly, the proposed 2012 AQMP is not expected to affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities for the reasons given in discussion IV. a), b) and d).

Conclusion

Based upon the above considerations, significant adverse project-specific biological resources impacts are not expect to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
V. CULTURAL RESOURCES. Would the project:				
a) Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Cause a substantial adverse change in the significance of an archaeological resource as defined in §15064.5?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
c) Directly or indirectly destroy a unique paleontological resource, site, or feature?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
d) Disturb any human remains, including those interred outside formal cemeteries?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential cultural resources impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse cultural resources impacts as explained in the following discussions.

Significance Criteria

Impacts to cultural resources will be considered significant if:

- The project results in the disturbance of a significant prehistoric or historic archaeological site or a property of historic or cultural significance to a community or ethnic or social group.
- Unique paleontological resources are present that could be disturbed by construction of the proposed project.
- The project would disturb human remains.

Discussion

V. a), b), c), & d) All control measures in the 2012 AQMP were evaluated to identify those control measures with potential cultural resources impacts. No control measures were identified that could generate significant adverse cultural resources impacts. CEQA Guidelines §15064.5(a)(3) states in part, “Generally, a resource shall be considered ‘historically significant’ if the resource meets the criteria for listing in the California Register of Historical Resources including the following:

- A) Is associated with events that have made a significant contribution to the broad patterns of California’s history and cultural heritage;
- B) Is associated with the lives of persons important in our past;
- C) Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values;
- D) Has yielded or may be likely to yield information important in prehistory or history.”

The California Register eligibility criteria are modeled on those of the eligibility criteria of the National Register of Historic Places. Resources (buildings, structures, equipment) that are less than 50 years old are excluded from listing in the National Register of Historic Places unless they can be shown to be exceptionally important). Even resources that are 50 years or older, are not necessarily considered to be historically significant if they do not represent any of the above four criteria.

Implementing the proposed 2012 AQMP control measures is primarily expected to result in controlling stationary source emissions at existing commercial or industrial facilities or accelerate the penetration of low emission vehicles into the regional vehicle fleet. Affected facilities where physical modifications may occur are typically located in appropriately zoned commercial or industrial areas that have previously been disturbed and are not typically considered to be historically significant. It is unlikely that construction activities, including heavy construction activities, such as cut-and-fill activities or excavation, at potentially affected existing facilities would uncover cultural resources as these existing facilities are located in previously disturbed areas. Some affected facilities, e.g., refineries, may have equipment older than 50 years that may need to be modified to comply with 2012 AQMP control measures. However, such equipment does not typically meet the criteria identified in CEQA Guidelines §15064.5(3). Based these considerations, it is unlikely that implementing control measures in the proposed 2012 AQMP would: adversely affect historical or archaeological resources as defined in CEQA Guidelines §15064.5, destroy unique paleontological resources or unique geologic features, or disturb human remains interred outside formal cemeteries.

In spite of the fact that most facilities that would be affected by 2012 AQMP control measures are located on previously disturbed sites where there is little likelihood of any remaining identifiable artifacts, it is possible, that implementing control measures could result in construction activities to install pollution control equipment at affected existing facilities that uncover cultural or archaeological resources. Even if this circumstance were to occur, significant adverse cultural resources impacts are not anticipated because there are existing laws in place that are designed to protect and mitigate potential adverse impacts to cultural resources. As with any construction activity, should archaeological resources be found during construction that results from implementing the proposed AQMP control measures, the activity would cease until a thorough archaeological assessment is conducted as required by state or federal law.

Conclusion

Based upon the above considerations, significant adverse cultural resources impacts are not expect to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
VI. ENERGY. Would the project:				
a) Conflict with adopted energy conservation plans?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Result in the need for new or substantially altered power or natural gas utility systems?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
c) Create any significant effects on local or regional energy supplies and on requirements for additional energy?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
d) Create any significant effects on peak and base period demands for electricity and other forms of energy?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
e) Comply with existing energy standards?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential energy resources impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse energy resources impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse energy resources impacts.

Significance Criteria

Impacts to energy resources will be considered significant if any of the following criteria are met:

- The project conflicts with adopted energy conservation plans or standards.
- The project results in substantial depletion of existing energy resource supplies.
- An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities.
- The project uses non-renewable resources in a wasteful and/or inefficient manner.

Discussion

VI. a) & e) To address energy and climate change issues, the 2012 AQMP includes a number of control measures that promote energy efficiency and conservation (INC-01, Economic Incentive Programs to Adopt Cleaner, More Efficient Combustion Equipment; and EDU-01, Further Criteria Pollutant Reductions from Education, Outreach and Incentives: Energy and Environmental Benefits), thereby providing potential energy conservation benefits. In general, implementing the proposed INC and EDU control measures, as well as other 2012 AQMP control measures is not anticipated to result in any conflicts with adopted energy conservation plans or violations of any energy conservation standards by affected facilities. It is expected that owners/operators of affected facilities would comply with any applicable energy conservation standards in effect at the time of installation. Based upon these considerations, however, the net effect of implementing the proposed 2012 AQMP is that it is not expected to conflict with any adopted energy conservation plans or energy efficiency standards. These topics, therefore, will not be further evaluated in the Draft Program EIR

VI. b), c), & d) Implementing a number of the proposed 2012 AQMP control measures could increase energy demand in the region at affected facilities that install control equipment powered

by electricity or natural gas. For example, CMB-01, Further NO_x Reductions from RECLAIM, CMB-03, Reductions from Commercial Space Heating, FUG-01, Further VOC Reductions from Vacuum Trucks etc., have the potential to increase demand for electricity to operate control equipment, such as thermal oxidizers; electricity to operate chillers refrigerated condensers, liquid scrubbers; water from liquid scrubbers.

Many of the mobile source control measures rely on accelerated penetration of electric vehicles, which have the potential to increase demand for electrical power, and alternative fuel vehicles, which have the potential to increase demand for natural gas. Although, increased use of alternative fuels would likely reduce demand for petroleum fuels, increased energy demand impacts could occur as described in the following sentences. Mobile source control measures that have the potential to increase energy demand in the region include: ONRD-01, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels While at Berth; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; ADV-02, Actions for the Development of Zero- and Near-Zero Emission Locomotives; ADV-03, Actions for the Development of Zero- and Near-Zero Emission Cargo Handling Equipment, ADV-04, Actions for the Development of Cleaner Commercial Harborcraft; ADV-05, Actions for the Development of Cleaner Ocean-Going Marine Vessels; ADV-06, and Actions for the Development of Cleaner Off-Road Equipment). Similarly, some mobile source control measures may result in potentially significant adverse energy demand impacts from reduced fuel economy due to some engine designs or post combustion control equipment (OFFRD-02, Further Emission Reductions from Freight Locomotives; and OFFRD-03, Further Emission Reductions from Passenger Locomotives).

If the net effect of implementing AQMP control measures is an increase in regional energy demand in spite of implementing energy efficiency and energy conservation measures, the proposed 2012 AQMP has the potential to: result in the need for new or substantially altered power or natural gas utility systems; create significant effects on peak and base period demands for electricity and other forms of energy; and create significant effects on peak and base period demands for electricity and other forms of energy.

Conclusion

Based upon the above considerations, the potentially significant adverse impacts of the 2012 AQMP on energy resources will be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
VII. GEOLOGY AND SOILS. Would the project:				
a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
i. Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
ii. Strong seismic ground shaking?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
iii. Seismic-related ground failure, including liquefaction?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
iv. Landslides?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Result in substantial soil erosion or the loss of topsoil?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
c) Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Be located on expansive soil, as defined in Table 18-1-B of the California Building Code (1994) (formerly referred to as the Uniform Building Code), creating substantial risks to life or property?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e) Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential adverse geology and soils impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse geology and soils impacts as explained in the following discussions.

Significance Criteria

Impacts on the geological environment will be considered significant if any of the following criteria apply:

- Topographic alterations would result in significant changes, disruptions, displacement, excavation, compaction or over covering of large amounts of soil.
- Unique geological resources (paleontological resources or unique outcrops) are present that could be disturbed by the construction of the proposed project.
- Exposure of people or structures to major geologic hazards such as earthquake surface rupture, ground shaking, liquefaction or landslides.
- Secondary seismic effects could occur which could damage facility structures, e.g., liquefaction.
- Other geological hazards exist which could adversely affect the facility, e.g., landslides, mudslides.

Discussion

VII. a), c) & d) The proposed 2012 AQMP control measures would not directly or indirectly expose people or structures to earthquake faults, seismic shaking, seismic-related ground failure including liquefaction, landslides, mudslides or substantial soil erosion for the following reasons. In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets, would not affect geology or soils because for on-road vehicles, they would continue to operate on existing roadways (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.). Although some AQMP control measures would accelerate the penetration of zero or low emission off-road equipment, replacing one type of off-road engine with a lower emitting off-road engine would not be expected to affect construction activities. Further, construction activities occur for reasons other than complying with AQMP control measures.

When implemented as rules or regulations, AQMP control measures regulating stationary sources do not directly or indirectly promote new land use projects that could be located on earthquake faults, seismic zones, etc. Any seismic-related activities in areas where facilities that may be subject to AQMP control are located would be part of the existing setting. Some minor structural modifications, however, at existing affected facilities may occur as a result of installing control equipment or making process modifications. Such modifications would not likely require large heavy-duty construction equipment or substantial site modifications. In any event, existing affected facilities or modifications to existing facilities would be required to comply with relevant California Building Code (formerly referred to as the Uniform Building Code) requirements in effect at the time of initial construction or modification of a structure.

Southern California is an area of known seismic activity. Structures must be designed to comply with the California Building Code Zone 4 requirements if they are located in a seismically active area. The local city or county is responsible for ensuring that a proposed project complies with current California Building Code requirements as part of the issuance of the building permits and can conduct inspections to ensure compliance. The California Building Code is considered to be a standard safeguard against major structural failures and loss of life. The goal of the code is to provide structures that will: 1) resist minor earthquakes without damage; 2) resist moderate earthquakes without structural damage but with some non-structural damage; and 3) resist major earthquakes without collapse but with some structural and non-structural damage.

The California Building Code bases seismic design on minimum lateral seismic forces (“ground shaking”). The California Building Code requirements operate on the principle that providing appropriate foundations, among other aspects, helps to protect buildings from failure during earthquakes. The basic formulas used for the California Building Code seismic design require determination of the seismic zone and site coefficient, which represent the foundation conditions at the site. Accordingly, buildings and equipment at existing affected facilities are likely to conform to the California Building Code and all other applicable state codes in effect at the time they were constructed.

Any potentially affected facilities that are located in areas where there has been historic occurrence of liquefaction, e.g., coastal zones, or existing conditions indicate a potential for liquefaction, including expansive or unconsolidated granular soils and a high water table, may have the potential for liquefaction-induced impacts at the project sites. The California Building Code requirements consider liquefaction potential and establish more stringent requirements for building foundations in areas potentially subject to liquefaction. Compliance with the California Building Code requirements is expected to minimize the potential impacts associated with liquefaction. The issuance of building permits from the local cities or counties will assure compliance with the California Building Code requirements. Finally, no AQMP control measures require the location of new, or relocation of existing facilities in areas prone to liquefaction. Land use decisions are under the authority of the local jurisdictions, typically cities or counties. Neither the SCAQMD nor CARB has authority over land use decisions except to impose specific air pollution control requirements, which do not drive the land use approval process, and CEQA does not grant an agency new powers independent of the powers granted to the agency by other laws (CEQA Guidelines §15040(b)). Therefore, no significant impacts from liquefaction are expected and this potential impact will not be considered further.

Because facilities affected by any AQMP control measures are typically located in appropriately zoned areas such as industrial or commercial areas, which are not typically located near known geological hazards (e.g., landslide, mudflow, seiche, tsunami or volcanic hazards), no significant adverse geological impacts are expected. Even if potentially affected facilities are located near such geological hazards, the hazards are part of the existing setting and are not made worse by installing control equipment or other activities to comply with emission control rules and regulations. For example, tsunamis at the ports, i.e., Port of Los Angeles and Port of Long Beach, are not expected because the ports are surrounded by breakwaters that protect the area from wave action. In any event, AQMP control measures would not increase potential exposures to tsunamis. As a result, these topics will not be further evaluated in the Draft Program EIR.

VII. b) Although the proposed 2012 AQMP control measures may require minor modifications at existing industrial or commercial facilities, such modifications are not expected to require substantial grading or construction activities. Typically, existing facilities have already been graded and soil stabilization is already in place, e.g., through the placement of buildings, paving, or other soil stabilization measures currently required pursuant to SCAQMD Rule 403 – Fugitive Dust. In other cases, potentially affected areas may have already been graded or displaced in some way for other reasons, e.g., leveling the site, stabilization of slopes, etc. Accelerating the penetration of low emission vehicles into the regional vehicle fleet, (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.), does not require modifications requiring construction activities at existing facilities, as explained in discussion VII. a), c), and d). Therefore, significant adverse soil erosion impacts are not anticipated from implementing the 2012 AQMP and will not be further analyzed in the Draft Program EIR.

VII. e) Septic tanks or other similar alternative waste water disposal systems are typically associated with small residential projects in remote areas. The proposed 2012 AQMP does not contain any control measures that generate construction of residential or other types of land use projects in remote areas. As explained in discussion VII. a), c), and d), neither the SCAQMD nor CARB has land use approval authority. Consequently, construction of small residential land uses with septic systems would occur for reasons other than complying with AQMP control measures. Further, AQMP control measures typically affect existing industrial or commercial facilities that are already hooked up to appropriate sewerage facilities and are subject to wastewater control requirements, typically through NPDES permits. Based on these considerations, the use of septic tanks or other alternative waste water disposal systems will not be further evaluated in the Draft Program EIR.

Conclusion

Based upon the above considerations, significant adverse project-specific impacts to geology and soils are not expect to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
VIII. HAZARDS AND HAZARDOUS MATERIALS. Would the project:				
a) Create a significant hazard to the public or the environment through the routine transport, use, and disposal of hazardous materials?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
b) Create a significant hazard to the public or the environment through reasonably foreseeable upset conditions involving the release of hazardous materials into the environment?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Emit hazardous emissions, or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
d) Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code §65962.5 and, as a result, would create a significant hazard to the public or the environment?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public use airport or a private airstrip, would the project result in a safety hazard for people residing or working in the project area?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
f) Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
g) Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
h) Significantly increased fire hazard in areas with flammable materials?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures that have the potential to generate significant adverse hazards or hazardous materials impacts. Review of the 2012 AQMP control measures identified several control measures that have the

potential to generate significant adverse hazards or hazardous materials impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse hazards or hazardous materials impacts.

Significance Criteria

Impacts associated with hazards will be considered significant if any of the following occur:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.
- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

Discussion

VIII. a), b), & c) The proposed 2012 AQMP has the potential to create direct or indirect hazard impacts in several ways. Some control measures that would regulate VOC emissions by establishing VOC content requirements for products such as coatings, solvents, consumer products, etc., may result in reformulating these products with materials that are low or exempt VOC materials. It is possible that such reformulated products could have hazardous physical or chemical properties (e.g., highly flammable or acutely hazardous), which could create hazard impacts through the routine transport or disposal of these materials or through upset conditions involving the accidental release of these materials into the environment. Some control measures may increase the use of SCR control equipment (CMB-01, Further NO_x Reductions from RECLAIM; OFFRD-02, Further Emission Reductions from Freight Locomotives; OFFRD-03, Further Emission Reductions from Passenger Locomotives; OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels While at Berth; etc.), which could result in the increased use of ammonia in SCR units. Greater use of alternative clean fuels (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; ADV-02, Actions for the Development of Zero- and Near-Zero Emission Locomotives; ADV-03, Actions for the Development of Zero- and Near-Zero Emission Cargo Handling Equipment; ADV-04, Actions for the Development of Cleaner Commercial Harborcraft; ADV-05, Actions for the Development of Cleaner Ocean-Going Marine Vessels; ADV-06, Actions for the Development of Cleaner Off-Road Equipment; and ADV-07, Actions for the Development of Cleaner Aircraft Engines) could also create hazard impacts in the event of an accidental release of these materials into the environment. These potential hazard impacts will be further evaluated in the Draft Program EIR.

VIII. d) Government Code §65962.5 typically refers to a list of facilities that may be subject to Resource Conservation and Recovery Act (RCRA) permits or site cleanup activities. For any facilities affected by control measures that are on the list, it is anticipated that they would be required to continue to manage any and all hazardous materials in accordance with federal, state and local regulations. Implementing AQMP control measures is not expected to interfere with site cleanup activities or create additional site contamination. Therefore, this topic will not be further evaluated in the Draft Program EIR.

VIII. e) The proposed project is not expected to adversely affect any airport land use plan or result in any safety hazards for people residing or working in the district. Federal Aviation Administration, 14 CFR Part 77 – Safe, Efficient Use and Preservation of the Navigable Airspace⁴, provides information regarding the types of projects that may affect navigable airspace. Projects that involve construction or alteration of structures greater than 200 feet above ground level within a specified distance from the nearest runway; objects within 20,000 feet of an airport or seaplane base with at least one runway more than 3,200 feet in length and the object would exceed a slope of 100:1 horizontally (100 feet horizontally for each one foot vertically from the nearest point of the runway); etc., may adversely affect navigable airspace. Control measure ADV-03, Actions for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment, could result in installation electric gantry cranes at the Ports of Los Angeles and Long Beach, which can be as tall as 230 feet. However, control measure ADV-03 would likely result in replacing existing gantry cranes that are also as tall as 230 feet. Further, there are no airports within 20,000 feet (3.8 miles) of the San Pedro Bay Ports complex. The nearest airport, Zamperini Field Airport, is approximately nine miles (47,520 feet) from the Ports complex. Similarly, Long Beach Airport is approximately 13 miles (68,640 feet) and Los Angeles International Airport is approximately 20 miles (105,600 feet) from the Ports complex. As a result, all local airports well outside the maximum 20,000-foot navigable space boundaries. Another control measure (ADV-07, Action for the Development of Cleaner Aircraft Engines) would establish lower emission standards for airplane fleets serving the district, but are not expected to require construction of tall structures that could interfere with airport activities. No other control measures in the proposed 2012 AQMP were identified that could result in construction of tall structures, especially structures 200 feet tall, near airports so potential impacts to airport land use plans or safety hazards to people residing or working in the vicinity of local airports are not anticipated. This topic will not be further addressed in the Draft Program EIR.

VIII. d) Even if some affected facilities are designated pursuant to Government Code §65962.5 as a large quantity generator of hazardous waste, it is not anticipated that complying with AQMP control measures would alter in any way how operators of affected facilities manage their hazardous wastes and that they will continue to be managed in accordance with all applicable federal, state, and local rules and regulations. This topic will not be further addressed in the Draft Program EIR.

VIII. f) The proposed project will not impair implementation of, or physically interfere with any adopted emergency response plan or emergency evacuation plan. Operators of any existing commercial or industrial facilities affected by proposed 2012 AQMP control measures are already required to have approved emergency response plans for their facilities already in place. Emergency response plans are typically prepared in coordination with the local city or county emergency plans to ensure the safety of not only the public, but the facility employees as well.

Health and Safety Code §25506 specifically requires all businesses handling hazardous materials to submit a business emergency response plan to assist local administering agencies in the

⁴ DEPARTMENT OF TRANSPORTATION. Federal Aviation Administration, 14 CFR Part 77 [Docket No. FAA–2006–25002; Amendment No. 77–13] RIN 2120–AH31. *Safe, Efficient Use and Preservation of the Navigable Airspace*. 42296 Federal Register / Vol. 75, No. 139 / Wednesday, July 21, 2010 / Rules and Regulations. <http://www.gpo.gov/fdsys/pkg/FR-2010-07-21/pdf/2010-17767.pdf>.

emergency release or threatened release of a hazardous material. Business emergency response plans generally require the following:

- Identification of individuals who are responsible for various actions, including reporting, assisting emergency response personnel and establishing an emergency response team;
- Procedures to notify the administering agency, the appropriate local emergency rescue personnel, and the California Office of Emergency Services;
- Procedures to mitigate a release or threatened release to minimize any potential harm or damage to persons, property or the environment;
- Procedures to notify the necessary persons who can respond to an emergency within the facility;
- Details of evacuation plans and procedures;
- Descriptions of the emergency equipment available in the facility;
- Identification of local emergency medical assistance; and
- Training (initial and refresher) programs for employees in:
 - The safe handling of hazardous materials used by the business;
 - Methods of working with the local public emergency response agencies;
 - The use of emergency response resources under control of the handler;
 - Other procedures and resources that will increase public safety and prevent or mitigate a release of hazardous materials.

In general, every county or city and all facilities using a minimum amount of hazardous materials are required to formulate detailed contingency plans to eliminate, or at least minimize, the possibility and effect of fires, explosion, or spills. In conjunction with the California Office of Emergency Services, local jurisdictions have enacted ordinances that set standards for area and business emergency response plans. These requirements include immediate notification, mitigation of an actual or threatened release of a hazardous material, and evacuation of the emergency area.

Implementing certain control measures could result in the need for additional storage of hazardous materials (e.g., ammonia). Such modifications may require revisions to emergency response plans if new hazardous are introduced to a facility. However, these modifications would not be expected to interfere with emergency response procedures. Adopting the proposed 2012 AQMP is not expected to interfere with any emergency response procedures or evacuation plans and, therefore, will not be further evaluated in the Draft Program EIR.

VIII. g) The proposed 2012 AQMP would typically affect existing commercial or industrial facilities in appropriately zoned areas. Since commercial and industrial areas are not typically located near wildland or forested areas, implementing AQMP control measures has no potential to increase the risk of wildland fires. Further, for many industrial facilities, site preparation often includes removal of vegetation for fire safety reasons, so many affected industrial facilities

would be devoid of any plant life, especially undisturbed wildland areas. This topic will not be further evaluated in the Draft Program EIR.

In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration zero or low emission vehicles into district fleets, would not promote wildfires because for on-road vehicles, they would continue to operate on existing roadways (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.). Although some AQMP control measures would accelerate the penetration of zero or low emission off-road equipment, replacing one type of off-road engine with a lower emitting off-road engine would not be expected to affect the location of construction activities. Construction activities occur for reasons other than complying with AQMP control measures. This topic will not be further evaluated in the Draft Program EIR.

VIII. h) The 2012 AQMP may contain some control measures that could result in increased transport, handling, or use of flammable materials, such as alternative clean fuels (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; ADV-02, Actions for the Development of Zero- and Near-Zero Emission Locomotives; and ADV-03, Actions for the Development of Zero- and Near-Zero Emission Cargo Handling Equipment) or coatings reformulated with potentially flammable materials that may increase potential fire hazards in areas with flammable materials (e.g., CTS-01, Further VOC Reductions from Architectural Coatings; CTS-02, Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants; CTS-03, Further VOC Reductions from Mold Release Products; and CTS-04, Further VOC Reductions from Consumer Products). The potential for increased probability of explosion, fire, or other hazards will be addressed in the Draft Program EIR. Impacts related to public exposure to toxic air contaminants will be addressed in the “Air Quality” section of the Draft Program EIR.

Conclusion

Based upon the above considerations, the potentially adverse significant hazard impacts due to the increased probability of explosion, fire, or other risk of upset occurrences associated with the 2012 AQMP will be addressed in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
IX. HYDROLOGY AND WATER QUALITY. Would the project:				
a) Violate any water quality standards, waste discharge requirements, exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board, or otherwise substantially degrade water quality?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g. the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Substantially alter the existing drainage pattern of the site or area, including through alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in substantial erosion or siltation on- or off-site or flooding on- or off-site?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e) Place housing or other structures within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map, which would impede or redirect flood flows?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
f) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam, or inundation by seiche, tsunami, or mudflow?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
g) Require or result in the construction of new water or wastewater treatment facilities or new storm water drainage facilities, or expansion of existing facilities, the construction of which could cause significant environmental effects?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
h) Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
i) Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential hydrology and water quality impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse hydrology and water quality impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse hydrology and water quality impacts.

Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use more than 262,820 gallons per day of potable water.
- The project increases demand for total water by more than five million gallons per day.

Water Quality:

- The project will cause degradation or depletion of ground water resources substantially affecting current or future uses.
- The project will cause the degradation of surface water substantially affecting current or future uses.

- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.
- The project results in alterations to the course or flow of floodwaters.

Discussion

IX. a), g) & i) The proposed 2012 AQMP control measures may require modifications at existing industrial or commercial facilities that could result in increased or altered wastewater streams. Control measures that may result in installing control technologies that generate wastewater, e.g., wet gas scrubbers or other types of liquid scrubbers (BCM-01, Emission Reductions from Under-Fired Charbroilers; FUG-01, Further VOC Reductions from Vacuum Trucks) could create water quality impacts.

Some proposed AQMP coatings and solvents control measures may involve reformulating coatings and solvents with low VOC or exempt solvents (e.g., CTS-01, Further VOC Reductions from Architectural Coatings; CTS-02, Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants; and CTS-03, Further VOC Reductions from Mold Release Products). It is not expected that there will be a substantial increase in the volume of wastewater generated by facilities affected by the coatings control measures, but there could be a slight change in the nature and toxicity of wastewater effluent. The stationary source measures may generate potentially significant adverse water quality impacts from add-on air pollution control equipment such as wet scrubbers, alternative transportation fuels and reformulated low-VOC consumer products, etc.

Mobile source control measures that require increasing the manufacture and use of alternative fuels (ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; ADV-02, Actions for the Development of Zero- and Near-Zero Emission Locomotives; ADV-03, Actions for the Development of Zero- and Near-Zero Emission Cargo Handling Equipment; ADV-04, Actions for the Development of Cleaner Commercial Harborcraft; ADV-05, Actions for the Development of Cleaner Ocean-Going Marine Vessels; and ADV-06, Actions for the Development of Cleaner Off-Road Equipment may have the potential to create water quality or groundwater quality impacts in the event of accidental releases of alternative fuels during transport, storage, or handling.

Implementing 2012 AQMP control measures may result in the generation of increased volumes of wastewater that could adversely affect water quality standards or waste discharge requirements resulting in the need for new or increased wastewater treatment capacity. Therefore, these topics will be evaluated further in the Draft Program EIR.

IX. b) & h) Implementing some 2012 AQMP control measures also has the potential to increase demand for water used if wet scrubber technologies are installed at affected facilities (BCM-01, Emission Reductions from Under-Fired Charbroilers; FUG-01, Further VOC Reductions from

Vacuum Trucks). Thus, implementing the proposed project would require additional water, some of which could come from ground water supplies or require new or expansion of existing water supply facilities. This topic is potentially significant and will be evaluated further in the Draft Program EIR.

IX. c) & d) AQMP control measures would not be expected to generate construction of new structures that could alter existing drainage patterns by altering the course of a river or stream that would result in substantial erosion, siltation, or flooding on or offsite, increase the rate or amount of surface runoff that would exceed the capacity of existing or planned stormwater drainage systems, etc. Construction of new structures would occur for reasons other than complying with AQMP control. Although minor modifications might occur at commercial or industrial facilities affected by the proposed 2012 AQMP control measures, these facilities have, typically, already been graded and the areas surrounding them have likely already been paved over or landscaped. As a result, further minor modifications at affected facilities that may occur as a result of implementing the 2012 AQMP are not expected to alter in any way existing drainage patterns or stormwater runoff. Since this potential adverse impact is not considered to be significant, it will not be further evaluated in the Draft Program EIR.

In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets, would not promote wildfires because for on-road vehicles, they would continue to operate on existing roadways (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.). Although some AQMP control measures would accelerate the penetration of zero or low emission off-road equipment, replacing one type of off-road engine with a lower emitting off-road engine would not be expected to affect the location of construction activities. Construction activities occur for reasons other than complying with AQMP control measures. Therefore, this topic will not be further evaluated in the Draft Program EIR.

IX. e) & f) The proposed project does not directly or indirectly include the construction of new or relocation of existing housing or other types of facilities and, as such, would not require the placement of housing or other structures within a 100-year flood hazard area. Construction of new structures would occur for reasons other than complying with AQMP control. (See also XIII “Population and Housing”). As a result, the proposed project would not be expected to create or substantially increase risks from flooding; expose people or structures to significant risk of loss, injury or death involving flooding; or increase existing risks, if any, of inundation by seiche, tsunami, or mudflow. Consequently, this topic will not be evaluated further in the Draft Program EIR.

Conclusion

Based upon the above considerations, implementing several of the proposed 2012 AQMP control measures could result in increased water demand and wastewater generation that could result in potentially significant adverse hydrology and water quality impacts. Consequently, these impacts will be addressed in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
X. LAND USE AND PLANNING.				
Would the project:				
a) Physically divide an established community?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential land use and planning impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse land use and planning impacts as explained in the following discussions.

Significance Criteria

Land use and planning impacts will be considered significant if the project conflicts with the land use and zoning designations established by local jurisdictions.

Discussion

X. a) The proposed 2012 AQMP contains control measures that may result in installing control equipment on stationary sources at existing commercial or institutional facilities and establishing emission exhaust specifications for mobile sources. Construction of new structures affecting land use planning would occur for reasons other than complying with AQMP control. Further, neither the SCAQMD nor CARB has land use approval authority except to impose air pollution control requirements, which do not drive the land use approval process; this authority lies within the jurisdiction of public agencies with general government authority such as cities or counties. As a result, the proposed 2012 AQMP does not require construction of structures or new land use developments in any areas of the district and, therefore, is not expected to physically divide any established communities within the district.

In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets, would not create land use impacts because for on-road vehicles, they would continue to operate on existing roadways (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.) and, therefore, would not require construction of new

roadways that could physically divide communities. Although some AQMP control measures would accelerate the penetration of zero or low emission off-road equipment, replacing one type of off-road engine with a lower emitting off-road engine would not be expected to affect the location of construction activities. Construction activities that could result in physically dividing existing communities would occur for reasons other than complying with AQMP control measures. Therefore, this topic will not be further evaluated in the Draft Program EIR.

X. b) Any facilities affected by the proposed 2012 AQMP would still be expected to comply with, and not interfere with, any applicable land use plans, policies, or regulations of an agency with jurisdiction over the project (including, but not limited to the general plans, specific plans, local coastal programs or zoning ordinances). There are no provisions of the proposed project that would directly affect these plans, policies, or regulations. The SCAQMD is specifically excluded from infringing on existing city or county land use authority (California Health & Safety Code §40414). Land use and other planning considerations are determined by local governments and no present or planned land uses in the region or planning requirements will be altered by the proposed project in any way. There are existing links between population growth, land development, housing, traffic and air quality. SCAG’s 2012 RTP/SCS accounts for these links when designing ways to improve air quality, transportation systems, land use, compatibility and housing opportunities in the region. Land use planning is handled at the local level and contributes to development of the AQMP growth projections, for example. The AQMP does not affect local government land use planning decisions; instead it is revised to accommodate local land use planning decisions and population growth. The proposed 2012 AQMP complements SCAG’s Regional Comprehensive Plan.

Conclusion

Based upon the above considerations, significant adverse project-specific land use and planning impacts are not expect to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XI. MINERAL RESOURCES. Would the project:				
a) Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential mineral resources impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse mineral resources impacts as explained in the following discussions.

Significance Criteria

Project-related impacts on mineral resources will be considered significant if any of the following conditions are met:

- The project would result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state.
- The proposed project results in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Discussion

XI. a) & b) There are no provisions of the proposed 2012 AQMP that would directly result in the loss of availability of a known mineral resource of value to the region and the residents of the state, such as aggregate, coal, clay, shale, etc., or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan. Moreover, the 2012 AQMP is not expected to deplete non-renewable mineral resources in a wasteful manner. Therefore, significant adverse impacts to mineral resources are not anticipated.

Conclusion

Based upon the above considerations, significant adverse project-specific impacts to mineral resources are not expect to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XII. NOISE. Would the project result in:				
a) Exposure of persons to or generation of permanent noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
c) A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
d) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public use airport or private airstrip, would the project expose people residing or working in the project area to excessive noise levels?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential noise impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse noise impacts as explained in the following discussions.

Significance Criteria

Impacts on noise will be considered significant if:

- Construction noise levels exceed the local noise ordinances or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three decibels (dBA) at the site boundary. Construction noise levels will be considered significant if they exceed federal Occupational Safety and Health Administration (OSHA) noise standards for workers.
- The proposed project operational noise levels exceed any of the local noise ordinances at the site boundary or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three dBA at the site boundary.

Discussion

XII. a), & b): The proposed project may require existing commercial or industrial owners/operators of affected facilities to install air pollution control equipment or modify their operations to reduce stationary source emissions. Potential modifications would occur at facilities typically located in appropriately zoned industrial or commercial areas. Installing air pollution control equipment could generate noise impacts, but virtually all of the control equipment would be installed within the industrial and commercial facilities. Similarly, it is assumed that operations in these areas near airports are subject to and in compliance with existing community noise ordinances and applicable OSHA or Cal/OSHA workplace noise reduction requirements.

Ambient noise levels in commercial and industrial areas are typically driven primarily by freeway and/or highway traffic in the area and any heavy-duty equipment used for materials manufacturing or processing at nearby facilities. It is not expected that any modifications to install air pollution control equipment would substantially increase ambient [operational] noise levels in the area, either permanently or intermittently, or expose people to excessive noise levels that would be noticeable above and beyond existing ambient levels because of high levels of

local ambient noise, the noise dampening effects of building walls, and attenuation of noise over distance. It is not expected that affected facilities would exceed noise standards established in local general plans, noise elements, or noise ordinances currently in effect. Affected facilities would be required to comply with local noise ordinances and elements, which may require construction of noise barriers or other noise control devices.

Some control measures would provide an incentive for the early retirement of older mobile sources and replacing them with zero emission electric vehicle technologies. With respect to electric vehicles, they generate much less noise than older engines, especially diesel engines, because the electric engines have substantially fewer moving parts than diesel or gasoline vehicles. Similarly, there are documented comments of reduced noise from alternative fuel vehicle customers, in particular for alternative fuel refuse trucks. Therefore, mobile source control measures that accelerated the penetration of electric vehicles into the regional fleet (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; OFFRD-02, Further Emission Reductions from Freight Locomotives; OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels While at Berth; OFFRD-05, Emission Reductions from Ocean-Going Marine Vessels; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; ADV-02, Actions for the Development of Zero- and Near-Zero Emission Locomotives; ADV-03, Actions for the Development of Zero- and Near-Zero Emission Cargo Handling Equipment; ADV-04, Actions for the Development of Cleaner Commercial Harborcraft; ADV-05, Actions for the Development of Cleaner Ocean-Going Marine Vessels; ADV-06, and Actions for the Development of Cleaner Off-Road Equipment) could result in noise reductions in high vehicle miles traveled areas such as industrial/commercial facilities or along freeways/highways/streets or from marine vessels traveling into and out of the San Pedro Bay Ports complex.

It is also not anticipated that the proposed project would cause an increase in groundborne vibration levels because air pollution control equipment is not typically vibration intensive equipment. Further, as noted above, early penetration of zero emission electric vehicles would not generate groundborne vibration impacts because they have fewer moving parts that could generate vibrations compared to gasoline or diesel vehicles. Consequently, the 2012 AQMP will not directly or indirectly cause substantial noise or excessive groundborne vibration impacts. These topics, therefore, will not be further evaluated in the Draft Program EIR.

XII. c): Construction activities at industrial/commercial facilities could generate temporary or periodic noise impacts. However, most construction activities to comply with AQMP control measures are not expected to require heavy-duty construction equipment that would be necessary for site preparation as existing affected facilities have already been graded, paved and landscaped. Further, any affected facilities would also be required to comply with local noise ordinances, which establish acceptable noise levels during the day and generally prohibit construction during the nighttime, in order to minimize noise impacts. Compliance with the local noise ordinances is expected to minimize noise impacts associated with construction activities to less than significant.

XII. d): It is not expected that affected facilities located within an airport land use plan or, if airport land use plan has been adopted, within two miles of a public use airport or private airstrip for the same reasons identified in discussion items VII. a) and b) and VII. c).

Conclusion

Based upon the above considerations, significant adverse project-specific noise impacts are not expected to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XIII. POPULATION AND HOUSING.				
Would the project:				
a) Induce substantial growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (e.g. through extension of roads or other infrastructure)?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Displace substantial numbers of people or existing housing, necessitating the construction of replacement housing elsewhere?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential population or housing impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse population or housing impacts as explained in the following discussions.

Significance Criteria

Impacts of the proposed project on population and housing will be considered significant if the following criteria are exceeded:

- The demand for temporary or permanent housing exceeds the existing supply.
- The proposed project produces additional population, housing or employment inconsistent with adopted plans either in terms of overall amount or location.

Discussion

XIII. a) According to SCAG⁵ (2012), current population in the SCAG region (which includes all of the district, the non-district portions of Los Angeles and San Bernardino counties, and all of Ventura and Imperial counties) is approximately 18 million people and is expected to increase by another four million people by 2035. The proposed 2012 AQMP generally affects existing commercial or industrial facilities located in predominantly industrial or commercial urbanized areas throughout the district and, as such, is not anticipated to generate any significant effects,

⁵ Southern California Association of Governments. 2012. Final 2012 Regional Transportation Plan. April. <http://rtpsc.scag.ca.gov/Documents/2012/final/f2012RTPSCS.pdf>.

either directly or indirectly, on the district's population or population distribution as explained in the following paragraphs.

Consistent with past experience, it is expected that the existing labor pool within the southern California area would accommodate the labor requirements for any modifications requiring construction at affected facilities. This is especially true in the current recession. For example, California has a seasonally adjusted unemployment rate of 10.9 percent⁶. Unemployment rates (not seasonally adjusted) in each of the four district counties are as follows: Los Angeles County, 11.5 percent; Orange County, 8.1; Riverside County, 12.8 percent, and San Bernardino County, 12.1 percent⁷.

It is expected that few or no new employees would need to be hired at affected facilities to operate and maintain new control equipment on site because air pollution control equipment is typically not labor intensive equipment. In the event that new employees are hired, it is expected that the existing local labor pool in the district can accommodate any increase in demand for workers that might occur as a result of adopting the proposed 2012 AQMP. Based on the above, it is not expected that the 2012 AQMP would induce population growth resulting in the need for new housing, roads or other infrastructure. As such, adopting the proposed 2012 AQMP is not expected to result in changes in population densities or induce significant growth in population.

In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.), would not induce population growth because there is a finite number of drivers in the region at any one time, so drivers who purchase low or zero emission vehicles would not be driving the old high emitting vehicles at the same time they are driving the new low emitting vehicles. Although projected increases in population in the region may result in the continued use of the replaced high emitting vehicles, as already noted, future population growth in the region would occur for reasons other than complying with AQMP control measures.

XIII. b) There are no provisions in any AQMP control measures that would cause displacement of substantial numbers of people or housing necessitating construction of replacement housing elsewhere. As noted in the discussions under "Land Use and Planning, the proposed 2012 AQMP contains control measures that may result in installing control equipment on stationary sources at existing commercial or institutional facilities and establishing emission exhaust specifications for mobile sources. Construction of new structures affecting land use planning would occur for reasons other than complying with AQMP control. As a result, the proposed 2012 AQMP would not be expected to affect the location of people or housing in any areas of the district.

Conclusion

Based upon the above considerations, significant adverse project-specific population and housing impacts are not expected to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XIV. PUBLIC SERVICES. Would the proposal result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the following public services:				
a) Fire protection?	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
b) Police protection?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Schools?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Other public facilities?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential public services impacts. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse public services impacts as explained in the following discussions.

Significance Criteria

Impacts on public services will be considered significant if the project results in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or the need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response time or other performance objectives.

Discussion

XIV. a), & b): There is little potential for significant adverse public service impacts as a result of adopting the proposed 2012 AQMP. The 2003 AQMP EIR analyzed potential adverse impacts to public services as a result of implementing AQMP control measures and concluded that existing resources at services such as fire departments, police departments and local governments would not be significantly adversely affected as a result of implementing AQMP control measures even if there are slight increases in potential flammability impacts from implementing AQMP control measures. Similarly, the 2007 NOP/IS concluded that implementing AQMP control measures would not significantly adversely affect fire departments,

police departments and local governments for the same reasons as identified in the 2003 Program EIR, which include the following considerations. Although implementing 2012 AQMP control measures may increase the use of alternative clean fuels, for example, there would be a commensurate reduction in currently used petroleum fuels. As first responders to emergency situations, police and fire departments may assist local hazmat teams with containing hazardous materials, putting out fires, and crowd control to reduce public exposures to hazardous materials releases. In many situations, implementing AQMP control measures may reduce hazardous materials use, e.g., formulating coatings with less hazardous aqueous formulations. Some AQMP control measures may increase the use of air pollution control equipment that uses hazardous materials. In spite of this, there are no components of any control measures that would result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times or other performance objectives. Further, most large industrial facilities have on-site security that controls public access to facilities so no increase in the need for police services are expected. Many large industrial facilities also have on-site fire protection personnel and/or have agreements for fire protection services with local fire departments. Even in the absence of onsite police or fire protection services, implementing AQMP control measures in no way hinders service ratios or response times and is not expected to require physical modifications to existing government facilities to a greater extent than is currently the case. Finally, pursuant to the Health and Safety Code, emergency or rescue vehicles operated by local, state, and federal law enforcement agencies, police and sheriff departments, fire department, hospital, medical or paramedic facility, and used for responding to situations where potential threats to life or property exist, including, but not limited to fire, ambulance calls, or life-saving calls are specifically exempt from regulations requiring alternative clean fueled vehicles. For these reasons, implementing the 2012 AQMP is not expected to require additional fire protection services to an extent that it would cause a need for construction of new facilities, which could cause potentially significant environmental impacts.

XIV. c) As noted in the discussions under topic “XIII. Population and Housing,” adopting the proposed 2012 AQMP is not expected to induce population growth. Thus, implementing the proposed control measures would not increase or otherwise alter the demand for schools in the district. No significant adverse impacts to schools, such as the need for new or physically altered facilities, are foreseen as a result of adopting the proposed 2012 AQMP.

XIV. d): As indicated in the discussions under item “XIII. Population and Housing,” the 2012 AQMP is not anticipated to affect population growth in the district, which would not be expected to adversely affect existing public services or facilities or physically alter or require new public service facilities. Anticipated development to accommodate future population growth would occur for reasons other than complying with AQMP control measures. To address future growth it is the responsibility of local land public agencies with general land use authority, typically cities or counties, over fire departments, police departments and other public services to address potential impacts to public services that may require new or physically altered facilities or affect service ratios, response times, or other performance objectives. Consequently, no significant adverse impacts to schools or parks are foreseen as a result of adopting the proposed 2012 AQMP.

Conclusion

Based upon the above considerations, significant adverse project-specific public services impacts are not expected to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XV. RECREATION.				
a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Does the project include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment or recreational services?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential impacts to recreation resources. Evaluation of the 2012 AQMP control measures did not result in identifying any control measures that have the potential to generate significant adverse impacts recreation resources as explained in the following discussions.

Significance Criteria

Impacts to recreation will be considered significant if:

- The project results in an increased demand for neighborhood or regional parks or other recreational facilities.
- The project adversely affects existing recreational opportunities.

Discussion

XV. a) & b) As discussed under “Land Use and Planning” and “Population and Housing” above, there are no provisions in the proposed 2012 AQMP that would affect land use plans, policies, ordinances, or regulations. Land use and other planning considerations are determined by local governments. No land use or planning requirements, including those related to recreational facilities, will be altered by the proposal. The proposed project does not have the potential to directly or indirectly induce population growth or redistribution that could adversely affect recreational resources. As a result, the proposed project would not increase the use of, or demand for existing neighborhood and/or regional parks or other recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment.

Conclusion

Based upon the above considerations, no significant adverse project-specific impacts to population and housing are expected to occur due to implementation of the 2012 AQMP and, therefore, will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVI. SOLID/HAZARDOUS WASTE.				
Would the project:				
a) Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
b) Comply with federal, state, and local statutes and regulations related to solid and hazardous waste?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential solid or hazardous waste impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse solid or hazard waste impacts. Table A-1 in Appendix A lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse solid or hazardous waste impacts.

Significance Criteria

The proposed project impacts on solid/hazardous waste will be considered significant if the following occurs:

- The generation and disposal of hazardous and non-hazardous waste exceeds the capacity of designated landfills.

Discussion

XVI. a) The proposed 2012 AQMP could require affected facility operators to install air pollution control equipment on stationary sources, such as carbon adsorption devices, particulate filters, catalytic incineration, selective catalytic reduction or other types of control equipment that could increase the amount of solid/hazardous wastes generated in the district (e.g., FUG-01, Further VOC Reductions from Vacuum Trucks; CMB-01, Further NOx Reductions from RECLAIM – Phase I and Phase II) due to the disposal of spent catalyst, filters or other mechanisms used in the control equipment. Solid waste impacts would be considered significant if the impacts resulted in a violation of local, state or federal solid waste standards. Also, solid waste impacts would be significant if the additional potential waste volume exceeded the existing capacity of district landfills.

Some mobile source control measures may result in potentially significant adverse solid and hazardous waste impacts from the use of particulate filters or SCR units (e.g., OFFRD-02, Further Emission Reductions from Freight Locomotives; OFFRD-03, Further Emission Reductions from Passenger Locomotives; OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels While at Berth ADV-04, Actions for the Deployment of Cleaner Commercial Harborcraft; and ADV-05, Actions for the Deployment of Cleaner Ocean-Going Marine Vessels), early retirement of inefficient, older equipment (ONRD-02, Accelerated Retirement of Older Light- and Medium-Duty Vehicles), etc. The potential solid/hazardous waste impacts from implementing the proposed 2012 AQMP will be analyzed in the Draft Program EIR.

XVI. b): Adopting the proposed 2012 AQMP is not expected to interfere with affected facilities' abilities to comply with federal, state, or local statutes and regulations related to solid and hazardous waste handling or disposal. Health and Safety Code Section 40727 requires that prior to adopting or amending AQMP control measures into rules or regulations or when repealing rules, the AQMD Governing Board shall make certain findings. One of these findings is consistency, which requires that SCAQMD rules are in harmony with, and not in conflict with or contradictory to, existing statutes, court decisions, or federal or state regulations. This specific topic will not be further evaluated in the Draft Program EIR.

Conclusion

Based upon the above considerations, the potential adverse solid/hazardous waste impacts from implementing the proposed 2012 AQMP will be analyzed in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVII. TRANSPORTATION/TRAFFIC.				
Would the project:				
a) Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
b) Conflict with an applicable congestion management program, including but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
c) Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
d) Substantially increase hazards due to a design feature (e.g. sharp curves or dangerous intersections) or incompatible uses (e.g. farm equipment)?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
e) Result in inadequate emergency access?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
f) Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Introduction

All control measures in the 2012 AQMP were evaluated to identify those control measures with potential transportation or traffic impacts. Evaluation of the 2012 AQMP control measures identified one control measure (ADV-01) that has the potential to generate significant adverse transportation or traffic impacts as explained in the following discussions.

Significance Criteria

Impacts on transportation/traffic will be considered significant if any of the following criteria apply:

- Peak period levels on major arterials are disrupted to a point where level of service (LOS) is reduced to D, E or F for more than one month.
- An intersection’s volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- The project conflicts with applicable policies, plans or programs establishing measures of effectiveness, thereby decreasing the performance or safety of any mode of transportation.

- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 employees
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day
- Increase customer traffic by more than 700 visits per day.

Discussion

XVII. a): Adopting the proposed 2012 AQMP is not expected to substantially increase vehicle trips or vehicle miles traveled in the district. The 2012 AQMP relies on transportation and related control measures developed by SCAG (SCAG, 2012) (see Appendix B). These transportation control measures include strategies to enhance mobility by reducing congestion through transportation infrastructure improvements, mass transit improvements, increasing telecommunications products and services, enhanced bicycle and pedestrian facilities, etc. Specific strategies that serve to reduce vehicle trips and vehicle miles traveled, such as strategies resulting in greater reliance on mass transit, ridesharing, telecommunications, etc., are expected to result in reducing traffic congestion. Although population in the district will continue to increase, implementing the transportation control measures, in conjunction with the 2012 Regional Transportation Plan, would ultimately result in greater percentages of the population using transportation modes other than single occupancy vehicles. As a result, relative to population growth, existing traffic loads and the level of service designation for intersections district-wide would not be expected to decline at current rates, but could possibly improve to a certain extent. Even if congestion in the region increases compared to the baseline, this would occur for reasons other than complying with 2012 AQMP control measures. Therefore, it is expected implementing the AQMP, including the transportation control measures could ultimately provide transportation improvements and congestion reduction benefits.

In general, AQMP control measures affecting mobile sources, such as those that would accelerate the penetration of zero or low emission vehicles into district fleets (e.g., ONRD-1, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; etc.), would not induce population growth because there is a finite number of drivers in the region at any one time, so drivers who purchase low or zero emission vehicles would not be driving the old high emitting vehicles at the same time they are driving the new low emitting vehicles. Although projected increases in population in the region may result in the continued use of the replaced high emitting vehicles, as already noted, future population growth in the region would occur for reasons other than complying with AQMP control measures.

The 2012 AQMP would revise the previous motor vehicle emissions budget with new emission calculations using the latest motor vehicle emission factors and planning assumptions. The U.S. EPA's Transportation Conformity Rule requires that transportation plans and projects must not exceed SIP motor vehicle emission budgets for attaining and maintaining health-based air quality standards or a conformity lapse would occur (preventing further funding of transportation projects). By avoiding a conformity lapse, the region would continue to receive federal funding

for future transportation projects, which would generally improve traffic flow, thus, providing a beneficial traffic impact.

XVII. b): Comments were received on the June 27, 2012 NOP/IS that potentially significant traffic impacts could occur as a result of implementing ADV-01 – §182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles. The comment suggested that constructing the overhead electrical catenary lines could adversely affect traffic. Therefore, this potential impact will be evaluated in the Program EIR.

XVII. c): Neither air traffic nor air traffic patterns are expected to be directly or indirectly affected by adopting the proposed 2012 AQMP. As discussed in item VIII. e), the proposed project is not expected to adversely affect any airport land use plan or result in any safety hazards for people residing or working in the district because no AQMP control measures would result in construction or alteration of structures greater than 200 feet above ground level within the maximum 20,000-foot navigable space boundaries. In addition, it is not expected that implementing 2012 control measures would require transporting goods and materials by plane. Finally, although the 2012 AQMP includes control measure ADV-07, Actions for the Deployment of Cleaner Aircraft Engines, it is expected that this measure establish lower airplane exhaust emission standards, such standards would not result in a change in air traffic patterns, including either increases in traffic levels or changes in locations that result in substantial safety risks

XVII. d): It is not expected that adopting the proposed 2012 AQMP will directly or indirectly increase roadway design hazards or incompatible risks. Most AQMP control measures do not involve roadway construction or modifications. However, to the extent that implementing components of some of the transportation control measures and related measures to further develop roadway infrastructure to improve traffic flow may implicate construction, it is expected that there would ultimately be reductions in roadway hazards or incompatible risks as part of any roadway infrastructure improvements and reduced congestion.

XVII. e): Controlling emissions at existing commercial or industrial facilities and promoting accelerated penetration of low or zero emission vehicles into the regional fleet are not expected to affect in any way emergency access routes at any affected commercial or industrial facilities. The reason for this conclusion is that controlling emissions (from stationary sources in particular) is not expected to require major construction of any structures that might obstruct emergency access routes at any affected facilities. Similarly, control measures accelerating penetration of low or zero emission vehicles into the regional fleet would likely result in similar travel patterns on regional roadways compared to the baseline. Although some mobile source control measures may result in installing battery charging stations (e.g., ONRD-01, Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles; ONRD-03, Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles; ADV-01, Actions for the Development of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles; etc.), most jurisdictions have ordinances pertaining to maintaining at existing, or constructing adequate emergency access to many existing facilities and new land use projects.

XVII. f): Adopting the proposed 2012 AQMP will not conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the

performance or safety of such facilities. Specifically the 2012 RTP/SCS states that the safety of people and goods is one of the most important considerations in developing, maintaining, and operating the region’s multimodal transportation system. While the RTP/SCS’s multimodal strategy aims to reduce per capita vehicle miles traveled (VMT) over the next 25 years, total demand to move people and goods will continue to grow due to the region’s population increase. A strategic expansion of the regional transportation system is needed in order to provide the region with the mobility it needs. The RTP/SCS targets this expansion around transportation systems that have room to grow, including transit, high-speed rail, active transportation, express/high occupancy transit lanes, and goods movement. The 2012 RTP/SCS calls for an impressive expansion of transit facilities and services over the next 25 years. The local county sales tax programs, most recently Measure R in Los Angeles County, are providing for most of this expansion in facilities and services. In fact, the transportation and related control measures would specifically encourage and provide incentives for implementing alternative transportation programs and strategies. See also response XVI. B) regarding consistency with other regulations.

Conclusion

Adopting the proposed 2012 AQMP is not expected to generate any significant adverse project-specific impacts to transportation or traffic systems, so this topic will not be further evaluated in the Draft Program EIR.

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
XVIII. MANDATORY FINDINGS OF SIGNIFICANCE.				
a) Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
b) Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)

	Potentially Significant Impact	Less Than Significant With Mitigation	Less Than Significant Impact	No Impact
c) Does the project have environmental effects that will cause substantial adverse effects on human beings, either directly or indirectly?	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Discussion

XVIII. a): Specifically with regard to the biological resources identified in this item, the proposed project is not expected to significantly adversely affect any biological resources including wildlife and the resources on which it relies (see the discussions under item “IV. Biological Resources). Overall improvements in air quality are, ultimately, expected to provide substantial benefits to local biological resources in the district. Therefore, this topic will not be evaluated further in the Draft Program EIR.

XVIII. b): Because the proposed project has the potential to generate significant adverse project-specific environmental impacts in several environmental areas, the proposed project also has the potential to create significant adverse cumulative impacts if project-specific impacts are also deemed to be cumulatively considerable. Significant adverse impacts will be further analyzed in the Draft Program EIR if impacts to any of the following project-specific environmental topic areas are deemed significant: aesthetics, air quality, energy, hazards and hazardous materials impacts, hydrology and water resources, and solid and hazardous waste.

The 2012 AQMP also includes TCMs from SCAG’s 2012 RTP/SCS. SCAG prepared the Final Program EIR for the 2012 RTP/SCS to analyze environmental impacts from the 2012 RTP/SCS. The Draft 2012 AQMP Program EIR will consider cumulative impacts from implementing the 2012 AQMP and the TCMs evaluated in SCAG’s Final Program EIR for the 2012 RTP/SCS for those project-specific topics analyzed in the Draft Program EIR.

XVIII. c): The proposed 2012 AQMP has the potential to create significant adverse impacts to human beings as a result of the possibility that it could create potentially significant adverse impacts in the following areas: air quality, energy, hazards and hazardous materials impacts, hydrology and water resources, and solid and hazardous waste. Significant adverse impacts to any of these areas have the potential to adversely affect public health. Potentially significant adverse environmental impacts that could cause substantial adverse effects on human beings, either directly or indirectly will be evaluated in the Draft Program EIR. If any impacts are concluded to be significant, any evaluation of feasible mitigation measures and alternatives to the project will be included in the Draft Program EIR.

**APPENDIX A (OF THE NOP/IS FOR THE PEIR FOR THE 2012
AQMP)**

2012 AQMP Control Measure Environmental Analysis

PROPOSED SHORT-TERM MEASURES – 24-HR PM 2.5 PLAN										
Control Measure Number	Title	Pollutant	Source of Impact		Potential Impact					
				Not Significant	Aesthetics	Air	Energy	Hazard	Water	Waste
PM SOURCES										
BCM-01 <i>(formerly MCS-04B)</i>	Further Reductions from Residential Wood Burning Devices	PM2.5	Control program would be to decrease the mandatory wood burning curtailment threshold from 35 µg/m ³ to 30 µg/m ³ , no impacts identified	1						
BCM-02	Further Reductions from Open Burning	PM2.5	Control program would be to decrease the mandatory wood burning curtailment threshold from 35 µg/m ³ to 30 µg/m ³ , no impacts identified	1						
BCM-03 <i>(formerly BCM-01 & BCM-05 in the 2007 AQMP)</i>	Emission Reductions from Under-Fired Charbroilers	PM2.5	Electricity to operate equipment; control options include ESPs, HEPA filters, wet scrubbers, and thermal oxidizers.			X	X		X	X
BCM-04 <i>(formerly MCS-04B)</i>	Further Ammonia Reductions from Livestock Waste in Mira Loma Region	Ammonia	Potential groundwater quality impacts from applying acidifier sodium bisulfate						X	

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
COMBUSTION SOURCES										
CMB-01	Further NOx Reductions from RECLAIM – <i>Phase I and Phase II</i>	NOx	Construction; emissions from electricity to operate control equipment; exposure to ammonia vapors; potential increases in solid waste due to burner replacement & SCR catalyst disposal			X	X	X		X
CMB-02	NOx Reductions from Biogas Flares	NOx, VOCs	Construction air quality impacts; solid waste from replacing old with new flares			X				X
CMB-03	Reductions from Commercial Space Heating	NOx	Potential increase in electricity and natural gas demand for ventilation and hood systems; potential increases in solid waste due to burner replacement				X			X

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
COATINGS AND SOLVENTS										
CTS-01	Further VOC Reductions from Architectural Coatings (R1113)	VOCs	Reformulate coatings with more toxic or flammable sovents; potential increased use of water based formulations			X		X	X	
CTS-02	Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants	VOCs	Reformulate coatings with more toxic or flammable sovents; potential increased use of water based formulations			X		X	X	
CTS-03	Further VOC Reductions from Mold Release Products	VOCs	Reformulate coatings with more toxic or flammable sovents; potential increased use of water based formulations			X		X	X	
CTS-04	Further VOC Reductions from Consumer Products	VOCs	Reformulate consumer products with more toxic or flammable sovents; potential increased use of water based formulations			X		X	X	
PETROLEUM OPERATIONS AND FUGITIVE VOC										
FUG-01	Further VOC Reductions from Vacuum Trucks	VOCs	Emissions from thermal oxidizers; electricity to operate chillers refrigerated condensers, liquid scrubbers; water from liquid scrubbers			X	X		X	
FUG-02	Emission Reduction from LPG Transfer and Dispensing – <i>Phase II</i>	VOCs	Construciton emissions			X				

Control Measure Number	Title	Pollutant	Source of Impact		Potential Impact					
					Not Significant	Aesthetics	Air	Energy	Hazard	Water
FUG-03	Further VOC Reductions from Fugitive VOC Emissions	VOCs	None identified	2, 3						
MULTIPLE COMPONENT SOURCES										
MCS-01	Application of All Feasible Measures Assessment	All Pollutants	None identified	4						
MCS-02	Further Emission Reductions from Green Waste Processing (Chipping and Grinding Operations not associated with composting)	VOC	Construction; electricity to operate enclosures, biofilters, in-vessel treatment equipment			X	X			
MCS-03 <i>(formerly MCS-06 in the 2007 AQMP)</i>	Improved Start-up, Shutdown and Turnaround Procedures	All Pollutants	None identified	1, 2						
INDIRECT SOURCES										
IND -01 <i>(formerly MOB-03)</i>	Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources	NOx, SOx, PM2.5	No control technologies identified, relies on future development of compliance plan in the event existing emission reduction are not met							

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
INCENTIVE PROGRAMS										
INC-01	Economic Incentive Programs to Adopt Cleaner, More Efficient Combustion Equipment	All Pollutants	Control technologies for funding include fuel cells, diesel particulate filters (DPF), NOx reduction catalysts, alternative electricity generation, such as wind and solar, battery electric, hybrid electric, and usage of low NOx and alternative fuels such as natural gas				X	X		X
INC-02	Expedited Permitting and CEQA Preparation Facilitating the Manufacturing of Zero and Near-Zero Technologies	All Pollutants	None identified	5						
EDUCATIONAL PROGRAMS										
EDU-01 <i>(formerly MCS-02, MCS-03)</i>	Further Criteria Pollutant Reductions from Education, Outreach and Incentives	All Pollutants	None identified	5						

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
8-HR OZONE MEASURES –ON-ROAD MOBILE SOURCES										
ONRD-01	Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles	VOCs, NOx, PM	“Clean Vehicle Rebate Project” (CVRP) incentives program through 2023; to purchase low-emitting vehicles; potential increase in electricity and natural gas demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; waste impacts from EV battery disposal no requirements for replaced vehicles			X	X	X	X	X
ONRD-02	Accelerated Retirement of Older Light- and Medium-Duty Vehicles	VOCs, NOx, PM	Would continue Enhanced Fleet Modernization Program (EFMP) through 2023, no requirements for replaced vehicles, but implements the voluntary vehicle scrap provisions of AB 118; air quality and energy from scrapping; water quality from vehicle liquieds; solid waste from disposal of vehicle			X	X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact		Potential Impact					
					Not Significant	Aesthetics	Air	Energy	Hazard	Water
ONRD-03	Accelerated Penetration of Partial Zero Emission and Zero Emission Light-Heavy- and Medium-Heavy-Duty Vehicles	NOx, PM	Would continue the state hybrid truck and bus voucher incentive project (HVIP) through 2023; incentives to purchase low-emitting vehicles, no requirements for replaced vehicles; potential increase in electricity and natural gas demand; use of alternative fuels and fuel additives can result in hazard impacts; waste impacts from EV battery disposal			X	X	X	X	X
ONRD-04 <i>(includes former control measure MCS-04A)</i>	Accelerated Retirement of Older On-Road Heavy-Duty Vehicles	NOx, PM	Incentives to purchase low-emitting vehicles; potential increase in electricity and other alternative clean fuels demand; solid waste from EV battery disposal; no requirements for replaced vehicles			X	X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
ONRD-05	Further Emission Reductions from Heavy-Duty Vehicles Serving Near-Dock Railyards	NOx, PM	Accelerated use of hybrid electric or fuel cell trucks: aesthetics from overhead power lines; emissions from electricity generation; increased electricity demand; use of alternative fuels and fuel additives can result in hazard impacts; solid waste from EV battery disposal, etc.		X	X	X	X	X	X
8-HR OZONE MEASURES –OFF-ROAD MOBILE SOURCES										
OFFRD-01	Extension of the SOON Provision for Construction/Industrial Equipment	NOx	Extend SOON program from 2014 to 2023; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; waste impacts from EV battery disposal				X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
OFFRD-02	Further Emission Reductions from Freight Locomotives	NOx, PM	Replace existing engines with tier 4 engines with control equipment, e.g., SCRs; potential increase in ammonia emissions/exposures; use of alternative fuels and fuel additives can result in hazard & water quality impacts; DPM filters and electric batteries producing solid waste; no requirements for replaced locomotives			X	X	X	X	X
OFFRD-03	Further Emission Reductions from Passenger Locomotives	NOx, PM	Repower existing engines with tier 4 engines with control equipment, e.g., SCRs; potential increase in ammonia emissions/exposures, DPM filters and electric batteries producing solid waste; alternative fuels creating hazard & water quality impacts; no requirements for replaced locomotives			X	X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact		Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
				Not Significant						
OFFRD-04	Further Emission Reductions from Ocean-Going Marine Vessels While at Berth	NOx, PM	Calls for increased percentage of ships at berth to cold iron; potential air quality impacts from energy generation; energy impacts; hazards, waste impacts from ships that dispose of catalysts at berth in the ports, etc.			X	X	X		X
OFFRD-05	Emission Reductions from Ocean-Going Marine Vessels	NOx	Would enhance Ports' existing financial incentive programs for early deployment of Tier 3 vessels calling at the Ports; no requirements for replaced vessels; hazards, waste impacts from ships that dispose of catalysts while in the ports, etc.	2				X		X

Control Measure Number	Title	Pollutant	Source of Impact		Potential Impact					
				Not Significant	Aesthetics	Air	Energy	Hazard	Water	Waste
EARLY ACTION TO DEPLOY ADVANCED CONTROL TECHNOLOGIES										
ADV-01	Actions for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles	NOx	Aesthetic impacts from construction of "wayside" electric or magnetic infrastructure; air quality from construction of battery charging or fueling infrastructure; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; waste impacts from EV battery disposal. Traffic impacts have been added because of construction of catenary electricity lines potentially affecting traffic routes.		X	X	X	X	X	
ADV -02	Actions for the Deployment of Zero- and Near-Zero Emission Locomotives	NOx	Aesthetic impacts from construction of "wayside" electric or magnetic infrastructure; air quality from construction of battery charging or fueling infrastructure; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; waste impacts from EV battery disposal		X	X	X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
ADV -03	Actions for the Deployment of Zero- and Near-Zero Emission Cargo Handling Equipment	NOx	Aesthetic impacts from construction of electric gantry cranes; air quality from construction of battery charging or fueling infrastructure; increased energy demand; use of alternative fuels and fuel additives can result in hazard impacts; waste impacts from EV battery disposal.		X	X	X	X	X	X
ADV -04	Actions for the Deployment of Cleaner Commercial Harborcraft	NOx	Air quality from construction of battery charging or fueling infrastructure; ammonia emissions from SCR; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; solid waste from SCR catalyst & EV battery disposal			X	X	X	X	X

Control Measure Number	Title	Pollutant	Source of Impact	Not Significant	Potential Impact					
					Aesthetics	Air	Energy	Hazard	Water	Waste
ADV -05	Actions for the Deployment of Cleaner Ocean-Going Marine Vessels	NOx	Increased use of aftertreatment control technologies: SCR, wet/dry scrubbers; air quality impacts from ammonia; energy & hazard impacts from alternative fuels; water impacts from wet scrubbers; solid waste from dry scrubbers catalyst disposal			X	X	X	X	X
ADV -06	Actions for the Deployment of Cleaner Off-Road Equipment	NOx	Air quality from construction of battery charging or fueling infrastructure; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts; waste impacts from EV battery disposal			X	X	X	X	X
ADV -07	Actions for the Deployment of Cleaner Aircraft Engines	NOx	Potential low emission aircraft technologies include alternative fuels, lean combustion burners, high rate turbo bypass, advanced turbo-compressor design, and engine weight reduction; increased energy demand; use of alternative fuels and fuel additives can result in hazard & water quality impacts			X	X	X	X	

- 1 Control strategies do not generate significant adverse impacts.
- 2 Changes in operating practices with no impact identified.
- 3 Changes in testing, inspection, or enforcement procedures with no impact identified.
- 4 Potential impacts are considered to be speculative because no control technologies identified or relies on development of future technologies.
- 5 No impacts identified for control measures promoting education & outreach, which do not require installation of control equipment.

**APPENDIX B (OF THE NOP/IS FOR THE PEIR FOR THE 2012
AQMP)**

2012 AQMP TCM PROJECTS (FROM 2012 RTP/SCS)

**TABLE B-1
2012 AQMP Transportation Control Measure (TCM) Projects**

Lead Agency	PROJECT ID	PROJECT DESCRIPTION	COMPLETION DATE
LOS ANGELES COUNTY			
Baldwin Park	LAFA141	Baldwin Park Metrolink Transportation Center. Funded Thru STIP Augmentation Construction A Transportation Center And Parking Structure At The Baldwin Park Metrolink Station.	11/1/2014
Foothill Transit Zone	LA0B311	Park And Ride Facility Transit Oriented Neighborhood Program SAFETEA-LU # 341 (E-2006-Busp-092) (E-2006-Busp-173)	12/31/2013
Glendale	LA0G406	Fairmont Ave. Park-N-Ride Facility (83 Parking Spaces) To Serve Commuters Using Sr-134, I-5. The Location Of The Park-N-Ride Is Fairmont Avenue And San Fernando Rd.	12/30/2013
Los Angeles County	LAF1514	Emerald Necklace Bike Trail Project. Design And Construct 1.1 Miles Of Class I Bike Path To Connect Duarte Road To The San Gabriel River Bicycle Trail.	6/30/2013
Los Angeles County MTA	LA0G270	Expansion And Improvement To Existing Transit Center In The City Of Palmdale. E2009-Busp-137.	9/30/2013
Los Angeles County MTA	LA0F021	Exposition Light Rail Transit System Phase II – From Culver City To Santa Monica	12/31/2017
Los Angeles County MTA	LA29202W	Mid -City Transit Corridor: Wilshire Blvd. From Vermont To Santa Monica Downtown- Mid-City Wilshire Brt Incl. Div. Expansion And Bus Only Lane	12/31/2014
Los Angeles County MTA	LA0G194	Acquire Four (4) Alternate Fuel Buses For The City Of Artesia To Be Used For New Fixed Route Service Earmark Id #E2008-Busp-0694	10/31/2012
Los Angeles County MTA	LA0C10	Mid-City/Exposition Corridor Light Rail Transit Project Phase I To Venice-Robertson Station	12/31/2012
Los Angeles County MTA	LA0G431	Multi-Modal Transit Center At CSUN To Include Passenger Loading Areas And Bus Shelters	10/1/2012
Los Angeles	LA974165	Macarthur Park Station Improvements Include Design And Construction Of A Plaza To Accommodate Public Access (Pedestrian Entrances, Walkways,	12/30/2011

County MTA		Bicycle Facilities) PPNO# 3417	
Los Angeles, City Of	LA0G155	LACRD – Transit Signal Priority In The City Of Los Angeles.	02/28/2012
Pasadena	LAE3790	The Pasadena ITS Integrates 3 Components; Traffic Signal Communication And Control, Transit Vehicle Arrival Info And Public Parking Availability Info. SAFETEA-LU Prj #3790 And #399	6/30/2013
Pico Rivera (Previously Lead Agency Was SGVCOG)	LA0C57	Ace/Gateway Cities-Construct Grade Sep. At Passons Blvd In Pico Rivera (& Modify Profile Of Serapis Av,)(Part Of Alameda Corr East Proj.)SAFETEA-LU HPP # 1666 (TCRP #54.3)	12/31/2012
Rolling Hills Estate	LAF1529	Palos Verdes Drive North Bike Lanes. Construction Of Class Ii Bike Lane And Related Improvements On Palos Verdes Drive North	12/31/2013
Santa Clarita	LAF1424	McBean Regional Transit Center Park And Ride. Purchase Land, Design, And Construct A Regional Park-And-Ride Lot Adjacent To The Mc Bean Regional Transit Center In The City Of Santa Clarita.	10/1/2013
Whittier	LA0G257	Whittier Greenway Trailhead Park. Extension Of Whittier Greenway Trail From Mills Avenue To 300 Feet East Of Mills Avenue On City Owned Right-Of-Way In Conjunction With The Construction Of New Trailhead Park With A Park And Ride Parking Lot For Nearby Public Transit Stop. New 20 Space Parking Lot Would Be Constructed Of “Green” Permeable Pavement In Compliance With NPDES Requirements. Includes The Installation Of Park Amenities, Drinking Fountain For The Convenience Of Pedestrian And Bicycle Patrons Of The Whittier Greenway Trail. Construction Of New Sidewalks Along Mills Avenue To Provide Whittier Greenway Trail Crossing Connection At The Signalized Intersection Of Mills Avenue At Lambert Road.	9/30/2014
Artesia	LAF1607	South Street Pedestrian, Bikeway And Transit Improvement. Improve Pedestrian Environment And Transit Stop Locations With Landscaped Medians, Transit Shelters, Benches, Sidewalk Enhancements And Lighting. Close Existing Bike Lane Gap.	10/1/2014
Avalon	LAF1501	County Club Drive Bikeway Improvement Project. Construction Of A 4-Foot Wide Class Ii Bike Lane In Both Directions Along A One Mile Section Of Country Club Drive.	10/1/2013
Azusa	LAF3434	Azusa Intermodal Transit Center. Construct Regional Azusa Intermodal Transit Center To Accommodate Existing And Future Parking Demand And	6/30/2015

		Support Effective Transit Use.	
Baldwin Park	LAE0076	Construct Add'l Vehicle Parking (200 To 400 Spaces), Bicycle Parking Lot And Pedestrian Rest Area At The Transit Center	12/31/2014
Baldwin Park	LAF1654	Baldwin Park Metrolink Pedestrian Overcrossing. Construct A Pedestrian Overcrossing Over Bogart Ave And The Metrolink Line To Link The Station With Vital Bus Transfer Points And To Provide Access To Parking Overflow Areas.	10/1/2015
Burbank	LAF1502	San Fernando Bikeway. Implement A Class I Bikeway Along San Fernando Blvd, Victory Place And Burbank Western Channel To Complete The Burbank Leg Of A 12 Mile Bikeway.	6/30/2014
Caltrans	LA000358	Route 5: – From Route 134 To Route 170 HOV Lanes (8 To 10 Lanes) (CFP 346)(2001 CFP 8355). (Ea# 12180, 12181,12182,12183,12184, 13350 PPNO 0142f,151e,3985,3986,3987) SAFETEA-LU# 570. Construct Modified Ic @ I-5 Empire Ave, Aux Lns Nb & Sb Between Burb	12/31/2014
Caltrans	LA000548	Route 10: From Puente To Citrus HOV Lanes From 8 To 10 Lanes (C-ISTEA 77720) (Ea# 117080, PPNO# 0309n)	2/12/2016
Caltrans	LA0B875	Route 10: HOV Lanes From Citrus To Route 57/210 – (Ea# 11934, PPNO# 0310b)	3/15/2016
Caltrans	LA0D73	Route 5: La Mirada, Norwalk & Santa Fe Springs-Orange Co Line To Rte 605 Junction. Widen For HOV & Mixed Flow Lns, Reconstruct Valley View (Ea 2159a0, PPNO 2808). TCRP#42.2&42.1	12/1/2016
Caltrans	LA000357	Route 5: From Route 170 To Route 118 One HOV Lane In Each Direction (10 To 12 Lanes) Including The Reconstruction Of The I-5/Sr-170 Mixed Flow Connector And The Construction Of The I-5/Sr-170 HOV To HOV Connector (CFP 345) (2001 CFP 8339; CFP2197).	12/31/2013
Caltrans	LA01342	Route 10: Rt 10 From Rt 605 To Puente Ave HOV Lanes (8+0 To 8+2) (Ea# 117070, PPNO 0306h) PPNO 3333 3382 Ab 3090 Rep (TCRP #40)	10/28/2013
Caltrans	LA996134	Route 5: Rte. 5/14 Interchange & HOV Lns On Rte 14 – Construct 2 Elevated Lanes – HOV Connector (Direct Connectors) (Ea# 16800)(2001 CFP 8343) (PPNO 0168m)	5/24/2013
Claremont	LAF1510	Claremont Portion Of The Citrus Regional Bikeway. This Project Proposes The Implementation Of The Claremont Portion Of The Citrus Regional Bikeway Utilizing Bonita Avenue And First Street As Primary Class Ii Bike Routes.	10/1/2012

El Monte	LAF1504	El Monte: Transit Cycle Friendly. El Monte Proposes To Implement The 1st Phase Of The El Monte Bike-Transit Hub Component (Metro Bicycle Transportation Strategic Plan) A Countywide Effort To Improve Bike Facilities	10/1/2013
Long Beach	LAE1296	Long Beach Intelligent Transportation System	9/30/2012
Long Beach	LAF1530	Bicycle System Gap Closures & Improved La River Bike Path. Project Will Construct Priority Class I & Iii Bicycle System Gap Closures In Long Beach And Improve Connection To La River.	10/1/2014
Los Angeles County MTA	LA0D198	Crenshaw Transit Corridor	12/31/2018
Los Angeles County MTA	LA0G010	Regional Connector – Light Rail In Tunnel Allowing Through Movements Of Trains, Blue, Gold, Expo Lines. From Alameda / 1st Street To 7th Street/Metro Center	12/31/2019
Los Angeles County MTA	LA0G154	Lacrd – El Monte Transit Center Improvements And El Monte Busway Improvements, Including Bike Lockers, Ticket Vending Machines At El Monte Busway Stations And Up To 10 Bus Bays.	12/31/2012
Los Angeles County MTA	LA0G447	Metro Purple Line Westside Subway Extension Segment 1 – Wilshire/Western To Fairfax	12/31/2019
Los Angeles County MTA	LA0C8114	La City Rideshare Services; Provide Commute Info, Employer Assistance And Incentive Programs Through Core & Employer Rideshare Services & MTA Incentive Programs. PPNO 9003	12/30/2016
Los Angeles County MTA	LA963542	Acquisition Revenue Vehicles – 2,513 Clean Fuel Buses: Leased Veh, Fy02 (370) Fy03 (30 HC) + Fy04 (70 HC) + (200 Artics); Fy05-Fy10 Total Of 1000 Buses.	6/30/2014
Los Angeles County MTA	LAE0036	Wilshire/ Vermont Pedestrian Plaza Improvements And Intermodal Pedestrian Linkages	2012
Los Angeles County MTA	LAE0195	Design And Construct Improved Pedestrian Linkages Between Los Angeles Pierce College And MTA’S Rapid Bus Transit Stops To Include Passenger Amenities, 2007 CFP # F1658	10/1/2014
Los Angeles, City Of	LA0C8164	Exposition Blvd Right-Of-Way Bike Path-Westside Extension. Design And Construction Of 2.5 Miles Of Class 1 Bikeway, Lighting, Landscaping & Intersection Improvements. (PPNO# 3184)	2/2/2012

Los Angeles, City Of	LAF1704	Downtown L.A. Alternative Green Transit Modes Trial Program. Offer Shared Ride-Bicycle And Neighborhood Electric Vehicle Transit Services To La City Hall As An Alternative To Overcrowded Dash Service	6/27/2014
Los Angeles, City Of	LA002738	Bikeway/Pedestrian Bridge Over La River At Taylor Yard Class I (CFP 738, 2077) (PPNO# 3156)	7/31/2015
Los Angeles, City Of	LA0B7330	San Fernando Rd Row Bike Path Phase II – Construct 2.75 Miles Clas I Frm First St To Branford St,On MTA-Ownd Row Parlel To San Fernando Rd. Link Cyclsts To Numerous Bus Lne. PPNO 2868.	1/30/2014
Los Angeles, City Of	LAF1450	Encino Park-And-Ride Facility Renovation. Renovation Of The Encino Park-And-Ride Facility In Order To Address Physical And Structural Deficiencies And Add Capacity To This Heavily Utilized Facility. Includes 50 New Parking Spaces And Bike Lockers.	10/1/2013
Los Angeles, City Of	LAF1520	Imperial Highway Bike Lanes. This Project Involves The Modification Of The Median Island And The Widening Of Imperial Highway Along 1000 Ft East Of Pershing Drive To Accomodate Bike Lanes.	6/1/2014
Los Angeles, City Of	LAF1524	San Fernando Rd. Bike Path Ph. IIIA/IIIB – Construction. Recommend Phase IIIA-Construction Of A Class I Bike Path Within Metro Owned Rail Right-Of-Way Along San Fernando Rd. Between Branford St. And Tuxford St Incl Bridge.	10/1/2015
Los Angeles, City Of	LAF1615	Eastside Light Rail Pedestrian Linkage. Improve Linkages Within 1/4 Mile Of Metro’s Gold Line Lrt.	6/29/2012
Los Angeles, City Of	LAF1657	Los Angeles Valley College (LAVC) Bus Station Extension. Project Will Extend The Orange Line Station At The La Valley College By Providing A Direct Pedestrian Connection From The Station To A New Pedestrian Entrance To LAVC.	10/1/2013
Los Angeles, City Of	LAF1708	Hollywood Integrated Modal Information System. Installation Of Electronic, Direction And Parking Availability Signs With Internet Connectivity To Provide Advance And Real-Time Information Intended To Increase Transit Ridership	9/21/2015
Los Angeles, City Of	LAF3419	Sunset Junction Phase 2. Create A Multi-Modal Transit Plaza To Integrate Public Transportation, Pedestrian & Bicycle Improvements That Would Result In Regional & Local Benefits (CFP3844). Triangle Property On Sunset Blvd Bwt Manzanita And Santa Monica.	6/30/2017
Monrovia	LAE0039	Transit Village – Provide A Trans. Facility For Satellite Parking For Sierra	12/31/2012

		Madre Villa Gold Line Sta, P-N-R For Commuters, A Foothill Transit Store.	
Port Of Los Angeles	LAF3170	Port Truck Traffic Reduction Program: West Basin Railyard. Intermodal Railyard Connecting Port Of La With Alameda Corridor To Accommodate Increased Loading Of Trains At The Port, Thereby Reducing Truck Trips To Off-Dock Railyards.	12/1/2014
Rancho Palos Verdes	LAF1506	Bike Compatible Rdwy Safety And Linkage On Palos Verdes Dr. The Project Will Have A Class Ii Bike Lane On Both Sides Of Palos Verdes Drive South, With An Unpaved Shoulder For Emergency Use.	10/9/2014
Rancho Palos Verdes	LAF1605	Pedestrian Safe Bus Stop Linkage. Linking 11 Bus Stops Currently Inaccessible Because Of Lack Of Sidewalks On Both The East And West Side Of Hawthorne Blvd. From Crest Rd. To Palos Verdes Dr. South (About 13,000")	12/9/2013

Subject: Initial Study for the Draft Program Environmental Impact Report for: 2012 Air Quality Management Plan (AQMP)

Dear Dr. Smith:

- 1-2 { The Consumer Specialty Products Association (CSPA)¹ appreciates the opportunity to offer initial comments on the South Coast Air Quality Management District's ("South Coast's" or "AQMD's") Draft Program Environmental Impact Report (Program EIR) for the 2012 Air Quality Management Plan (AQMP), which was issued for comment on June 28, 2012.² In these initial comments, CSPA will focus on the draft Program EIR, and related available documents, and the Stationary Source Control Measures for Coatings and Solvents numbered CTS-1, CTS-02, CTS-03, and CTS-04.³
- 1-3 { CSPA strongly objects to the inclusion of these measures in the AQMP, and urges that the measures not be included in the final 2012 AQMP. We will submit comments at a later date on the draft AQMP and its other components (these documents were issued to the public on July 17, 2012).⁴
- 1-4 { CSPA and the consumer products industry has worked cooperatively with the California Air Resources Board (ARB) for nearly 25 years to develop numerous regulations controlling the emissions of volatile organic compounds (VOCs) from the use of our products. These regulations to date have obtained more than 50% reductions in VOC emissions from our

¹ CSPA is a voluntary, non-profit national trade association representing approximately 240 companies engaged in the manufacture, formulation, distribution, and sale of products for household, institutional, commercial and industrial use. CSPA member companies' wide range of products includes home, lawn and garden pesticides, antimicrobial products, air care products, automotive specialty products, detergents and cleaning products, polishes and floor maintenance products, and various types of aerosol products. Through its product stewardship program Product Care[®], and scientific and business-to-business endeavors, CSPA provides its members a platform to effectively address issues regarding the health, safety, sustainability and environmental impacts of their products.

products while maintaining the ability of our products to provide the significant environmental, public health and safety benefits that consumers require and expect. We believe that this is a very significant accomplishment for both our industry and the ARB, and continue in our commitment to assure that consumer products provide maximum benefits and minimal impacts in California and elsewhere.

However, CSPA is extremely concerned to see that South Coast is proposing to include further reductions in VOCs from consumer products in this AQMP that are neither necessary nor cost effective, as well as being technologically and commercially infeasible. There are significant scientific data showing that further VOC reductions for consumer products are not effective or necessary for ozone attainment in the South Coast Air Basin. It is especially unwarranted to include CTS-4 which targets Low Vapor Pressure compounds (LVPs), since scientific studies clearly show that the small percentage of these compounds that are even capable of being in the vapor phase have very limited atmospheric availability and primarily have other environmental fates that do not involve tropospheric photochemistry.

The four control measures potentially impacting consumer products are listed in Table 1-2 under Coatings and Solvents as follows:

- CTS-01 Further VOC Reductions from Architectural Coatings (R1113) [VOC]
- CTS-02 Further Emission Reduction from Miscellaneous Coatings, Adhesives, Solvents and Lubricants [VOC]
- CTS-03 Further VOC Reductions from Mold Release Products [VOC]
- CTS-04 Further VOC Reductions from Consumer Products [VOC]

In the following sections, we will describe the scientific, legal and policy reasons why these four VOC reduction measures cannot and should not be included in the AQMP or the California State Implementation Plan (SIP).

I. The Four CTS Measures Being Proposed Are Neither Effective Nor Necessary for Ozone Attainment.

CSPA strongly believes that the scientific and technical evidence clearly demonstrates that none of the four Coatings and Solvents control measures would be effective in reducing ozone formation and attaining ozone air quality standards.

1-5

A. The AQMD's Initial Attainment Modeling for the AQMP Clearly Shows that the South Coast Air Basin is NOx-Limited and Insensitive to Additional VOC Reductions.

At the June 14th meetings of the South Coast AQMP Advisory Group and Scientific, Technical & Modeling Peer Review Advisory Group, Joe Cassmassi provided updates on preliminary air quality modeling for the AQMP.⁵ These updates included numerous ozone isopleth graphs showing the combinations of nitrogen oxides (NOx) and VOC reductions needed to attain a

⁵ South Coast Scientific, Technical & Modeling Peer Review Advisory Group Meeting #8 for 2012 AQMP (June 14, 2012). See Agenda Item #3 "Update on Technical Analysis and 2008 Ozone Modeling Performance/Carrying Capacity" by Joe Cassmassi, and Sang Mi Lee. The document is posted on South Coast's website at: http://www.aqmd.gov/gb_comit/stmpradvgrp/2012AQMP/meetings/2012/jun14/Item3.pdf

1-5
 Cont.

even ozone standard overall and in various locations in the South Coast air basin. In every sector, the isopleths for attaining a 75 ppb ozone standard were “flatlined” and showed essentially the same NO_x reduction being needed for attainment no matter what reductions were made in VOCs. The isopleths were especially consistent at VOC reduction levels between 0% and 50%. For lower ozone isopleths, the “flatline” extends all the way to 100% VOC reduction; in other words, no amount of VOC reductions will have any impact on ozone levels.

These modeling runs provide clear scientific evidence that the South Coast Air Basin is now largely NO_x-limited, and is moving toward more completely NO_x-limited conditions as NO_x reductions allow lower and lower ozone levels to be attained. VOC reductions are therefore not an effective tool in seeking ozone attainment in the region.

We urge South Coast to include sensitivity modeling runs for all of the control measures (or groups thereof) proposed for inclusion in the AQMP. CSPA strongly believes that such runs will clearly demonstrate that many, if not all, of the VOC reduction strategies being proposed are ineffective and unnecessary.

B. Air Modeling from 2007 Also Clearly Show that Further Reductions in Consumer Products Are Not Needed.

Subsequent to the 1994 California SIP revision, CSPA and other consumer product industry associations conducted a study to assess the sensitivity of ozone in the South Coast and Sacramento Air Basins to consumer product VOC emissions. Our 1997 attainment remodeling study was conducted under 2010 attainment conditions that remained sensitive to overall VOC emissions. Therefore, the results of that 1997 study demonstrated that even under VOC-limited conditions where ozone formation was sensitive to overall VOC levels, ozone formation was *not* sensitive to consumer product VOC emissions.

1-6

The attainment demonstration modeling for the 2007 SIP and South Coast AQMP, on the other hand, was under atmospheric conditions that were far more NO_x-limited, and far less sensitive to overall VOC emissions. We therefore had reason to expect that consumer product VOC emissions should have even less relative impact on ozone attainment in this 2023 attainment scenario than in our earlier study. To determine whether this was indeed the case, CSPA contracted in 2007 with Sierra Research and Environ to conduct a remodeling study, co-funded by CSPA and eight other national consumer product industry associations, to determine the ozone sensitivity of consumer product VOC emissions in the South Coast Air Basin in 2023, and determine what level of emission reductions might actually be necessary. The remodeling study was completed after the adoption of the 2007 AQMP, but prior to the adoption of the 2007 California SIP. The final report from the study, “Assessment of the Need for Long-Term Reduction in Consumer Product Emissions in the South Coast Air Basin”⁶ was submitted as part of the record for the 2007 SIP.

The results of the 2007 Sierra Research study clearly demonstrated that ozone attainment status in the South Coast Air Basin would not be impacted in 2023 if no further reductions in consumer product VOC emissions are made after 2014. The data show that the 50 tons per day of additional statewide consumer products VOC emissions reductions suggested in the South Coast

1-6
 Cont. Socio Econ

AQMP would have no impact on ozone attainment anywhere in the South Coast Air Basin. These VOC emission reductions would likely cost the consumer products industry more than \$1 billion just to determine their feasibility, despite not being necessary for ozone attainment. Clearly those control measures were neither effective nor cost-effective.

CSPA continues to believe that the results of these types of source-sensitivity studies provide important information to support the development of effective ozone attainment strategies. It is important that the control measures in the SIP be focused primarily on those emissions sources that play a significant role in ozone non-attainment in the South Coast and other non-attainment districts.

C. The Vision for Clear Air Modeling Provides Further Evidence that NOx Reduction Is the Key to Clean Air in California.

1-7

Concurrent with the development of the proposed 2012 AQMP, South Coast has been working with the ARB and the San Joaquin Valley Unified Air Pollution Control District (San Joaquin Valley) on a long-term plan for air quality and climate management entitled, "Vision for Clean Air: a Framework for Air Quality and Climate Planning." A public review draft of that plan was released last month.⁷ This longer-term plan, extending to 2050 and beyond, uses a fundamentally different modeling tool based on the Argonne National Laboratory Vision 2011 Model, but clearly comes to the same conclusion: NOx reductions are key to California's Clean Air future for both the South Coast and San Joaquin Valley Air Basins. VOCs are not even mentioned in the 40-page document, and the only mention of "reactive organic gases" is to confirm that the modeling tool used is able to forecast both ROG and NOx. In contrast, the term "NOx" is mentioned a total of 72 times and the document includes extensive discussions about the reduction levels needed to achieve attainment with applicable state and federal ozone standards.⁸

1-8

It is also important to note that the new transportation, fuel and energy sector technologies that the Vision for Clean Air projects as necessary for clean air and climate change mitigation would also result in significant reductions in VOCs as well as NOx from those sources. In general, these sources of VOCs have much higher photochemical reactivity than emissions from consumer products, and therefore will provide more than adequate VOC reductions as a side benefit to the NOx reductions needed for ozone and particulate matter standards attainment. These factors provide more evidence that further VOC reductions from consumer products are not necessary or cost-effective, and should not be included in the 2012 AQMP.

D. Scientific Studies and Analyses Clearly Show that LVPs Have Minimal Impacts on VOC Emissions and Ozone Formation.

1-9

The draft Program EIR description of CTS-04 states that, "Recent testing has shown that low vapor pressure (LVP) solvents readily evaporate and are available to contribute to ozone

⁷ "Vision for Clean Air: a Framework for Air Quality and Climate Planning," Public Review Draft (June 27, 2012). (Hereinafter referred to as "the Vision for Clean Air.") The full text of the document is posted on the ARB's website at: http://www.arb.ca.gov/planning/vision/docs/Vision_for_Clean_Air_Public_Review_Draft.pdf

⁸ The 53-page appendix to Visions for Clean Air has only one mention of VOCs in relation to diesel engine after-treatment systems, on page 31. The text of this document is posted on the ARB website at: http://www.arb.ca.gov/planning/vision/docs/Vision_for_Clean_Air_Appendix_Public_Review_Draft.pdf

CSPA Initial Comments on Draft Program EIR for the 2012 AQMP

July 19, 2012

Page 5 of 7

formation.”⁹ No further information is cited regarding what “recent testing” has occurred, but we believe that there has been substantial research over the past two decades to show that neither of these allegations is true.

LVP compounds are defined in the ARB Consumer Products Regulation as organic materials with vapor pressures less than 0.1 mm Hg at 20 degrees C.¹⁰ These materials range in volatility (ability to enter the vapor phase) from totally non-volatile (incapable of being in the vapor phase at ambient temperatures and pressures) to semi-volatile (capable of temporary existence in the vapor phase at ambient temperatures and pressures).¹¹ This does not mean, however, that even the most volatile LVPs should be considered to “readily evaporate” and certainly does not mean that they “are available to contribute to ozone formation.” Indeed, they are quite resistant to spending significant time in the vapor phase, and can be shown to have very limited availability to be involved in the photochemistry of stratospheric ozone formation.

CSPA and other government and academic partners first began to investigate the environmental fate and atmospheric availability of low volatility organics in 1999 within the Reactivity Research Working Group (RRWG) effort that was soon to be brought under the aegis of NARSTO.¹² The goal of the work was to see if reactivity scales (such as the Maximum Incremental Reactivity scale) and air quality modeling (such as the Urban Airshed Model) could be made to consider the limited vapor-phase availability and alternative environmental fates of organic materials that attenuate their ability to participate in the photochemical reactions that lead to ozone formation. Both the smog chambers where incremental reactivity is assessed, and the computer models used for ozone attainment planning, fail to consider the partitioning of materials between environmental compartments (air, water, soil, vegetation, sediment, etc.) and the various removal mechanisms for materials from the vapor phase (wet deposition, dry deposition, diffusion/adsorption, dissolution, etc.).

The early RRWG efforts culminated in a June 2000 Workshop on Combining Environmental Fate and Air Quality Modeling¹³ at the U.S. Environmental Protection Agency (EPA) in Research Triangle Park, NC, which focused on using fugacity modeling (also known as intermedia transport modeling) such as that recently developed by Dr. Mackay to determine the fate and availability of organic emissions. The work by various scientists demonstrated that standard smog chamber and computer modeling overestimated the ozone formation potential of many organic gases, especially those of low volatility or other factors showing high affinity for removal from the vapor phase.

As an example of that early work, fugacity modeling for 2-butoxyethanol (a water-soluble VOC solvent with vapor pressure between 0.1 mm and 1.0 mm, and therefore of low volatility but not

⁹ Draft Program EIR at p. I – 15.

¹⁰ 17 CCR § 94508(a)(98).

¹¹ At higher temperatures and/or lower pressures, of course, the ability of a given material to remain in the vapor phase increases. Ambient temperatures and pressures, however, are in a relatively very narrow range.

¹² RRWG participants included scientists from the U.S. Environmental Protection Agency, California Air Resources Board, various other state agencies, numerous academics from California and other major universities, and industry scientists from CSPA, the American Chemistry Council, and many other associations. RRWG was active from the late-1990s through the mid-2000s.

¹³ A Final Proceedings to the Workshop was released in January, 2001.

1-9
Cont.

 July 19, 2012
 Page 6 of 7

1-9
 Cont. { an LVP) demonstrated that even for air emissions, only 30% remained in the ambient air long enough to participate in photochemistry; most was removed to other media (water and soil where it was readily biodegraded). If emitted to water not air, virtually none reached ambient air. For a highly volatile organic such as acetone, 96% stayed in ambient air. For the LVP compounds, the range was between 9% and 0% in these initial studies. It was indeed found that if availability were considered along with reactivity, LVPs and some of the lower-volatility VOCs have lower ozone formation potential than acetone, which is VOC exempted as negligibly reactive.

Continued efforts on fate and availability resulted in a 2004 study designed by various RRWG participants and funded by one participant, entitled "Integration of Air Quality and Environmental Multimedia Modeling Task 3.2" by SENES Consultants Limited (Richmond Hill, Ontario, Canada). The 96-page report on this significant study concludes that multimedia dispersion modeling could be used to estimate actual concentrations of emissions in ambient air, which is not done in current air quality modeling.

More recent discussions occurred a few years ago in the newer Reactivity Implementation Working Group (RIWG) have sought to continue work to provide easier mechanisms to take into account the vast differences in relative ozone impacts between various emissions in terms of photochemical reactivity, alternative environmental fates, atmospheric availability and other factors. While further work is needed in this area, it would clearly be unproductive to target LVP compounds for reductions in this AQMP when the use of those compounds serves to lower ozone impacts significantly when compared to high reactivity, high volatility, and high-atmospheric-availability alternatives.

1-10 { Under applicable California law, the state implementation plan for the air basin "...shall only include those provisions necessary to meet the requirements of the [federal] Clean Air Act (42 U.S.C. Sec. 7401 et seq.)."¹⁴ For reasons stated above, it is clear that Control Measure CTS-04, which is aimed at requiring ARB to remove the LVP exemption from the Consumer Products Regulation, is not necessary, and is indeed counterproductive for ozone attainment. Therefore, Control Measure CTS-04 must not be included in the final 2012 AQMP.

II. Summary and Conclusions

1-11 { CSPA appreciates the opportunity to comment on the Initial Study for the Draft Program Environmental Impact Report for: 2012 Air Quality Management Plan (AQMP). We support South Coast's goal to provide healthy air quality in California. However, the consumer product measures in this proposed AQMP that commit to further reductions of VOC emissions for consumer products are neither necessary nor feasible, and would harm the consumers and businesses in the state who rely on our products to help provide a clean and healthy environment in which to live and work.

1-12 { In these comments, we have shown that further VOC reductions from consumer products or other low-reactivity sources are not needed for ozone attainment. In addition, we have shown that reducing LVP materials in consumer products would have little or no impact in VOC emissions and ozone formation. The control measures impacting consumer products noted in the

Cont.

draft EIR to the 2012 AQMP are not feasible, necessary or cost-effective, and should not be considered for inclusion in the final 2012 AQMP.

1-13

CSPA and the consumer products industry take seriously the environmental health and safety benefits of its products, and continuously seek to improve them. Thus, the consumer specialty products industry worked constructively and cooperatively with ARB staff for nearly 25 years to lower VOC content in consumer products in California. We plan to continue to work in a cooperative manner to improve air quality in California while maintaining our industry's ability to supply effective products that consumers can rely upon to contribute positively to their health, safety, and quality of life.

Consumer Specialty Products Association (CSPA) – Joe Yost (7/19/12)

- 1-1 This comment notifies the SCAQMD that a comment letter is attached. No further response is necessary.
- 1-2 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Initial Study for the Draft Program EIR for the 2012 AQMP. No further response is necessary.
- 1-3 This comment is a general comment opposing including control measure CTS-04 in the 2012. Given the proximity of the attainment dates with respect to both the federal PM 2.5 and 8-hour ozone standards, the inclusion of CTS-01, CTS-02, CTS-03 and CTS-04 in the 2012 AQMP represent a modest but very important commitment to ensure continuity in achieving reductions on all PM 2.5 precursors and the region's efforts towards achieving the 8-hour ozone standard, by minimizing ozone exposure and especially during the interim years, until a more comprehensive 8-hour ozone attainment strategy is developed. See also Response to comment 1-4 for a comprehensive response to this.
- 1-4 SCAQMD staff appreciate the efforts and partnership with CARB to date to reduce VOC emissions by 50 percent; however, SCAQMD staff is concerned that reformulation of products by substituting low vapor pressure volatile organic compounds (LVP-VOC) for other solvents considered to be VOCs may not achieve the ozone reduction benefits anticipated by the Consumer Products Regulation (CPR), considering the increasing use of LVP-VOCs used in formulations to comply with the CPR, as well as their relative evaporation under ambient conditions and Maximum Increment Reactivity (MIR) values that are much higher than ethane's MIR value.

SCAQMD staff research indicates that estimated cost effectiveness of the proposed control measures are within the range of acceptability for previously adopted SCAQMD VOC rules. Please note that the estimated cost effectiveness figures are conservative estimates and likely overstate the actual costs as the California Department of General Services' "Green Building Initiative" concludes that, "Environmentally preferred cleaners are generally competitively. This includes the purchase price of the product, the cost of meeting regulations for worker safety and environmental rules, and the costs of disposal for leftover product." As an example, the City of Santa Monica reported spending five percent less on its cleaning products costs when it switched from conventional cleaners to less toxic brands a decade ago.¹

CTS-01 and CTS-03 do not impact Consumer Products. Portions of CTS-02 (e.g., Adhesives and Sealants and Metalworking Fluids/Lubricants) may impact some products also regulated under the CPR to the extent they are utilized in a manufacturing or commercial setting?

¹ U.S. Environmental Protection Agency, Environmentally Preferable Purchasing Program, *The City of Santa Monica's Environmental Purchasing: A Case Study*, EPA742-R-98-001, March 1998; www.epa.gov/epp/pubs/case/santa.pdf.

CTS-02 is aimed at investigating and implementing as appropriate all feasible measures, which include control measure implemented by other air pollution control agencies, including state air pollution control districts and federal control techniques guidelines. Adoption and implementation by other agencies indicates that such measures have been evaluated for technological feasibility and cost-effectiveness, and the SCAQMD is obligated to investigate the applicability to the region. Further, this proposed control measure focuses on technological advancements in low-VOC products that are covered by a gamut of coatings and solvents rules, adhesives/sealants, as well as metalworking fluids/lubricant rules.

CTS-03 is aimed at investigating and implementing as appropriate lower VOC Mold Release Product alternatives. This control measure focuses on stationary sources that utilize mold release agents during manufacturing and some area sources.

CTS-04 represents potentially one of the largest VOC emission source categories. VOC emissions from consumer products are projected in 2020 to be the largest source of emissions in the district exceeding light duty passenger vehicles and dwarfing emissions from stationary sources such as coatings and petroleum marketing. As such, it is incumbent on the SCAQMD to investigate all areas for potential emission reductions, including evaluation of any existing regulatory exemptions or exclusions. {We could include the Top Ten Emitting Categories in the South Coast Air Basin In 2010 and 2020 from the CARB CPR staff report to illustrate }

Current emissions inventory and photochemical air quality models include speciation profiles that account for total organic gases (TOGs), including reactive compounds, unreactive and exempt compounds, as well as LVP-VOC compounds. Model results for ozone non-attainment areas have demonstrated that even compounds with low photochemical reactivity or LVP-VOCs contribute to photochemical ozone formation and not including these would compromise the ozone attainment demonstrations. Further, these models do not include “Atmospheric Availability” or “Environmental Fate” concepts. SCAQMD staff will continue to work with U.S. EPA and CARB staff on updating the ozone models, especially as additional peer-reviewed fugacity studies justify incorporation into these predictive models.

Because substitution of traditional VOC containing materials indicates an increased use of LVP-VOCs, a review of the specific and extent of LVP-VOCs utilized and the associated applications is required to ensure that VOC emission reductions and ozone reduction benefits are maintained as originally intended. Following an internal study that indicates that some LVP-VOCs can evaporate nearly as rapidly as other VOC materials, SCAQMD staff believes that additional review of specific materials and applications and the associated LVP-VOC qualification criteria may help identify air quality improvement opportunities.

The proposed control measure is intended to study the air quality improvement potential for replacing LVP-VOC containing compositions with alternative low VOC formulations. The SCAQMD, through the implementation of the Clean Air Cleaners Program and Rule 1143 – Consumer Paint Thinners and Multi-Purpose Solvents, has identified alternative low-VOC, cost-effective technologies that are currently commercially available and used that do not rely upon the LVP-VOC exemption. The proposed control measure may

- involve eliminating or amending the CARB LVP-VOC criteria based on scientific data, which may include MIR and similar photochemical reactivity parameters. Consultation with external stakeholders including technical experts as well as manufacturers, end users and other concerned interests is expected during the rule development process to ensure overall efforts are feasible, productive and cost-effective.
- 1-5 The overall control strategy for the 2012 AQMP is designed to meet applicable federal and state requirements. While the 2012 AQMP focuses on PM reductions to attain the federal 24-hour PM_{2.5} standard by 2014, the Plan also includes ozone reduction strategies to make expeditious progress in attaining the state one-hour and eight-hour standards and the federal eight-hour ozone standards. Although the ozone strategy focuses primarily on NO_x reductions, VOC emission reductions are also needed to reduce ozone exposure, especially in the western portions of the Basin. As shown in the NO_x/VOC isopleths in Appendix V of the Draft 2012 AQMP, VOC reductions help to achieve attainment of the ozone standards at all the air quality monitoring stations. As such, a nominal amount of VOC reductions are proposed in the Draft Plan. The proposed VOC control measures in the Draft 2012 AQMP are based on implementing all feasible control measures through the application of available technologies and management practices and to seek a fair share reduction from both mobile and stationary sources. As zero or near-zero technologies are implemented for mobile sources to reduce NO_x emissions, concurrent VOC reductions are expected, contributing to their fair share of reductions.
- 1-6 The Draft 2012 mobile source emissions inventory reflects the changes from CARB's 2010 rulemaking, which have resulted in a different baseline VOC/NO_x ratio. The resulting precursor mix has increased ozone forming potential, particularly near source areas. As briefly discussed in the response to comment 1-5, the Draft 2012 baseline emissions inventory indicates that the Basin VOC/NO_x ratio will increase steadily with time. Given the non-linearity of ozone formation, localized ozone concentrations will increase regionally before sharply decreasing as NO_x emissions are reduced. As stated in the comment, for projected future concentrations near the 2006 federal eight-hour ozone standard, the reduction of ozone is mainly driven by NO_x controls. However, the cross-over between ozone formation and loss is dependent upon both the magnitude of the ozone observed concentration and location along the transport path dependent. While the implementation of NO_x controls needed to attain the eight-hour standard are projected to begin in the early 2020's, additional VOC short-term controls implemented prior to 2020 will help lower ozone concentrations in and downwind of the metropolitan emissions source areas such as the San Gabriel Valley.
- 1-7 While the commenter correctly identifies NO_x reductions as the focus of the Vision document it is important to note that the proposed strategy discussed in the Vision document is targeting levels of ozone at and beyond the new federal eight-hour ozone standard attainment level of 75 ppb. As stated in the response to comments 1-5 and 1-6 limited VOC reductions will be beneficial to the reduction of ozone in the western portion of the Basin in the interim years before the full impact of the NO_x "heavy" strategy becomes effective.
- 1-8 The SCAQMD recognizes and accounts for the so-called side benefit of VOC reductions associated with enacting control measures that primarily focused on other pollutants such

as NOx. However, the 2012 AQMP takes into account reductions in all areas and from all measures and does not overweight VOC reductions from targeted VOC control measures. The AQMP analysis concludes that the collective VOC reductions from all measures are necessary in the SCAQMD's efforts to attain and maintain air quality standards. See also response to Comment #1-4.

- 1-9 The quoted text is a summary of the background description which states that "...Further testing indicated that many of the LVP-VOC solvent evaporate nearly as quickly as the traditional solvents they were meant to replace and have Maximum Incremental Reactivity (MIR) values well above the threshold considered to be non-reactive, currently based on ethane." The statement in the Proposed Method of Control section of the control measure has been updated to indicate that not all qualifying LVP-VOC solvents readily evaporate and are available to contribute to ozone formation. The testing is a result of an internal study over a six month period culminating in the presentation entitled "Non-Volatile, Semi-Volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds" provided by SCAQMD staff at the 2012 Air and Waste Management Association conference earlier this year. While the study found widely used LVP-VOC solvents to evaporate in timeframes similar to traditional VOC solvents, it also notes that some LVP-VOC solvents do not readily volatilize in ambient conditions. In the near future, SCAQMD staff plans to publish a more detailed technical paper summarizing the evaporation study.

The SCAQMD's experience with Rule 1143 – Consumer Paint Thinners and Multi-Purpose Solvents has demonstrated that LVP-VOC solvents are not needed to meet lower VOC thresholds in the consumer products arena—in the case of Rule 1143, 25 grams per liter VOC. Under Rule 1143, compliant products that use soy, aqueous, and exempt solvents are already available and in use today. Furthermore, CARB does not list any specific LVP-VOCs that can be used for reformulation of paint thinners, and the LVP-VOC exemption was not specifically added to address the paint thinners or multi-purpose solvent categories. However, the LVP-VOC exemption allows manufacturers to relabel their products as General Purpose Degreasers and add up to 100% LVP-VOCs. Further, as a part of developing the Clean Air Cleaners Certification program, staff tested and determined that LVP-VOCs may add up to 50% on average VOCs in formulations of certain industrial and institutional cleaners. Of the 17 products tested, LVP-VOC solvents comprised more than two-thirds of the VOC contribution and five products had more than 80 percent LVP-VOC with the highest containing 98.8% LVP-VOC. Finally, as a result of AQMD's evaluation of semi-volatile materials, most notably the recent development of Rule 1144 – Metalworking Fluids and Direct-Contact Lubricants, it is clear that some of these LVP-VOC solvents do evaporate and therefore are available to react with oxides of nitrogen to form ozone.

The SCAQMD supports a reactivity-based approach to control ozone and in fact has committed staff to study the effects of a reactivity based approach by activity participating in the North American Research Strategy for Tropospheric Ozone (NARSTO) work related to reactivity. AQMD staff also participated in the Reactivity Industry Working Group to assess the toxicity, enforceability, fate and availability, and implementation committees

Current emissions inventory and photochemical air quality models include speciation profiles that account for total organic gases (TOGs), including reactive compounds, unreactive and exempt compounds, as well as LVP-VOC compounds. Model results for ozone non-attainment areas have demonstrated that even compounds with low photochemical reactivity or LVP-VOCs contribute to photochemical ozone formation and not including these would compromise the ozone attainment demonstrations. Further, these models do not include “Atmospheric Availability” or “Environmental Fate” concepts. SCAQMD staff will continue to work with USEPA and CARB staff on updating the ozone models, especially as additional peer-reviewed fugacity studies justify incorporation into these predictive models.

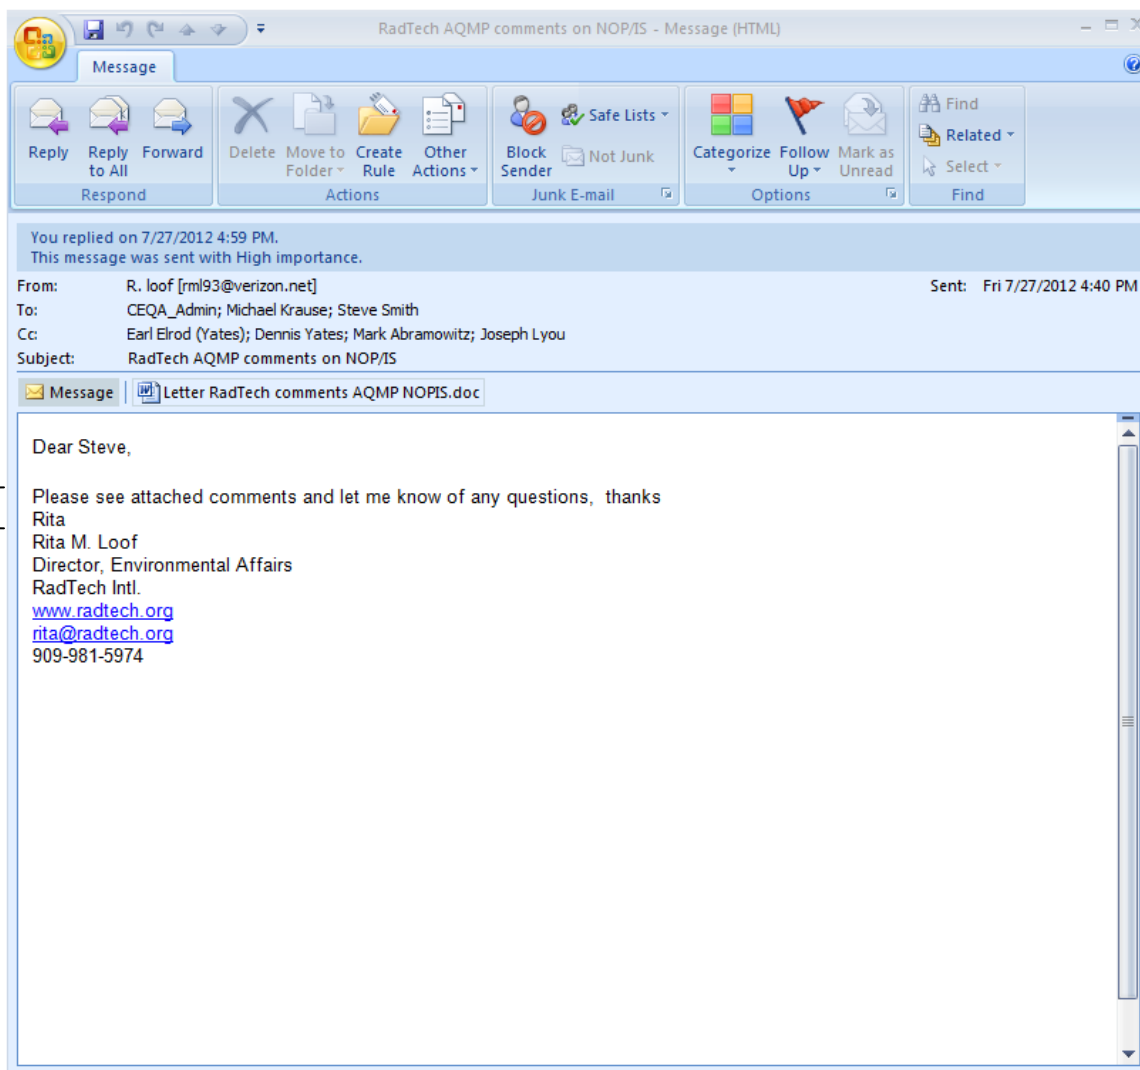

While the SCAQMD study indicates that some LVP solvents do not readily volatilize under tested conditions, the purpose of the proposed control measure is to focus on those specific LVP-VOCs that represent the highest potential contributor to ozone formation based on evaluated volatility, relative MIR value, and overall usage. Addressing CARB qualifying LVP-VOCs in this manner would ensure that only additional air quality improvement gains would be pursued rather than sacrificing any gains from substituting out of any previously used high reactivity, high volatility, and high-atmospheric-availability alternatives.

The SCAQMD looks forward to sharing and working with CSPA in the development of technically feasible and cost-effective strategies towards improving air quality. See also response to Comment # 1-4.

- 1-10 The comment correctly cites the Health and Safety Code provision stating that the SIP for the Basin shall “only include those measures necessary to meet the requirements of the [federal] Clean Air Act...” However, in order to attain either the (revoked) one-hour ozone standard or the 8-hour ozone standard, additional emission reductions of both VOC and NO_x must be obtained. At present, the SIP relies on additional reductions of both VOC and NO_x described in measures authorized under Section 182(e)(5), commonly called the “black box.” Control Measure CTS-04 is intended to obtain additional emission reductions of VOC and reduce reliance on the “black box.” SCAQMD staff disagrees with the conclusion that CTS-04 is not necessary.
- 1-11 Consumer products, despite the significant past emission reduction efforts, represent the largest source of VOC emissions in the South Coast Basin. As pointed out in the control measure, a significant fraction of the emission reductions from this sources category originate from the use of LVP products. Recent studies, however, set in question the efficiency of the LVP products in reducing ozone formation as was originally assumed during the adoption of these programs. While there are no emission reductions associated with this control measure, CTS-04 commits to evaluate the LVP issue and ensure that the emission reduction and ozone reduction benefits assumed in the already adopted consumer regulation do indeed occur. Further, experience with VOC-containing products and solvents used in industrial and commercial settings indicate that further reductions from this source category, without the use of LVPs, are feasible and cost effective. Moreover, VOC emissions remain as a precursor for both PM 2.5 and ozone. And, while the Draft 2012 AQMP, which includes the assumed ozone reduction benefit of the LVP products, identifies NO_x reductions as one of the most effective precursor reduction to rely on for attainment of the 8-hour ozone standard, further reductions on VOC can be

helpful by reducing ozone exposure, especially during the interim years and in certain VOC-limited regions of the South Coast Basin. Further, reductions in VOCs would provide some insurance for the attainment efforts during the outer years and can certainly support the one-hour ozone attainment demonstration efforts. Therefore, for all the reasons stated above, staff believes the inclusion of CTS-04 in the 2012 AQMP is very important.

- 1-12 The comment states that further VOC reductions from consumer products or low-reactivity sources are not needed for ozone attainment. Additionally, the comment states that reducing LVP materials in consumer products would have little or no impact in VOC emissions and ozone formation. Therefore, control measures impacting consumer products noted in the Draft EIR to the 2012 AQMP are not feasible, necessary or cost-effective, and should not be considered for inclusion in the Final 2012 AQMP. The responses provided to Comments 1-4 through 1-9 address the continued need for VOC emission reductions and the significant role the use of consumer products has in the generation of VOC emissions and ozone formation. The Clean Air Choices Cleaner program has nearly 50 different products that do not rely upon LVP-VOC solvents to meet VOC limits. During research conducted to determine to establish the program, staff determined that more than 90 percent of the environmentally preferable cleaning products already on the market meet current standards without relying on the LVP-VOC exemption. These products are cost competitive with those that do contain LVP-VOC solvents. One of the providers of certified cleaners testified before the CA State Assembly in 2008 that the prices of its “green” cleaners are equivalent to its conventional cleaning chemicals. For consumer paint thinners and multi-purpose solvents, compliant alternatives not containing LVP-VOC solvents were less expensive than their 100% LVP-VOC containing counterparts until recently. In the last year, there has been a significant increase in acetone cost and a decrease in LVP-VOC containing consumer paint thinner and multi-purpose solvent cost. Despite the changes in cost, the cost-effectiveness is less than \$2,300 per ton of VOC reduced – comparable to other adopted VOC regulations. Therefore a cost-effectiveness of less than \$10,000 per ton is included in the control measure, considering that some consumer products categories such as consumer paint thinners and multi-purpose solvents may be formulated with more LVP solvents than other categories that may include a smaller portion.
- 1-13 This comment concludes the letter. No further response is necessary.

2-1

 Diamond Bar, California 91765

Re: Public comments to Notice of Preparation of a Draft Environmental Impact Report for the 2012 Air Quality Management Plan

Dear Mr. Smith:

2-2

RadTech International is pleased to comment on the proposed Notice of Preparation and Initial Study for the 2012 AQMP. RadTech supports the district's efforts to improve air quality in the Basin without sacrificing a healthy business climate and believes that the implementation of UV/EB technology can help accomplish both goals.

As you know, I am also a member of the district's AQMP advisory committee and have been making comments during those meetings as well. I would like to encourage the district to consider UV/EB technology as one of the many alternatives to achieve clean air standards. The table below gives a picture of the categories where our technology can play a role. A notation is included to differentiate between areas where the technology is currently being used versus areas where the technology is under development but not necessarily commercially available.

2-3

2-4

We commend district staff for proposing incentive programs such as INC-01 and INC-02 that encourage voluntary emission reductions. Unfortunately the current proposal does not make these programs available to stationary sources of VOCs. We urge the district to extend the incentives program to VOC stationary sources.

We have seen voluntary conversions to UV/EB technology, even without regulatory drivers. Typical UV/EB materials have VOC contents of less than 50 grams per liter. In contrast, the typical VOC limits in district rules are in the neighborhood of 300 grams per liter. The sources that have voluntarily converted and are achieving emission reductions above and beyond those required by district rules, get little if any, rewards for going the extra mile. Instead, we see incentive programs focusing on mobile sources while stationary sources are impacted by command and control approaches.

2-5

We appreciate your attention to these issues and look forward to a productive rulemaking effort.

Sincerely

Rita M. Loof
Director, Environmental Affairs

Responses to Comment Letter #2
RadTech International North America – Rita Loof (7/27/12)

- 2-1 The email informs the reader that the comments are included as an attachment and that the commenter is available to answer questions about the comment letter. No further response is necessary.
- 2-2 The comment states in the introductory paragraph of the letter that RadTech supports efforts to improve air quality and a healthy business climate and believes that ultraviolet (UV)/electron beam (EB) coating technology can assist with both goals. No further response is necessary.
- 2-3 The comment asks for UV/EB coating technology to be considered as one of the many alternatives to achieve clean air standards in SCAQMD rules including pharmaceutical and cosmetic, coating, adhesive and sealant, and chrome plating and chromic acid anodizing. SCAQMD staff appreciates work done by trade organizations to develop low emission technologies. SCAQMD is neutral on technologies as long as they comply with rule requirements.
- 2-4 The comment states that incentive programs such as control measures INC-01 and INC-02 are not available to stationary sources of VOCs. The comment asks for the incentive programs to be extended to stationary sources of VOCs.

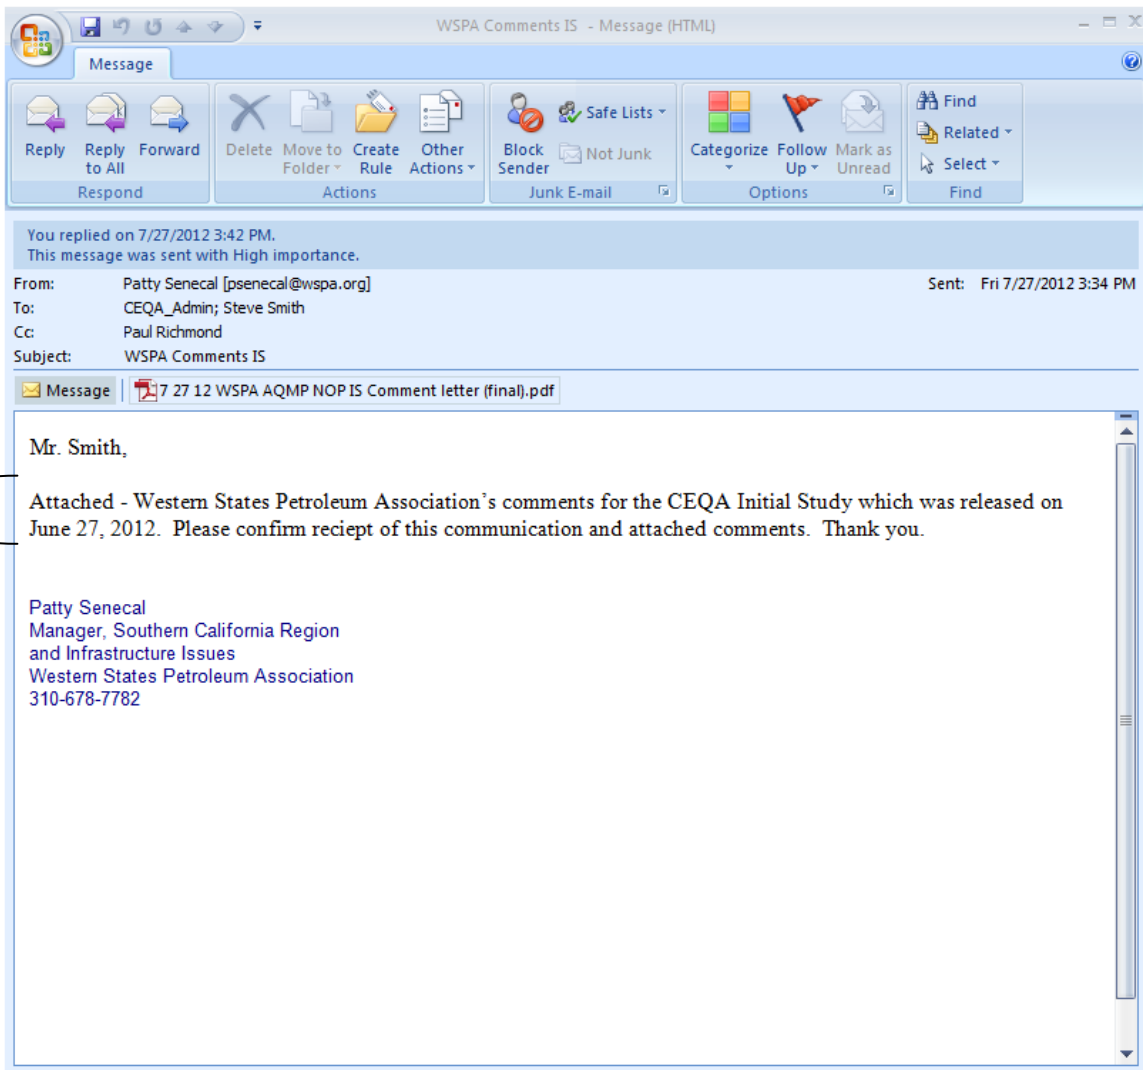

While the region has made great progress in reducing emissions from all sources of pollution, significant more reductions above and beyond to those that have already been achieved or anticipated to be achieved by 2023 are necessary in order for this region to meet the California and federal ambient air quality standards for PM 2.5 and ozone. To reach the percent pollutant reductions levels necessary for attainment, especially for NO_x, the region needs to redouble its pollution reduction efforts and explore avenues that complement its current regulatory efforts and accelerate and catalyze emission reductions in the Basin.

The Carl Moyer program, providing funding to accelerate the fleet turnover of mobile sources, has been extremely successful in reducing emissions above and beyond what is expected from the regulatory program. The purpose of INC-01 is to create a Carl Moyer type program for stationary sources, to accelerate their turnover to newer, less polluting equipment and resulting in greater emission reductions than those anticipated by the current regulatory structure that relies on natural fleet turnover rates. The control measure focuses on NO_x reductions because NO_x happens to be the key precursor of PM 2.5 and ozone that needs to be reduced to levels that far exceed those needed for other precursors. INC-02, on the other hand, seeks to provide incentives for the manufacture of zero and near-zero technologies (stationary or mobile) in our region and, hence, help the region's pollution reduction efforts and its economy through the creation of local manufacturing jobs.

Please note that incentives for the use of ultra-low emission products by stationary sources already exist through "Supercompliant" designation and the associated streamlined recordkeeping under Rule 109, reduced emission fees and flexibility in expanding production by remaining within the facility's permit limits.

- 2-5 No response required. This comment concludes remarks made in the letter and requests the SCAQMD to address the previous comments.

Ceqa_admin@aqmd.gov

July 27, 2012

Steve Smith, Ph.D.
Program Supervisor, CEQA
South Coast Air Quality Management District - CEQA
21865 Copley Drive
Diamond Bar, CA 91765

Dear Dr. Smith:

INITIAL STUDY FOR THE DRAFT PROGRAM EIR FOR THE 2012 AQMP

3-2

Western States Petroleum Association (WSPA) is a non-profit trade association representing twenty- seven companies that explore for, produce, refine, transport and market petroleum, petroleum products, natural gas and other energy supplies in California, Arizona, Nevada, Oregon, Washington and Hawaii. WSPA-member companies operate petroleum refineries and other facilities in the South Coast Air Basin that will be impacted by the 2012 Air Quality Management Plan (AQMP) and the rule development that might stem from the final AQMP as adopted by the Governing Board.

3-3

WSPA appreciates the opportunity to submit these comments for the CEQA Initial Study (IS), as released on June 27, 2012. WSPA's comments fall into two general categories, 1) inconsistencies between the descriptions of the draft proposed control measures in the IS compared to the language of the draft control measures¹ themselves, and 2) potentially significant impact areas that have not been identified as candidate areas for study in the Draft Program EIR (DPEIR).

I. Descriptions of the Control Measures in the Initial Study

3-4

WSPA recognizes that the descriptions in the IS of the proposed AQMP control measures might only be intended to paraphrase the control measures themselves, but there are some discrepancies that need to be resolved prior to preparation of the DPEIR. The analysis in the DPEIR needs to be based on the actual language of the control measures. Following, are several examples of the discrepancies that are associated with control measures that are of particular interest to WSPA:

3-5

CMB-01. The IS states that the control measure would seek further reductions in RECLAIM NO_x allocations "for the years 2015 through 2017" and "for the years 2017 through 2020" for Phases I and II, respectively. This contradicts the proposed timing in the actual control measure, which is 2014 and 2023 for

¹ Control measures in the Draft AQMP as released by the District on or about July 17, 2012.

- 3-5 Cont. { Phases I and II, respectively. In addition, the description in the IS refers to a BARCT review for Phase I when in fact the current control measure itself potentially involves a "shave" of NOx RTCs from the market but no BARCT review. A BARCT review is only being contemplated for Phase II.
- 3-6 { FUG-02. Whereas the description in the IS states that the purpose of the control measure is to reduce emissions "... by expanding rule applicability... to ... currently exempted facilities ...", the current draft control measure seems to suggest that the potential control measure will first evaluate the potential for further reductions if applicability of Rule 1177 were to be extended. In other words, the extension of Rule 1177 to currently exempt facilities should not necessarily be assumed to be the outcome evaluated in the EIR.
- 3-7 { FUG-03. "Smart" Leak Detection and Repair (Smart-LDAR) is mentioned as a possible option in the description of the control measure in the IS, but the current draft control measure suggests that Smart-LDAR will be an added requirement on top of at least some existing programs.
- { Further, the description in the IS includes consideration of vapor recovery systems whereas there is no such mention in the control measure itself. That is as it should be. LDAR programs and vapor recovery systems are completely separate and distinct topics, and they should not be linked in either a control measure or a future rule that might follow from the control measure.
- 3-8 { MCS-03. The description of the control measure in the IS states that the control measure "... would reduce emissions during equipment startup, shutdown and turnaround." But, the description goes on to say that "Opportunities for further reducing emissions ... potentially exist ..." In WSPA's view, the latter statement is clearly the more appropriate one. As a practical matter, the District believes that it does not have sufficient usable data regarding emissions attributable to startups, shutdowns, or turnarounds and those circumstances are the basis for Phase I of the control measure, which is a data gathering effort.
- 3-9 { **II. Additional Candidate Areas for Study in the Draft Program EIR**
- { WSPA's review of the proposed stationary source control measures in the draft AQMP has led us to the conclusion that there are potentially significant impact areas, which have not been identified in the IS, but that should be evaluated in the DPEIR.
- 3-10 { FUG-01. Further VOC Reductions from Vacuum Trucks. Among the potential methods of control listed in the control measure itself are carbon adsorption and liquid scrubbers. Both of these methods involve the generation of wastes that require proper disposal. Thus, there is a potential impact in the "Solid/Hazardous Waste" category, and that impact needs to be evaluated in the DPEIR.
- 3-11 { MCS-03. Improved Start-up, Shutdown and Turnaround Procedures. Although the control measure itself includes a broad, "catch-all" set of potential requirements, its clear focus is on modifications to refinery operational procedures. In fact, "procedures" are mentioned no less than six times, including the statement in the section titled "Implementing Agency" that, "The District has authority to regulate non-vehicular sources, including to establish procedures ..." (Emphasis added.)
- { The District has not demonstrated any linkage between any type of refinery procedures - operating procedures, shutdown/startup/turnaround procedures, or any other procedures - and emissions. Nor has the

- 3-11
Cont. District demonstrated that its Staff has the requisite experience and qualifications to prepare refinery procedures of any description. In direct contrast, existing refinery procedures have been developed by the individual refineries themselves based on their considerable expertise and total familiarity with their respective facilities. Existing refinery procedures are designed to accomplish various tasks while maintaining a strong focus on personnel and plant safety, operational reliability, and environmental considerations.
- If the District, during the course of subsequent rule development, and in spite of its lack of knowledge of refinery operations, were to seek to impose "procedures" of their invention on facilities, it is conceivable and even likely that any such procedures could adversely affect safety and reliability at the facilities, as well as have an adverse effect on the environment.
- 3-12 WSPA notes that the IS has not recognized that there are any potential impacts whatsoever associated with MCS-03. Further, according to footnotes 1 and 2 of Appendix A (page A-11), the IS has discounted the possibility that operating procedures or practices - particularly those potentially imposed through regulatory action - can have significant adverse consequences. These are serious shortcomings. Therefore, multiple potentially significant impact areas will need to be evaluated in the DPEIR.
- 3-13 CEQA established checklists of various environmental topics and requires that the potential impacts of a project in these areas be evaluated. WSPA has identified key issues below.
- **CEQA Topic III, Air Quality and Greenhouse Gas Emissions. Question "d".**
- If, as is proposed in the AQMP, a new and untested regulatory requirement were mandated upon a refinery or other complex operation, and that requirement was inconsistent or conflicted with standard refinery procedures, then situations could result with unintended adverse consequences, including but not limited to, substantially increased pollutant concentrations. This is especially the case because AQMD staff is unfamiliar with the complexities of refinery operations and could, inadvertently increase the risk of upsets, malfunctions, etc.
- **CEQA Topic VII, Hazards and Hazardous Materials. Questions "b" and "h".**
- 3-14 As stated earlier, mandated changes to well-established safe and effective operating procedures could significantly affect refinery operations and result in upset conditions involving a release of hazardous materials into the environment, or an increased fire hazard. The IS should review this potential including an evaluation of all environmental and health risks that could be the unintentional consequence of new regulations or procedures.
- 3-15 WSPA appreciates the opportunity to submit these comments and please contact me with any questions.

Sincerely,

Responses to Comment Letter #3
Western States Petroleum Association (WSPA) – Patty Senecal (7/27/12)

- 3-1 This comment notifies the SCAQMD that a comment letter is attached. No further response is necessary.
- 3-2 This comment provides background information describing the nature of the commenter's business and the types of industries represented by the commenter. No further response is necessary.
- 3-3 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Initial Study for the Draft Program EIR for the 2012 AQMP. Regarding the individual discrepancies identified, see Responses to Comments 3-4 to 3-8.
- 3-4 This comment notifies the SCAQMD that there are discrepancies in the descriptions of the Control Measures in the Initial Study that need to be corrected in the Draft Program EIR. Examples of these discrepancies are identified and described in further detail in Comments 3-5 through 3-8. For individual responses to the issues raised, refer to Responses to Comments 3-5 through 3-8.
- 3-5 Subsequent to the submittal of this comment letter, the NOP/IS was recirculated on August 2, 2012 because changes were made to the 2012 AQMP project description subsequent to release of the original NOP/IS on June 27, 2012. The recirculated NOP/IS now correctly identifies the implementation dates of Control Measure CMB-01 as year 2014 for Phase I and year 2020 for Phase II. In addition, the NOP/IS has been corrected to reflect that periodic BARCT evaluation will be implemented during Phase II. The analysis in the Draft PEIR will also reflect these corrected descriptions of the control measure.
- 3-6 The suggestion made in the comment for the SCAQMD to not assume that all currently exempted facilities in Rule 1177 will lose their exempt status as a result of implementing Control Measure FUG-02 is inconsistent with the CEQA requirement to analyze reasonably foreseeable environmental impacts of the methods of compliance. Because the scope is still unknown, the analysis will evaluate a worst-case scenario for impacts. For control measure FUG-02 specifically, the analysis would need to consider the potential outcome and associated beneficial and adverse environmental impacts of requiring all of the facilities that were previously exempted to comply with the requirements in Rule 1177 by year 2017.
- 3-7 With regard to Control Measure FUG-03 and Smart LDAR, the recirculated NOP/IS and the Draft 2012 AQMP both state the following: *"This control measure would explore the opportunity of incorporating a recently developed advanced optical gas imaging technology to detect leaks (Smart LDAR) to more easily identify and repair leaks in a manner that is less time consuming and labor intensive."* In other words, the requirement for Smart LDAR could potentially be a future requirement for improved leak detection.
- With regard to Control Measure FUG-03 and vapor recovery systems, the recirculated NOP/IS and the Draft 2012 AQMP both state the following: *"Additionally, vapor recovery systems are currently required to have a control efficiency of 95 percent. In an effort to further reduce VOC emissions from these types of operations, this control*

measure would explore opportunities and the feasibility of further improving the collection/control efficiency of existing control systems, resulting in additional VOC reductions.”

While both technologies, (e.g., Smart LDAR and vapor recovery systems) are mentioned in the same control measure, the description of vapor recovery systems is clearly separate and distinct from the description of Smart LDAR. The common link between the two is that they are technologies for controlling fugitive VOC emissions. As such, contrary to the comment, both technologies are appropriately included in Control Measure FUG-03.

- 3-8 With regard to Control Measure MCS-03, the recirculated NOP/IS and the Draft 2012 AQMP have been revised to state the following: *“This proposed control measure seeks to reduce emissions during equipment startup, shutdown, and turnaround. Opportunities for further reducing emissions from start-up, shut-down and turnaround activities potentially exist at refineries as well as other industries.”* SCAQMD staff believes this revised language addresses the concerns raised in the comment.
- 3-9 Because potentially significant environmental impacts were identified as a result of implementing the proposed 2012 AQMP, SCAQMD staff is preparing a Draft Program EIR in accordance with CEQA Guidelines §15168. These potentially significant impact areas will be evaluated in the Draft Program EIR. Regarding the comments suggesting additional areas that were not identified in the NOP/IS but that should be evaluated in the Draft Program EIR, see Responses to Comments 3-10 to 3-14.
- 3-10 With regard to potential solid/hazardous waste impacts from FUG-01, the solid/hazardous waste discussion in the recirculated NOP/IS has been revised to specifically acknowledge that there could be an increase in the amount of solid/hazardous wastes generated from installing air pollution control equipment such as “carbon adsorption devices, particulate filters, catalytic incineration, selective catalytic reduction or other types of control equipment.” While liquid scrubbers were not specifically mentioned in the solid/hazardous waste discussion in the recirculated NOP/IS, any potential solid/hazardous wastes from liquid scrubbers will also be evaluated as part of the “other types of control equipment” discussion in the Draft Program EIR.
- 3-11 The comment that Control Measure MCS-03 – Improved Start-Up, Shutdown and Turnaround Procedures, is a general “catch-all” designed specifically to modify operational requirements at refineries exclusively is inaccurate as MCS-03 could apply to other industries such as chemical plants, for example.

With regard to the remark alleging that the SCAQMD has not demonstrated a link between MCS-03 and emissions, the commenter is referred to two examples: SCAQMD Rule 1123 – Refinery Process Turnarounds and SCAQMD Rule 1173 – Control of Volatile Organic Compound Leaks and Releases from Components at Petroleum Facilities and Chemical Plants. Rule 1123 was designed to minimize organic vapors from being released to the atmosphere during turnarounds. Rule 1173 also contains VOC control requirements that pertain to refineries and other industries during process unit turnarounds. Both of these rules have been effective at reducing VOC emissions, but they are not exhaustive. For this reason, MCS-03 was designed to explore additional emission reduction possibilities during startups, shutdowns and turnarounds.

With regard to the comment that MCS-03 would undermine safety, operational reliability, or other environmental issues, an example to the contrary, Rule 1123 currently contains specific exemptions in the rule language that address (and prevent) situations that could potentially damage equipment, cause the malfunction of pollution control or safety devices, or cause violations of safety regulations. As with all control measures and the rule development process, participation by the affected parties, including the refineries and their representatives, as well as other industries and their representatives, will be paramount in effectively and safely implementing MCS-03. Thus, it is not accurate to assume that the development and implementation of MCS-03 would ignore these issues. However, control measure MCS-03 will be re-evaluated in the Draft Program EIR to determine the potential for safety impacts.

To respond to the comment that SCAQMD staff does not have the expertise to work on refinery-based or other heavy industry-based projects, SCAQMD has been lead agency for a multitude of refinery projects since 1992 and has successfully implemented refinery-based control measures. For example, SCAQMD Rule 1105.1 – Reduction of PM10 and Ammonia Emissions From Fluid Catalytic Cracking Units, was a new rule adopted in November 2003 that was developed to implement Control Measure CMB-09 - Emission Reductions from Petroleum Fluid Catalytic Cracking Units to reduce PM10 and ammonia emissions from refineries. Another example, the November 2010 amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), also known as SO_x RECLAIM, implemented Control Measure CMB-02 - Further SO_x Reduction for RECLAIM (CM #2007CMB-02) to achieve additional SO_x emission reductions from not only refineries but from other sources such as petroleum coke calciners, container glass melting furnace, sulfuric acid manufacturers, and other sources.

Further, the SCAQMD staff, supervisors and management who will be working to develop MCS-03 have strong technical and engineering backgrounds, especially in the disciplines of chemical, petroleum, and mechanical engineering, and are quite capable and qualified to work on refinery-based and other heavy industrial projects. However, if additional specific technical expertise is required, as was the case with the adoption of Rule 1105.1 and amendments to the SO_x RECLAIM program (when SCAQMD in cooperation with the refineries and the other industries co-hired industry-specific consultants for technical assistance), then the option to bring in additional expertise during the development of MCS-03 could be available.

Finally, with regard to the comment that the NOP/IS has not identified any potential adverse environmental impacts that may be associated with the development and implementation of MCS-03, the commenter has also not provided any insight as to what the potential adverse environmental impacts may occur. In its current form, MCS-03 is in its early stages and is very broad. As such, to identify any impacts at this time without knowing the specific design features would be speculative. However, when implementation of MCS-03 begins, and if a proposed rule or rule amendment is developed as a result, the CEQA document for the proposed rule or rule amendment will identify and analyze the specific environmental impacts at that time.

- 3-12 This comment refers to the CEQA checklist in CEQA Guidelines, Appendix G and the 17 environmental topics addressed in the checklist. For responses to the issues raised relative to the specified environmental topics, see Responses to Comments 3-13 and 3-14.

- 3-13 The comment claims, without providing any supporting evidence, that unintended consequences such as increased pollutant concentrations may occur if new and untested regulatory requirements are imposed that are inconsistent or conflicting with standard refinery procedures. Any such evaluation would be speculative at this time. However, this issue will be evaluated during actual rule development. This issue was previously addressed in Response to Comment 3-11.
- 3-14 The comment claims, without providing any supporting evidence, that increased hazardous material emissions and fire hazards may occur if regulatory changes to refinery procedures are made. Any such evaluation would be speculative at this time. However, this issue will be evaluated during actual rule development. This issue was previously addressed in Response to Comment 3-11.
- 3-15 This comment concludes the letter. No further response is necessary.

*Re: Notice of Preparation of a Draft Program Environmental Impact Report
and Initial Study for the 2012 Air Quality Management Plan*

Dear Mr. Smith:

4-2 This letter is submitted on behalf of the County of Orange ("County") in its capacity as the owner and operator of John Wayne Airport, Orange County ("JWA"). This letter contains the County's written comments on the Notice of Preparation and Initial Study ("NOP/IS") for the proposed 2012 Air Quality Management Plan ("2012 AQMP"), issued by the South Coast Air Quality Management District ("SCAQMD" or "District") on June 28, 2012.

The County's comments on the NOP/IS are intended to serve the two following principal objectives:

- 4-3
1. To express our appreciation for the opportunity to continue to work constructively and cooperatively with the SCAQMD in evaluating and developing realistic airport emission reduction strategies for the proposed 2012 AQMP and analyzing the potential environmental impacts of the proposed measures; and,
 2. To express our concerns regarding the accuracy of the baseline emissions inventory, and offer other discrete comments on the NOP/IS.

4-4 As to the County's comments on the baseline emissions inventory assumptions utilized in the California Environmental Quality Act ("CEQA;" Pub. Resources Code, §21000 et seq.) analysis for the 2012 AQMP, in early May 2012, JWA staff (specifically Kari Rigoni) provided aircraft activity data specific to JWA for incorporation into the 2012 AQMP at the District's

Page 2

request. Ms. Rigoni coordinated with Zorik Pirveysian when providing the following information:

May 1, 2012: Ms. Rigoni provided aircraft activity data for JWA – averaged over 2007 through 2009¹ – and a list of the number and type of aircraft based at JWA, and confirmed that 100 percent of JWA’s gates are equipped with power and pre-conditioned air;

May 4, 2012: Ms. Rigoni provided the average combined taxi-in/taxi-out time that should be used for commercial air carriers at JWA and the average annual fuel consumption for general aviation aircraft at JWA. Ms. Rigoni also confirmed that the County is amenable to utilizing SCAG’s Regional Transportation Plan projections for purposes of forecasting future aircraft activity, subject to the caveat that such projections may change in connection with pending negotiations arising from the County’s settlement agreement with various parties concerning airport operations;² and,

May 10, 2012: Ms. Rigoni provided the disaggregated taxi-in and taxi-out times for commercial air carriers at JWA. Also, after Mr. Pirveysian advised Ms. Rigoni that he needed to finalize all data inputs for purposes of the 2012 AQMP’s baseline emissions inventory, such that there was no additional time for the County to submit JWA-specific data, Ms. Rigoni explained that JWA was continuing to collect engine type data and requested that such data ultimately be used in lieu of default data from another information source.

Since May 10, 2012, the County has completed its data gathering efforts relative to aircraft engine types that operate at JWA. The compiled data is enclosed with this letter.³ And, in order to ensure that the baseline emissions inventory accurately and reasonably reflects

¹ Ms. Rigoni explained that the aircraft activity data was based on a three-year average (2007, 2008, and 2009) because the County does not believe 2008 is a representative year for most airports in the South Coast Air Basin as it was the beginning of the economic downturn.

² For information regarding the currently applicable provisions of the Settlement Agreement, see <http://www.ocair.com/aboutjwa/settlementagreement.aspx>.

³ This letter is being provided to the District by e-mail, and the electronic transmittal includes four files in addition to this comment letter: one Word file and three Excel files. The Word and Excel files provide the additional enclosed data in a “raw” electronic format in order to allow District staff to more readily incorporate the data into the AQMP’s aircraft emissions modeling.

GATZKE DILLON & BALLANCE LLP

Mr. Steve Smith, Ph.D.

July 27, 2012

Page 3

4-4 Cont. { operating conditions at JWA in 2008, the County respectfully requests that the baseline emissions inventory be updated and modified to incorporate this new information.

4-5 { Having also reviewed the NOP/IS, the County first expresses its appreciation of the District's efforts to develop control measures intended to achieve compliance with the U.S. Environmental Protection Agency's ("USEPA") 24-hour, PM_{2.5} National Ambient Air Quality Standard ("NAAQS") and 8-hour, ozone NAAQS in the South Coast Air Basin. Second, based on our review, the following two Control Measures presently are of interest: MCS-03 (formerly MCS-06), Improved Start-Up, Shutdown and Turnaround Procedures [All Pollutants]; and, ADV-07, §182(e) Proposed Implementation Measures for the Deployment of Cleaner Aircraft Engines [NOx].

4-6 { Relative to Control Measure MCS-03, we find it difficult to assess the measure itself – and its environmental impacts – without further information on its proposed parameters. We suspect that such detail will be provided in the Draft 2012 AQMP, and look forward to better understanding the District's proposal relative to that control measure. That being said, in many instances, controlling emissions during start-up and shutdown is constrained by operational, technological, and economic limitations. Therefore, we encourage the District to be sensitive to and informed of such constraints when designing the measure's parameters and predicting associated emission reductions.

4-7 { Relative to Control Measure ADV-07, generally speaking, the NOP/IS recognizes that the USEPA is responsible for establishing emission standards for aircraft. (See, e.g., IS, p. 1-6.) Nonetheless, we ask that Table 1-3 and its related text, to the extent it is utilized again in the Draft 2012 AQMP of Draft Environmental Impact Report, be revised to expressly recognize that Control Measure ADV-07 is within the purview of the USEPA. The IS suggests that the "descriptions of individual control measures in Table 1-3" will indicate whether action is required from the USEPA; however, no such description is provided relative to Control Measure ADV-07. (See IS, pp. 1-19 to 1-20, and 1-25.) In order to clearly inform the public and decisionmakers of the District's lack of regulatory purview relative to aircraft emissions, such disclosure needs to be provided.

4-8 { The County also requests additional information on the District's decision to include information in the 2012 AQMP on "ultrafine particulates formation, transport, exposure, and health effects and potential control strategies." (IS, p. 1-10.) As acknowledged in the NOP/IS, "there are no ambient air quality standards specifically for ultrafine particulates" (*ibid.*); as such, the District has no authority to regulate such particulates. The County is concerned with the District's decision to include such information in a regulatory document (i.e., the 2012 AQMP), as its inclusion in such a type of document may misleadingly suggest to the public that ultrafine particulates are subject to regulation at a federal, state, regional, and/or local level.

4-9

In closing, the County thanks the District again for this opportunity to comment on the NOP/IS for the 2012 AQMP. We look forward to engaging in an open, thorough and responsive public process on the 2012 AQMP, and assisting the District with its efforts to improve air quality in the South Coast Air Basin. If you have any questions regarding the comments set forth in this letter, please do not hesitate to contact me at your convenience.

Very truly yours,

Lori D. Ballance

Courtney Wiercioch, Deputy Director, Public Affairs, John Wayne Airport
Larry Serafini, Deputy Director, Facilities, John Wayne Airport

ENCLOSURE***Air Carrier and Air Taxi Operations by Aircraft/Engine Combinations
at John Wayne Airport, 2007-2009***

In response to the District's request for data pertaining to JWA's operations, the County retained Mestre Greve Associates, a Division of Landrum & Brown, to compile airport-specific data regarding Air Carrier and Air Taxi operations by aircraft/engine combinations for the years 2007 through 2009. The results are presented in these enclosed materials.

By way of explanation, the Summary Table (Annual LTO by EDMS Aircraft Type and Engine Model for John Wayne Airport) below directly corresponds to the data needed to estimate aircraft emissions using the FAA's Emissions and Dispersion Modeling Software (EDMS).¹ The sources of information used to generate the Summary Table are operational data from the Bureau of Transportation Statistics (BTS) and aircraft/engine data from JP Airline Fleets International 2008/2009 (JP Fleets). The BTS data was used to determine the number of operations at JWA by each unique air carrier/aircraft combination, and the JP Fleets data was used to determine the engine models used by each air carrier/aircraft combination.

The BTS data was downloaded from their online "Air Carrier Statistics (Form 41 Traffic) - All Carriers" database² and specifically the "T-100 Segment, All Carriers" database.³ This database contains a list of monthly aircraft operations by origin and destination airport for each airline and aircraft operation between those airports based on data provided to BTS by the air carriers. Annual data for 2007, 2008, and 2009 was downloaded from the BTS website and operations originating from or terminating at JWA were extracted. This data was processed to determine the annual number of arrivals and departures by airline and aircraft type, and summarized in the enclosed "BTS Data Summary.xls" workbook. The raw T-100 data files for each year can be provided on request (while the annual data files are only 13.6 MB each, the three files that include the Excel Pivot Tables used to extract data by carrier/aircraft combination are 121.1 MB each).

JP Fleets is a book published annually that lists detailed information for all aircraft in the fleets of all commercial aircraft operators worldwide. The fleet information for all commercial aircraft operators operating at JWA based on the BTS data was extracted from the JP Fleets book and copied into a Microsoft Excel workbook. The Pivot Table function was used to determine the number of aircraft in each airline's fleet with unique aircraft/engine combinations.

¹ The Summary Table shows that engine types could not be determined for four Air Taxi aircraft. This was because the BTS data listed operations for these aircraft, but JP Fleets did not include an aircraft of the type reported by BTS in the aircraft listings for three air taxi operators, Swift Air, LLC, Triair, and Avjet Corporation. However, these aircraft only represent an average of four annual LTO and, therefore, the specific engine assumption would not substantially affect the overall aircraft emissions estimate for JWA. The EDMS default engine type for these aircraft should be used to determine emissions.

² See

http://www.transtats.bts.gov/Tables.asp?DB_ID=111&DB_Name=Air%20Carrier%20Statistics%20%28Form%2041%20Traffic%29-%20All%20Carriers&DB_Short_Name=Air%20Carriers.

³ See

http://www.transtats.bts.gov/Tables.asp?DB_ID=111&DB_Name=Air%20Carrier%20Statistics%20%28Form%2041%20Traffic%29-%20All%20Carriers&DB_Short_Name=Air%20Carriers

ENCLOSURE***Air Carrier and Air Taxi Operations by Aircraft/Engine Combinations
at John Wayne Airport, 2007-2009***

The percentage of each aircraft/engine combination by EDMS aircraft type was then derived from this data. This data is presented in the enclosed “JP Fleets 2008 Extracted.xls” workbook. The 2008 version of JP Fleets was used to best represent the air carrier fleets during the 2007-2009 timeframe. The JP Fleets data includes the date that the aircraft was delivered to the airline, along with listings of aircraft that are “on order” and the anticipated delivery year. Aircraft shown to be delivered in 2008 were excluded from the 2007 data and aircraft expected to be delivered in 2009 were included in the 2009 data.⁴

The BTS and JP fleets data discussed above were combined in the “07-09 SNA Comm Ops By Aircraft & Engine Combo.xlsx” workbook. The “Analysis” worksheet presents the BTS and JP Fleets data and calculates the number of Landing-Take Off operations (LTO) by each aircraft/engine combination for each airline. The annual operations, arrivals, departures, and LTO, by airline and aircraft for 2007, 2008, and 2009 derived from the BTS data are listed along with the corresponding EDMS aircraft type and the percentage of engine model used on that type of aircraft in each airline’s fleet derived from the JP Fleets data.

The “Results” worksheet uses a Pivot Table to extract the number of LTO by aircraft/engine combination and used to generate the attached table. The annual LTO for each EDMS aircraft type and engine manufacturer and model is presented for each year along with the three-year average.

The results of the analysis were compared with average operational data by aircraft provided by JWA to confirm that the validity of the BTS. JWA provided annual average operations data by aircraft type for the three years being assessed. The “Type” column in the Summary Table shows how the data derived for this analysis was grouped to be compared to the data provided by JWA. The operations for each aircraft type were summed and are compared to the JWA data in Tables 1 and 2. Table 1 shows excellent agreement for the most part with some considerable differences in the A3XX family of aircraft and in the B737X family of aircraft. Table 2 shows that, when grouped together, the annual average LTO’s from this analysis and the JWA data agree excellently. This confirms that the BTS data is consistent with the JWA-provided data.

4-10
Cont.

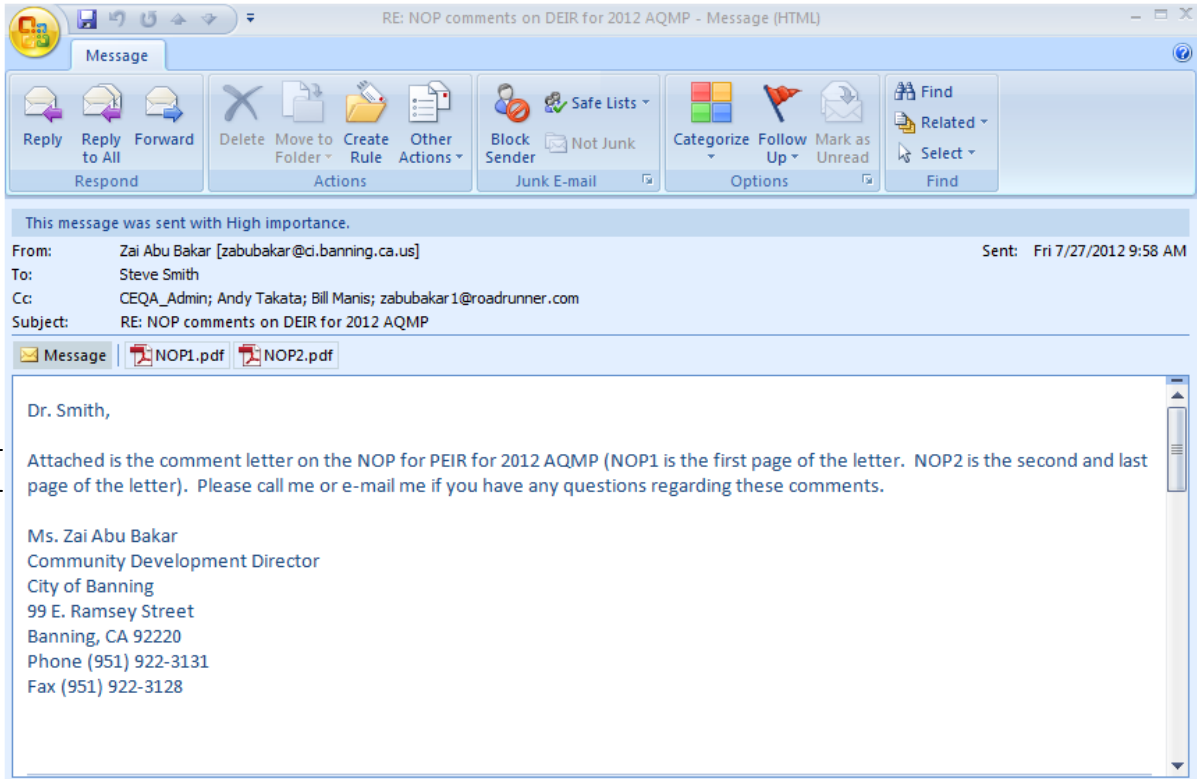

⁴ America West Airlines merged with US Air in 2005 and JP Fleets did not include America West Airlines in the 2008 edition. The airline was included in the 2007 edition and the aircraft/engine combinations for America West were taken from this edition.

Responses to Comment Letter #4
Gatzke Dillon & Balance Representing Orange County – Lori Balance (7/27/12)

- 4-1 This comment, submitted on behalf of Orange County as the operator of John Wayne Airport (JWA), notifies the SCAQMD that a comment letter pertaining to the Initial Study for the Draft Program EIR for the 2012 AQMP is attached. No further response is necessary.
- 4-2 This comment, submitted on behalf of Orange County as the operator of JWA, notifies the SCAQMD that the comment letter pertaining to the Initial Study for the Draft Program EIR for the 2012 AQMP follow. No further response is necessary.
- 4-3 With regard to inventory information on the planes accessing the JWA, please refer to Responses 4-4 and 4-7.
- 4-4 John Wayne Airport staff had supplied updated emissions inventory information that was included in the Draft 2012 AQMP. SCAQMD Staff will now consider the request to include additional updated emissions inventory information in the Final 2012 AQMP and determine the magnitude of the change from the information provided in the Draft 2012 AQMP.
- 4-5 This comment states that the JWA operators appreciate the SCAQMD's efforts to attain the federal 24-hour ozone standard. Further, the comment indicates that JWA is interested in 2012 AQMP control measures MCS-06 and ADV-07. With regard to control measure MCS-03, please refer to Response 4-6. With regard to control measure ADV-07, please refer to Response 4-7.
- 4-6 Please note that this control measure will be implemented in two phases. The first phase will focus on procedures to better quantify emission impacts from start-up, shutdown and turnarounds. Once the first phase is completed and emission impacts found to be significant, staff intends to continue with Phase II of the control measure and explore improved operating procedures that minimize emission from such processes through the use of best management practices and/or installation of additional hardware. Operational, technological and economic variables will be among the key variables to be considering during this phase of implementation.
- 4-7 The comment suggests that the CEQA document should "clearly inform the public and decisionmakers of the SCAQMD's lack of regulatory purview relative to aircraft emissions." As a legal matter, this statement is overbroad. The Clean Air Act expressly preempts state and local agencies from adopting or enforcing "any standard respecting emissions of any air pollutant from any aircraft or engine thereof unless such standard is identical to a standard [adopted by EPA and FAA] applicable to aircraft under this part." 42 U.S.C. §7573. However, the term "standard" as used in Title II of the CAA (relative to mobile sources) does not include in-use or operational requirements. *Engine Manufacturers' Association v. EPA*, 88 F. 3d 1075 (D.C. Cir. 1996). Whether any individual measure, which does not constitute a "standard" preempted under the CAA, would be preempted by any other law would need to be decided on the facts of each case.
- 4-8 The comment correctly notes that there are at present no ambient air quality standards specifically for ultrafine particulates, but then incorrectly concludes that as a result, the

SCAQMD has no authority to regulate such particulates. In the first place, such particulates are already regulated as a subset of PM_{2.5}, although not separately from the remainder of PM_{2.5}. Moreover, the lack of a NAAQS for ultrafine particulates does not mean that the SCAQMD has no authority to regulate them. Under California law, the district has primary authority to regulate “air pollution from all sources, other than emissions from motor vehicles” which are the primary responsibility of CARB. Health & Safety Code §40000. The term “air pollutant” is broadly defined to include “any discharge, release, or other propagation into the atmosphere and includes, but is not limited to, smoke, charred paper, dust, soot, grime, carbon, fumes, gases, odors, particulate matter, acids, or any combination thereof.” Health & Safety Code §39013. This definition is broad enough to encompass ultrafine particles. The district regulates a whole host of substances for which there are no NAAQS, including its air toxics regulations found in Rules 1401, 1402, etc, as well as its regulation of odors under Rule 401. The 2012 AQMP does not imply that ultrafine particles are subject to regulation as a criteria pollutant separately from their status as a subset of PM_{2.5}. The 2012 AQMP does not contain any control measures specific to ultrafine particles apart from their status as a subset of PM_{2.5}.

- 4-9 This comment concludes the letter. No further response is necessary.
- 4-10 There are several attachments to this comment letter. The attachment entitled *Enclosure - Air Carrier and Air Taxi Operations by Aircraft/Engine Combinations at John Wayne Airport, 2007-2009*, describes the sources and methodologies used to compile airport-specific data regarding Air Carrier and Air Taxi operations by aircraft/engine combinations for the years 2007 through 2009. The results of the evaluation are presented in three Excel spreadsheets, also attached to the comment letter. According to the commenter, the data were provided upon request by the SCAQMD. Further, it is assumed that the commenter is providing the aircraft data to incorporate into the baseline for the 2012 AQMP. These data have been forwarded to SCAQMD AQMP inventory staff. No further response to this comment is necessary or the attached spreadsheets is necessary.

Subject: Notice of Preparation (NOP) for the Draft Environmental Impact Report for 2012
Air Quality Management Plan (AQMP)

Dear Mr. Smith:

5-2

This letter is to provide comments on the NOP. The City is concerned that there are a number of regulations that are proposed in the 2012 AQMP that have direct impact on cities' operations resulting in negative fiscal impacts. These regulations must be off-set with incentives to ensure that there is a win-win situation between protecting the environment and maintaining a healthy fiscal environment so that cities can continue to provide services to their residents. Additionally, all aspects of the system that support a particular measure shall be analyzed to ensure that not only the measure contributes to clean-air but also provides sound fiscal investment and improves the current economy.

5-3

Measure ONRD-01 seeks acceleration of commercial deployment of partial zero-emission and zero emission vehicle penetration into the market. This measure proposes to continue the Clean Vehicle Rebate Project (CVRP) through 2023 which would provide incentives to a minimum of 1000 vehicles per year.

Although this measure proposes to provide incentives for the development, the incentives should also be provided for the systems that support the successful deployment of the vehicles in the future. This includes infrastructure, trained technicians, and technology that support the maintenance aspects of the vehicles. AQMD, State, and Federal EPA should partner with local colleges to provide hands on training for new technology. This could be done through the junior colleges and universities. The City of Banning has Mt. San Jacinto Junior College, which provides curriculums that tailored to the needs of the communities and future job markets. The College currently has a satellite campus which will eventually be built out and accommodate approximately 5000 students. This Junior College could be

5-3
Cont

a training ground for deployment of new technologies. In addition to the infrastructure and systems, the regulating agencies such as SCAQMD, State and Federal EPA should work closely with the association of building officials to ensure that permitting processes are addressed and incorporated into the building codes for ease of implementation and success in the deployment of partial zero-emission or zero emission vehicles.

5-4

Measure ONRD-02 seeks accelerated retirement of older light-duty and medium duty vehicles that are gasoline and diesel-powered up to 8,500 pounds gross vehicle weight (GVW). The measure proposes incentives up to \$2,500, which include a replacement voucher. The vehicles that are included are passenger cars, sport utility vehicles, vans, and light-duty pick-up trucks. This measure gives first priority to those vehicles identified as high emitters that are off-cycle to California Smog Check Program and Pre-1992 model year vehicles. This measure does not describe as to whether the incentive is available to individual consumers or fleet. It is recommended that incentives also be provided to fleet vehicles for public and private sectors.

5-5

These are also measures in the AQMP that would affect existing businesses and land development and construction industries which lead to increase costs that would eventually be passed on to consumers or drives businesses out of the State of California. These include the following measures:

1. BCM-01 - Emission Reduction from Under-Fired Charbroilers
2. CTS-01 - Further VOC reduction from architectural coatings
3. CTS-02 - Further Reduction from Miscellaneous Coatings, Adhesives, Solvent, and Lubricant
4. CTS-03 - Further VOC Reductions from Mold Release Products
5. MCS-02 - Further Emission Reductions from Green Water Processing (Chipping and Grinding Not Associated with Composting).

These measures do not appear to have incentives. The concern is that these measures (regulations) will drive businesses out of the region and the State of California. Please analyze not only the positive impacts to the environment but also the fiscal impacts to the businesses and consumers if these measures are adopted.

5-6

If you have any questions regarding these comments, please call me at (951) 822-3131 or e-mail me at zabubakar@ci.banning.ca.us.

Sincerely,

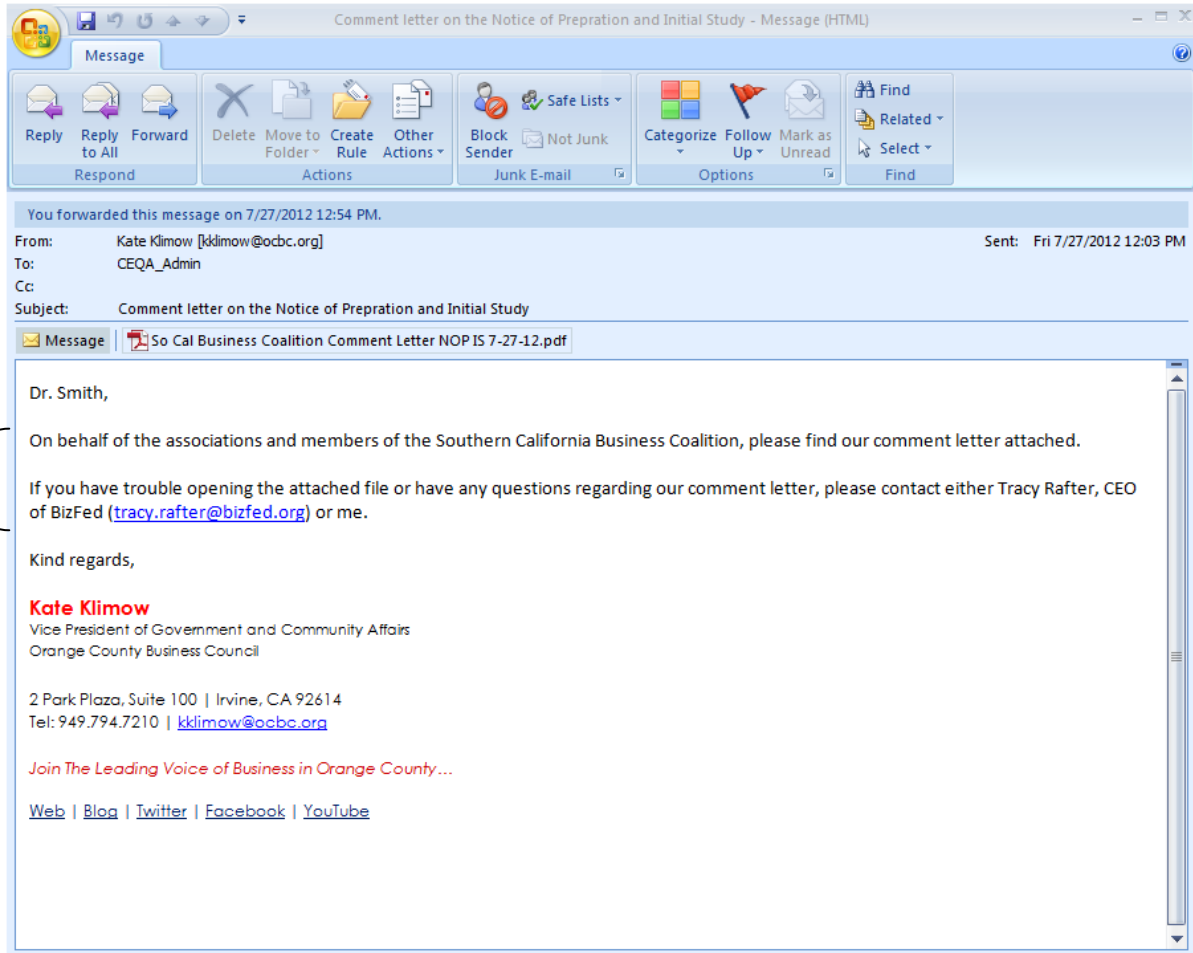

Zai Abu Bakar
Community Development Director

cc: Andrew J. Takata, City Manager
Bill Manis, Economic Development Director

Responses to Comment Letter #5
City of Banning – Zai Abu Bakar (7/27/12)

- 5-1 This comment notifies the SCAQMD that a comment letter pertaining to the Initial Study for the Draft Program EIR for the 2012 AQMP is attached. No further response is necessary.
- 5-2 There are two stationary source control measures specifically aimed at offering different incentives for companies that either manufacture or employ zero and near-zero emission technologies in the Basin (refer to Appendix IV-A: INC-01, and INC-02). The incentive programs will be designed to promote voluntary introduction of new technologies on an accelerated schedule. These measures provide manufacturers with incentives for production and commercialization of the cleaner, more advanced technologies while encouraging economic growth by creating local manufacturing jobs and populating the market with lower cost equipment. However, as with any limited public funding, any financial incentives will be allocated towards programs or projects that demonstrate emission reductions in the areas most critical to the achievement and maintenance of the Basin's air quality goals.
- 5-3 The funding programs identified in control measure ONRD-01 are available only for purchasing zero emission vehicles. There are separate funding programs for infrastructure that are not included. However, given that the deployment of infrastructure enables the deployment of the advanced technology vehicles, the emission reductions associated with the vehicle deployment will be accounted for in ONRD-01. The SCAQMD has been working with local community colleges to offer training for new technologies. The commenter is welcome to contact the SCAQMD staff for more information.
- 5-4 The voluntary vehicle retirement program has focused primarily on private individual consumers. Typically a vehicle operated by a public agency or fleet licensed and registered pursuant to Health and Safety Code sections 44019 and 44020 is deemed ineligible under a vehicle retirement or replacement program. However, cities and other municipalities have access to AB2766 funds to help offset incremental cost differences for cleaner advanced technology vehicles. Private fleets have typically taken advantage of Carl Moyer and Mobile Source Review Reductions Committee (MSRRC) programs.
- 5-5 As incentive funding becomes available, it may be directed at specific source categories to aid compliance. See Response to Comment 5-2. For all control measures, during the rulemaking process, and as additional information on new technologies and/or control equipments becomes more well-defined, a detailed assessment of their socioeconomic and environmental impacts will be conducted including the costs to businesses and the effects on the economy and environment. The economic impacts are included in the socioeconomic analysis for the AQMP to the extent that they can be analyzed at this point.
- 5-6 This comment concludes the letter. No further response is necessary.

6-1

RE: INITIAL STUDY FOR THE DRAFT EIR FOR THE 2012 AQMP

Dear Dr. Smith:

6-2

The Southern California Business Coalition is comprised of the leaders of some of California's largest regional business entities and associations. The final 2012 Air Quality Management Plan, and the rule making that will eventually stem from it, will directly affect many of these business interests.

In our ongoing effort to work with SCAQMD to develop a well-balanced strategy that addresses federal requirements through economically feasible compliance, we appreciate the opportunity to provide these comments on the Initial Study (IS) for the Draft Program Environmental Impact Report (DPEIR) for the AQMP.

6-3

1. The draft proposed control measures are not accurately described in the IS.

Although the District released an initial version of the draft proposed AQMP control measures on or about June 12th, the descriptions of those control measures in the IS, which is dated June 28th, conflict with the actual measures themselves. To further confuse the process, the Draft AQMP, including the proposed control measures, which was released by the District on or about July 17th, had, in some cases, the requirements of the proposed control measures changed again.

6-3
Cont.

The evaluations conducted for the DPEIR will need to be based on the requirements of the draft proposed control measures as they currently exist - not as they are described in the IS.

2. Discrepancies associated with changes to the control measures have effectively shortened the comment period for the IS from thirty days to approximately ten days.

The several sets of proposed control measures and the resultant inaccurate descriptions of the control measures in the IS have made it more challenging for stakeholders to review the IS for appropriateness. Noting that the latest revisions to the proposed control measures were released in the draft AQMP on or about July 17th, as a practical matter, stakeholders have actually had only ten days to analyze the IS and prepare comments.

6-4

Considering that the AQMP serves as the "project description" for the ensuing environmental documents, the delay in the release of the draft AQMP necessitated a revised determination the impacts of the project.

We must also note that four of the five public workshops/CEQA scoping meetings ~~were~~ held prior to the release of the project description (i.e., the Draft AQMP). Thus it was nearly impossible to provide quality information on the scope of the environmental analysis of the proposed project.

While we wanted to note the challenges we faced in reviewing the IS, we also wanted to raise this concern now so that the District will avoid these sorts of timing problems for the upcoming 2015 AQMP update.

3. Comments on specific proposed control measures.

6-5

Although our ability to assess the potential adverse environmental impacts resulting from the AQMP was severely hampered, we offer the following brief comments on some specific control measures and as examples of additional areas of study that need to be considered for the DPEIR. We would also note that there may be additional study areas that have been overlooked due to the limited review time and the conflicting documents:

6-6

- CMB-03. The discussion in Appendix A refers to ventilation hood systems; however there is no mention of such systems in the description of the measure in the IS (page 1-14) or in the current version of the control measure itself.

6-7

- CTS-01, CTS-02, CTS-03, CTS-04, FUG-01, and MCS-02. These proposed control measures may have waste issues associated with them for various reasons; however the IS does not recognize this possibility.

6-8

- INC-01. Incentive programs such as INC-01 depend upon the availability of funding. If funding is potentially taken from existing programs, there could be an adverse air quality impact that is not acknowledged in the IS.

6-9

- MCS-03. The potential imposition of District-developed operating or maintenance procedures on a facility is not without potential adverse impacts. Adverse impacts could be the result of upsets or malfunctions which, in turn, are consequences of being required to follow arbitrary or inappropriate procedures.

6-10 **4. Proposed alternative to the project as currently defined (i.e., the draft AQMP)**
 We respectfully request that the CEQA analysis of alternatives to the current project consider a case comprised of only the eight short-term PM2.5 control measures, an alternative that would not include the Section 182(e)(5) implementation measures for ozone for either stationary sources or mobile sources. Considering this alternative in the CEQA analysis would allow the Governing Board to consider this option for attaining the PM2.5 standards at a cost that is considerably less than that of the dull draft AQMP, and which places less reliance on actions by other agencies (e.g., the ARB).

6-11 We can appreciate that the District is operating under a tight schedule with respect to this 2012 AQMP update; however, the compressed timeline is concerning to the business community as it impacts our ability to provide meaningful input. Without reasonable review time, the EIR become susceptible to more vigorous challenges on its completeness.

6-12 Please know the business community remains committed to assisting SCAQMD in producing a balanced and workable AQMP document that provides for both environmental and economic success. If there are questions regarding these comments, please contact either Tracy Rafter, CEO of BizFed (tracy.rafter@bizfed.org) or Kate Klimow, Vice President of Government Affairs for Orange County Business Council (kklimow@ocbc.org).

Sincerely,

Responses to Comment Letter #6
Southern California Business Coalition – Kate Klimow (7/27/12)

- 6-1 No further response is necessary. The email informs the reader that the comments are included as an attachment and that the commenter is available to answer questions about the comment letter.
- 6-2 The introductory paragraphs provide background on the Southern California Business Coalition and state their appreciation at the opportunity to comment on the IS for the Draft AQMP. No further response is necessary.
- 6-3 The comment states that the proposed control measures in the IS for the Draft AQMP conflict with the draft control measures provided to the public on June 12, 2012 and July 17, 2012. Please see Response to Comment 3-4.
- 6-4 The comment states that the discrepancies between the draft control measures in the IS and those provided on July 17, 2012 have caused difficulties in their review of the IS and did not provide sufficient time for them to thoroughly review the IS and revised proposed control measures. The comment also states since four of the five public workshops/CEQA scoping meetings were held prior to the release of the Draft AQMP, quality information on the scope of the environmental analysis of the proposed project was lacking.

On June 27, 2012, the CEQA NOP/IS for the 2012 AQMP was released for a 30-day public review period. Subsequent to release of the NOP/IS, some changes were made to the control strategy in the Draft 2012 AQMP. Specifically, the following changes were made to the Draft 2012 AQMP measures: control measure MCS-04a was folded into control measure ONRD-04; control measure MCS-04b is now control measure BCM-01; control measure MCS-04c is now control measure BCM-04. With the exception of BCM-04, these control measures would now apply to the entire Basin instead of just the Mira Loma area; and new control BCM-02 – Further Reductions from Open Burning, has been added to the Draft 2012 AQMP and applies to the entire Basin. These changes are not considered to be substantive changes for the following reasons.

Control measure BCM-01 (formerly MCS-04b) would prohibit using wood burning fireplaces when PM_{2.5} concentrations exceed 30 ug/m³ at the design monitoring station in Mira Loma. No control equipment or other emission reduction technologies are required to be installed. Based on past monitoring data, this prohibition would occur approximately 15 – 20 times per year. Regardless, whether or not the control measure applies only to Mira Loma or to the entire Basin, it would not generate any impacts.

New control measure BCM-02 would also not generate any impacts for the same reasons as BCM-01, that is, open burning would be prohibited when PM_{2.5} concentrations exceed 30 ug/m³ at the design monitoring station in Mira Loma, which is expected to occur about 15 – 20 times per year. No other actions would be necessary.

The effects of control Measure BCM-04 (formerly MCS-04c) would not change as is still only applies to the Mira Loma area.

Merging control measure MCS-04a into control measure ONRD-04 has no practical effect because ONRD-04, which applies to the entire Basin, seeks accelerated retirement

of heavy-duty vehicles and replacement with new year 2010 vehicle models or later. This would essentially be the same effect as reducing emissions from heavy-duty vehicles serving warehouses in Mira Loma.

Because the changes to the 2012 AQMP are not considered to be substantive changes to the project, there is no requirement to recirculate the NOP/IS. Minor changes to projects often occur after circulation of an NOP/IS and before and during circulation of the draft CEQA document. However, in response to public comment, SCAQMD staff has updated the control measures and analysis in the IS and recirculated it for a 30-day public review and comment period on August 2, 2012. The SCAQMD will accept comments on the recirculated NOP/IS up to close of business August 31, 2012, and responses to those comments will be included in the Draft Program EIR.

It should be noted that the 2012 AQMP itself is not the “project description,” it is the project. Detailed project descriptions were included in both the June 28 NOP/IS and the August 2, 2012 NOP/IS.

The public workshops were intended to introduce the elements of the Draft 2012 AQMP before its release and provide an overview of the contents of the NOP/IS, which was released two weeks earlier. The workshops allowed for comments on ideas for the 2012 AQMP and the content of the CEQA document. While comments on the 2012 AQMP can be submitted up until the Governing Board hearing, it is strongly recommended, however, for comments to be submitted by August 31, 2012 in order to provide time for the response to be addressed and included in the Final 2012 AQMP.

Finally, regional hearings on the 2012 AQMP are scheduled from September 11, 2012 to September 13, 2012 in the four-county region to provide for more opportunity for public comment. The revision and recirculation of the IS with the associated 30-day public review and comment period, and regional hearings should address the concerns raised in the comments.

- 6-5 The comment states that specific control measures were provided despite complications they had because of changes to the proposed control measures after the release of the first IS. Responses to comments on the specific control measures are provided in Response to Comments 6-6 through 6-8 below. As stated in Response to Comment 6-4, the IS has been updated with the current proposed control measures and associated analysis. The revised IS and new NOP were released on August 2, 2012 for a 30-day public review and comment period. Finally, regional hearings on the 2012 AQMP are scheduled from September 11-13 in the four-county regional to provide for more opportunity for public comment. The revision and recirculation of the IS with the associated 30-day public review and comment period, and regional hearings should address the concerns raised in the comment. It should be noted that the 2012 AQMP itself is not the “project description,” it is the project. Detailed project descriptions were included in both the June 28 NOP/IS and the August 2, 2012 NOP/IS.
- 6-6 The comment states that ventilation hood systems are referred to in Appendix A of the IS, but there is no mention of such systems in the description of the measure in the IS or in the control measure itself. The sources of impacts in Appendix A were developed from the description of the control measures. The IS and Draft Program EIR examine impacts from secondary effects that may not be directly stated in the control measure. Therefore,

the IS and Draft Program EIR may provide more detail than is provided in the control measure to address these secondary effects.

6-7 The comment states that control measures CTS-01, CTS-02, CTS-03, CTS-04, FUG-01 and MSC-02 may have associated waste issues that were not identified in the IS. The comment does not describe or identify waste issues that they believe may be associated with control measures CTS-01, CTS-02, CTS-03, CTS-04, FUG-01 and MSC-02. SCAQMD staff will address any waste issues identified in the more thorough analysis in the Draft Program EIR for the 2012 AQMP.

6-8 The comment states that if funding is taken from existing programs to implement INC-02, there could be an adverse air quality impact. Funding for INC-02 will not be taken from existing programs and resources. Rather, staff intend to work with the stakeholders to identify a new funding source to implement INC-02, separate and different than the funding for existing programs. Therefore, no air quality impacts are expected from the funding of INC-02, since funds will not be taken from existing programs.

6-9 The comment states that imposition of SCAQMD-developed operating or maintenance procedures on a facility is not without potential impacts. The comment states that adverse impacts could result from upsets or malfunctions caused by arbitrary or inappropriate procedures required by the control measure MSC-03.

Operating or maintenance procedures required by SCAQMD control measures, rules or regulations are to ensure that equipment and associated control and/or monitoring equipment are operating correctly and within manufacturer specifications and comply with applicable rules. No evidence is presented of any arbitrary or inappropriate procedures. Any procedures that industry or the public believes to be arbitrary or inappropriate should be identified during the public review period of the AQMP or rules or regulations. SCAQMD staff addresses all such concerns and works to prevent any procedures that are not appropriate. Therefore, since no arbitrary or inappropriate procedures are expected, there would not be any adverse impacts to control measure MSC-03 or associated rules and regulations developed from MSC-03.

6-10 The comment requested the Draft Program EIR for the AQMP to include an alternative comprised only of the “eight short-term PM_{2.5} control measures, an alternative that would not include the Section 182(e)(5) implementation measures for ozone for either stationary or mobile sources” because the cost of such an alternative would place less reliance on actions by other agencies and be considerable less than the proposed project. AQMP controls should not be placed solely on sources under SCAQMD’s authority. Eighty to 90 percent of NO_x emissions are from mobile sources. Therefore, the District has to rely on CARB/EPA to reduce their fair share of reductions. Not including ozone measures in the proposed project would be less costly, but these costs are not avoided, just deferred.

The Draft Program EIR includes an alternative comprised only of PM_{2.5} control measures. Please see Alternative 4 in Chapter 6 of the Draft Program EIR.

6-11 The comment states that the “compressed” timeline for the adoption of the 2012 AQMP is concerning to them and impacts their ability to provide meaningful input. As stated in Response to Comment 6-4, the IS has been updated with the current proposed control

measures and associated analysis. The revised IS and new NOP were released on August 2, 2012 for a 30-day public review and comment period. The additional public review period should address the concerns raised in the comment. When released, the Program EIR will be available for a 45-day review period, as required by law. Therefore, it will not be subject to a “compressed” review period.

- 6-12 The concluding paragraph states the business community’s commitment to the AQMP process and provides information on Southern California Business Coalition contacts. No further response is necessary.

Dear Mr. Smith:

SUBJECT: COMMENTS ON THE NOTICE OF PREPARATION FOR THE PROPOSED 2012 AIR QUALITY MANAGEMENT PLAN PROGRAM ENVIRONMENTAL IMPACT REPORT

7-2

The City of Los Angeles Harbor Department (Harbor Department) appreciates the opportunity to comment on the Notice of Preparation (NOP) for a Draft Program Environmental Impact Report (EIR) for the 2012 Air Quality Management Plan (AQMP). Regarding the Draft 2012 AQMP, the Harbor Department submitted initial comments on July 10, 2012 related to the proposed backstop measure for indirect sources of emissions from ports and port-related sources. For your reference, a copy of the letter is enclosed. Regarding the preparation of the Draft Program EIR, we offer the following scoping comments for the South Coast Air Quality Management District (SCAQMD) to consider during its environmental review process under the California Environmental Quality Act (CEQA):

7-3

Schedule
The Program EIR schedule is very aggressive, with the scoping period ending on July 27, 2012, the release of the Draft Program EIR scheduled for August 2012, and final approval planned for October 5, 2012. There does not appear to be adequate time allocated to allow for meaningful input on the scope and content of the Draft Program EIR or the AQMP. In fact, the schedule would suggest that the Draft Program EIR may be well underway without the benefit of this scoping process. Hopefully, the SCAQMD will conduct the scoping process in a manner that allows for the integration of new information or analysis into the Draft Program EIR based on public comments received.

An Affirmative Action, Equal Opportunity Employer / Recycled and Recyclable

Mr. Smith
South Coast Air Quality Management District

Page 2

- 7-4 *Aesthetics*
The Initial Study identifies potential significant impacts on aesthetics due to: 1) control devices at port facilities to control ship emissions from ships at berth, such as hoods or bonnets on ship exhaust stacks that could be as high as 80 feet; and 2) the use of overhead catenary power lines as a potential control measure to promote the use of zero emissions trucks powered by electricity. The Draft Program EIR should analyze potential aesthetic impacts to scenic corridors. Specifically, Harbor Boulevard and John S. Gibson Boulevard are identified in local plans as major scenic highways, thereby making views from these roadways highly sensitive. Like container cranes, any structures should be evaluated that impact views from Harbor Boulevard and John S. Gibson Boulevard or obstruct views of the Vincent Thomas Bridge, a local landmark that is eligible for listing in the National Register of Historic Places.
- 7-5 *Energy*
The Draft Program EIR should analyze how the mobile source control measures related to the electrification of on-road and off-road heavy-duty vehicles, marine vessels, locomotives, cargo handling equipment, and harborcraft will impact regional energy demand, the need for new electrical power or natural gas utility systems, and peak demand periods.
- 7-6 *Hazards and Hazardous Materials*
As noted on page 2-27 of the Initial Study, some control measures, such as OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels while at Berth, could result in the increased use of ammonia in SCR units and the need for local ammonia storage. Additional hazardous waste generation and disposal for filtration systems applied to large vessels could also occur. Greater use of alternative fuels could also create hazard impacts in the event of an accidental release of these materials. The Draft Program EIR should evaluate the hazard impacts related to ammonia and LNG storage and fueling stations among port facilities, along with the potential for increased hazardous waste generation and disposal.
- 7-7 *Transportation/Traffic*
The NOP/IS states that the Draft 2012 AQMP is not expected to generate any significant adverse project-specific impacts to transportation or traffic systems and that no further evaluation will be conducted in the Draft Program EIR. However, the SCQAMD has not addressed impacts to traffic circulation on major freeways due to construction and operation of potential control measures related to on-road heavy-duty vehicles, such as the use of overhead catenary power lines. Traffic impacts due to the increased need for battery charging stations or LNG fueling stations are also not addressed. We would like to see these potential impacts analyzed in the Draft Program EIR.

Mr. Smith
South Coast Air Quality Management District

Page 3

7-8

Socioeconomics

While not required under CEQA, the Draft 2012 AQMP should include a thorough socioeconomic impact analysis for each proposed control measure, most notably the proposed backstop measure. This could be accomplished with an expanded discussion under the cost effectiveness section of each control measure summary in the Draft AQMP.

7-9

We look forward to reviewing both the Draft Program EIR and the Draft 2012 AQMP and working with the SCAQMD throughout the environmental review process.

Sincerely,

CHRISTOPHER CANNON
Director of Environmental Management

Re: Initial Comments on the Proposed 2012 Air Quality Management Plan,
Control Measure IND-01

Dear Dr. Wallerstein:

7-10

The Port of Long Beach and Port of Los Angeles (Ports) appreciate the opportunity to participate in the South Coast Air Quality Management District's (AQMD) 2012 Air Quality Management Plan (AQMP) Advisory Committee. We support the AQMD's clean air goals and have worked aggressively with the port industry to reduce our fair share of air quality impacts to the region from port-related operations, as outlined in the San Pedro Bay Ports Clean Air Action Plan (CAAP) and the associated San Pedro Bay Standards. As a result, between 2005 and 2010, emissions from port-related sources were reduced by 70 percent for diesel particulate matter and by 49 percent for nitrogen oxides. Emissions inventory work currently underway indicates additional, continued emission reductions in 2011.

7-11

While we continue to remain a committed partner in the effort to improve air quality in the region, we disagree with AQMD's proposed control strategy for port-related sources in the Draft 2012 AQMP. The inclusion of proposed measure IND-01, "Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources," is unnecessary and counter-productive.

The two Ports have a proven track record of developing and implementing appropriate and effective emission reduction strategies. These efforts have been entered into voluntarily, working cooperatively with operators in the port area and the air quality regulatory agencies (i.e. Environmental Protection Agency, California Air Resources Board and AQMD). Since the Ports initially implemented the CAAP, many of the port-related control strategies have been or will be superseded by state or international requirements, such as the rules for replacing drayage trucks, switching to cleaner marine fuels, and using shore power while at berth. The Ports' emissions inventories in 2010 show reductions that are meeting or are in excess of the emission reductions that the Ports committed to in the San Pedro Bay Standards. However, it is important to note that in order to remain on track to meet the Standards, a collaborative and concerted effort with our agency partners is essential, with the understanding that while the Ports can achieve significant emission

The San Pedro Bay Ports Clean Air Action Plan was developed with the participation and cooperation of the staff of the US Environmental Protection Agency, California Air Resources Board and the South Coast Air Quality Management District.

Dr. Wallerstein
 July 10, 2012
 Page -2-

7-11
 Cont.

reductions, no single entity can accomplish this task. The previous State Implementation Plan identified several regulatory strategies that have not yet materialized into regulations for various reasons. Moving forward, the Ports will need agency assistance, particularly on the development and deployment of zero-emission technologies and at-berth controls for non-regulated vessels, as well as on the preferential deployment of cleaner vessels to the basin.

The Ports are sustaining and growing long-standing successful CAAP programs, such as the Vessel Speed Reduction Incentive Program and, on July 1, 2012, the Ports implemented new, groundbreaking incentive programs to encourage cleaner ocean-going vessels to call at the Ports. With programs such as these, along with the above-referenced regulatory rules becoming effective and ensuring significant additional emission reductions by 2014, there is no identified need for implementing a backstop measure. The AQMD's proposed backstop measure will not result in any additional benefit for the region beyond what is currently being achieved and expected to be achieved in the near future, and is therefore unnecessary.

7-12

It is inappropriate for the AQMD to attempt to regulate the Ports, which are the Harbor Departments of the cities of Long Beach and Los Angeles, in an attempt to control emissions from equipment within our boundaries, but which we do not own or operate. Further, the proposed backstop measure identifies that the "...requirements will be triggered if the reported emissions for 2014 for port-related sources exceed the 2014 target milestone, or the Basin fails to meet the 24-hour PM2.5 standard as demonstrated in the 2012 AQMP and basin-wide reductions are needed, in which case a new reduction target for each pollutant will be established." (emphasis added). While clarification has been provided by AQMD staff that any effort to make up for a basin-wide shortfall will be the responsibility of all sectors, not just the Ports, this statement still implies that if the port industry meets their targeted emission reductions, but other sectors fail to meet their fair share obligations, then the AQMD will mandate additional reductions from the Ports. This is counter to the cooperative relationship that our agencies have established since we began working together on the CAAP in 2006, and ignores the tremendous air quality benefits that have been gained from voluntary actions.

7-13

Lastly, based on the preliminary calculations by AQMD, the majority of the region is expected to be in attainment for PM2.5 by the target year of 2014, with the remainder anticipated to be in attainment by the expected extension date of 2019. The inclusion of IND-01 is therefore unnecessary for the region to reach attainment. If these emission reductions are needed in the baseline emissions calculation, there is precedent for mechanisms other than control measures to be used for this purpose, and we would like to discuss those options with your staff.

7-14

We strongly believe that the voluntary and cooperative CAAP process established by the Ports remains the most appropriate forum for the Ports and the air regulatory agencies to discuss technical and policy issues related to reducing emissions from port-related sources. As stated above, we remain committed to achieving our fair share of clean air goals identified in the CAAP and working with port industry and the air regulatory agencies on implementation of appropriate strategies.

For your reference, attached is a comment letter dated May 4, 2010, in which the Ports initially expressed concerns regarding backstop rules. The letter was submitted as a public comment on the proposed Rules 4010 and 4020, which were proposed backstop rules for health risk and criteria pollutant emissions.

Dr. Wallerstein
July 10, 2012

**Responses to Comment Letter #7
Port of Los Angeles – Christopher Cannon (7/26/12)**

- 7-1 This comment notifies the SCAQMD that a comment letter is attached. No further response is necessary.
- 7-2 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Initial Study for the Draft Program EIR for the 2012 AQMP. This comment also refers to a separate comment letter submitted on July 10, 2012 that is attached to this comment letter (see Responses to Comments 7-10 through 7-15). No further response is necessary.
- 7-3 Subsequent to the submittal of this comment letter, the NOP/IS was recirculated for an additional 30-day public comment period on August 2, 2012 because changes were made to the 2012 AQMP project description subsequent to release of the original NOP/IS on June 27, 2012. The comment period for the recirculated NOP/IS closes on August 31, 2012. Two additional public workshops/CEQA scoping meetings have also been scheduled for August 9, 2012 and August 23, 2012 to seek additional input regarding the scope and content of the Draft Program EIR. To accommodate the timing needed to recirculate the NOP/IS, the public hearing date has been moved from October 5, 2012 to November 2, 2012 (subject to change). See also Response to Comment 6-11. All comments received during the scoping process will be considered when preparing the Program EIR.
- 7-4 Consistent with the suggestion in the comment, the recirculated NOP/IS acknowledges that there may be potentially significant adverse project-specific aesthetics impacts to scenic corridors. These impacts will be analyzed in the Draft Program EIR.
- 7-5 Consistent with the suggestion in the comment, the recirculated NOP/IS acknowledges that there may be potentially significant adverse energy demand impacts from various mobile source control measures related to the electrification of on-road and off-road heavy-duty vehicles, marine vessels, locomotives, cargo handling equipment, and harborcraft. These impacts will be analyzed in the Draft Program EIR.
- 7-6 Consistent with the suggestion in the comment, the recirculated NOP/IS acknowledges that there may be potentially significant adverse hazards and hazardous materials impacts from: 1) hazardous waste generation and disposal associated with filtration systems applied to large vessels related to ammonia storage and use; and, 2) the potential for accidental release of alternative fuels, such as LNG, as the use of these alternative fuels increases as a result of implementing various control measures, including but not limited to Control Measure OFFRD-04. These impacts will be analyzed in the Draft Program EIR.
- 7-7 Consistent with the suggestion in the comment, the recirculated NOP/IS acknowledges that potentially significant adverse traffic impacts could occur as a result of implementing ADV-01 – §182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles, due to constructing overhead electrical catenary lines. Therefore, this potential impact will be evaluated in the Draft Program EIR

- 7-8 The SCAQMD is currently conducting a socioeconomic analysis of the 2012 AQMP, which would include costs of control measures, benefits of clean air, job impacts, and other socioeconomic impacts. The analysis will be presented in a stand-alone report. To date, the SCAQMD has released the cost of each measure. The proposed backstop measure would be triggered if the reported emissions for port-related sources are more than the 2014 target milestone, if the Basin fails to meet the PM_{2.5} standard as prescribed in the 2012 AQMP, or if there is a change in the Basinwide carrying capacity. If any one of those conditions is met, the cost of the measure will be assessed. It is too speculative to predict whether the backstop measure would be triggered, the level of emission exceedance, and the requisite control technology at this time. It is also speculative to forecast future changes in carrying capacity or whether the 2012 AQMP would fall short of compliance.
- 7-9 This comment concludes the letter. No further response is necessary.
- 7-10 This comment begins the attached referenced letter mentioned in Comment 7-2. This comment notifies the SCAQMD that the comments contained in the letter pertain to commenter's participation in the 2012 AQMP Advisory Committee. This comment also remarks on the commenter's past and present emission reduction efforts. No further response is necessary.
- 7-11 The SCAQMD staff acknowledges the Ports' efforts in reducing emissions from port related sources. The SCAQMD staff will continue to be an active participant on zero-emission technology development and demonstration projects. The SCAQMD staff also supports the Port's Clean Air Action Plan (CAAP) Technology Action Plan (TAP) which calls for current and future efforts to demonstrate technology with a high potential to further reduce emissions from port-related sources.

Control Measure IND-01 – Backstop Measure for Indirect Sources of Emissions from Ports and Port-related Facilities was included in the Draft 2012 AQMP in order to provide an “insurance policy” to ensure that the assumed emission reductions from port-related sources are met. This control measure is based on emission targets from port-related sources, and “backstops” those emissions expected from existing air quality rules, regulations, and commitments by 2014.

It should be noted that the PM_{2.5} attainment strategy contained in the Draft 2012 AQMP does not rely on additional reductions from port-related sources, beyond what is projected for the future baseline emissions inventory.

SCAQMD staff considers this control measure to be necessary to ensure that the Basin achieves the federal 24-hour PM_{2.5} ambient air quality standard by 2014. Reductions will occur and be enforceable, so that the additional emission benefits from port-related sources are possible. For instance, there are other control strategies that could be put in place that the Ports are not currently implementing and are not otherwise required by state and federal law. These include accelerating the use of lower emitting locomotives operated by Class I Railroads, and zero- and near-zero emission reduction technologies.

- 7-12 The comment states that “it is inappropriate for the SCAQMD to attempt to regulate the Ports, which are the Harbor Departments in the cities of Long Beach and Los Angeles, in an attempt to control emissions from equipment within our boundaries, but which we do

not own or operate.” The SCAQMD may regulate Ports sources under its existing authority. As stated in control Measure IND-01, the SCAQMD has the authority to adopt rules to control emissions from “indirect sources” under existing law. The Clean Air Act defines an indirect source as a “facility, building, structure, installation, real property, road or highway which attracts, or may attract, mobile sources of pollution,” 42 U.S.C. § 7410(a)(5)(C); CAA § 110(a)(5)(C). Under this definition, the Ports are an indirect source. As provided in the California Health & Safety Code, districts are further authorized to adopt rules to “reduce or mitigate emissions from indirect sources” of pollution. (Health & Safety Code § 40716(a)(1)). The SCAQMD is also required to adopt indirect source rules for areas where there are “high-level, localized concentrations of pollutants or with respect to any new source that will have a significant impact on air quality in the South Coast Air Basin.” (Health & Safety Code § 40440(b)(3))

The Ports are also concerned that if the port industry meets their targeted reductions, but other sectors fail to meet their fair share obligations, then the SCAQMD will mandate additional reductions from the Ports. As the control measure explains, if the current situation where the original basin-wide carrying capacity is lowered in the future, the SCAQMD will seek additional reductions from all available sources, including port-related sources. Under this scenario, all sources will have a new “fair share” reduction target, including port-related sources.

- 7-13 The comment regarding attainment dates is correct based on current inventories and projections, and no additional emission reductions from port-related sources are needed to demonstrate attainment for the federal 24-hr PM_{2.5} ambient air quality standard by 2014. However, as discussed in Response to Comments 7-11 and 7-12, Control Measure IND-01 is necessary to ensure that if additional emission reductions are needed to demonstrate attainment of the federal 24-hr PM_{2.5} ambient air quality standard due to changes in the basin-wide carrying capacity, a mechanism for further emission reductions from port-related sources is included as a control measure in the AQMP.
- 7-14 The SCAQMD staff remains committed to working with both Ports in a collaborative manner to reduce emissions and develop and demonstrate promising zero- and near-zero-emission technologies for port-related sources. We believe this shouldn't be limited to the CAAP process, and can be done either within the framework of the CAAP or other public and private partnerships. The inclusion of Control Measure IND-01 should not adversely affect this process in anyway.
- 7-15 This comment concludes the letter. No further response is necessary.

2012 Air Quality Management Plan-South Coast Air Quality District- Initial Study/Notice of Preparation Comments - Message (HTML)

 Subject: 2012 Air Quality Management Plan- South Coast Air Quality District- Initial Study/Notice of Preparation Comments

Dear Dr. Steve Smith:

**Initial Study/Notice of Preparation
 2012 Air Quality Management Plan
 South Coast Air Quality District**

8-1 Thank you for the opportunity to review the Initial Study/Notice of Preparation for the 2012 Air Quality Management Plan (AQMP). The 2012 AQMP identifies control measures to demonstrate that the region will attain the federal standard for particulate matter less than 2.5 microns in diameter (PM2.5) by the applicable target dates and provides Clean Air Act §182(e)(5) proposed implementation measures to assist in achieving the 8-hour ozone standard.

The following comments are for your consideration and relate to the environmental document only.

Hazards-Environmental Safety

8-2 Initial Study of the 2012 AQMP
 Section MCS-02: Further Emission Reductions from Green Waste Processing (page 1-16)

It is recommended that a timeline be specified as to when 1) the existing database would be reviewed to refine green waste material inventory, and 2) a rule would potentially be developed to incorporate technically feasible and cost-effective BMPs or controls.

If you have any questions regarding the environmental safety comment, please contact Mr. Corey Mane at (626) 458-3524 or cmayne@dpw.lacounty.gov.

Services-Traffic/Access

8-3 Road Maintenance Division is currently seeing operational impacts as a result of current requirements for alternative fueled vehicle use in lieu of clean-diesel technology. Many of the proposed regulations seem to build on the current ones which are causing negative impacts. Specifically, Counties typically maintain and respond to rural areas far from urban centers. This is as opposed to most cities which are fairly compact and do not require staff to respond beyond several miles of their City facilities. Counties such as Los Angeles may literally respond dozens of miles from their de-centralized facility, in rural/mountain terrain, far from urbanized areas. Therefore, infrastructure for fueling of alternative fueled vehicles is not present. Note that many areas do not even have natural gas lines to make CNG even a possibility. Also, because of the distances, current technology has not provided a means to allow a vehicle to operate in the remote areas for a full 12-hour shift in order to provide road clearing, snow plowing, debris removal, tree trimming, etc. Note that operationally, staff and equipment in Road Maintenance Division provide mutual Support during and subsequent to major storms and other natural disasters. We caution implementing rules requiring technology which would not allow equipment/vehicles to be used for at least 12 hours, in remote areas, 60 miles or more from their facility or origin, without special infrastructure (charging stations, CNG fueling). Finally, cost of purchase, maintenance, and additional infrastructure to maintain alt. fuel vehicles causes already strained and reduced transportation related revenues to be

(charging stations, CNG fueling). Finally, cost of purchase, maintenance, and additional infrastructure to maintain alt. fuel vehicles causes already strained and reduced transportation related revenues to be utilized on items other than the roadway infrastructure itself.

We would request that a process be implemented to take these unique circumstances into consideration as the rules are implemented in order to not adversely impact public safety. Again, this affect Los Angeles County more than individual Cities due to the more rural nature of our facilities and the Mutual Aid provided following storms and other Natural disasters.

8-4 Section XIV PUBLIC SERVICES has been checked off that there are no Impacts to other public facilities. We believe that actually there could be Potentially significant impacts in rural, County Unincorporated areas and mountain roads because of the issues presented above. There would likely be physical impacts to our facilities if alternate fuels/methods are required. Additionally, construction of costly fueling sites would be required where there are no public fueling sites available, or the sole public site was not constructed with on-road, heavy duty trucks in mind and therefore it is unable to be utilized. Most of our decentralized facilities are not physically able to be utilized for public/private fueling. Several do not have necessary infrastructure available. Therefore, response times would be adversely affected and performance goals impacted due to inability of alternate fueled vehicles to operate an entire shift in remote, unincorporated areas. In addition, mutual aid within the Department would be adversely impacted by inability to respond to remote areas or areas served in the Antelope Valley AQMD by our staff and vehicles assigned to a facility in SCAQMD.

8-5 In the discussion, Section XIV a) and b), page 2-43 it states that per Health and Safety Code, emergency or rescue vehicles operated by law enforcement, fire, medical, paramedic are specifically exempt from requirements of alternate fueled vehicles. That was likely the basis for determination of no adverse impact. Unfortunately, that code does not take into account that Public Works, specifically those involved in roadway maintenance, are not considered in that same code. However, roadway maintenance is the first to be called by those responders in order to maintain public roadways in an open and safe condition in order for those mentioned in the code to respond themselves. Also, in the restoration efforts, emergency responders by that code are largely not involved, while Public Works staff continue to work towards restoring access on public roadways for every extended periods of time. Typically in remote areas.

8-6 If you have any questions regarding the traffic/access comments, please contact Mr. Mark Caddick at (661) 947-7173 or mcaddick@dpw.lacounty.gov.

If you have any other questions or require additional information, please contact:

Toan Duong

 Land Development Division
 Los Angeles County Department of Public Works

Responses to Comment Letter #8
Los Angeles County Department of Public Works – Toan Duong (7/26/12)

8-1 No response necessary. The email informs the reader that the comments are included are provided on the environmental document only.

8-2 This comment requests that a timeline be provided noting when the existing green waste material inventory would be reviewed and that a rule be developed to incorporate technically feasible and cost effective BMPs or controls under MCS-02.

The proposed control measure MCS-02 Further Emission Reductions from Greenwaste Processing will consist of two phases. The first phase would cover developing emission factors from greenwaste chipping and grinding activities, refinement of the greenwaste material throughput by sector (e.g., landfill, landscapers, composters, etc.), and if needed, a survey of greenwaste generation and utilization to contribute to the development of a comprehensive material throughput and emissions inventory. During Phase 1, SCAQMD staff will conduct regular meetings of the Rule 1133 series working group to review and seek input on the data from Phase 1 as it is developed. Phase 1 is expected to be completed by late 2013 or 2014. Phase 2 rule development would commence as Phase 1 ends and is tentatively scheduled to be completed by 2015 with implementation of this proposed control measure one to two years after that. However, the exact timing and execution of Phase I, Phase II, rule adoption, and rule implementation will depend heavily upon the results of each preceding activity; therefore, no specific timelines are available at this time.

8-3 This comment cautions against the implementation of rules that require technology which would not allow equipment/vehicles to be used for at least 12 hours in remote areas, 60 miles or more from their facility or origin without special infrastructure. If fleet vehicle rules are amended in the future, the needs of affected fleets will be considered at that time.

The comment states that the cost of purchase, maintenance and additional infrastructure to maintain alternative fueled vehicles causes “strained and reduced” transportation related revenues to be used on items other than roadway infrastructure itself.

As already noted, any future fleet vehicle rules would consider needs such as fleets located in remote locations for example. Mobile alternative refuelers are available. Through the use of these mobile alternative fuel refuelers, the county would be able to extend the service distance available to alternative-fueled vehicles in the county fleet. The mobile alternative fuel refuelers can be rotated around the county based on need. Therefore, mobile alternative fuel refuelers would be less expensive to implement than building new infrastructure in areas that are not frequently accessed.

8-4 The comment states that there would be potentially significant impacts in rural, County Unincorporated areas and mountain road caused by alternative-fuel requirements in control measures, rules and regulations. The comment states there would be physical impacts to facilities from construction of refueling sites. Response times and performance goals may be impacted due to the inability of alternative fueled vehicles to operate an entire shift in remote, unincorporated areas.

Alternative fueled vehicles have become the preferred fuel for several types of fleets who are accustomed to either gasoline or diesel use. At a cost between \$1.50 - \$2.00 less a gallon, alternative fuels have become the preferred fuels in the refuse and transit bus industries. As stated in Response to Comment 8-3, mobile refuelers may be used in areas that are remote locations from alternative fueled stations and thereby allow the county to meet response times and performance goals, while reducing cost and air pollution. Should this option not be feasible for an individual circumstance, exemptions from any future alternative fuel requirements could be developed, similar to the SCAQMD's existing fleet Rule 1196. If fleet vehicle rules are amended in the future, the needs of affected fleets will be considered at that time. As already noted, any future fleet vehicle rules would consider needs such as fleets located in remote locations for example. Also, exemptions and exceptions can be carried out during rule development to address issues of infeasibility.

- 8-5 The comment states that Public Works vehicles, specifically road maintenance vehicles, are not considered in the exemption from requirements of alternative fueled vehicles under the Health and Safety Code. The comment also states that roadway maintenance is called first by emergency responders to maintain public roadways open and in a safe condition.

Roadway maintenance vehicles are not defined as emergency vehicles in accordance with the California Vehicle Code. Alternative-fueled maintenance vehicles can be supported by alternative fueled mobile refuelers. This would allow public roadways to remain open and in a safe condition while emergency vehicles that are exempt under the Health and Safety code respond to emergencies.

- 8-6 No response is required. The concluding paragraph provides contact information for the Los Angeles County Department of Public Works.

Subject: Comments to 2012 Draft AQMP due 7.27.2012 5PM

Message City Light Pollution Affects Air Pollution.pdf

9-1 "Vision" may be your operative word and "imaginary" may be one left out.

9-2 Do you know all your sources of pollutions.

9-3 Take, for instance, the Midway Yard in Los Angeles used as Metrolink's Central Maintenance Facility. There has never been a Full environmental Impact Report for that use and only interim use is mentioned in:

Pasadena-Los Angeles Rail Transit Project
State Clearinghouse No. 88042713

Burbank-Glendale-Los Angeles Rail Transit Project
State Clearinghouse No. 93051016

9-4 Being in the center of downtown Los Angeles, near freeways and industry, what are the pollutant loads? There can be NO proper assessment and data for SCAG or other agencies to do proper planning. Obviously, without an EIR there is no monitoring.

9-5 There are no Scenarios created to address the problem.

9-6 You can also affect Impaired Water Bodies such as the LA River and increase the Greenhouse Gas effect.

9-7 There is (City of Los Angeles) reference to a three-party Settlement Agreement was signed by the City of Los Angeles, the Los Angeles County Transportation Commission (LACTC), and the Southern California Regional Rail Authority in 1992. The Agreement was developed to avert legal action by the City of Los Angeles regarding the LACTC's and SCRRA's conformity with California Environmental Quality Act (CEQA) requirements in building the commuter rail maintenance facility (CMF)Taylor Yard.

That Settlement Agreement cannot be found, to date, and does not reduce emissions.

9-8 You do not take into effect emissions from methane and other gases discharging from the geology because of its oil content and soil contamination-or even because of fracking. Failed Methane Monitoring Systems can add to air pollution. Some activists have rented cameras to film the dangerous discharges.

9-9 What municipalities have supplied data on their Methane Monitoring systems?

9-10 Monitoring stations need to be identified in this report. The push to bicycles may just be a method of reducing emission around monitoring stations and, because of the minority of population buy-in, not a sustainable solution. Is there a consistent system amongst governing agencies?

9-11 Same with Transit Oriented Districts. The data given by Brian Taylor from UCLA shows a less affluent user of transit. Would that method really be replacing automobiles? SCAG has created scenarios as if TOD would be replacement methods. We believe this to be false.

9-12 Considering the state of the economy and high unemployment in the Los Angeles area, will new technology in cars be considered reliable in the projections? In other words, can the public afford the new vehicles that would reduce emissions?

9-13 Have you looked at density and idling in traffic?

9-14 Have you looked at density in the increased usage of landfills and their emissions? Is there a consistent system amongst governing agencies in their reporting and monitoring?

9-15 Have you looked at major projects such as the Los Angeles Convention and Event Center (NFL Stadium) and the concentration of automobiles to a single location and the number of days effected? Have you analyzed those transportation patterns within the SCAQMD to events at the stadium?

9-16 Have you looked at Digital Signage, Light Pollution and the impacts on Ozone (City Light Pollution Affects Air Pollution-Harald Stark-NOAA)?

9-17 What differentials have occurred since the 2001 Baseline Air Emissions Inventory used in reports?

9-18 This plan is TOO concentrated on vehicle and truck emissions, and attainment has not been achieved to date.

City Light Pollution Affects Air Pollution

Poster # A21C-0117
 Location: Moscone South
 Tuesday, December 14th
 8am-12pm

Harald Stark*, S.S. Brown, W.P. Dubé, N. Wagner, T.B. Ryerson, I.B. Pollack, C.D. Elvidge, D. Ziskin, D.D. Parrish

* harald.stark@noaa.gov, Phone: 303-497-5426

National Oceanic and Atmospheric Administration, Earth System Research Laboratory, 325 Broadway, Boulder, CO 80305, USA

* Also associated with Cooperative Institute for Research in Environmental Sciences, University of Colorado, Boulder, CO 80309, USA

First airborne measurements of city lights intensities

- o City lights over Los Angeles are 10,000 times dimmer than sun light but 25 times brighter than the full moon
- o Two street light types identified by color fingerprints: high-pressure sodium (HPS) and metal halide lamps (MH)
- o Light intensities were converted into chemical destruction strength
- o Satellite data can be used to estimate light intensities over other cities
- o City lights can
 - Destroy nighttime cleansing chemicals
 - Slow down night time cleansing of pollution
 - Lead to more starting chemicals for the next day
 - Affect ozone levels after sunrise

Aircraft data calibrates satellite

Los Angeles at night: City lights and chemistry, viewed from the air

Responses to Comment Letter #9
Ms. Joyce Dillard (7/27/12)

- 9-1 The correct title of the document it is assumed that the commenter is referring to is *Vision for Clean Air: A Framework for Air Quality and Climate Planning*. This document is a collaborative effort by the SCAQMD, CARB and the San Joaquin Valley Air Pollution Control District that examines how strategies developed for air quality and climate change planning should be coordinated to make the most efficient use of limited resources and the time needed to develop cleaner technologies. The Vision document can be found at: <http://www.aqmd.gov/aqmp/2012aqmp/VisionDocument/index.htm>.
- 9-2 The comment asks if the SCAQMD knows all sources of pollution within its jurisdiction. The 2012 AQMP, like previous AQMPs prepared by the SCAQMD, includes a comprehensive emissions inventory that includes the best available information about emissions in the Basin. The SCAQMD, CARB, and SCAG, make every effort to identify and quantify all sources of pollution. For example, the emissions inventory contains emissions data on a wide range of stationary sources such as boilers, heaters, and other stationary emissions sources located at a wide variety of types of facilities, including refineries, utilities, dry cleaners, gas stations, etc. Emissions inventory data on consumer products including paints, lacquers, cleaning solvents, etc, are also included in the 2012 AQMP emissions inventory. Similarly, CARB provides a comprehensive inventory of emissions from mobile sources, both on-road mobile such as passenger vehicles; light-duty, medium-duty, and heavy-duty trucks; off-road mobile sources such as construction equipment, marine vessels, etc. Each emissions inventory includes improvements and refinements compared to emissions inventories prepared for past AQMPs. The SCAQMD, CARB, and SCAG, make every effort to identify and quantify all sources of pollution. For additional information on the emission inventory in the 2012 AQMP, the commenter is referred to 2012 AQMP Appendix III - Base and Future Year Emission Inventory at <http://www.aqmd.gov/aqmp/2012aqmp/draft/Appendices/AppIII.pdf>.
- 9-3 The comment states that there has never been a full EIR conducted for the Midway Yard in Los Angeles which is used as Metrolink's Central Maintenance Facility, and only interim use of this facility is mentioned in the following two documents:
- Pasadena-Los Angeles Rail Transit Project
State Clearinghouse No. 88042713
 - Burbank-Glendale-Los Angeles Rail Transit Project
State Clearinghouse No. 93051016
- The two projects cited are not part of the 2012 AQMP. In addition, as a single purpose agency regulating air quality, the SCAQMD has little discretionary approval authority over the two rail projects mentioned. Although these projects may include some stationary sources such as backup electricity generators, the more appropriate lead agencies under CEQA would be agencies with general land use authority, such as a city or county, or transit agencies. No further response is necessary.
- 9-4 The comment asks about the pollutant loads in downtown Los Angeles. The comment also states that there is no proper data for SCAG or other agencies to conduct proper planning and without an EIR, there can be no monitoring. The SCAQMD operates 35

permanent, multi-pollutant monitoring stations, and 5 Lead (Pb) air monitoring sites in the South Coast Air Basin and a portion of the Salton Sea Air Basin in Coachella Valley. This area includes Orange County and the non-desert portions of Los Angeles (including downtown Los Angeles), Riverside, and San Bernardino Counties. Each year, the SCAQMD prepares an Annual Air Quality Monitoring Network Plan that includes a review of actions taken during the previous fiscal year, and outlines plans for action in the year ahead. Federal regulations require that the air quality monitoring network be reviewed annually to identify any need for additions, relocations, or terminations of monitoring sites or instrumentation. After a 30-day comment period, the Plan is submitted to the U.S. EPA by July 1 of each year. The Final 2012 Annual Air Quality Monitoring Network Plan can be found on SCAQMD's website at: <http://www.aqmd.gov/tao/AQ-Reports/AQMonitoringNetworkPlan/AQnetworkplan.htm>.

9-5 The comment states that there are no scenarios created to address the problem. The SCAQMD is committed to undertaking all necessary steps to protect public health from air pollution, with sensitivity to the impacts of its actions on the community and businesses. This is accomplished through a comprehensive program of planning, regulation, compliance assistance, enforcement, monitoring, technology advancement, and public education. The SCAQMD develops and adopts an AQMP, which serves as the blueprint to bring this area into compliance with federal and state clean air standards. Rules are adopted to reduce emissions from various sources, including specific types of equipment, industrial processes, paints and solvents, even consumer products. Permits are issued to many businesses and industries to ensure compliance with air quality rules. SCAQMD staff conducts periodic inspections to ensure compliance with these requirements. The test of whether these efforts are working is the quality of the air we breathe. The SCAQMD continuously monitors air quality at 38 locations throughout the four-county area. This also allows the SCAQMD to notify the public whenever air quality is unhealthful.

9-6 The comment states that SCAQMD actions can also affect impaired water bodies such as the Los Angeles River and increase the greenhouse gas effect. All control measures in the 2012 AQMP were evaluated to identify those control measures with potential hydrology and water quality impacts. Review of the 2012 AQMP control measures identified several control measures that have the potential to generate significant adverse hydrology and water quality impacts. Table A-1 in Appendix A of the NOP/IS document lists all 2012 AQMP control measures and shows those control measures that have the potential to generate significant adverse hydrology and water quality impacts. These control measures will be further evaluated in the Program EIR that is being prepared for the 2012 AQMP.

While the 2012 AQMP is not designed to specifically regulate GHG emissions, the 2012 AQMP includes two new categories of control measures, incentive (INC) and education (EDU) programs. In addition to GHG reductions generated as co-benefits of implementing other AQMP control measures, INC and EDU measures are expected to reduce GHG emissions primarily through increasing energy efficiency and conservation (INC-01, EDU-01). Improving energy efficiency can be accomplished by layering smart grid systems onto the existing electricity distribution system. A smart grid is a digitally enabled electrical grid that gathers, distributes, and acts on information about the

behavior of all participants (suppliers and consumers) in order to improve the efficiency, importance, reliability, economics, and sustainability of electricity services². Establishing a smart grid system does not necessarily require constructing a new grid system; use of smart technologies allows the existing grid system to be used more efficiently.

Some 2012 control measures, however, have the potential to generate combustion emissions that could increase GHG emissions. For example, implementing BCM-01 – Emission Reductions from Under-fired Charbroilers, may result in increased combustion emissions through installation of afterburner technologies. Other control measures, e.g., ONRD-01 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Vehicles, ONRD-03 – Accelerated Penetration of Partial Zero-Emission and Zero Emission Medium-Heavy-Duty Vehicles, etc., have the potential to increase demand for electricity resulting in increased combustion emissions, GHG emissions in particular, from increased electricity generation. Therefore, potential GHG emission impacts will be analyzed in the Program EIR.

9-7 The comment refers to a three-party settlement agreement that was signed by the City of Los Angeles, the Los Angeles County Transportation Commission (LACTC) and the Southern California Regional Rail Authority in 1992 regarding LACTC's and SCRRA's conformity with CEQA requirements in building the commuter rail maintenance facility (CMF) Taylor Yard. The comment also states that the settlement agreement cannot be found and does not reduce emissions. While the 2012 AQMP contains three measures related to future rail activities, it is not directly related to the specific project or settlement agreement that is referred to in the comment.

9-8 The comment states that the SCAQMD does not take into effect emissions from methane and other gases discharging from the geology because of its oil content and soil contamination or because of fracking. The SCAQMD currently does not regulate fracking operations and the 2012 AQMP does not contain any control measures related to fracking operations. In California, the Division of Oil, Gas and Geothermal Resources (DOGGR) has authority to regulate all phases of oil and gas development and has the statutory authority to regulate fracking (see California Pub. Res. Code §3106). However, the Division does not track, regulate or monitor any aspect of hydraulic fracturing and it does not require reporting to track the different methods or the fluids injected into the ground. While the agency requires drilling permits and enforces groundwater protections, once those permits are acquired, drillers are allowed to employ techniques such as fracking to get the oil/gas out of the ground without additional reporting.

For the first time, EPA will regulate air emissions from natural gas wells that are hydraulically fractured, as well as other emission sources associated with exploration, production, processing, and transportation of oil and natural gas. On April 17, 2012, EPA issued a set of regulatory standards for the oil and gas industry under the Clean Air Act, requiring the reduction of emissions of VOCs, air toxics and methane from sources in the industry, including the hydraulic fracturing of horizontal natural gas wells drilled or hydraulically re-fractured after August 23, 2011.

² http://en.wikipedia.org/wiki/Smart_grid, accessed December 16, 2011.

- 9-9 The comment questions what municipalities have supplied data on their methane monitoring systems. Municipalities reporting their VOC emissions and methane (CH₄) emissions are estimated from CARB's VOC speciation profile. The SCAQMD provides CARB the VOC emissions inventory from the sources in our jurisdiction obtained from the Annual Emissions Reporting (AER) Program every year. In turn, CARB generates the CH₄ emissions from their speciation profile.
- 9-10 The comment states that monitoring stations need to be identified in this report and incentives for a transition to bicycles may just be a method of reducing emission around monitoring stations. Please refer to the Response to Comment 9-4 for a discussion of the SCAQMD's network of monitoring stations.
- SCAG's 2012 – 2035 RTP/SCS endeavors to encourage bicycling and other forms of active transportation. These efforts, however, are not tied in any way to SCAQMD's monitoring stations.
- 9-11 The comment states that SCAG has created scenarios as if transit oriented districts would be replacement methods for automobiles. The commenter believes this to be a false notion, but does not provide any evidence to support this opinion. It should be noted that the 2012-2035 RTP/SCS includes consideration of transit oriented development, which is included as part of the baseline for the 2012 AQMP.
- 9-12 The comment questions, considering the state of the economy and high unemployment in the Los Angeles area, whether new technology in cars be considered reliable in the projections (i.e., whether the public can afford to purchase new vehicles that would reduce emissions). New advanced technology vehicles are typically more expensive than conventional gasoline fueled vehicles, at least initially. Historically, there has been a steady increase in sales of hybrid vehicles. SCAQMD staff believes that this trend will be similar for the next generation of advanced technology vehicles. As the sales volume increase, the cost of the vehicle goes down. This has been the trend with the current generation hybrid vehicles. In addition, consumers operating the advanced technology vehicles realize a fuel savings, which help offset the additional upfront cost of the vehicle.
- 9-13 The comment asks if traffic density and idling were analyzed. There are no control measures in the 2012 AQMP that are directly related to idling. All control measures were evaluated to identify those control measures with potential transportation or traffic impacts. Adopting the proposed 2012 AQMP is not expected to substantially increase vehicle trips or vehicle miles traveled in the district. The 2012 AQMP relies on transportation and related control measures developed by SCAG (SCAG, 2012) (see Appendix B of the NOP/IS). These transportation control measures include strategies to enhance mobility by reducing congestion through transportation infrastructure improvements, mass transit improvements, increasing telecommunications products and services, enhanced bicycle and pedestrian facilities, etc. Specific strategies that serve to reduce vehicle trips and vehicle miles traveled, such as strategies resulting in greater reliance on mass transit, ridesharing, telecommunications, etc., are expected to result in reducing traffic congestion. Although population in the district will continue to increase, implementing the transportation control measures, in conjunction with the 2012 Regional Transportation Plan, would ultimately result in greater percentages of the population

using transportation modes other than single occupancy vehicles. As a result, relative to population growth, existing traffic loads and the level of service designation for intersections district-wide would not be expected to decline at current rates, but could possibly improve to a certain extent. Even if congestion in the region increases compared to the baseline, this would occur for reasons other than complying with 2012 AQMP control measures. Therefore, it is expected that implementing the AQMP, including the transportation control measures could ultimately provide transportation improvements and congestion reduction benefits.

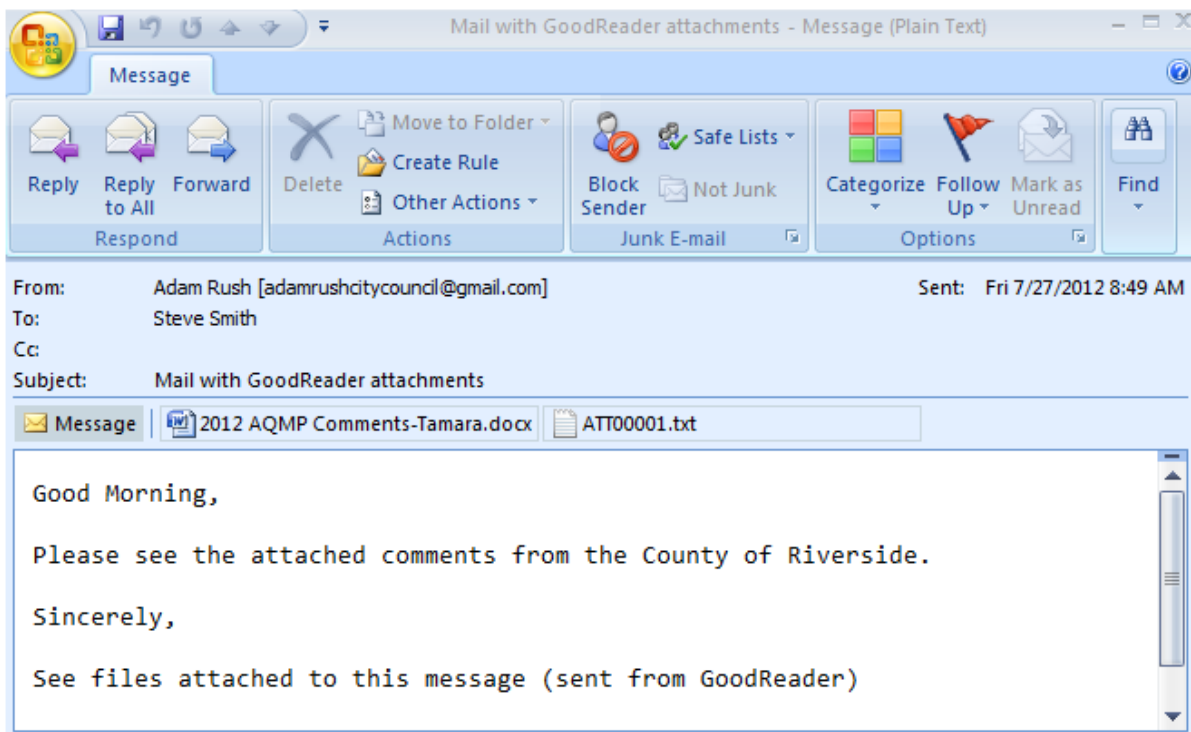

However, comments were received on the June 27, 2012 NOP/IS that potentially significant traffic impacts could occur as a result of implementing ADV-01 – §182(e) Proposed Implementation Measures for the Deployment of Zero- and Near-Zero Emission On-Road Heavy-Duty Vehicles. The comment suggested that constructing the overhead electrical catenary lines could adversely affect traffic. Therefore, this potential impact will be evaluated in the Program EIR.

- 9-14 The comment asks if the SCAQMD has evaluated increased usage of landfills and their emissions. The comment also questions if there is a consistent system amongst governing agencies in their reporting and monitoring. All control measures in the 2012 AQMP were evaluated to identify those control measures with potential solid or hazardous waste impacts. The proposed 2012 AQMP could require affected facility operators to install air pollution control equipment on stationary sources, such as carbon adsorption devices, particulate filters, catalytic incineration, selective catalytic reduction or other types of control equipment that could increase the amount of solid/hazardous wastes generated in the district (e.g., FUG-01, Further VOC Reductions from Vacuum Trucks; CMB-01, Further NO_x Reductions from RECLAIM – Phase I and Phase II) due to the disposal of spent catalyst, filters or other mechanisms used in the control equipment. Solid waste impacts would be considered significant if the impacts resulted in a violation of local, state or federal solid waste standards. Also, solid waste impacts would be significant if the additional potential waste volume exceeded the existing capacity of district landfills.

Some mobile source control measures may result in potentially significant adverse solid and hazardous waste impacts from the use of particulate filters or SCR units (e.g., OFFRD-02, Further Emission Reductions from Freight Locomotives; OFFRD-03, Further Emission Reductions from Passenger Locomotives; OFFRD-04, Further Emission Reductions from Ocean-Going Marine Vessels While at Berth ADV-04, Actions for the Deployment of Cleaner Commercial Harborcraft; and ADV-05, Actions for the Deployment of Cleaner Ocean-Going Marine Vessels), early retirement of inefficient, older equipment (ONRD-02, Accelerated Retirement of Older Light- and Medium-Duty Vehicles), etc. The potential solid/hazardous waste impacts from implementing the proposed 2012 AQMP will be analyzed in the Draft Program EIR.

All municipal solid waste facilities are subject to existing SCAQMD rules which contain reporting requirements. For example, Rule 1150.1- Control of Gaseous Emissions from Municipal Solid Waste Landfills, is applicable to any owner or operator of an active or inactive municipal solid waste landfill. This rule requires gas collection and control systems with specified destruction efficiency rates, integrated sampling protocols, and active monitoring and reporting requirements.

- 9-15 The comment asks if the SCAQMD has looked at major projects such as the Los Angeles Convention and Event Center (NFL Stadium) and the concentration of automobiles to a single location and the number of days effected. The comment also asks if the SCAQMD has analyzed those transportation patterns within the SCAQMD to events at the stadium. The lead agency for the NFL stadium project is the City of Los Angeles. The City of Los Angeles prepared a CEQA document for this project and the SCAQMD submitted a comment letter on the CEQA document. The SCAQMD comment letter for the NFL stadium project can be found at:
<http://www.aqmd.gov/ceqa/igr/2012/May/DEIRconvention.pdf>
- 9-16 The comment questions if the SCAQMD has evaluated digital signage, light pollution and the impacts on ozone. Night lighting of public areas, including roadways, sidewalks, and other open spaces, is often done by local jurisdictions for public safety purposes. The SCAQMD does not regulate lighting or signage and the 2012 AQMP does not contain any control measures related to lighting or signage.
- 9-17 The comment questions what differentials have occurred since the 2001 Baseline Air Emissions Inventory used in reports. Year 2002 is the base year in the 2007 AQMP. As stated and illustrated in the Draft Appendix III to the Draft 2012 AQMP, emissions decreased between 2002 to 2008 for all pollutants. The changes are due to (a) the effect of additional regulations; (b) the improved methodologies or models to calculate the emissions; and (c) the recessionary impacts. Please refer to “Inventory Sources Categories” section from Page III 1-5 to 1-24 in the Draft Appendix III for further details.
- 9-18 The comment states that the 2012 AQMP is too concentrated on vehicle and truck emissions. Approximately 25 percent of this area's ozone-forming air pollution comes from stationary sources, both businesses and residences. The other 75 percent comes from mobile sources consisting mainly of cars, trucks and buses, but also construction equipment, ships, trains and airplanes. Therefore, it is important to implement control measures for mobile sources in order to continue to reduce air pollution in the basin.
- 9-19 This attachment is an article summarizing how light may affect air pollution, therefore, see Response to Comment 9-16.

10-1

10-2 **1).** As the environmental checklist discusses, implementation of some of the proposed control measures may have the potential to generate secondary air quality impacts for various reasons including impacts related short-term construction, etc. In the case of those control measures where construction is necessary to reduce emissions at existing commercial or industrial facilities the following should be considered:

10-3

a) Incentives and/or regulations should be used to reduce the use of those building materials that generate excessive pollutants.

10-4

b) Particulate matter from construction, demolition and debris hauling should be reduced to the greatest extent possible.

10-5

c) The encouragement of stricter state and federal legislation on bias belted tires, smoking vehicles and vehicles that spill debris on streets and highways, to better control particulate matter.

10-6

d) Encourage the use of building materials which reduce emissions.

Responses to Comment Letter #10
County of Riverside – Adam Rush (7/27/12)

- 10-1 This comment notifies the SCAQMD that a comment letter is attached. No further response is necessary.
- 10-2 This comment contains several suggestions pertaining to potential impacts related to construction activities necessary to reduce emissions at existing commercial or industrial facilities. Responses to the specific suggestions are described in Responses to Comments 10-3 through 10-6.
- 10-3 There are two stationary source control measures specifically aimed at offering different incentives for companies that either manufacture or employ zero and near-zero emission technologies in the Basin (refer to Appendix IV-A: INC-01, and INC-02). The incentive programs will be designed to promote voluntary introduction of new technologies on an accelerated schedule. These measures provide manufacturers with incentives for production and commercialization of the cleaner, more advanced technologies while encouraging economic growth by creating local manufacturing jobs and populating the market with lower cost equipment. In addition, there is an educational control measure (EDU-01) designed to provide outreach and incentives for consumers to contribute to clean air efforts, such as the use of energy efficient products, new lighting technology, “super compliant” coatings, tree planting, and use of lighter colored roofing and paving materials, which reduce energy usage by lowering the ambient temperature and, ultimately, lowers emissions from less need for energy generation.
- 10-4 PM emissions from construction, demolition and debris hauling will be analyzed in the Draft Program EIR. It is important to note the PM emissions during construction activities are regulated by SCAQMD Rule 403 – Fugitive Dust, which is designed to minimize PM emissions to the greatest extent possible.
- 10-5 The comment requests that the SCAQMD encourage stricter state and federal legislation on bias belted tires, smoking vehicles, and vehicles that spill debris on roadways. With regard to vehicle tires, belted tires are already regulated by the Secretary of Transportation pursuant to the TREAD Act, §10, Endurance and Resistance Standards for Tires. Further, 49 Code of Federal Regulations (CFR) 571.109 and 49 CFR 571 119 provides authority for the Secretary of Transportation to conduct rulemaking to revise and update the tire standards. Similarly, The National Highway Traffic Safety Administration has a legislative mandate under Title 49 of the United States Code, Chapter 301, Motor Vehicle Safety, to issue Federal Motor Vehicle Safety Standards (FMVSS) and Regulations to which manufacturers of motor vehicle and equipment items must conform and certify compliance. The current tire standards are primarily included in the following FMVSSs: FMVSS No. 109, New pneumatic tires; FMVSS No. 110, Tire selection and rims; FMVSS No. 119, New pneumatic tires for vehicles other than passenger cars; and FMVSS No. 120; Tire selection and rims for vehicles other than passenger cars.
- State law currently addresses smoking vehicles under Motor Vehicle Code §27153. Operators of equipment may be cited for excessive visible smoke by any uniformed law officer. State law also addresses dumping and littering from off-road vehicles under

Motor Vehicle Code §38320. Construction sites and operators use various measures to comply with §38320 including: 1) rubble plates or gravel strips to remove dirt and small rocks from tires before exiting a job site to public roads; and 2) tarps to cover debris which may spill onto roadways. Most heavy duty off-road construction equipment is currently regulated under the CARB In-Use Off-Road Diesel-Fueled Fleets rule in the California Code of Regulations Title 13, Article 4.8, Chapter 9, §2449. Depending on fleet size and total horsepower rating, this regulation requires turnover of equipment to newer lower emitting equipment and includes labeling and reporting requirements. Contractors who remediate hazardous or contaminated sites will be encouraged to require Tier 3 or cleaner construction equipment to minimize gaseous (NO_x and HC) emissions and diesel particulate (PM) emissions and to implement best practice on prevention of fugitive emissions on and near the remediation construction sites.

- 10-6 This comment repeats the suggestion made in Comment 10-3. See Response to Comment 10-3.

RE: Comments on the Notice of Preparation for the Proposed 2012 Air Quality Management Plan Program Environmental Impact Report

Dear Dr. Smith:

11-1 { The Port of Long Beach has reviewed the Notice of Preparation of a Draft Program Environmental Impact Report (EIR) for the Proposed 2012 Air Quality Management Plan Program and appreciates the opportunity to comment. Regarding preparation of the Draft Program EIR, we offer the following scoping comments for use by your agency during its environmental review process under the California Environmental Quality Act (CEQA):

Schedule

11-2 { The EIR schedule is very aggressive, with the scoping period ending on July 27, 2012, followed immediately by the release of the Draft EIR scheduled for August 2012, and final approval planned for October 5, 2012. There does not appear to be sufficient time allowed for meaningful input on the proposed scope and content of the Draft Program EIR by the public. Further, the Port is concerned that, given the quick turnaround between closure of the scoping period and the scheduled release of the Draft Program EIR, insufficient time will be allowed for thorough review of the scoping comments and inclusion of said comments in the Draft Program EIR.

www.polb.com

Dr. Steve Smith
 July 27, 2012
 Page 2

- 11-3 *Aesthetics*
 The Initial Study identifies potential significant impacts on aesthetics due to the implementation of control devices such as hoods or bonnets on ship exhaust stacks. The Port agrees with the SCAQMD that such control devices and equipment would be similar in structure and design to existing features within the Port environment and would not constitute a significant aesthetic impact. Further, control measure ADV-03, which may include the construction of electric gantry cranes within the Port, should not be considered aesthetically significant as gantry cranes are an existing feature within the Port environment.
- 11-4 *Energy*
 The Draft Program EIR should analyze how the mobile source control measures related to the electrification of vehicles will impact regional energy demand. Additionally, the need for new electrical power or natural gas utilities should be analyzed, including analysis of times of peak energy demand.
- 11-5 *Land Use*
 The Draft Program EIR should analyze whether the implementation of specific control measures could physically divide established communities. Control measure ONRD-05 states that this control could be “implemented with the development of zero-emission fixed-guideway systems” and that to the extent feasible this would be extended beyond “near-dock application.” The construction and operation of such structures may impact established communities.
- 11-6 *Noise*
 The Port requests that the Draft Program EIR evaluate potential noise impacts related to the construction and implementation control measures in support of the AQMP. Section XII fails to account for noise impacts resulting from the construction and operation of control measure ONRD-05, which may include fixed-guideway systems near sensitive receptors.
- 11-7 *Transportation/Traffic*
 Section XVII of the Initial Study concludes that adoption of the proposed 2012 AQMP is not expected to generate any significant adverse project-specific impacts to transportation or traffic systems, and that no further evaluation will be conducted in the Draft Program EIR.

Dr. Steve Smith
July 27, 2012
Page 3

11-7
Cont.

However, impacts on major freeways or other transportation corridors as a result of construction and operation of potential zero emission control measures related to on-road heavy-duty vehicles, such as the use of overhead catenary power lines, which will potentially affect lane choice by trucks and traffic flow patterns on major traffic corridors, has not been fully analyzed. The Port requests that these potential impacts be analyzed in the Draft Program EIR.

11-8

Socioeconomics

While not required under CEQA, the Draft 2012 AQMP should include a thorough socioeconomic impact analysis for each proposed control measure, most notably the proposed backstop measure and the measures related to zero emission technologies. This could be accomplished with an expanded discussion under the cost effectiveness section of each control measure summary in the Draft AQMP.

11-9

The Port of Long Beach appreciates the opportunity to comment on the NOP/IS for the Draft 2012 AQMP and reviewing both the Draft Program EIR and the Draft 2012 AQMP. We look forward to working with the SCAQMD throughout the environmental review process.

Sincerely,

Richard D. Cameron
Director of Environmental Planning

DP:hat

Responses to Comment Letter #11
Port of Long Beach – Richard D. Cameron (7/27/12)

- 11-1 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Notice of Preparation of the Draft Program EIR for the 2012 AQMP. No further response is necessary.
- 11-2 Regarding the comment about the schedule for the Program EIR and the SCAQMD's ability to integrate new information and analysis into the Draft Program EIR in response to public comments, see Responses to Comments 6-11 and 7-3.
- 11-3 While the comment indicates that implementation of control devices such as hoods or bonnets on ship exhaust stacks would not constitute a significant aesthetic impact, the SCAQMD received a separate comment requesting that the Draft Program EIR analyze potentially adverse aesthetics impacts from these devices. In addition, while the comment indicates that the construction of gantry cranes as part of implementing control measure ADV-03 should not be considered aesthetically significant, the SCAQMD received a separate comment suggesting that container (gantry) cranes may obstruct views. For these reasons, the Draft Program EIR will consider both this comment and the other comments received when analyzing the potentially adverse aesthetics impacts in the Draft Program EIR. See also Response to Comment 7-4.
- 11-4 Regarding the comment about energy demand and electrification of vehicles, see Response to Comment 7-5.
- 11-5 In response to the suggestion in the comment that implementation of Control Measure ONRD-05 may physically divide or impact established communities, the Draft Program EIR will analyze these potential land use impacts.
- 11-6 In response to the suggestion in the comment that implementation of Control Measure ONRD-05 may create noise impacts near sensitive receptors, the Draft Program EIR will analyze these potential noise impacts.
- 11-7 Regarding the comment that the Draft Program EIR should contain transportation/traffic impacts analysis that addresses the potential for constructing overhead electrical catenary lines, see Response to Comment 7-7.
- 11-8 Regarding the suggestion that a socioeconomic impact analysis should be conducted for each proposed control measure in the 2012 AQMP, see Response to Comment 7-8.
- 11-9 This comment concludes the letter. No further response is necessary.

**APPENDIX C (OF THE FINAL PROGRAM EIR FOR THE 2012
AQMP)**

**COMMENTS AND RESPONSES TO COMMENTS ON THE
AUGUST 2, 2012 RECIRCULATED NOTICE OF PREPARATION
/ INITIAL STUDY**

There were no comment letters received for the NOP/IS that was recirculated on August 2, 2012.

**APPENDIX D (OF THE FINAL PROGRAM EIR FOR THE 2012
AQMP)**

**SCOPING MEETING COMMENTS AND RESPONSES TO
COMMENTS**

SCOPING MEETING COMMENTS AND RESPONSES TO COMMENTS

July 10, 2012 Scoping Meeting in Buena Park, Orange County

No CEQA comments were made.

July 11, 2012 Scoping Meeting in Jurupa Valley, Riverside County

Steve Smith: San Bernardino Area Governments

Comment: What areas of controversy were identified as part of the preparation the Program Environmental Impact Report (EIR) analysis for the 2012 AQMP?

Response: No areas of controversy with regard to the environmental analysis were identified by SCAQMD staff. Further, no areas of controversy regarding the environmental analysis were submitted in response to the 6/28/12 Notice of Preparation/Initial Study (NOP/IS) comment period or the 8/2/12 NOP/IS comment period.

July 10, 2012 Scoping Meeting in San Bernardino, San Bernardino County

No CEQA comments were made.

July 12, 2012 Scoping Meeting in San Pedro, Los Angeles County

No CEQA comments were made.

July 24, 2012 Scoping Meeting in Diamond Bar, Los Angeles County

Philip Lo: Los Angeles County Sanitation District

Comment: As part of the analysis of the coating control measures, will SCAQMD staff consider the state Paint Stewardship Program (PSP)?

Response: The analysis of potential environmental impacts from 2012 AQMP control measures, including the control measures affecting coatings, includes an evaluation of potentially significant adverse impacts that could be generated using a worst-case assumption. The analysis of the coating control measures identified potential human health and water quality issues, but these impacts were concluded to be less than significant. However, when promulgating the control measures as new rules or rule amendments, staff will consider the principles in the PSP to ensure that leftover paint is properly managed in a manner that is sustainably funded.

Comment: Have you considered potential environmental impacts from accidental releases of ammonia associated with the 2012 AQMP?

Response: The analysis of potential environmental impacts from 2012 AQMP control measures, includes an analysis of potential human health, water quality, and hazard impacts associated with an accidental release of ammonia from onsite storage and during transport. The analysis concluded that an accidental release of ammonia could generate potentially significant adverse hazard impacts. Mitigation measures were identified that could reduce these impacts to less than significant. As a result, human health, water quality, and hazards impacts from an accidental release of ammonia were concluded to be less than significant.

August 9, 2012 Scoping Meeting in Palm Desert, Riverside County

No CEQA comments were made.

August 23, 2012 Scoping Meeting in Diamond Bar, Los Angeles County

Lee Wallace: Southern California Gas Company

Comment: The scope of the project alternatives appears somewhat narrow. Can you explain them in more detail?

Response: The project alternatives were developed by modifying the pollutant reduction strategies and include: a PM_{2.5} control strategy that includes localized episodic PM_{2.5} control measures that would apply only to the Mira Loma area; a NO_x heavy control strategy that would not only achieve PM_{2.5} emission reductions, but additional NO_x and VOC emission reductions (from mobile sources) that would also help make expeditious progress in attaining the federal one-hour and eight-hour ozone standards; and, at the request of the public, a PM_{2.5} only alternative, which would also continue implementing the ozone portion of the 2007 AQMP. Alternatives were developed in a way that clearly shows the differences in environmental impacts so the benefits and impacts are clear to the public and the SCAQMD's decisionmakers.

**APPENDIX E (OF THE FINAL PROGRAM EIR FOR THE
2012 AQMP)**

2012 AQMP TCM PROJECTS (FROM 2012 RTP/SCS)

APPENDIX F

EXAMPLES OF MEASURES THAT COULD REDUCE IMPACTS FROM PLANNING, DEVELOPMENT AND TRANSPORTATION PROJECTS

EXAMPLES OF MEASURES THAT COULD REDUCE IMPACTS FROM PLANNING, DEVELOPMENT AND TRANSPORTATION PROJECTS

The following list of example measures is intended to function as a resource for lead agencies to consider in identifying mitigation measures to reduce impacts anticipated to result from future projects, as deemed applicable and feasible by such agencies. Some example measures are oriented to planning projects, while some measures are oriented to development and/or transportation projects. Some example measures are oriented to all types of projects. The list is non-exclusive and will not be used by SCAG in any way in reviewing regionally significant projects or project EIRs as part of SCAG’s intergovernmental review (IGR) process. Nor are the example measures intended to serve as any kind of checklist to be used on a project-specific basis. Since every project and project setting is different, project specific analysis is needed to identify applicable and feasible mitigation. The following measures may be too generic to be applied on a project-by-project basis and therefore they are presented as examples of measures rather than templates to be followed.

Some of the example mitigation measures include legal requirements that may overlap with federal, state, and/or local regulation. Such legal requirements that incorporate or reference existing regulations are mandatory and any mitigation imposed as a result of a project-specific CEQA process cannot supersede these existing regulations. Nevertheless, SCAG has included these regulations for informational purposes only and to help the reader understand the existing regulatory framework that would assist in mitigating potential environmental impacts.

In addition, the inclusion of these measures that may overlap with existing regulation is not intended to supplant current law. While potential impacts are normally assessed assuming implementation of applicable legal requirements, here, many of the legal requirements are flexible and may require further interpretation or consultation with resource agencies. As such, the resulting reduction in impacts may be difficult to quantify. Thus, in the interest of providing information to the public, SCAG has included these measures containing legal requirements among the example measures.

As part of the CEQA process for each planning, development or transportation project, the Lead Agency is required to identify significant and potentially significant impacts and then mitigate them to the extent feasible. All mitigation measures below are phrased as “may” to allow for tailoring to project and agency-specific conditions as may be applicable and feasible. Use of the word “may” in measures that include legal requirements, or requirements that are otherwise committed, should not be construed to mean that compliance with legal requirements and existing commitments is optional. Furthermore, the text boxes below set forth additional details for the example measures which may apply should agencies choose to implement those measures.

AESTHETICS

AV1: Prior to the issuance of permits, project sponsors may construct noise barriers of materials whose color and texture complements the

surrounding landscape and development. Noise barriers may be graffiti resistant and landscaped with plants that screen the barrier, preferably with either native vegetation or landscaping that complements the dominant landscaping of surrounding areas. Natural landscaping may be used to minimize contrasts between the project and surrounding areas. Wherever possible, interchanges and transit lines at the grade of the surrounding land may limit view blockage.

- AV2:** Project sponsors may use natural landscaping to minimize contrasts between the project and surrounding areas. Wherever possible, structures may be designed to limit view blockage. Edges of major cut-and-fill slopes may be contoured to provide a more natural looking finished profile. Project sponsors may replace and renew landscaping along corridors with road widenings, interchange projects, and related improvements. New corridor landscaping may be designed to respect existing natural and man-made features and to complement the dominant landscaping of surrounding areas.
- AV3:** Prior to project approval, project sponsors may implement design guidelines, local policies, and programs aimed at protecting views of scenic corridors and avoiding visual intrusions. Projects may be designed to minimize contrasts in scale and massing between the project and surrounding natural forms and developments. Avoid, if possible, large cuts and fills when the visual environment (natural or urban) would be substantially disrupted. Site or design of projects may minimize their intrusion into important viewsheds and use contour grading to better match surrounding terrain.
- AV4:** Project sponsors may construct sound walls of materials whose color and texture complements the surrounding landscape and development and use color, texture, and alternating facades to “break up” large facades and provide visual interest. Where there is room, project sponsors may landscape the sound walls with plants that screen the sound wall, preferably with either native vegetation or landscaping that complements the dominant landscaping of surrounding areas.
- AV5:** Project sponsors may avoid construction of transportation facilities in state and locally designated scenic highways and/or vista points. When avoidance is not possible, project sponsors may minimize visual quality intrusions to the maximum extent feasible.
- AV6:** For projects in designated or eligible Scenic Highway corridors, prior to project approval, project sponsors may complete design studies and develop site-specific mitigation measures to minimize impacts on the quality of the views or visual experience that originally qualified the highway for scenic designation.

AV7: If projects are constructed in state- and locally-designated scenic highways and/or vista points, design, construction, and operation of the transportation facility may be consistent with applicable guidelines and regulations for the preservation of scenic resources along the designated scenic highway.

AV8: Project sponsors may design projects to minimize contrasts in scale and massing between the project and surrounding natural forms and development. Project sponsors may design projects to minimize their intrusion into important viewsheds and use contour grading to better match surrounding terrain. To the maximum extent feasible, landscaping along highway corridors may be designed to add significant natural elements and visual interest to soften the hard-edged, linear travel experience that would otherwise occur.

AV9: Project sponsors may develop design guidelines projects that make elements of proposed buildings/facilities visually compatible with surrounding areas. Visual design guidelines may, at a minimum, include setback buffers, landscaping, color, texture, signage, and lighting criteria. The following methods may be employed whenever possible:

- Transportation systems may be developed to be compatible with the surrounding environment (i.e., colors and materials of construction material).
- Vegetation used as screening and landscaping may blend in and complement the natural landscape.
- Trees bordering highways may remain or be replaced so that clear-cutting is not evident.
- Grading may blend with the adjacent landforms and topography.

- AV10:** In visually sensitive areas and prior to project approval, local land use agencies may apply development standards and guidelines to maintain compatibility with surrounding natural areas, including site coverage, building height and massing, building materials and color, landscaping, site grading, etc.
- AV11:** Project sponsors may ensure that sites may be kept in a blight/nuisance-free condition. Any existing blight or nuisance may be abated within 60-90 days of approval, unless an earlier date is specified elsewhere.
- AV12:** Project sponsors may ensure that proposed lighting fixtures are adequately shielded to a point below the light bulb and reflector and that prevent unnecessary glare onto adjacent properties. Plans may be submitted to the Lead Agency (or other government agency as appropriate) for review and approval. All lighting may be architecturally integrated into the site.

AIR QUALITY

- AQ1:** Transportation Control Measures (TCMs) may be implemented by local agencies and project sponsors as appropriate. TCMs included in the Plan are identified in the Transportation Conformity Appendix to the 2012-2035 RTP/SCS (starting on page 26). CAA Section 108(f)(1)(A) lists sixteen measures as illustrative of TCMs.
- AQ2:** Local air districts, local jurisdictions and project sponsors may implement measures adopted by ARB designed to attain federal air quality standards for PM_{2.5} and 8-hour ozone. ARB's strategy includes the following elements:
- Set technology forcing new engine standards;
 - Reduce emissions from the in-use fleet;
 - Require clean fuels, and reduce petroleum dependency;
 - Work with USEPA to reduce emissions from federal and state sources; and
 - Pursue long-term advanced technology measures.
 - Proposed new transportation-related SIP measures include:
 - On-road and off-road Sources
 - Improvements and Enhancements to California's Smog Check Program
 - Expanded Passenger Vehicle Retirement

- Off-Road Recreational Vehicle Expanded Emission Standards

AQ3: Project sponsors may ensure that water or “toxic free” dust suppressants are applied to exposed earth surfaces to control emissions as necessary to control dust and comply with applicable regulations.

AQ4: Project sponsors may ensure that all excavating and grading activities cease during second stage smog alerts and periods of high winds.

AQ5: Project sponsors may ensure that all trucks hauling dirt, sand, soil, or other loose materials off-site be covered or wetted or maintain at least two feet of freeboard (i.e., minimum vertical distance between the top of the load and the top of the trailer).

AQ6: Project sponsors may ensure that all construction roads that have high traffic volumes, be surfaced with base material or decomposed granite, or be paved or otherwise be stabilized.

AQ7: Project sponsors may ensure that public streets be cleaned, swept or scraped at frequent intervals or at least three times a week if visible soil material has been carried onto adjacent public roads.

AQ8: Project sponsors may ensure that construction equipment be visually inspected prior to leaving the site and loose dirt be washed off with wheel washers as necessary.

AQ9: Project sponsors may ensure that water, hydroseed, or non-toxic soil stabilizers are applied to inactive construction areas as needed to reduce off-site transport of fugitive dust.

AQ10: Project sponsors may ensure that traffic speeds on all unpaved surfaces may not exceed 25 mph.

AQ11: Project sponsors may ensure that all construction diesel engines with a rating of 50 horsepower or higher meet, at a minimum, the USEPA Tier 3 standards for non-road engines. From January 1, 2015 onward, project sponsors may ensure that all construction equipment meets or exceeds equivalent emissions performance to that of USEPA Tier 4 standards for

non-road engines. In the event that Tier 3 or 4 engines are not available for any off-road equipment larger than 100 hp, that equipment be equipped with a Tier 2 engine, or an engine that is equipped with retrofit controls to reduce exhaust emissions of nitrogen oxides and diesel particulate matter to no more than Tier 2 levels unless certified by engine manufacturers or the on-site air quality construction mitigation manager that the use of such devices is not practical for specific engine types. For purposes of this condition, the use of such devices is “not practical” for the following, as well as other, reasons.

1. There is no available retrofit control device that has been verified by either the ARB or USEPA to control the engine in question to Tier 2 equivalent emission levels and the highest level of available control using retrofit or Tier 1 engines is being used for the engine in question; or
2. The construction equipment is intended to be on site for five days or less.
3. Relief may be granted from this requirement if a good faith effort has been made to comply with this requirement and that compliance is not practical.

The use of a retrofit control device may be terminated immediately, provided that a replacement for the equipment item in question meeting the required controls occurs within ten days of termination of the use, if the equipment would be needed to continue working at this site for more than 15 days after the use of the retrofit control device is terminated, if one of the following conditions exists:

1. The use of the retrofit control device is excessively reducing the normal availability of the construction equipment due to increased down time for maintenance, and/or reduced power output due to an excessive increase in back pressure.
2. The retrofit control device is causing or is reasonably expected to cause engine damage.
3. The retrofit control device is causing or is reasonably expected to cause a substantial risk to workers or the public.
4. Any other seriously detrimental cause which has the approval of the project manager prior to implementation of the termination.

AQ12: Project sponsors may ensure that deliveries related to construction activities that affect traffic flow may be scheduled during off-peak hours (e.g., 10:00 a.m. and 3:00 p.m.) and coordinated to achieve consolidated truck trips, where feasible. When the movement of construction materials and/or equipment impacts traffic flow, temporary traffic control may be provided to improve traffic flow (e.g., flag person).

- AQ13:** Project sponsors may ensure that to the extent possible, that construction activities utilize electricity from power poles rather than temporary diesel power generators and/or gasoline power generators.
- AQ14:** Local jurisdictions or agencies may, as practical and feasible, revegetate exposed earth surfaces following construction. Application of xeriscape principles, including such techniques and materials as native or low water use plants and low precipitation sprinklers heads, bubblers, drip irrigation systems and timing devices, may also be considered.
- AQ15:** Local jurisdictions may set, and enforce, specific limits on idling time for commercial vehicles, including delivery and construction vehicles, which prohibit vehicle and engine idling in excess of five minutes, where conditions allow.
- AQ16:** Project sponsors may ensure that sandbags or other erosion control measures are installed to prevent silt runoff to public roadways as needed.
- AQ17:** Project sponsors may designate a person or persons to monitor the dust control program and to order increased watering, as necessary, to prevent transport of dust offsite. Their duties may include holidays and weekend periods when work may not be in progress. The name and telephone number of such persons may be provided to the local air district prior to the start of construction as well as posted on-site over the duration of construction.
- AQ18:** Project sponsors may ensure that appropriate wind-breaks are installed at the construction site to minimize windblown dust.
- AQ19:** In order to address the California Air Resources Board Air Quality and Land Use Handbook (June 2005) and achieve an acceptable interior air quality level for sensitive receptors, project sponsors may identify appropriate measures, to be incorporated into project building design for residential, school and other sensitive uses located within 500 feet of freeways, heavily travelled arterials, railways and other sources of Diesel Particulate Matter and other known carcinogens. The appropriate measures may include one or more of the following methods as may be appropriate:
1. The project sponsor may retain a qualified air quality consultant to prepare a health risk assessment (HRA) in accordance with the California Air Resources Board and the Office of Environmental Health and Hazard Assessment requirements to determine the exposure of project residents/occupants/users to stationary and mobile (e.g., cars and trucks) sources of air pollution prior to issuance of a demolition, grading, or building permit. The HRA may be submitted to the Lead Agency for review and approval. The sponsor may implement the approved HRA recommendations, if any. If the HRA concludes that the air quality risks

from nearby sources are at or below acceptable levels, then additional measures are not required.

2. The project sponsor may implement the following features that have been found to reduce the air quality risk to sensitive receptors and may be included in the project construction plans. These may be submitted to the appropriate agency for review and approval prior to the issuance of a demolition, grading, or building permit and ongoing.
 - a. Do not locate sensitive receptors near distribution center's entry and exit points.
 - b. Do not locate sensitive receptors in the same building as a perchloroethylene dry cleaning facility.
 - c. Maintain a 50-foot buffer from a typical gas dispensing facility (under 3.6 million gallons of gas per year).
 - d. Install, operate and maintain in good working order a central heating and ventilation (HV) system or other air take system in the building, or in each individual residential unit, that meets the efficiency standard of the MERV 13. The HV system may include the following features: Installation of a high efficiency filter and/or carbon filter-to-filter particulates and other chemical matter from entering the building. Either HEPA filters or ASHRAE 85% supply filters may be used.
 - e. Retain a qualified HV consultant or HERS rater during the design phase of the project to locate the HV system based on exposure modeling from the mobile and/or stationary pollutant sources.
 - f. Maintain positive pressure within the building.
 - g. Achieve a performance standard of at least one air exchange per hour of fresh outside filtered air.
 - h. Achieve a performance standard of at least 4 air exchanges per hour of recirculation
 - i. Achieve a performance standard of .25 air exchanges per hour of unfiltered infiltration if the building is not positively pressurized.

3. Project sponsor may maintain, repair and/or replace HV system or prepare an Operation and Maintenance Manual for the HV system and the filter. The manual may include the operating instructions and maintenance and replacement schedule. This manual may be included in the CC&R's for residential projects and distributed to the building maintenance staff. In addition, the sponsor may prepare a separate Homeowners Manual. The manual may contain the operating instructions and maintenance and replacement schedule for the HV system and the filters. It may also include a disclosure to the buyers of the air quality analysis findings.

AQ20: To the maximum extent practicable the Lead Agency may ensure that private (individual and common) exterior open space, including playgrounds, patios, and decks, may either be shielded from sources of air pollution by buildings or otherwise buffered to further reduce air pollution for project occupants.

AQ21: As applicable and feasible, local jurisdictions may investigate (using for example procedures and guidelines for PM hotspot analysis consistent with USEPA (2010) PM guidance) the relationship between 1) any increases in PM10 and PM2.5 within 500 feet of freeways in their jurisdiction, and 2) existing sensitive receptors in that area that do not have adequate air filtration to reduce such impacts to a less than significant level. To the extent that existing sensitive receptors are identified that do not have adequate air filtration, local jurisdictions may establish a program by which project sponsors can mitigate significant increases in PM10 and PM2.5 (e.g., by providing a retrofit program for older higher emitting vehicles, anti-idling requirements or policies, controlling fugitive dust, routing traffic away from populated zones, replacing older buses with cleaner buses, and paying in to a fund established to retrofit sensitive receptors with HEPA filters when sensitive receptors are located within 500 feet of freeways and high-traffic volume roadways that generate substantial diesel particulate emissions).

AQ22: As applicable and feasible, project sponsors may plant appropriate vegetation to reduce PM10/PM2.5 when constructing a sensitive receptor within 500 feet of freeways and high-traffic volume roadways generating substantial diesel particulate emissions.

AQ23: As applicable and feasible, for major transportation projects (especially those that generate substantial diesel particulate emissions) in the region, if health risks are shown to increase significantly at sensitive receptors within 500 feet of a transportation facility, project sponsors are required under CEQA to consider applicable mitigation. Examples include planting appropriate vegetation and retrofitting existing sensitive uses with air filtration to reduce potential health risk impacts to a less than significant level.

BIOLOGICAL RESOURCES AND OPEN SPACE

Ecosystems in the SCAG Region

- BIO/OS1:** Project sponsors may assess displacement of habitat due to removal of native vegetation during route planning/project location planning. Routes/project sites may be planned in coordination with state and local resources agencies and may consider inventories of natural resources, such as CDFG and CNDDDB. Routes may be planned in order to avoid and/or minimize removal of native vegetation, by comparing proposed infrastructure with state and local conservation plans and by creating maps of resource habitat overlaid with the transportation network. Projects located in or adjacent to habitat areas may incorporate buffers to minimize lighting, noise, and other project impacts that can severely disrupt wildlife. Vegetation buffers may be appropriate to the adjacent vegetation association and protect the genetic integrity of the adjacent habitat. If avoidance is not possible, agencies/project sponsors may consult with the appropriate resource agencies to develop mitigation activities.
- BIO/OS2:** When avoidance of native vegetation removal is not possible, project sponsors may replant disturbed areas with commensurate native vegetation of high habitat value adjacent to the project that will result in a net environmental benefit (i.e., as opposed to ornamental vegetation with relatively less habitat value). When possible, habitat rehabilitation may use recycled material from rehabilitated infrastructure.
- BIO/OS3:** Project sponsors may include on-site habitat enhancement as a first priority and offsite habitat enhancement or restoration to compensate for unavoidable habitat losses from each project site as appropriate and necessary.

Special Status Species and Natural Communities

- BIO/OS4:** Pre-construction special status species surveys may be conducted by a qualified biologist to verify presence or absence of species at risk. For rare plants, surveys may be conducted when: 1) natural vegetation occurs on the site; 2) it is unknown if rare, threatened, or endangered plants or habitats occur on the site; and 3) the project has the potential for direct or indirect effects on vegetation. Species surveys may occur during the portion of the species' life cycle where the species is most likely to be identified within the appropriate habitat. In all cases, impacts on special status species and/or their habitat may be avoided during construction to the maximum extent feasible.
- BIO/OS5:** For projects located in sensitive habitat areas, project sponsors may develop and implement a Worker Awareness Program (environmental

education) to inform project workers of their responsibilities in regards to avoiding and minimizing impacts on sensitive biological resources.

BIO/OS6: Project sponsors may appoint an Environmental Inspector to serve as a contact for issues that may arise concerning implementation of mitigation measures, and to document and report on adherence to these measures.

BIO/OS7: Project sponsors may schedule construction activities to avoid sensitive times for biological resources (e.g., steelhead spawning periods during the winter and spring) and to avoid the rainy season when erosion and sediment transport is increased.

BIO/OS8: Project sponsors may schedule projects to avoid construction during critical life stages or sensitive seasons (e.g., the nesting season; see Mitigation Measures **BIO/OS25**, and **BIO/OS15** through **BIO/OS35**).

BIO/OS9: Project sponsors may precede construction, as appropriate, by pre-construction monitoring to ensure no sensitive species' habitat would be unnecessarily destroyed (also see Mitigation Measures **BIO/OS4** through **BIO/OS13**). All discovered sensitive species habitat may be avoided where feasible, or disturbance may be minimized.

BIO/OS10: Project sponsors may fence and/or mark sensitive habitat to prevent unnecessary machinery or foot traffic during construction activities.

BIO/OS11: Project sponsors may ensure that sensitive habitats (native vegetative communities identified as rare and/or sensitive by the CDFG) and special-status plant species (including vernal pools) impacted by projects may be restored and augmented. Project sponsors may consult with CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. The Lead Agency may require other activity as described below.

- If impacts are temporary, mitigation may be at a 1:1 ratio (compensation acres to impacted acres). Permanent impacts may be compensated for by creating or restoring habitats at a 3:1 ratio as close as possible to the site of the impact. The CDFG may recommend mitigation ratios that vary on a project-by-project basis.

BIO/OS12: When work is conducted in or adjacent to identified sensitive habitat areas, and/or areas of intact native vegetation, construction protocols may require the salvage of perennial plants and the salvage and stockpile of topsoil (the surface material from 6 to 12 inches deep) and may be used in restoring native vegetation to all areas of temporary disturbance within the project area.

BIO/OS13: When removal and/or damage to sensitive species habitat are unavoidable during construction, project sponsors may ensure that any disturbed

natural areas are replanted with appropriate native vegetation following the completion of construction activities. In the case of permanent losses to sensitive species habitat, mitigation may follow the offsite habitat compensation guidance.

- BIO/OS14:** A qualified wetland scientist may review construction drawings as part of each project-specific environmental analysis to determine whether wetlands will be impacted, and if necessary, perform a formal wetland delineation. Appropriate state and federal permits may be obtained, and each project EIR may contain language clearly stating the provisions of such permits, including avoidance measures, restoration procedures, and in the case of permanent impacts compensatory creation or enhancement measures to ensure a no net loss of wetland extent or function and values.
- BIO/OS15:** Suitable habitat for listed vernal pool crustaceans may be avoided to the extent feasible. If infeasible, impacts may be mitigated in accordance with the Programmatic Biological Opinion (PBO) for vernal pool invertebrates, issued by the USFWS Sacramento Field Office in 1995. Surveys may be conducted, with USFWS approval, in accordance with the 1996 *Interim Survey Guidelines to Permittees for Recovery Permits under Section 10(a)(1)(A) of the Endangered Species Act for the Listed Vernal Pool Branchiopods*, to establish whether or not listed invertebrates are present.
- BIO/OS16:** Project sponsors may avoid removal of wetland or riparian vegetation. Specific vegetation that is not to be removed may be so marked during construction. Wetland and riparian vegetation removal may be minimized as much as possible.
- BIO/OS17:** Project sponsors may replace any disturbed wetland, riparian or aquatic habitat, either on-site or at a suitable off-site location at ratios to ensure no net loss. See Mitigation Measures **BIO/OS1** through **BIO/OS14**.
- BIO/OS18:** Project sponsors may ensure that when individual projects include unavoidable losses of riparian or aquatic habitat, adjacent or nearby riparian or aquatic habitat be enhanced (e.g., through removal of non-native invasive wetland species and replacement with more ecologically valuable native species).
- BIO/OS19:** For projects near water resources project sponsors may implement Best Management Practices (BMPs) at construction sites to minimize erosion and sediment transport from the area. BMPs include encouraging growth of vegetation in disturbed areas, using straw bales or other silt-catching devices, and using settling basins to minimize soil transport. (See also Water Resources Mitigation Measures.)
- BIO/OS20:** If specific project area trees are designated as “Landmark Trees” or “Heritage Trees”, then approval for removals may be obtained through the

appropriate entity, and appropriate mitigation measures may be developed at that time, to ensure that the trees are replaced. Mitigation trees may be locally-collected native species.

BIO/OS21: Project sponsors may prioritize retention of trees on-site consistent with local regulations. For example, the Lead Agency may require additional protection during the construction period for any trees that are to remain standing, including the actions described below.

1. Before the start of any clearing, excavation, construction or other work on the site, every protected tree deemed to be potentially endangered by said site work, may be securely fenced off. Such fences may remain in place for duration of all such work. All trees to be removed may be clearly marked. A scheme may be established for the removal and disposal of logs, brush, earth and other debris that will avoid injury to any protected tree.
2. Where proposed development or other site work could encroach upon the protected perimeter of any protected tree, special measures can habitat for listed vernal pool crustaceans may be avoided to the extent feasible. If infeasible, impacts may be mitigated in accordance with the Programmatic Biological Opinion (PBO) for vernal pool invertebrates, issued by the USFWS Sacramento Field Office in 1995. Surveys may be conducted, with USFWS approval, in accordance with the 1996 Interim and may be incorporated to allow the roots to breathe and obtain water and nutrients. Any excavation, cutting, filing, or compaction of the existing ground surface within the protected perimeter may be minimized. No change in existing ground level may occur from the base of any protected tree at any time. No burning or use of equipment with an open flame may occur near or within the protected perimeter of any protected tree.
3. No storage or dumping of oil, gas, chemicals, or other substances that may be harmful to trees may occur from the base of any protected trees, or any other location on the site from which such substances may enter the protected perimeter. No heavy construction equipment or construction materials may be operated or stored within a distance from the base of any protected trees. Wires, ropes, or other devices may not be attached to any protected tree, except as needed for support of the tree. No sign, other than a tag showing the botanical classification, may be attached to any protected tree.
4. Periodically during construction, the leaves of protected trees may be thoroughly sprayed with water to prevent buildup of dust and other pollution that would inhibit leaf transpiration.
5. If any damage to a protected tree occurs during or as a result of work on the site, the project sponsor may immediately notify the appropriate local agency of such damage. If, such tree cannot be preserved in a healthy

state, the local agency may require replacement of any tree removed with another tree or trees on the same site deemed adequate by the local agency to compensate for the loss of the tree that is removed.

6. All debris created as a result of any tree removal work may be removed by the project sponsor from the property within two weeks of debris creation, and such debris may be properly disposed of by the project sponsor in accordance with all applicable laws, ordinances, and regulations.

BIO/OS22: Project sponsors with projects within the range and within suitable habitat for species listed as threatened or endangered under California Endangered Species Act (such as the Mohave ground squirrel) or the Federal Endangered Species Act (such as the Arroyo toad) may conduct surveys, with CDFG and/or USFWS approval, in accordance with established and approved survey methods appropriate for the species of interest, such as the 1999 USFWS *Survey Protocol for the Arroyo Toad*, to establish whether or not the species is present. If species is determined present, project sponsors may consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. Project sponsors should obtain an Incidental Take Permit under Section 2081 of the Fish and Game Code before proceeding with authorization of any project subject to CESA. Additional authorization may be required by the USFWS for take of federal-listed species or their occupied habitat. The Lead Agency may require other activity as described below.

- A pre-construction survey may be conducted by a qualified biologist at each site to identify suitable habitat for the species of interest and to determine what avoidance measures, including relocation, fencing installation, and avoidance of breeding season may be required.
- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG).
- Project sponsors must obtain an Incidental Take Permit under Section 2081 of the Fish and Game Code before proceeding with authorization of any project subject to CESA. Additional authorization may be required by the USFWS for take of federal-listed species or their occupied habitat.

BIO/OS23: Project sponsors with projects within the range and within suitable habitat for the blunt-nosed leopard lizard may conduct surveys, with USFWS approval, in accordance with the 2004 CDFG *Approved Survey Methodology for the Blunt-Nosed Leopard Lizard*, to establish whether or not the species is present. If species is determined present project sponsors should consult with the USFWS and/or CDFG, as applicable, to

ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG). No direct taking of the blunt-nosed leopard lizard may occur as this is a CDFG fully protected species with no regulatory mechanism to authorize direct taking (killing) of individuals.

BIO/OS24: Project sponsors with projects within the range and within suitable habitat for the California red-legged frog may implement the measures detailed in the Programmatic Biological Opinion (PBO) for construction impacts to the red-legged frog that was issued by the USFWS (Federal Register 1999) to the USACE. The measures listed below are taken largely from the PBO and, if applied to the western pond turtle as well as the frog, would be adequate as standard mitigation for both species. A similar level of effort for survey protocol can also be applied to the Mountain yellow-legged frog, with adjustments to its climate, habitat, and breeding requirements.

- The name and credentials of a biologist qualified to act as a construction monitor may be submitted to USFWS for approval at least 15 days prior to commencement of work;
- The USFWS-approved biologist may survey the site two weeks prior to the onset of work activities and immediately prior to commencing work. If red-legged frog adults, tadpoles, or eggs are found, the approved biologist may contact USFWS to determine whether relocating any life stages is appropriate;
- The USFWS-approved biologist may ensure that the introduction or spread of invasive exotic plant species is avoided to the maximum extent possible, by removing weeds from areas of exposed bare soil within the construction zone where construction occurs in riparian vegetation.
- The number and size of access routes, staging areas, and total area of activity may be limited to the minimum necessary to achieve the project goal;
- If work sites require dewatering, the intakes may be screened with a maximum mesh sizes of 5 millimeters;
- The USFWS-approved biologist may permanently remove and destroy from within the project area any individuals of exotic species, such as bullfrogs, crayfish, and centrarchid fishes, to the maximum extent practicable.

BIO/OS25: Project sponsors with projects within the range and within suitable habitat for the Coachella Valley fringe-toed lizard may conduct surveys, with USFWS/CDFG approval, in accordance with the CDFG *Protocol for Determining Coachella Valley Fringe-Toed Lizard (CVFTL) Presence*, to establish whether or not the species is present. If species is determined present, project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG).

BIO/OS26: Project sponsors with projects within the range and within suitable habitat for the desert tortoise may conduct surveys, with USFWS approval, in accordance with the 1992 USFWS *Field Survey Protocol For Any Federal Action That may Occur Within The Range Of The Desert Tortoise*, to establish whether or not the species is present. If the species is determined present, project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- Upon approval by the USFWS, preconstruction surveys of project impact areas may be required to salvage and relocate individual desert tortoise out of harm's way. Following removal of individuals, construction areas may be fenced with temporary exclusionary silt fencing.
- Mitigation for occupied habitat impacted is likely to be compensatory acquisition of mitigation credits or off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG).

BIO/OS27: California species of special concern (CSC), such as the two-striped garter snake and several bat species are considered special-status species that meet the definition of rare, threatened or endangered species for the purposes of CEQA. Projects within the range and within suitable habitat for California species of special concern may conduct surveys in accordance with the best professional judgment of a qualified biologist. : Project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- Preconstruction surveys of project impact areas may be required to salvage and relocate individual two-striped garter snakes out of harm's

way. Following removal of individuals, construction areas may be fenced with temporary exclusionary silt fencing.

- Similarly appropriate survey, salvage, and mitigation measures may be taken with regard to other CSC classified species. If avoidance of impacts to species is not feasible, on site and/or off site protection of appropriate mitigation lands in perpetuity may be secured for these species.
- Mitigation for occupied habitat is likely to be compensatory acquisition of mitigation credits or off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG. The two-striped garter snake is not formally listed but considered a special-status species worthy of measures to avoid and minimize impacts to the extent feasible.

BIO/OS28: Project sponsors may ensure avoiding disrupting nesting Swainson's hawks, by conducting construction activities at known nesting locations between September and March, outside the nesting season (nesting typically occurs from March 1 through September 15). Alternatively, if construction activities take place during the nesting season, a qualified biologist may conduct a pre-construction survey. Pre-construction surveys may commence in January utilizing approved protocol methods in consultation with CDFG and before the start of construction for any given milepost. If pre-construction surveys locate a nest site within one-half mile of any project (assuming available authorized access) a Swainson's hawk Monitoring and Mitigation Plan may be prepared in consultation with CDFG. Plans may be prepared by a qualified biologist approved by the CDFG. Plans may include detailed measures to avoid and minimize impacts to Swainson's hawks in and near the construction areas. The Lead Agency may require other activity as described below.

1. If a nest site is found, design the project to allow sufficient foraging and fledging area to maintain the nest site.
2. During the nesting season, ensure no new disturbances, habitat conversions, or other project-related activities that may cause nest abandonment or forced fledging occur within one-half mile of an active nest between March 1 and September 15. Buffer zones may be adjusted in consultation with CDFG and the Lead Agency.
3. Do not remove Swainson's hawk nest trees unless avoidance measures are determined to be infeasible. Removal of such trees may occur only during the timeframe of October 1 and the last day in February.

BIO/OS29: Project sponsors may ensure that no more than two weeks before construction in any given milepost, a survey for burrows and burrowing owls may be conducted by a qualified biologist within 500 feet of the

project (assuming available authorized access). The Lead Agency may require subsequent mitigation to be performed in conformance with applicable guidelines as described below.

The survey may conform to the protocol described by the California Burrowing Owl Consortium's 1993 Burrowing Owl Protocol and Mitigation Guideline which includes up to four surveys on different dates if there are suitable burrows present as well as the CDFG's 1995 Staff Report on Burrowing Owl Mitigation. Both mitigation guidelines also recommend habitat land acquisition and protection in perpetuity for project-related loss of occupied wintering and breeding habitat for burrowing owls. If occupied burrowing owl dens are found within the survey area, a determination may be made by a qualified biologist in consultation with CDFG whether or not project work will impact the occupied burrows or disrupt reproductive behavior.

- If it is determined that construction will not impact occupied burrows or disrupt breeding behavior, construction may proceed without any restriction or mitigation measures.
- If it is determined that construction will impact occupied burrows during August through February, the subject owls may be passively relocated from the occupied burrow(s) using one-way doors. There may be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows may be in place at least one-week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated.
- If it is determined that construction will physically impact occupied burrows or disrupt reproductive behavior during the nesting season (March through July) then avoidance is the only mitigation available. Construction may be delayed within 300 feet of occupied burrows until it is determined that the subject owls are not nesting or until a qualified biologist determines that juvenile owls are self-sufficient or are no longer reliant on the natal burrow as their primary source of shelter and survival.
- Mitigation for occupied habitat is likely to be compensatory acquisition of mitigation credits or off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG.

BIO/OS30: Project sponsors may ensure that when working within 100 feet of salt or brackish marshland presence for the California black rail, California clapper rail, and Yuma clapper rail may be assumed for either species during the period February 1- August 31 and construction may be scheduled to begin no earlier than September 1 and end no later than January 31 to avoid potential impact on reproduction. The Department of

Fish and Game and United States Fish and Wildlife Service may be consulted when projects identify occupied habitat or habitat capable of supporting California clapper rail, light-footed clapper rail, and Yuma clapper rail.

BIO/OS31: Project sponsors with projects within the range and within suitable habitat for the coastal California gnatcatcher may conduct surveys, with USFWS approval, in accordance with the 1997 USFWS *Coastal California Gnatcatcher Presence/Absence Survey Guidelines*, to establish whether or not the species is present. If the species is determined to be present, project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- To avoid disrupting nesting coastal California gnatcatchers, construction activities at known nesting locations may occur between September and March outside the nesting season (nesting typically occurs from March 1 through September 1). Alternatively, if construction activities take place during the nesting season, a qualified biologist may conduct a pre-construction survey no more than two weeks before the start of construction for any given milepost and report whether or not there are nesting coastal California gnatcatchers within 500 feet of any project (assuming available authorized access). If there are nesting coastal California gnatcatchers present within the 500-foot buffer areas, construction may be delayed until the USFWS and/or CDFG has been consulted to determine suitable avoidance measures. A potential avoidance measure may include delaying all construction activity within 500 feet of an active coastal California gnatcatchers nest until the adults and/or young of the year are no longer reliant on the nest site for survival as determined by a qualified biologist.
- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG).

BIO/OS32: Project sponsors with projects within the range and within suitable habitat for the least Bell's vireo may conduct surveys, with USFWS approval, in accordance with the 2001 USFWS *Least Bell's Vireo Survey Guidelines*, to establish whether or not the species is present. If the species is determined to be present, project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- To avoid disrupting nesting least Bell's vireo, construction activities at known nesting locations may occur between September and March outside the nesting season (nesting typically occurs from March 1 through September 1). Alternatively, if construction activities take place during the nesting season, a qualified biologist may conduct a pre-construction survey no more than two weeks before the start of construction for any given milepost and report whether or not there are nesting least Bell's vireo within 500 feet of any project (assuming available authorized access). If there are nesting least Bell's vireo present within the 500-foot buffer areas, construction may be delayed until the CDFG has been consulted to determine suitable avoidance measures. A potential avoidance measure may include delaying all construction activity within 500 feet of an active least Bell's vireo nest until the adults and/or young of the year are no longer reliant on the nest site for survival as determined by a qualified biologist.
- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted or other similar ratio with the approval of the USFWS and/or CDFG).

BIO/OS33: Project sponsors with projects within the range and within suitable habitat for the southwestern willow flycatcher may conduct surveys, with USFWS approval, in accordance with the 2000 USFWS *Southwestern Willow Flycatcher Protocol Survey Guidelines (Revision 2000)*, to establish whether or not the species is present. Project sponsors should consult with the USFWS and/or CDFG, as applicable, to ensure that significant impacts are avoided, mitigated, and/or minimized to the extent feasible. As part of the consultation, the Lead Agency may require other activity as described below.

- To avoid disrupting nesting southwestern willow flycatcher, construction activities at known nesting locations may occur between September and March outside the nesting season (nesting typically occurs from March 1 through September 15). Alternatively, if construction activities take place during the nesting season, a qualified biologist may conduct a pre-construction survey no more than two weeks before the start of construction for any given milepost and report whether or not there are nesting southwestern willow flycatcher within 500 feet of any project (assuming available authorized access). If there are nesting southwestern willow flycatchers present within the 500-foot buffer areas, construction may be delayed until the CDFG has been consulted to determine suitable avoidance measures. A potential avoidance measure may include delaying all construction activity within 500 feet of an active southwestern willow flycatcher nest until the adults and/or young of the year are no longer reliant on the nest site for survival as determined by a qualified biologist.

- Mitigation for occupied habitat impacted is likely to be compensatory off-site acquisition or protection of similar habitats at a ratio of 3:1 (compensation acres to that impacted) or other similar ratio with the approval of the USFWS and/or CDFG).

BIO/OS34: Project sponsors may ensure that suitable nesting sites for migratory nongame native bird species protected under the Federal Migratory Bird Treaty Act and/or trees with unoccupied raptor nests (large stick nests or cavities) may only be removed prior to February 1, or following the nesting season.

A survey to identify active raptor and other migratory nongame bird nests may be conducted by a qualified biologist at least two weeks before the start of construction at project sites from February 1st through August 31st. Any active non-raptor nests identified within the project area or within 300 feet of the project area may be marked with a 300-foot buffer, and the buffer area may need to be avoided by construction activities until a qualified biologist determines that the chicks have fledged. Active raptor nests within the project area or within 500 feet of the project area may be marked with a 500-foot buffer and the buffer avoided until a qualified biologist determines that the chicks have fledged. If the 300-foot buffer for non-raptor nests or 500-foot buffer for raptor nests cannot be avoided during construction of the project, the project sponsor may retain a qualified biologist to monitor the nests on a daily basis during construction to ensure that the nests do not fail as the result of noise generated by the construction. The biological monitor may be authorized to halt construction if the construction activities cause negative effects, such as the adults abandoning the nest or chicks falling from the nest.

- Beginning thirty days prior to the disturbance of suitable nesting habitat, the project sponsor may arrange for weekly bird surveys conducted by a qualified biologist with experience in conducting breeding bird surveys to detect protected native birds occurring in the habitat that is to be removed and any other such habitat within 300 feet of the construction work area (within 500 feet for raptors) as access to adjacent areas allows. The last survey may be conducted no more than 3 days prior to the initiation of clearance/construction work.
- If an active raptor nest is found within 500 feet of the project or nesting habitat for a protected native bird is found within 300 feet of the project a determination may be made by a qualified biologist in consultation with CDFG whether or not project construction work will impact the active nest or disrupt reproductive behavior.
- If it is determined that construction will not impact an active nest or disrupt breeding behavior, construction will proceed without any restriction or mitigation measure. If it is determined that construction will impact an active raptor nest or disrupt reproductive behavior then avoidance is the only mitigation available. Construction may be

delayed within 300 feet of such a nest (within 500 feet for raptor nests), until August 31 or as determined by CDFG, until the adults and/or young of the year are no longer reliant on the nest site for survival and when there is no evidence of a second attempt at nesting as determined by a qualified biologist. Limits of construction to avoid a nest may be established in the field with flagging and stakes or construction fencing marking the protected area 300 feet (or 500 feet) from the nest. Construction personnel may be instructed on the sensitivity of the area.

- Documentation to record compliance with applicable State and Federal laws pertaining to the protection of native birds may be recorded.

Natural Lands

BIO/OS35: Project sponsors may conduct site-specific analyses of opportunities to preserve or improve habitat linkages with areas on- and off-site before project construction begins. Habitat linkages/wildlife movement corridors may be analyzed on a broader and cumulative impact analysis scale to avoid adverse impacts from linear projects that have potential for impacts on a broader scale or critical narrow choke points that could reduce function of recognized movement corridors on a larger scale. Before construction, a qualified biologist may review construction drawings and habitat connectivity mapping provided by the CDFG or CNDDDB may be used to determine the risk of habitat fragmentation. Mitigation banking to preserve habitat linkages and corridors (opportunities to purchase, maintain, and/or restore off-site habitat) is one opportunity that project sponsor and local jurisdictions may pursue.

BIO/OS36: Project sponsors may evaluate the potential for overpasses, underpasses, and culverts in cases where a roadway or other transportation project may interrupt the flow of species through their habitat. Wildlife crossings/access may be provided in accordance with proven standards, such as FHWA's Critter Crossings or Ventura County Mitigation Guidelines and the Wildlife Crossings Assessment & Mitigation Manual (Meese, et al., 2007.), and in consultation with wildlife corridor authorities with sufficient knowledge of both regional and local wildlife corridors, and at locations useful and appropriate for the species of concern.

BIO/OS37: Project sponsors may include analysis of wildlife corridors during project planning, in order to minimize or avoid impacts to these corridors. In addition, project sponsors may include analysis to identify where additional linkages and/or culverts/under crossings would be needed that do not exist.

BIO/OS38: Project sponsors may use wildlife fencing where appropriate to minimize the probability of wildlife injury due to direct interaction between wildlife and roads. Wildlife fencing used may be based on proven designs for impacted species and developed in conjunction with wildlife corridor

authorities with sufficient knowledge of both regional and local wildlife corridors. Project sponsors may take advantage of natural environmental buffers (i.e., streams or fields) to protect wildlife habitat from nearby transportation infrastructure. Inclusion of this mitigation measure may be considered on a case-by-case basis, as use of wildlife fencing could further increase the effects of habitat fragmentation and isolation for many species. Also see **BIO/OS1** through **BIO/OS21**.

BIO/OS39: Project sponsors may avoid siting new 2012-2035 RTP/SCS transportation facilities within areas not presently exposed to impacts from transportation facilities. If avoidance is infeasible, the project may minimize vehicular accessibility to areas beyond the actual transportation surface. This can be accomplished through fencing and signage. Additionally, the area of native habitats to be lost to proximity to a transportation facility may be assessed and habitat at a quality of equal or superior value may be secured and protected in perpetuity.

Threats to Biological Resources in the SCAG Region

BIO/OS40: Project sponsors may establish litter control programs in appropriate areas, such as receptacles at road turnouts, rest stops, and viewpoints. All refuse containers may be provided with mechanisms which prevent scavenging animals from gaining access to the contents of such containers.

BIO/OS41: Project sponsors may use road noise minimization methods, such as brush and tree planting, at heavy noise-producing transportation areas that may affect wildlife. Native vegetation may be used.

BIO/OS42: Project sponsors may avoid and/or minimize construction activities that have the potential to expose species to noise, smoke, or other disturbances. Pre-construction surveys may be conducted as appropriate to determine the presence of any species that would need to be protected from such an impact.

Protection of Biological Resources in the SCAG Region

BIO/OS43: Any Conservation opportunity areas identified by SCAG or others may be used by local jurisdictions and project sponsors as priority areas for mitigating impacts to open space resources. SCAG's forthcoming regional conservation planning policy will include additional information on conservation opportunity areas.

BIO/OS44: Project sponsors may ensure that transportation systems proposed in the 2012-2035 RTP/SCS avoid or mitigate significant impacts to natural lands, community open space and important farmland, including cumulative impacts and open space impacts from the growth associated with transportation projects and improvements.

- BIO/OS45:** Individual projects may either avoid significant impacts to regionally significant open space resources or mitigate the significant impacts. All projects submitted for IGR review may demonstrate consideration of alternatives that would avoid or reduce impacts to open space.
- BIO/OS46:** Project sponsors may include into project design, to the maximum extent practicable, mitigation measures and recommended best practices aimed at minimizing or avoiding impacts to natural lands, including, but not limited to FHWA's Critter Crossings, Ventura County Mitigation Guidelines, CDFG's Wildlife Action Plan and any applicable conservation plans.
- BIO/OS47:** For projects adjacent to natural watercourses, project sponsors may submit a vegetation management plan for review and approval by the Lead Agency that includes, as deemed appropriate, the following measures:
- Identify and do not disturb a buffer distance (to be determined as appropriate on a case-by-case basis) from the top of the natural watercourse. If the top of bank cannot be identified, leave a 50-foot buffer from the centerline of the watercourse or as wide a buffer as possible between the watercourse centerline and the proposed site development.
 - Identify and leave "islands" of vegetation in order to prevent erosion and landslides and protect nesting habitat.
 - Leave at least 6 inches of vegetation on the site.
 - Trim tree branches from the ground up (limbing up) and leave tree canopy intact.
 - Leave stumps and roots from cut down trees to prevent erosion.
 - Plant fire-appropriate, drought-tolerant, preferably native vegetation.
 - Err on the side of caution; if a plant, tree or area is sensitive, obtain a second opinion before cutting.
 - Provide erosion and sediment control protection if cutting vegetation on a steep slope.
 - Leave tall shrubbery at least 3-feet high.
 - Fence off sensitive plant habitats and creek areas to protect from animal grazing as appropriate and necessary.
 - Do not clear-cut vegetation. This can lead to erosion and severe water quality problems and destroy important habitat.
 - Do not remove vegetation within 20-feet of the top of bank. If the top of bank cannot be identified, do not cut within 50-feet of the centerline of the natural watercourse or as wide a buffer as possible between the natural watercourse centerline and the proposed site development.

- Do not trim/prune branches that are larger than 4 inches in diameter.
- Do not remove tree canopy.
- Do not dump cut vegetation in a creek.
- Do not cut tall shrubbery to less than 3-feet high.
- Do not cut off short vegetation (grasses, ground-cover) to less than 6-inches high.

BIO/OS48: As appropriate conduct a biological assessment for any site/corridor where there is the potential for impacts to significant biological resources including threatened or endangered species, sensitive habitats/species and/or protected trees.

BIO/OS49: Shade Tree Planting: Local jurisdictions or agencies may promote the planting of shade trees and establish shade tree guidelines and specifications, including:

- Recommendations for tree planting based on the land use (residential, commercial, parking lots, etc.);
- Recommendations for tree types based on species size, branching patterns, whether deciduous or evergreen, whether roots are invasive, etc.;
- Recommendations for placement, including distance from structures, density of planting, and orientation relative to structures and the sun.

BIO/OS50: Urban Forestry Management: Local jurisdictions or agencies may develop an Urban Forestry Program to consolidate policies and ordinances regarding tree planting, maintenance, and removal, including:

- Establish a tree-planting target and schedule to support the goals of the California Climate Action Team to plant 5 million trees in urban areas by 2020;
- Establish guidelines for tree planting, including criteria for selecting deciduous or evergreen trees low-VOC-producing trees, and emphasizing the use of drought-tolerant native trees and vegetation.

BIO/OS51: Local jurisdictions or agencies may establish policies and programs to restore, protect, manage and preserve conservation areas, including forested areas, agricultural lands, wildlife habitat and corridors, wetlands, watersheds, and groundwater recharge areas, that remove and sequester carbon from the atmosphere.

BIO/OS52: Conservation Area Development: Local jurisdictions or agencies may consider establishing programs and funding mechanisms to create protected conservation areas. For example, local jurisdictions may:

- Impose mitigation fees for development on lands that would otherwise be conservation areas, and use the funds generated to protect other areas from development;
- Consider proposals for voters to approve a small tax increment (e.g., a quarter cent sales tax, perhaps for a finite time period that could be renewed) to fund the purchase of development rights in conservation areas, or purchase of the land outright.

BIO/OS53: Conservation Area Preservation: Local jurisdictions or agencies may establish policies to preserve existing conservation areas, and to discourage development in those areas.

BIO/OS54: Local jurisdictions or agencies may manage its stock of vegetation to reduce GHG emissions.

BIO/OS55: Local jurisdictions may conduct a comprehensive inventory and analysis of the urban forest, and coordinate tree maintenance responsibilities with all responsible departments, consistent with best management practices.

BIO/OS56: Local jurisdictions or agencies may evaluate existing landscaping and options to convert reflective and impervious surfaces to landscaping, and install or replace vegetation with drought-tolerant, low-maintenance native species or edible landscaping that can also provide shade and reduce heat-island effects.

CULTURAL RESOURCES

CUL1: As part of the appropriate project/environmental review of individual projects, project sponsors may identify potential impacts to historic resources. A record search at the appropriate Information Center may be conducted to determine whether the project area has been previously surveyed and whether historic resources were identified.

CUL2: If indicated as necessary by a records search, prior to construction activities, project sponsors may obtain a qualified architectural historian to conduct historic architectural surveys as recommended by the Information Center. In the event the records indicate that no previous survey has been conducted, the Information Center may make a recommendation on whether a survey is warranted based on the sensitivity of the project area for historical resources within 1,000 feet of the project.

CUL3: Project sponsors may comply with Section 106 of the National Historic Preservation Act (NHPA) including, but not limited to, projects for which federal funding or approval is required for the individual project. This law requires federal agencies to evaluate the impact of their actions on resources included in or eligible for listing in the National Register. Federal agencies must coordinate with the State Historic Preservation Officer in evaluating impacts and developing mitigation. These mitigation measures may include, but are not limited to the following:

- Where appropriate, project sponsors may employ design measures to avoid historical resources and undertake adaptive reuse where appropriate and feasible. If resources are to be preserved, as feasible, project sponsors may carry out the maintenance, repair, stabilization, rehabilitation, restoration, preservation, conservation or reconstruction in a manner consistent with the Secretary of the Interior’s Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings. If resources would be impacted, impacts may be minimized to the extent feasible.
- Where feasible, noise buffers/walls and/or visual buffers/landscaping may be constructed to preserve the contextual setting of significant built resources.

CUL4: Project sponsors may secure a qualified environmental agency and/or architectural historian, or other such qualified person to document any significant historical resource(s), by way of historic narrative, photographs, and architectural drawings, as mitigation for the effects of demolition of a resource. However, such documentation will not mitigate the effects to less than significant.

CUL5: As part of the appropriate project/environmental review of individual projects, project sponsors may consult with the Native American Heritage

Commission (NAHC) to determine whether known sacred sites are in the project area, and identify the Native American(s) to contact to obtain information about the project site. Federal, State, counties, and cities lead agencies may require that a check of the NAHC sacred lands files be undertaken by all projects and that the Native American tribes or individuals identified by the NAHC be contacted by the project proponent for further information and consultation on the project.

CUL6: Prior to construction activities, project sponsors may obtain a qualified archaeologist to conduct a record search at the appropriate Information Center of the California Archaeological Inventory to determine whether the project area has been previously surveyed and whether resources were identified. Federal, State, counties, and cities lead agencies may require a qualified archeologist conduct a record search at the appropriate Information Center on the project.

CUL7: Prior to construction activities, project sponsors may obtain a qualified archaeologist or architectural historian (depending on applicability) to conduct archaeological and/or historic architectural surveys as recommended by the Information Center. In the event the records indicate that no previous survey has been conducted, the Information Center may make a recommendation on whether a survey is warranted based on the sensitivity of the project area for archaeological resources. Federal, State, counties, and cities lead agencies may conduct a phase I archeological or historic architectural survey for all project that have not been previously surveyed or have not been surveyed in the past ten years.

CUL8: If the record search indicates that the project is located in an area rich with cultural materials, project sponsors may retain a qualified archaeologist to monitor any subsurface operations, including but not limited to grading, excavation, trenching, or removal of existing features of the subject property. Federal, State, counties, and cities lead agencies require that a Native American monitor be employed by the project proponent or tribe to monitor the subsurface operations or any earth movement in all projects. It is also strongly recommended that a pre-excavation agreement be implemented with culturally affiliated tribes.

CUL9: Construction activities and excavation may be conducted to avoid cultural resources (if identified). If avoidance is not feasible, further work may be needed to determine the importance of a resource. Project sponsors may obtain a qualified archaeologist familiar with the local archaeology, and/or as appropriate, an architectural historian who may make recommendations regarding the work necessary to determine importance. If the cultural resource is determined to be important under state or federal guidelines, impacts on the cultural resource may need to be mitigated. Avoidance is the preferred alternative. If avoidance is not feasible, Federal, State, counties, and cities lead agencies may require that the project sponsor

consult with culturally affiliated Native American Tribes in the determination of importance of the resource.

CUL10: Project sponsors may stop construction activities and excavation in the area where cultural resources are found until a qualified archaeologist can determine the importance of these resources. Federal, State, counties, and cities lead agencies may require that the project sponsor consult with culturally affiliated Native American Tribes in the determination of importance of the resource.

CUL11: As part of the appropriate project/environmental review of individual projects, project sponsors may obtain a qualified paleontologist to identify and evaluate paleontological resources where potential impacts are considered high; the paleontologist may also conduct a field survey in these areas.

CUL12: Project sponsors may ensure that construction activities avoid known paleontological resources, if feasible, especially if the resources in a particular lithic unit formation have been determined through detailed investigation to be unique.

CUL13: Project sponsors may ensure that when a construction activity could significantly disturb soils or geologic formations in areas identified as having a moderate to high potential to support paleontological resources, a qualified researcher must be stationed on-site to observe during excavation operations and recover scientifically valuable specimens. As part of this mitigation, the following actions may be taken:

- A certified paleontologist may be retained (or required to be retained) by the project sponsor prior to construction to establish procedures for surveillance and the preconstruction salvage of exposed resources if fossil-bearing sediments have the potential to be impacted.
- The paleontologist may provide preconstruction coordination with contractors, oversee original cutting in previously undisturbed areas of sensitive formations, halt or redirect construction activities as appropriate to allow recovery of newly discovered fossil remains, and oversee fossil salvage operations and reporting.
- This measure may be placed as a condition on all plans where excavation and earthmoving activity is proposed in a geologic unit having a moderate or high potential for containing fossils.
- Excavations of paleontological resources may be overseen by the qualified paleontologist and the paleontological resources given to a local agency, or other applicable institution, where they could be displayed or used for research.

- CUL14:** Where practicable, project sponsors may avoid routes and project designs that would permanently alter unique features with archaeological and/or paleontological significance.
- CUL15:** As part of project oversight of individual projects, project sponsors may, in the event of discovery or recognition of any human remains during construction or excavation activities associated with the project, in any location other than a dedicated cemetery, may cease further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent human remains until the coroner of the county in which the remains are discovered has been informed and has determined that no investigation of the cause of death is required.
- CUL16:** If any discovered remains are of Native American origin:
- The coroner may contact the Native American Heritage Commission in order to ascertain the proper descendants from the deceased individual. The coroner may make a recommendation to the landowner or the person responsible for the excavation work, for means of treating or disposing of, with appropriate dignity, the human remains and any associated grave goods. This may include obtaining a qualified archaeologist or team of archaeologists to properly excavate the human remains; or
 - If the Native American Heritage Commission is unable to identify a descendant, or the descendant failed to make a recommendation within 24 hours after being notified by the commission, the landowner or their authorized representative may obtain a Native American monitor, and an archaeologist, if recommended by the Native American monitor, and rebury the Native American human remains and any associated grave goods, with appropriate dignity, on the property and in a location that is not subject to further subsurface disturbance where the following conditions occur:
 - The Native American Heritage Commission is unable to identify a descendent;
 - The descendant identified fails to make a recommendation; or
 - The landowner or their authorized representative rejects the recommendation of the descendant, and the mediation by the Native American Heritage Commission fails to provide measures acceptable to the landowner.

GEOLOGY, SOILS AND MINERAL RESOURCES

GEO1:Project sponsors may ensure that projects located within or across Alquist-Priolo Zones comply with design requirements provided in Special Publication 117, published by the California Geological Survey, as well as relevant local, regional, State, and federal design criteria for construction in seismic areas.

- GEO2:** Project sponsors may ensure that projects are designed in accordance with county and city code requirements for seismic ground shaking. The design of projects may consider seismicity of the site, soil response at the site, and dynamic characteristics of the structure, in compliance with the appropriate California Building Code and State of California design standards for construction in or near fault zones, as well as all standard design, grading, and construction practices in order to avoid or reduce geologic hazards.
- GEO3:** Project sponsors may ensure that site-specific geotechnical investigations conducted by a qualified geotechnical expert may be required prior to preparation of project designs. These investigations would identify areas of potential failure and recommend remedial geotechnical measures to eliminate any problems.
- GEO4:** Project sponsors may ensure that site-specific geotechnical investigations conducted by a qualified geotechnical expert are conducted to ascertain soil types and local faulting prior to preparation of project designs. These investigations would identify areas of potential failure and recommend remedial geotechnical measures to eliminate any problems.
- GEO5:** Project sponsors may ensure that project designs provide adequate slope drainage and appropriate landscaping to minimize the occurrence of slope instability and erosion. Design features may include measures to reduce erosion caused by stormwater. Road cuts may be designed to maximize the potential for revegetation.
- GEO6:** Project sponsors may ensure that, prior to preparing project designs, new and abandoned wells are identified within construction areas to ensure the stability of nearby soils.
- GEO7:** Project sponsors may ensure that projects avoid geologic units or soils that are unstable, expansive soils and soils prone to lateral spreading, subsidence, liquefaction, or collapse wherever feasible.
- GEO8:** Project sponsors may ensure that projects avoid landslide areas and potentially unstable slopes wherever feasible.
- GEO9:** Project sponsors may ensure that site-specific geotechnical investigations conducted by a qualified geotechnical expert may be required prior to preparation of project designs to identify the potential for subsidence and expansive soils. These investigations would identify areas of potential failure and recommend remedial geotechnical measures to eliminate any problems. Recommended corrective measures, such as structural reinforcement and replacing soil with engineered fill, may be implemented in project designs.

GEO10: Local jurisdictions may review availability of aggregate and mineral resources in their jurisdiction and may develop a long-range plan to meet demand.

GREENHOUSE GAS EMISSIONS

GHG1: SCAG member cities and the county governments may adopt and implement Climate Actions Plans (CAPS, also known as Plans for the Reduction of Greenhouse Gas Emissions as described in CEQA Guidelines Section 15183.5 Tiering and Streamlining the Analysis of Greenhouse Gas Emissions)

Climate Action Plans generally follow the steps and contain components described below.

1. Quantify GHG emissions, both existing and projected over a specified time period, resulting from activities within their respective jurisdictions;
2. Establish a level, based on substantial evidence, below which the contribution to GHG emissions from activities covered by the plan would not be cumulatively considerable;
3. Identify and analyze the GHG emissions resulting for specific actions or categories of actions anticipated within their respective jurisdictions;
4. Specify measures or a group of measures, including performance standards, that substantial evidence demonstrates, if implemented on a project-by-project basis, would collectively achieve the specified emissions level;
5. Establish a mechanism to monitor the plan's progress toward achieving that level and to require amendment if the plan is not achieving specified levels; and
6. Be adopted in a public process following environmental review.

CAPs may, when appropriate, incorporate planning and land use measures from the California Attorney General's latest list of example policies to address climate change at both the plan and project level. Specifically, at the plan level, land use plans may, when appropriate, incorporate planning and land use measures from the California Attorney General's latest list of example policies to address climate change (http://ag.ca.gov/globalwarming/pdf/GP_policies.pdf), including, but not limited to policies from that web page such as:

- Smart growth, jobs/housing balance, transit-oriented development, and infill development through land use designations, incentives and fees, zoning, and public-private partnerships

- Create transit, bicycle, and pedestrian connections through planning, funding, development requirements, incentives and regional cooperation, and create disincentives for auto use
- Energy and water-efficient buildings and landscaping through ordinances, development fees, incentives, project timing, prioritization, and other implementing tools

In addition, member cities and the county governments may incorporate, as appropriate, policies to encourage implementation of the Attorney General’s list of project specific mitigation measures available at the following web site: http://ag.ca.gov/globalwarming/pdf/GW_mitigation_measures.pdf, including, but not limited to measures from the web page such as:

- Adopt a comprehensive parking policy that discourages private vehicle use and encourages the use of alternative transportation
- Build or fund a major transit stop within or near development
- Provide public transit incentives such as free or low-cost monthly transit passes to employees, or free ride areas to residents and customers
- Incorporate bicycle lanes, routes and facilities into street systems, new subdivisions, and large developments
- Require amenities for non-motorized transportation, such as secure and convenient bicycle parking.

They may also incorporate, when appropriate, planning and land use measures from additional resources listed by the California Attorney General at the following webpage:

<http://ag.ca.gov/globalwarming/ceqa/resources.php>

In addition, CAPs may also incorporate analysis of climate change adaptation, in recognition of the likely and potential effects of climate change in the future regardless of the level of mitigation and in conjunction with Executive Order S-13-08, which seeks to enhance the State’s management of climate impacts including sea level rise, increased temperatures, shifting precipitation, and extreme weather events by facilitating the development of State’s first climate adaptation strategy.

GHG2: Project sponsors may require Best Available Control Technology (BACT) during construction and operation of projects, including:

1. Solicit bids that include use of energy and fuel efficient fleets;
2. Solicit preference construction bids that use BACT, particularly those seeking to deploy zero- and/or near zero emission technologies;
3. Employ use of alternative fueled vehicles;

4. Use lighting systems that are energy efficient, such as LED technology;
5. Use CEQA Guidelines Appendix F, Energy Conservation, to create an energy conservation plan;
6. Streamline permitting process to infill, redevelopment, and energy-efficient projects;
7. Use an adopted emissions calculator to estimate construction-related emissions;
8. Use the minimum feasible amount of GHG-emitting construction materials that is feasible;
9. Use of cement blended with the maximum feasible amount of flash or other materials that reduce GHG emissions from cement production;
10. Use of lighter-colored pavement where feasible;
11. Recycle construction debris to maximum extent feasible; and
12. Plant shade trees in or near construction projects where feasible.

GHG3: Local jurisdictions may establish a coordinated, creative public outreach activities, including publicizing the importance of reducing GHG emissions and steps community members may take to reduce their individual impacts.

GHG4: Pedestrian and Bicycle Promotion: Local jurisdictions may work with local community groups and business associations to organize and publicize walking tours and bicycle events, and to encourage pedestrian and bicycle modes of transportation.

GHG5: Waste Reduction: Local jurisdictions may organize workshops on waste reduction activities for the home or business, such as backyard composting, or office paper recycling, and may schedule recycling drop-off events and neighborhood chipping/mulching days.

GHG6: Water Conservation: Local jurisdictions may support and/or sponsor workshops on water conservation activities, such as selecting and planting drought tolerant, native plants in landscaping, and installing advanced irrigation systems.

GHG7: Energy Efficiency: Local jurisdictions may organize workshops on steps to increase energy efficiency in the home or business, such as weatherizing the home or building envelope, installing smart lighting systems, and how to conduct a self-audit for energy use and efficiency.

GHG8: Schools Programs: Local jurisdictions may develop and implement a program to present information to school children about climate change and ways to reduce GHG emissions, and may support school-based

programs for GHG reduction, such as school based trip reduction and the importance of recycling.

HAZARDOUS MATERIALS

HM1: Project sponsors may comply with all applicable laws, regulations, and health and safety standards set forth by federal, state, and local authorities that regulate the proper handling of such materials and their containers to the routine transport, use, and disposal of hazardous materials does not create a significant hazard to the public or the environment.

HM2: Project sponsors may consider any known or planned school locations when determining the alignment of new transportation projects and modifications to existing transportation facilities as well as any industrial or other use that could pose a hazard to students.

HM3: Project sponsors may ensure that Best Management Practices (BMPs) are implemented as part of construction to minimize the potential negative effects to groundwater and soils. These may include the following:

- Follow manufacturer’s recommendations on use, storage, and disposal of chemical products used in construction;
- Avoid overtopping construction equipment fuel gas tanks;
- During routine maintenance of construction equipment, properly contain and remove grease and oils;
- Properly dispose of discarded containers of fuels and other chemicals;
- Ensure that construction would not have a significant impact on the environment or pose a substantial health risk to construction workers and the occupants of the proposed development. Soil sampling and chemical analyses of samples may be performed to determine the extent of potential contamination beneath all UST’s, elevator shafts, clarifiers, and subsurface hydraulic lifts when on-site demolition, or construction activities would potentially affect a particular development or building; and
- If soil, groundwater or other environmental medium with suspected contamination is encountered unexpectedly during construction activities (e.g., identified by odor or visual staining, or if any underground storage tanks, abandoned drums or other hazardous materials or wastes are encountered), the project sponsor may cease work in the vicinity of the suspect material, the area may be secured as necessary, and the project sponsor may take all appropriate measures to protect human health and the environment. Appropriate measures may include notification of regulatory agency(ies) and implementation of actions as necessary, to identify the nature and extent of contamination. Work may not resume in the area(s) affected until the

measures have been implemented under the oversight of the City or regulatory agency, as appropriate.

HM4: As appropriate, project sponsors may submit documentation to determine whether radon or vapor intrusion from the groundwater and soil is located on-site as part of the Phase I documents. The Phase I analysis may be submitted to the appropriate government agency for review and approval, along with a Phase II report if warranted by the Phase I report for the project site. The reports may make recommendations for remedial action, if appropriate, and may be signed by a Registered Environmental Assessor, Professional Geologist, or Professional Engineer. The project sponsor may implement the approved recommendations.

HM5: As appropriate each project sponsor may submit a Hazardous Materials Business/Operations Plan for review and approval by the appropriate local agency. Once approved, this plan will then be kept on file with the Lead Agency (or other appropriate government agency) and may be updated as applicable. The purpose of the Hazardous Materials Business/Operations Plan is to ensure that employees are adequately trained to handle the materials and provides information to the local fire protection agency may emergency response be required. The Hazardous Materials Business/Operations Plan may include the following:

- The types of hazardous materials or chemicals stored and/or used on-site, such as petroleum fuel products, lubricants, solvents, and cleaning fluids
- The location of such hazardous materials
- An emergency response plan including employee training information
- A plan that describes the manner in which these materials are handled, transported and disposed

HM6: Project sponsors may implement all of the following Best Management Practices (BMPs) regarding potential soil and groundwater hazards.

- Soil generated by construction activities may be stockpiled on-site in a secure and safe manner. All contaminated soils determined to be hazardous or non-hazardous waste must be adequately profiled (sampled) prior to acceptable reuse or disposal at an appropriate off-site facility. Specific sampling and handling and transport procedures for reuse or disposal may be in accordance with applicable local, State and federal agencies laws.
- Groundwater pumped from the subsurface may be contained onsite in a secure and safe manner, prior to treatment and disposal, to ensure environmental and health issues are resolved pursuant to applicable laws and policies. Engineering controls may be utilized, which

include impermeable barriers to prohibit groundwater and vapor intrusion into the building.

- Prior to issuance of any demolition, grading, or building permit, the sponsor may submit for review and approval by the Lead Agency (or other appropriate government agency), written verification that the appropriate federal, State and/or local oversight authorities, including, but not limited to the Regional Water Quality Control Board (RWQCB), have granted all required clearances and confirmed that the all applicable standards, regulations and conditions for all previous contamination at the site.

HM7: Project sponsors may consult all known databases of contaminated sites and undertake a standard Phase I Environmental Site Assessment in the process of planning, environmental clearance, and construction for projects included in the 2012-2035 RTP/SCS, including development projects.

HM8: Where contaminated sites are identified, project sponsors may develop appropriate mitigation measures to assure that worker and public exposure is minimized to an acceptable level and to prevent any further environmental contamination as a result of construction.

HM9: If asbestos-containing materials (ACM) are found to be present in building materials to be removed project sponsors may submit specifications signed by a certified asbestos consultant for the removal, encapsulation, or enclosure of the identified ACM in accordance with all applicable laws and regulations, including but not necessarily limited to: California Code of Regulations, Title 8; Business and Professions Code; Division 3; California Health & Safety Code Section 25915-25919.7; and other local regulations as applicable.

HM10: Prior to issuance of demolition, grading, or building permits, project sponsors may submit to the appropriate agency responsible for hazardous materials/wastes oversight, a Phase II Environmental Site Assessment report if warranted by a Phase I report for the project site. The reports may make recommendations for remedial action, if appropriate, and may be signed by a Registered Environmental Assessor, Professional Geologist, or Professional Engineer.

HM11: Project sponsors may submit a comprehensive assessment report to the appropriate agency, signed by a qualified environmental professional, documenting the presence or lack thereof of ACM, lead-based paint, and any other building materials or stored materials classified as hazardous waste by State or federal law.

HM12: If a Phase II Environmental Site Assessment report recommends remedial action, the project sponsor may:

- Consult with the appropriate local, State, and federal environmental regulatory agencies to ensure sufficient minimization of risk to human health and environmental resources, both during and after construction, posed by soil contamination, groundwater contamination, or other surface hazards including, but not limited to, underground storage tanks, fuel distribution lines, waste pits and sumps;
- Obtain and submit written evidence of approval for any remedial action if required by a local, State, or federal environmental regulatory agency; and
- Submit a copy of all applicable documentation required by local, State, and federal environmental regulatory agencies, including but not limited to: permit applications, Phase I and II environmental site assessments, human health and ecological risk assessments, remedial action plans, risk management plans, soil management plans, and groundwater management plans.

HM13: If lead-based paint is present, project sponsors may submit specifications to the appropriate agency, signed by a certified Lead Supervisor, Project Monitor, or Project Designer for the stabilization and/or removal of the identified lead paint in accordance with all applicable laws and regulations, including but not necessarily limited to: California Occupational Safety and Health Administration's (Cal OSHA's) Construction Lead Standard, Title 8 California Code of Regulations (CCR) Section 1532.1 and Department of Health Services (DHS) Regulation 17 CCR Sections 35001-36100, as may be amended. If other materials classified as hazardous waste by State or federal law are present, the project sponsor may submit written confirmation to the appropriate local agency that all State and federal laws and regulations may be followed when profiling, handling, treating, transporting and/or disposing of such materials.

HM14: If materials classified as hazardous waste by State or federal law are present, project sponsors may submit written confirmation to appropriate local agency that all State and federal laws and regulations may be followed when profiling, handling, treating, transporting and/or disposing of such materials.

LAND USE AND AGRICULTURAL RESOURCES

LU1: Local jurisdictions may provide for new housing consistent with the regional Housing Needs Assessment (RHNA) to accommodate their share of the forecasted regional growth.

LU2: Significant adverse impacts to community cohesion resulting from the displacement of residences or businesses may be mitigated with specific relocation measures as dictated by local, state or federal requirements on a

project-by project basis. Such measures include assistance in finding a new location, assistance with moving, or compensation for losses. Where it has been determined that displacement is necessary and displaced individuals are eligible, a relocation assistance program consistent with the State Uniform Location Assistance and Real Properties Acquisition Policies Act provides compensation and assistance in finding new residence for displaced individuals.

- LU3:** Project sponsors may design new transportation facilities that consider access to existing community facilities. During the design phase of the project, community amenities and facilities may be identified and considered in the design of the project.
- LU4:** Project sponsors may design roadway improvements that minimize barriers to pedestrians and bicyclists. During the design phase, pedestrian and bicycle routes may be determined that permit connections to nearby community facilities.
- LU5:** For projects that require approval or funding by the USDOT, project sponsors may comply with Section 4(f) U.S. Department of Transportation Act of 1966 (USDOT Act).
- LU6:** Project sponsors may ensure that at least one acre of unprotected open space is permanently conserved for each acre of open space developed as a result of transportation projects/improvements.
- LU7:** Local jurisdictions may seek funding to prepare specific plans and related environmental documents to facilitate mixed-use development at selected sites, and to allow these areas to serve as receiver sites for transfer of development rights away from environmentally sensitive lands and rural areas outside established urban growth boundaries.
- LU8:** Local jurisdictions may preserve and create open space and parks. Preserve existing trees, and plant replacement trees at a set ratio.
- LU9:** Project sponsors may consider corridor realignment, buffer zones and setbacks, and berms and fencing where feasible, to avoid agricultural lands and to reduce conflicts between transportation uses and agricultural lands.
- LU10:** Prior to final approval of each project and when feasible and prudent, the project sponsor may establish conservation easement programs to mitigate impacts to prime farmland.
- LU11:** Prior to final approval of each project, the project sponsor may to the extent practical and feasible, avoid impacts to prime farmlands or farmlands that support crops considered valuable to the local or regional economy.

- LU12:** Local jurisdictions may establish programs to direct growth to less agriculturally valuable lands and ensure, where possible, the continued protection of the most agriculturally valuable land within each county. The following are offered as examples of programs:
- The development or participation in transfer of development rights programs to encourage the preservation of agricultural lands.
 - Tools for the preservation of agricultural lands such as eliminating estates and ranchettes and clustering to retain productive agricultural land.
 - Easing restrictions on farmer's markets and encourage cooperative farming initiatives to increase the availability of locally grown food.
 - Considering partnering with school districts to develop farm-to-school programs.
- LU13:** Local jurisdictions may avoid the premature conversion of farmlands by promoting infill development and the continuation of agricultural uses until urban development is imminent; if development of agricultural lands is necessary, growth may be directed to those lands on which the continued viability of agricultural production has been compromised by surrounding urban development on the loss of local markets.
- LU14:** Local jurisdictions may encourage patterns of urban development and land use, which reduce costs on infrastructure and make better use of existing facilities. Strategies that local jurisdictions may pursue include:
- Increasing the accessibility to natural areas lands for outdoor recreation.
 - Promoting infill development and redevelopment to revitalize existing communities
 - Utilizing "green" development techniques
 - Promoting water-efficient land use and development.
- LU15:** Project sponsors and local jurisdictions may promote infill development and redevelopment to encourage the efficient use of land and minimize the development of agricultural and open space lands.
- LU16:** Local jurisdictions may consider the following land use principles that use resources efficiently, and to the extent practical and feasible minimize pollution and reduce waste generation:
- Mixed-use residential and commercial development that is connected with public transportation and utilizes existing infrastructure.
 - Land use and planning strategies to increase biking and walking trips.

- LU17:** Individual projects must be consistent with federal, state, and local policies that preserve agricultural lands and support the economic viability of agricultural activities, as well as policies that provide compensation for property owners if preservation is not feasible.
- LU18:** For projects in agricultural areas, project sponsors may contact the California Department of Conservation and each county’s Agricultural Commissioner’s office to identify the location of prime farmlands and lands that support crops considered valuable to the local or regional economy. Impacts to such lands may be evaluated in project-specific environmental documents. The analysis may use the land evaluation and site assessment (LESA) analysis method (CEQA Guidelines §21095), as appropriate. The project sponsors or local jurisdictions may be responsible for ensuring adherence to the mitigation measures prior to construction. Mitigation measures may include conservation easements or the payment of in-lieu fees.
- LU19:** For those projects that require federal funding, the federal agency evaluates the effects of the action to agricultural resources using the criteria set forth in the Farmland Protection Policy Act (FPPA). The FPPA is administered by the NRCS, which determines impacts to farmland that could occur due to the proposed project. The determination is made through coordination between the federal agency proposing or supporting the project and NRCS. The assessment of potential impacts to farmland from corridor type projects, which is typical of transportation projects analyzed in this Program EIR, may require completion of Form NRCS-CPA-106, Farmland Conservation Impact Rating for Corridor Type Projects. NRCS may make a determination, using set thresholds, as to whether additional project specific mitigation would be required.
- LU20:** Prior to final approval of each project, the project sponsor may encourage enrollments of agricultural lands for counties that have Williamson Act programs, where applicable.
- LU21:** Project sponsors and local jurisdictions may submit for IGR review projects with potentially significant impacts to important farmlands.
- LU22:** Local jurisdictions may consider policies to preserve forested areas, agricultural lands, wildlife habitat and corridors, wetlands, watersheds, groundwater recharge areas and other open space that provide carbon sequestration benefits.
- LU23:** Local jurisdictions may require best management practices in agriculture and animal operations to reduce emissions, conserve energy and water, and utilize alternative energy sources, including biogas, wind and solar.

-
- LU24:** Local jurisdictions may encourage patterns of urban development and land use, which reduce costs on infrastructure and make better use of existing facilities.
- LU25:** Local jurisdictions may adopt and implement General Plan Housing Elements that accommodate the housing need identified through the RHNA process. Affordable housing may be provided consistent with the RHNA income category distribution adopted for each jurisdiction.
- LU26:** Local jurisdictions may consider shared regional priorities, as outlined in the Compass Blueprint, 2012-2035 RTP/SCS and other ongoing regional planning efforts, in determining their own development goals and drafting local plans.
- LU27:** Local jurisdictions and subregional organizations may encourage the cleanup and redevelopment of brownfield sites.
- LU28:** Local jurisdictions or agencies may consider adopting and implement a development pattern that utilizes existing infrastructure; reduces the need for new roads, utilities and other public works in new growth areas; and enhances non-automobile transportation.
- LU29:** Local jurisdictions or agencies may consider ordinances or programs to limit suburban sprawl; with measures that streamline entitlement processes for projects that are not considered sprawl.
- LU30:** Urban development may occur only where urban public facilities and services exist or can be reasonably made available.
- LU31:** The improvement and expansion of one urban public facility or service may not stimulate development that significantly precedes the local jurisdiction's ability to provide all other necessary urban public facilities and services at adequate levels.
- LU32:** Local jurisdictions may redirect new growth into existing city/urban reserve areas.
- LU33:** Local jurisdictions may maintain a one dwelling unit per 10-acre minimum lot size or lower density in areas outside designated urban service lines.
- LU34:** Local jurisdictions may consider encouraging high-density, mixed-use, infill development and creative reuse of brownfield, under-utilized and/or defunct properties within the urban core.
- LU35:** Local jurisdictions may consider increasing densities in urban core areas to support public transit.

- LU36:** Local jurisdictions may remove barriers to the development of accessory dwelling units in existing residential neighborhoods as appropriate
- LU37:** Local jurisdictions may reduce required road width standards wherever feasible to calm traffic and encourage alternative modes of transportation.
- LU38:** Local jurisdictions may reduce parking space requirements, unbundle parking from rents and charge for parking in new developments.
- LU39:** Local jurisdictions may add bicycle facilities to streets and public spaces.
- LU40:** Local jurisdictions may plan for and create incentives for mixed-use development.
- LU41:** Local jurisdictions may identify sites suitable for mixed-use development and establish appropriate site-specific standards to accommodate the mixed uses. Site-specific standards could include:
- Increasing allowable building height or allowing height limit bonuses;
 - Allowing flexibility in applying development standards (such as FAR2 and lot coverage) based on the location, type, and size of the units, and the design of the development;
 - Allowing the residential component to be additive rather than within the established FAR for that zone, and eliminating maximum density requirements for residential uses in mixed use zones;
 - Allowing reduced and shared parking based on the use mix, and establishing parking maximums where sites are located within 0.25 miles of a public transit stop;
 - Allowing for tandem parking, shared parking and off-site parking leases;
 - Requiring all property owners in mixed-use areas to unbundle parking from commercial and residential leases;
 - Creating parking benefit districts, which invest meter revenues in pedestrian infrastructure and other public amenities;
 - Establishing performance pricing of street parking, so that it is expensive enough to promote frequent turnover and keep 15 percent of spaces empty at all times.
- LU42:** Local jurisdictions may enable prototype mixed-use structures for use in neighborhood center zones that can be adapted to new uses over time with minimal internal remodeling.
- LU43:** Local jurisdictions may identify and facilitate the inclusion of complementary land uses not already present in local zoning districts, such

as supermarkets, parks and recreational fields, schools in neighborhoods, and residential uses in business districts, to reduce the vehicle miles traveled and promote bicycling and walking to these uses.

- LU44:** Local jurisdictions may work with employers developing larger projects to ensure local housing opportunities for their employees, and engage employers to find ways to provide housing assistance as part of their employee benefits packages; major projects in mixed-use areas may include work-force housing where feasible.
- LU45:** Local jurisdictions may revise zoning ordinance(s) to allow local-serving businesses, such as childcare centers, restaurants, banks, family medical offices, drug stores, and other similar services near employment centers to minimize midday vehicle use.
- LU46:** Local jurisdictions may develop form-based community design standards to be applied to development projects and land use plans, using a comprehensive community outreach, for areas designated mixed-use.
- LU47:** Local jurisdictions may mix affordable housing units with market rate units as opposed to building segregated affordable housing developments.
- LU48:** Where practical and feasible, local jurisdictions may develop programs that enable the reuse of underutilized commercial, office and/or industrial properties for housing or mixed-use housing.
- LU49:** Local jurisdictions may consider consistency with “smart growth” principles – mixed-use, infill, and higher density projects that provide alternatives to individual vehicle travel and promote the efficient delivery of services and goods.
- LU50:** Local jurisdictions may meet recognized “smart growth” benchmarks.
- LU51:** Project sponsors may incorporate public transit into the project’s design.
- LU52:** Project sponsors may include pedestrian and bicycle facilities within projects and ensure that existing non-motorized routes are maintained and enhanced.
- LU53:** Local jurisdictions may encourage residential development in High Quality Transit Areas (HQTAs). Such development may include a generally walkable transit village that has a minimum density of 20 dwelling units per acre and is within a ½ mile of a well-serviced transit stop, and includes transit corridors with minimum 15-minute or less service frequency during peak commute hours.
- LU54:** Local jurisdictions may promote greater linkage between land uses and transit, as well as other modes of transportation.

- LU55:** Local jurisdictions may ensure new development is designed to make public transit a viable choice for residents, including:
- Locating medium-high density development near activity centers that can be served efficiently by public transit and alternative transportation modes;
 - Locating medium-high density development near streets served by public transit whenever feasible;
 - Linking neighborhoods to bus stops by continuous sidewalks or pedestrian paths.
- LU56:** Local jurisdictions may establish city-centered corridors, directing development to existing transportation corridors.
- LU57:** Local jurisdictions may develop form-based community design standards to be applied to development projects and land use plans, using a comprehensive community outreach program, for areas designated mixed-use
- LU58:** Local jurisdictions may locate affordable housing in transit-oriented development whenever feasible
- LU59:** Local jurisdictions may consider jobs/housing balance, to the extent practical and feasible, and encourage the development of communities where people live closer to work, bike, walk, and take transit as a substitute for personal auto travel.
- LU60:** Project sponsors may consider community cohesion in designing projects through communities. Transit facilities may be designed to integrate with the community and encourage walking and bicycling as well as park and ride. New or widened roadways (and freeways) may be designed to minimize impacts to the extent feasible through landscaping, pedestrian furniture as appropriate. New roadways or freeways may consider feasible innovative designs such as cap parks that maintain community cohesion.
- LU61:** Local jurisdictions may promote development and preservation of neighborhood characteristics that encourage walking and bicycle riding in lieu of automobile-based travel.
- LU62:** Local jurisdictions may create and preserve distinct, identifiable neighborhoods whose characteristics support pedestrian travel, especially within, but not limited to, mixed-use and transit-oriented development areas, including:
- Designing or maintaining neighborhoods where the neighborhood center can be reached in approximately five minutes of walking;

- Increasing housing densities from the perimeter to the center of the neighborhood;
- Directing retail, commercial, and office space to the center of the neighborhood;
- Encouraging pedestrian-only streets and/or plazas within developments, and destinations that may be reached conveniently by public transportation, walking, or bicycling;
- Allowing flexible parking strategies in neighborhood activity centers to foster a pedestrian-oriented streetscape;
- Providing continuous sidewalks with shade trees and landscape strips to separate pedestrians from traffic;
- Encouraging neighborhood parks and recreational centers near concentrations of residential areas (preferably within one quarter mile) and include pedestrian walkways and bicycle paths that encourage non-motorized travel.

LU63: Local jurisdictions may ensure pedestrian access to activities and services, especially within, but not limited to, mixed-use and transit-oriented development areas, including:

- Ensuring new development that provides pedestrian connections in as many locations as possible to adjacent development, arterial streets, thoroughfares;
- Ensuring a balanced mix of housing, workplaces, shopping, recreational opportunities, and institutional uses, including mixed-use structures;
- Locating schools in neighborhoods, within safe and easy walking distances of residences served;
- For new development, primary entrances may be pedestrian entrances, with automobile entrances and parking located to the rear;
- Support development where automobile access to buildings does not impede pedestrian access, by consolidating driveways between buildings or developing alley access;
- Street parking provided may be utilized as a buffer between sidewalk pedestrian traffic and the automobile portion of the roadway;
- Establish pedestrian and bicycle connectivity standards for new development, with block sizes between 1 and 2 acres;
- For existing areas that do not meet established connectivity standards, prioritize the physical development of pedestrian connectors;

- Prioritizing grade-separated bicycle / pedestrian crossings where appropriate to enhance connectivity or overcome barriers such as freeways, railways and waterways.

LU64: Local jurisdictions may review fee structures and other opportunities to provide financial and administrative incentives to support desired land uses, development patterns, and alternative modes of transportation.

LU65: Local jurisdictions may promote desired land uses by considering criteria for scaled developer fees. Examples include:

- Increasing or reducing fees proportionally with distance from the city center or preferred transit sites;
- Increasing or reducing fees based on the degree to which mixed uses are incorporated into the project;
- Reducing fees for creative re-use of brownfield sites;
- Increasing fees for the use of greenfield sites.

LU66: Local jurisdictions may consider providing fast-track permitting and reductions in processing fees for desired projects. Local jurisdictions may research and implement a program of incentives for development projects that are fully consistent with the 2012-2035 RTP/SCS.

LU67: Local jurisdictions may consider providing incentive funding and/or infrastructure loans to support desired projects.

LU68: Local jurisdictions may give preference for infrastructure improvements that support or enhance desired land uses and projects.

LU69: Local jurisdictions may reduce heat gain from pavement and other hardscaping, including:

- Reduce street rights-of-way and pavement widths to pre-World War II widths (typically 22 to 34 feet for local streets, and 30 to 35 feet for collector streets, curb to curb), unless landscape medians or parkway strips are allowed in the center of roadways;
- Reinstate the use of parkway strips to allow shading of streets by trees;
- Include shade trees on south- and west-facing sides of structures;
- Include low-water landscaping in place of hardscaping around transportation infrastructure and in parking areas;
- Install cool roofs, green roofs, and use cool paving for pathways, parking, and other roadway surfaces;
- Establish standards that provide for pervious pavement options;
- Remove obstacles to xeriscaping, edible landscaping and low-water landscaping.

NOISE

NO1: To reduce noise impacts due to construction, project sponsors may require construction contractors to implement a site-specific noise reduction program, subject to the Lead Agency (or other appropriate government agency) review and approval, which includes the following measures:

- Equipment and trucks used for project construction may utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).
- Except as may be exempted by the Lead Agency (or other appropriate government agency), impact tools (e.g., jack hammers, pavement breakers, and rock drills) used for project construction may be hydraulically or electrically powered to avoid noise associated with compressed air exhaust from pneumatically powered tools. However, where use of pneumatic tools is unavoidable, an exhaust muffler on the compressed air exhaust may be used; this muffler can lower noise levels from the exhaust by up to about 10 dBA. External jackets on the tools themselves may be used, if such jackets are commercially available and this could achieve a reduction of 5 dBA. Quieter procedures may be used, such as drills rather than impact equipment, whenever such procedures are available and consistent with construction procedures.
- Stationary noise sources may be located as far from adjacent sensitive receptors as possible and they may be muffled and enclosed within temporary sheds, incorporate insulation barriers, or use other measures as determined by the Lead Agency (or other appropriate government agency) to provide equivalent noise reduction.

NO2: Prior to the issuance of a building permit, along with the submission of construction documents, each project sponsor may submit to the Lead Agency (or other government agency as appropriate) a list of measures to respond to and track complaints pertaining to construction noise. These measures may include:

- A procedure and phone numbers for notifying the Lead Agency staff and local Police Department; (during regular construction hours and off-hours);
- A sign posted on-site pertaining with permitted construction days and hours and complaint procedures and who to notify in the event of a problem. The sign may also include a listing of both the Lead Agency and construction contractor's telephone numbers (during regular construction hours and off-hours);
- The designation of an on-site construction complaint and enforcement manager for the project;

- Notification of neighbors and occupants within 300 feet of the project construction area at least 30 days in advance of extreme noise generating activities about the estimated duration of the activity; and
- A preconstruction meeting may be held with the job inspectors and the general contractor/on-site project manager to confirm that noise measures and practices (including construction hours, neighborhood notification, posted signs, etc.) are completed.

NO3: Project sponsor may implement use of portable barriers in the vicinity of sensitive receptors during construction including construction of subsurface barriers, debris basins, and storm water drainage facilities.

NO4: For projects that require pile driving or other construction noise above 90 dBA in proximity to sensitive receptors, to further reduce potential pier drilling, pile driving and/or other extreme noise generating construction impacts greater than 90dBA, a set of site-specific noise attenuation measures may be completed under the supervision of a qualified acoustical consultant. Prior to commencing construction, a plan for such measures may be submitted for review and approval by the Lead Agency (or other appropriate government agency) to ensure that maximum feasible noise attenuation is achieved. This plan may be based on the final design of the project. A third-party peer review, paid for by the project sponsor, may be required to assist the Lead Agency in evaluating the feasibility and effectiveness of the noise reduction plan submitted by the project sponsor. The criterion for approving the plan may be a determination that maximum feasible noise attenuation is achieved. The noise reduction plan may include, but not be limited to, an evaluation of implementing the following measures. These attenuation measures may include as many of the following control strategies as applicable to the site and construction activity:

- Erect temporary plywood noise barriers around the construction site, particularly along on sites adjacent to residential buildings;
- Implement “quiet” pile driving technology (such as pre-drilling of piles, the use of more than one pile driver to shorten the total pile driving duration), where feasible, in consideration of geotechnical and structural requirements and conditions;
- Utilize noise control blankets on the building structure as the building is erected to reduce noise emission from the site;
- Evaluate the feasibility of noise control at the receivers by temporarily improving the noise reduction capability of adjacent buildings by the use of sound blankets for example and implement such measure if such measures are feasible and would noticeably reduce noise impacts; and

- Monitor the effectiveness of noise attenuation measures by taking noise measurements.

- NO5:** Noise generated from any rock-crushing or screening operations performed within 3,000 feet of any occupied residence may be mitigated by the project sponsor by strategic placement of material stockpiles between the operation and the affected dwelling or by other means approved by the local jurisdiction.
- NO6:** Where feasible, pile holes may be pre-drilled to reduce potential noise and vibration impacts.
- NO7:** As necessary, each project sponsor may retain a structural engineer or other appropriate professional to determine threshold levels of vibration and cracking that could damage any adjacent historic or other structure subject to damage, and design means and construction methods to not exceed the thresholds.
- NO8:** Project sponsors may comply with all local sound control and noise level rules, regulations, and ordinances.
- NO9:** As part of the appropriate environmental review of each project, a project specific noise evaluation may be conducted and appropriate mitigation identified and implemented.
- NO10:** Project sponsors may employ, where their jurisdictional authority permits, land use planning measures, such as zoning, restrictions on development, site design, and use of buffers to ensure that future development is compatible with adjacent transportation facilities.
- NO11:** As a last resort, project sponsors may eliminate noise-sensitive receptors by acquiring freeway and rail rights-of-way. This would ensure the effective operation of all transportation modes.
- NO12:** Project sponsors may, to the extent feasible and practicable, maximize the distance between noise-sensitive land uses and new roadway lanes, roadways, rail lines, transit centers, park-and-ride lots, and other new noise-generating facilities.
- NO13:** Project sponsors may construct sound reducing barriers between noise sources and noise-sensitive land uses. Sound barriers can be in the form of earth-berms or soundwalls. Constructing roadways so as appropriate and feasible that they are depressed below-grade of the existing sensitive land uses also creates an effective barrier between the roadway and sensitive receptors.

- NO14:** Project sponsors may, to the extent feasible and practicable, improve the acoustical insulation of dwelling units where setbacks and sound barriers do not sufficiently reduce noise.
- NO15:** The project sponsors may implement, to the extent feasible and practicable, speed limits and limits on hours of operation of rail and transit systems, where such limits may reduce noise impacts.
- NO16:** As applicable and feasible, project sponsors may reduce noise impacts, by maximizing distance between sensitive receptors and new transportation projects. *Above measure is clarified and simplified.*
- NO17:** Transit-related passenger stations, central maintenance facilities, decentralized maintenance facilities, and electric substations may be located away from sensitive receptors to the maximum extent feasible.
- NO18:** Local jurisdictions or agencies may, as practical and feasible, adhere to published local, state and federal guidelines concerning groundborne vibration impacts.

POPULATION, HOUSING, AND EMPLOYMENT

- POP1:** For projects with the potential to displace homes and/or businesses, project sponsors may evaluate alternate route alignments and transportation facilities that minimize the displacement of homes and businesses. An iterative design and impact analysis would help where impacts to homes or businesses are involved in order to minimize impacts to the extent feasible. This may include use of existing rights-of-way.
- POP2:** Project sponsors may develop a construction schedule that minimizes potential neighborhood deterioration from protracted waiting periods between right-of-way acquisition and construction.
- POP3:** Project sponsors may mitigate impacts to affordable housing as feasible through construction of affordable units (deed restricted to remain affordable for an appropriate period of time) or payment of any fee established to address loss of affordable housing.

PUBLIC SERVICES AND UTILITIES

- PS1:** Project implementation agencies may ensure that prior to construction all necessary local and state road and railroad encroachment permits are obtained. The project implementation agency may also comply with all applicable conditions of approval. As deemed necessary by the governing jurisdiction, the road encroachment permits may require the contractor to prepare a traffic control plan in accordance with professional engineering standards prior to construction. Traffic control plans may include the following:

- Identification of all roadway locations where special construction techniques (e.g., directional drilling or night construction) would be used to minimize impacts to traffic flow.
- Development of circulation and detour plans to minimize impacts to local street circulation. This may include the use of signing and flagging to guide vehicles through and/or around the construction zone.
- Scheduling of truck trips outside of peak morning and evening commute hours.
- Limiting of lane closures during peak hours to the extent possible.
- Usage of haul routes minimizing truck traffic on local roadways to the extent possible.
- Inclusion of detours for bicycles and pedestrians in all areas potentially affected by project construction.
- Installation of traffic control devices as specified in the California Department of Transportation Manual of Traffic Controls for Construction and Maintenance Work Zones.
- Development and implementation of access plans for highly sensitive land uses such as police and fire stations, transit stations, hospitals, and schools. The access plans would be developed with the facility owner or administrator. To minimize disruption of emergency vehicle access, affected jurisdictions may be asked to identify detours for emergency vehicles, which may then be posted by the contractor. Notify in advance the facility owner or operator of the timing, location, and duration of construction activities and the locations of detours and lane closures.
- Storage of construction materials only in designated areas.
- Coordination with local transit agencies for temporary relocation of routes or bus stops in work zones, as necessary.

PS2: Project sponsors may identify projects in the 2012-2035 RTP/SCS that require police protection, fire service, and emergency medical service and may coordinate with local fire and police departments to ensure that the existing public services would be able to handle the increase in demand for their services. If the current levels of services at the project site are found to be inadequate, infrastructure improvements and/or personnel requirements for the appropriate public service may be identified in each project's CEQA documentation.

PS3: Project sponsors may ensure that during project construction, all construction vehicles and equipment may be fitted with spark arrestors to

minimize accidental ignition of dry construction debris and surrounding dry vegetation.

- PS4:** Project sponsors may encourage the use of fire-resistant vegetation native to Southern California and/or to the local microclimate (e.g., vegetation that has high moisture content, low growth habits, ignition-resistant foliage, or evergreen growth), eliminate brush and chaparral, and discourage the use of fire-promoting species especially non-native, invasive species (e.g., pampas grass, fennel, mustard, or the giant reed) in the immediate vicinity of development in areas with high fire threat.
- PS5:** Project sponsors may encourage natural re-vegetation or seeding with local, native species after a fire and discourage re-seeding of non-native, invasive species to promote healthy, natural ecosystem re-growth. Native vegetation is more likely to have deep root systems that prevent slope failure and erosion of burned areas than shallow-rooted non-natives.
- PS6:** Project sponsors may submit a fire safety plan (including phasing) to the Lead Agency and local fire agency for their review and approval. The fire safety plan may include all of the fire safety features incorporated into the project and the schedule for implementation of the features. The local fire protection agency may require changes to the plan or may reject the plan if it does not adequately address fire hazards associated with the project as a whole or the individual phase.
- PS7:** Local jurisdictions may discourage development on potentially hazardous developments in hillsides, canyons, areas with steep slopes or that are susceptible to flooding, earthquakes, wildfire and other known hazards, and areas with limited access for emergency equipment.
- PS8:** Local jurisdictions may promote Fire-wise Land Management: by encouraging the use of fire-resistant vegetation and the elimination of brush and chaparral in the immediate vicinity of development in areas with high fire threat.
- PS9:** Local jurisdictions may promote Fire Management Planning that help reduce fire threats in the region as part of the Compass Blueprint process and other ongoing regional planning efforts.
- PS10:** Local jurisdictions may encourage the use of fire-resistant materials when constructing projects in areas with high fire threat. Local jurisdictions may discourage development in high fire hazard areas and recommend using project design to reduce risk including building with a compact defensible footprint and minimizing perimeter length.
- PS11:** The growth inducing potential of individual RTP projects may be carefully evaluated so that the full implications of the projects are understood. Individual environmental documents may quantify indirect impacts

(growth that could be facilitated or induced) on public services and utilities to the extent feasible. Lead and responsible agencies may then make any necessary adjustments to the applicable General Plan. Any such identified adjustment may be communicated to SCAG.

- PS12:** Project sponsors may undertake project-specific review of the impacts to educational facilities as part of project specific environmental review. For any identified impacts, project sponsors may ensure that the appropriate school district fees are paid in accordance with State law. The project sponsors or local jurisdiction may be responsible for ensuring adherence to required mitigation. SCAG may be provided with documentation of compliance with any necessary mitigation measures.
- PS13:** Project sponsors may ensure that projects are consistent with federal, state, and local plans that preserve open space.
- PS14:** Project sponsors may consider corridor realignment, buffer zones and setbacks, and berms and fencing where feasible, to avoid open space and recreation land and to reduce conflicts between transportation uses and open space and recreation lands.
- PS15:** Project sponsors may identify open space areas that could be preserved and may include mitigation measures (such as dedication or payment of in-lieu fees) for the loss of open space.
- PS16:** Prior to final approval of each project, the project sponsor may conduct the appropriate project-specific environmental review, including consideration of loss of open space. Potential significant impacts to open space may be mitigated, as feasible. The project sponsors or local jurisdiction may be responsible for ensuring adherence to the mitigation measures prior to construction.
- PS17:** Local jurisdictions may prepare a Needs Assessment to determine the level of adequate community open space level for their areas.
- PS18:** Local jurisdictions may participate in regional efforts to identify regionally significant open space resources within their jurisdictions as feasible and appropriate.
- PS19:** Where practical and feasible, project sponsors and local jurisdictions may consider increasing the accessibility to natural areas and lands for outdoor recreation. Such measures may be coordinated with local and regional open space planning or management agencies.
- PS20:** Local jurisdictions may encourage multiple use spaces and encourage redevelopment in areas where it will provide more opportunities for recreational uses and access to natural areas close to the urban core.

- PS21:** Project level mitigation for significant cumulative and growth-inducing impacts on open space resources may include the conservation of natural lands, community open space and important farmland through existing projects in the region.
- PS22:** Local governments may consider the most recent annual report on open space conservation in planning and evaluating projects and programs in areas with regionally significant open space resources.
- PS23:** Local governments may encourage patterns of urban development and land use, which reduce costs on infrastructure and make better use of existing facilities. Strategies local governments may pursue include:
- Increasing the accessibility to natural areas lands for outdoor recreation.
 - Promoting infill development and redevelopment to revitalize existing communities
 - Utilizing "green" development techniques
 - Promoting water-efficient land use and development.
- PS24:** Project sponsors and local governments may encourage multiple use spaces and encourage redevelopment in areas where it will provide more opportunities for recreational uses and access to natural areas close to the urban core.
- PS25:** Future impacts to open space and recreation lands may be avoided through cooperation, information sharing, and program development as part of SCAG's ongoing regional planning efforts.
- PS26:** Project sponsors for projects identified in the 2012-2035 RTP/SCS may comply with applicable regulations related to solid waste disposal.
- PS27:** Projects sponsors may work with the respective local jurisdiction's Recycling Coordinator to ensure that source reduction techniques and recycling measures are incorporated into project construction.
- PS28:** Local jurisdictions may estimate the amount of solid waste generated during construction prior to construction, and appropriate disposal sites may be identified and utilized.
- PS29:** Project sponsors may integrate green building measures into project design such as those identified in the U.S. Green Building Council's Leadership in Energy and Environmental Design, energy Star Homes, Green Point Rated Homes, and the California Green Builder Program. These measures could include the following:

- Reuse and minimization of construction and demolition (C&D) debris and diversion of C&D waste from landfills to recycling facilities.
- The inclusion of a waste management plan that promotes maximum C&D diversion.
- Source reduction through: 1) use of materials that are more durable and easier to repair and maintain; 2) design to generate less scrap material through dimensional planning; 3) increased recycled content; 4) use of reclaimed materials; and, 5) use of structural materials in a dual role as finish material (e.g., stained concrete flooring, unfinished ceilings, etc.).
- Reuse of existing structure and shell in renovation projects.
- Design for deconstruction without compromising safety.
- Design for flexibility through the use of moveable walls, raised floors, modular furniture, moveable task lighting and other reusable building components.
- Development of indoor recycling program and space.

- PS30:** Local jurisdictions and waste management agencies may discourage the siting of new landfills unless all other waste reduction and prevention actions have been fully explored. If landfill siting or expansion is necessary, landfills may be sited with an adequate landfill-owned, undeveloped land buffer to minimize the potential adverse impacts of the landfill in neighboring communities.
- PS31:** Project sponsors may discourage exporting of locally generated waste outside of the SCAG region during the construction and implementation of a project. Disposal within the county where the waste originates may be encouraged as much as possible. Green technologies for long-distance transport of waste (e.g., clean engines and clean locomotives or electric rail for waste-by-rail disposal systems) and consistency with SCAQMD and 2012-2035 RTP/SCS policies may be required.
- PS32:** Project sponsors may encourage waste reduction goals and practices and look for opportunities for voluntary actions to exceed the 50 percent waste diversion target.
- PS33:** Project sponsors and local jurisdictions may encourage the development of local markets for waste prevention, reduction, and recycling practices by supporting recycled content and green procurement policies, as well as other waste prevention, reduction and recycling practices.
- PS34:** Local jurisdictions may develop ordinances that promote waste prevention and recycling activities such as: requiring waste prevention and recycling efforts at all large events and venues; implementing recycled content

procurement programs; and developing opportunities to divert food waste away from landfills and toward food banks and composting facilities.

- PS35:** Local jurisdictions and waste management agencies may develop alternative waste management strategies such as composting, recycling, and conversion technologies.
- PS36:** Project sponsors, local jurisdictions and waste management agencies, where practical and feasible, may develop and site composting, recycling, and conversion technology facilities that have minimum environmental and health impacts.
- PS37:** Local jurisdictions may require the reuse and recycle construction and demolition waste (including, but not limited to, soil, vegetation, concrete, lumber, metal, and cardboard).
- PS38:** Project sponsors may integrate reuse and recycling into residential industrial, institutional and commercial projects.
- PS39:** Local jurisdictions may provide easy and convenient recycling opportunities for residents, the public, and tenant businesses.
- PS40:** Local jurisdictions may provide education and publicity about reducing waste and available recycling services.
- PS41:** The California Integrated Waste Management Board may continue to enforce solid waste diversion mandates that are enacted by the Legislature.
- PS42:** Local jurisdictions may continue to adopt programs to comply with state solid waste diversion rate mandates and, where possible, may encourage further recycling to exceed these rates.
- PS43:** Local jurisdictions may implement or expand city or county-wide recycling and composting programs for residents and businesses. This could include extending the types of recycling services offered (e.g., to include food and green waste recycling) and providing public education and publicity about recycling services.
- PS44:** Local jurisdictions, waste management agencies and SCAG may coordinate regional approaches and strategic siting of waste management facilities.
- PS45:** Local jurisdictions and waste management agencies may encourage and, where practical and feasible, facilitate the creation of synergistic linkages between community businesses and the development of eco-industrial parks and materials exchange centers where one entity's waste stream becomes another entity's raw material.

- PS46:** Local jurisdictions and waste management agencies may prioritize siting of new solid waste management facilities including recycling, composting, and conversion technology facilities in conjunction with existing waste management or material recovery facilities.
- PS47:** Local jurisdictions and waste management agencies may increase programs to educate the public and increase awareness of reuse, recycling, composting, and green building benefits and raise consumer education issues at the county and city level, as well as at local school districts and education facilities.
- PS48:** For projects identified in the 2012-2035 RTP/SCS that require solid waste collection, project sponsors may coordinate with the local public works department to ensure that the existing public services and utilities would be able to handle the increase. If the current infrastructure servicing the project site is found to be inadequate, infrastructure improvements for the appropriate public service or utility may be identified in each project's CEQA documentation.
- PS49:** The growth inducing potential of individual projects may be carefully evaluated so that the full implications of the projects are understood. Individual environmental documents may quantify indirect impacts (growth that could be facilitated or induced) on public services and utilities to the extent feasible. Lead and responsible agencies then may make any necessary adjustments to the applicable General Plan. Any such identified adjustment may be communicated to SCAG.
- PS50:** Prior to construction, the project implementation agency may identify the locations of existing utility lines. The contractor may avoid all known utility lines during construction.
- PS51:** In reviewing projects Lead Agencies and project sponsors may consider energy implications of construction processes. In general the most energy efficient construction process and long-term operational design may be selected unless there is an overriding reason why not.
- PS52:** Local jurisdictions may include energy analyses in environmental documentation and general plans with the goal of conserving energy through the wise and efficient use of energy. For any identified energy impacts, appropriate mitigation measures may be developed and monitored. SCAG recommends the use of Appendix F, Energy Conservation, of the *CEQA Guidelines*.
- PS53:** Project sponsors may consider the most cost-effective alternative and renewable energy generation facilities.

- PS54:** Project sponsors may require that projects use efficient lighting. (Fluorescent lighting uses approximately 75% less energy than incandescent lighting to deliver the same amount of light.)
- PS55:** Project sponsors may require measures that reduce the amount of water sent to the sewer system. (Reduction in water volume sent to the sewer system means less water has to be treated and pumped to the end user, thereby saving energy.)
- PS56:** Project sponsors may pursue incentives to encourage the use of energy efficient equipment and vehicles.
- PS57:** State and federal lawmakers and regulatory agencies may pursue the design of programs to either require or incentivize the expanded availability including the expansion of alternative fuel filling stations and use of alternative-fuel vehicles to reduce the impact of shifts in petroleum fuel supply and price.
- PS58:** Local jurisdictions may consider various best practices and technological improvements that can reduce the consumption of fossil fuels, such as:
- Expanding light-duty vehicle retirement programs
 - Increasing commercial vehicle fleet modernization
 - Implementing driver training module on fuel consumption
 - Replacing gasoline powered mowers with electric mowers
 - Reducing idling from construction equipment
 - Incentivizing alternative fuel vehicles and equipment
 - Developing infrastructure for alternative fueled vehicles
 - Increasing use and mileage of High Occupancy Vehicle (HOV), High Occupancy Toll (HOT) and dedicated Bus Rapid Transit (BRT) lanes
 - Implementing truck idling rule, devices, and truck-stop electrification
 - Requiring electric truck refrigerator units
 - Reducing locomotives fuel use
 - Modernizing older off-road engines and equipment
 - Limit use and develop fleet rules for construction equipment
 - Requiring zero, and/or near zero-emission forklifts
- PS59:** Local jurisdictions or agencies with purview over utilities may, as practical and feasible, streamline permitting and provide public information to facilitate accelerated construction of geothermal, solar and wind power generation facilities and transmission line improvements.

-
- PS60:** Utilities may increase capacity of existing transmission lines to meet forecast demand that supports sustainable growth, where feasible and appropriate in coordination with local planning agencies.
- PS61:** Project sponsors may support programs to reduce single occupancy vehicle trips such as telecommuting, ridesharing, alternative work schedules, and parking cash-outs.
- PS62:** Project sponsors may submit projected electricity and natural gas demand calculations to the local electricity or natural gas provider, for any project anticipated to require substantial utility consumption. Any infrastructure improvements necessary for project construction may be completed according to the specifications of the energy provider.
- PS63:** Project sponsors may encourage, to the extent practical and feasible, ensure that new buildings incorporate solar panels in roofing and tap other renewable energy sources to offset new demand on conventional power sources. For example, transit providers may, as feasible, assure that designers of new transit stations incorporate solar panels in roofing.
- PS64:** Project sponsors may encourage energy efficient design for buildings, potentially including strengthening local building codes for new construction and renovation to achieve a higher level of energy efficiency. This may include strengthening local building codes for new construction and renovation to require a higher level of energy efficiency.
- PS65:** Local jurisdictions may seek funding through utility-sponsored programs to conduct energy efficiency “tune-ups” of existing buildings, as practical and feasible, by checking, repairing, and readjusting heating, ventilation, air conditioning, lighting, hot water equipment, insulation and weatherization.
- PS66:** Project sponsors may provide individualized energy management services for large energy users.
- PS67:** Local jurisdictions and project sponsors may encourage the use of energy efficient appliances and office equipment.
- PS68:** Project sponsors may pursue incentives and technical assistance for lighting efficiency.
- PS69:** Local jurisdictions may provide public education and publicity about energy efficiency programs and incentives in cooperation with local utility providers.
- PS70:** If a carbon trading system is established, a lead agency may consider whether carbon offsets would be an appropriate means of project mitigation. The project sponsor could, for example, fund off-site projects

(e.g., alternative energy projects) that will reduce carbon emissions, or could purchase “credits” from another entity that will fund such projects. The lead agency may ensure that any mitigation taking the form of carbon offsets is specifically identified and that such mitigation will in fact occur

PS71: Local jurisdictions may encourage the integration of green building measures into project design and zoning such as those identified in the U.S. Green Building Council’s Leadership in Energy and Environmental Design (LEED), Energy Star Homes, Green Point Rated Homes, and the California Green Builder Program. Energy saving measures for new and remodeled buildings include:

- Using energy efficient materials in building design, construction, rehabilitation, and retrofit
- Encouraging new development to exceed Title 24 energy efficiency requirements
- Developing Cool Communities measures including tree planting and light-colored roofs. These measures focus on reducing ambient heat, which reduces energy consumption related to air conditioning and other cooling equipment.
- Utilizing efficient commercial/residential space and water heaters: This could include the advertisement of existing and/or development of additional incentives for energy efficient appliance purchases to reduce excess energy use and save money. Federal tax incentives are provided online at:
http://www.energystar.gov/index.cfm?c=Productspr_tax_credits
- Encouraging landscaping that requires no additional irrigation: utilizing native, drought tolerant plants can reduce water usage up to 60 percent compared to traditional lawns.
- Encouraging combined heating and cooling (CHP), also known as cogeneration, in all buildings.
- Encouraging neighborhood energy systems, which allow communities to generate their own electricity
- Orienting streets and buildings for best solar access
- Encouraging buildings to obtain at least 20% of their electric load from renewable energy

PS72: Project sponsors may install energy efficient lighting (e.g., light emitting diodes (LEDs)), heating and cooling systems, appliances, equipment, and control systems.

PS73: Project sponsors may use passive solar design, e.g., orient buildings and incorporate landscaping to maximize passive solar heating during cool

seasons, minimize solar heat gain during hot seasons, and enhance natural ventilation.

- PS74:** Project sponsors may design buildings to take advantage of sunlight.
- PS75:** Project sponsors may install light colored “cool” roofs and cool pavements.
- PS76:** Install efficient lighting (including LEDs) for traffic, street and other outdoor lighting.
- PS77:** Project sponsors may reduce unnecessary outdoor lighting.
- PS78:** Project sponsors may use automatic covers, efficient pumps and motors, and solar heating for pools and spas.
- PS79:** Project sponsors may provide education on energy efficiency to residents, customers and/or tenants.
- PS80:** Project sponsors may use paving materials with a Solar Reflective Index (SRI) of at least 29, or open grid paving systems.
- PS81:** Project sponsors may use roofing material with SRI of at least 29 on covered parking (underground, beneath decking or roofs, or beneath a building).
- PS81:** Local jurisdictions may adopt a Heat Island Mitigation Plan that requires cool roofs, cool pavements, and strategically placed shade trees, and actively inspect and enforce state requirements for cool roofs on non-residential re-roofing projects.
- PS82:** Local jurisdictions may pursue policies and programs to improve energy efficiency of existing buildings.
- PS83:** Local jurisdictions may require the performance of energy audits for residential and commercial buildings prior to completion of sale, and that audit results and information about opportunities for energy efficiency improvements be presented to the buyer.
- PS84:** Local jurisdictions may create an outreach and incentive program to promote energy efficiency and conservation in the community, including:
- Launching an “energy efficiency challenge” campaign for community residents;
 - Implementing a low-income weatherization assistance program;
 - Implementing conservation campaigns specifically targeted to residents, and separately to businesses;

- Promoting the purchase of Energy Star® appliances, including, where feasible, incentive grants and vouchers;
- Promoting participation in the local “Green Business” program;
- Distributing free CFL bulbs or other efficiency fixtures to community members;
- Offering exchange programs for high-energy-use items, such as halogen torchiere lamps;
- Adopting an ordinance requiring energy upgrades at time of property sale.

PS85: Project sponsors may install solar, wind, and geothermal power systems and solar hot water heaters.

PS86: Project sponsors may install solar panels on unused roof and ground space and over carports and parking areas.

PS87: Project sponsors may include energy storage where appropriate to optimize renewable energy generation systems and avoid peak energy use.

PS88: Project sponsors may use combined heat and power (CHP) in appropriate applications.

PS89: Local jurisdictions may identify possible sites for production of renewable energy (such as solar, wind, small hydro, and biogas), as compatible with surrounding uses, and protect and promote that use, including:

- Designating suitable sites to prioritize their development for renewable energy generation;
- Evaluating potential land use, environmental, economic, and other constraints on that use, and mitigate such constraints, as feasible;
- Adopting measures to protect the renewable energy use of the sites and their resources, such as utility easements, rights-of-way, and land set-a-sides.

PS90: Local jurisdictions may allow renewable energy projects in areas zoned for open space, where consistent with the Open Space element, and other uses and values.

PS91: Local jurisdictions may promote and require renewable energy generation, and co-generation projects where feasible and appropriate.

PS92: Local jurisdictions may require that new office/retail/commercial or industrial development, or major rehabilitation (e.g., additions of 25,000 square feet commercial, or 100,000 square feet industrial) incorporate

renewable energy generation either on- or off-site to provide 15 percent or more of the project's energy needs.

- PS92:** Local jurisdictions may promote and encourage cogeneration projects for commercial and industrial facilities, provided they meet all applicable air quality standards and provide a net reduction in GHG emissions associated with energy production.
- PS93:** Local jurisdictions may require that, where feasible, all new buildings be constructed to allow for easy, cost-effective installation of solar energy systems in the future, using such "solar-ready" features as:
- Designing the building to include optimal roof orientation (between 20 to 55 degrees from the horizontal), with sufficient south-sloped roof surface;
 - Clear access without obstructions (chimneys, heating and plumbing vents, etc.) on the south sloped roof;
 - Designing the roof framing to support the addition of solar panels;
 - Installation of electrical conduit to accept solar electric system wiring;
 - Installation of plumbing to support a solar hot water system and provision of space for a solar hot water storage tank.
- PS94:** Local jurisdictions may require that residential projects of 6 units or more participate in the California Energy Commission's New Solar Homes Partnership, which provides rebates to developers who offer solar power in at least 50 percent of new units, or a program with similar provisions.
- PS95:** Local jurisdictions may require that any building constructed in whole or in part with local jurisdiction funds incorporate passive solar design features, such as daylighting and passive solar heating, where feasible.
- PS96:** Local jurisdictions may protect active and passive solar design elements and systems from shading by neighboring structures and trees, as consistent with existing tree shading requirements.
- PS97:** Local jurisdictions may provide, where feasible, creative financing for renewable energy projects, including subsidized or other low-interest loans, and the option to pay for system installation through long-term assessments on individual property tax bills.
- PS98:** Local jurisdictions may pursue partnerships with other governmental entities and with private companies and utilities to establish incentive programs for renewable energy.
- PS99:** Local jurisdictions may establish and maintain a clearinghouse of information on available funding alternatives for renewable energy

projects, rates of return, and other information to support developers and community members interested in pursuing renewable energy projects.

PS100: Local jurisdictions may establish targets for the purchase of renewable energy, in excess of the state Renewable Portfolio Standards, using such mechanisms as green tags or renewable energy certificates.

PS101: Local jurisdictions may evaluate the feasibility and effectiveness of using Community Choice Aggregation as a model for providing renewable energy to meet the community’s electricity needs, including potential partnerships with other jurisdictions.

PS102: Local jurisdictions may prepare and implement a comprehensive plan to improve energy efficiency of municipal facilities, including:

- Conduct energy audits for all municipal facilities;
- Retrofit facilities for energy efficiency where feasible and when remodeling or replacing components, including increased insulation, installing green or reflective roofs and low-emissive window glass;
- Implement an energy tracking and management system;
- Install energy-efficient exit signs, street signs, and traffic lighting;
- Install energy-efficient lighting retrofits and occupancy sensors, and institute a “lights out at night” policy;
- Retrofit heating and cooling systems to optimize efficiency (e.g., replace chillers, boilers, fans, pumps, belts, etc.);
- Install Energy Star® appliances and energy-efficient vending machines;
- Improve efficiency of water pumping and use at municipal facilities, including a schedule to replace or retrofit system components with high-efficiency units (i.e., ultra-low-flow toilets, fixtures, etc.);
- Provide chilled, filtered water at water fountains and taps in lieu of bottled water;
- Install a central irrigation control system and time its operation for off-peak use;
- Adopt an accelerated replacement schedule for energy inefficient systems and components.

PS103: Local jurisdictions may require that any newly constructed, purchased, or leased municipal space meet minimum standards as appropriate, such as:

- Requirements for new commercial buildings to meet LEED criteria established by the U.S. Green Building Council;

- Requirements for new residential buildings to meet criteria of the Energy Star® New Homes Program established by U.S. EPA;
- Incorporation of passive solar design features in new buildings, including daylighting and passive solar heating;
- Retrofitting of existing buildings to meet standards under Title 24 of the California Building Energy Code, or to achieve a higher performance standard as established by the local jurisdiction;
- Retrofitting of existing buildings to decrease heat gain from non-roof impervious surfaces with cool paving, landscaping, and other techniques.
- Training & Support: Local jurisdictions or agencies may ensure that staff receives appropriate training and support to implement objectives and policies to reduce GHG emissions, including:
 - Providing energy efficiency training to design, engineering, building operations, and maintenance staff;
 - Providing information on energy use and management, including data from the tracking and management system, to managers and others making decisions that influence energy use;
 - Providing energy design review services to departments undertaking new construction or renovation projects, to facilitate compliance with LEED standards.

PS104: Local jurisdictions may collaborate with local energy suppliers and distributors to establish energy conservation programs, Energy Star® appliance change-out programs, rebates, vouchers, and other incentives to install energy-efficient technology and products and to cooperate on advertising.

TRANSPORTATION, TRAFFIC & SECURITY

TR-1: Project-specific workshops on Sustainability Planning and Development may be held by local agencies.

TR-2: Transit operators may incorporate ITS technologies as part of their security and emergency preparedness and share that information with other operators. Aside from deploying ITS technologies for advanced customer information, transit agencies may work intensely with ethnic, local and disenfranchised communities through public information/outreach sessions ensuring public participation is utilized to its fullest. In case of evacuation, these transit dependent persons may need additional assistance to evacuate to safety.

- TR3:** Local jurisdictions may institute teleconferencing, telecommute and/or flexible work hour programs to reduce unnecessary employee transportation.
- TR4:** Local jurisdictions may create a ride-sharing program, including promoting existing ride sharing programs e.g., by designating a certain percentage of parking spaces for ride sharing vehicles, designating adequate passenger loading and unloading for ride sharing vehicles, and providing a web site or message board for coordinating rides.
- TR5:** Local jurisdictions may create or accommodate car sharing programs, e.g., provide parking spaces for car share vehicles at convenient locations accessible by public transportation.
- TR6:** Local jurisdictions may provide a vanpool for employees for commute trips.
- TR7:** Transportation Planning: Local jurisdictions may encourage that new developments incorporate both local and regional transit measures into the project design that promote the use of alternative modes of transportation.
- TR8:** As may be appropriate, project sponsors may submit fair share traffic payments to the local agency for funding capital improvement projects to accommodate future traffic demand in the area.
- TR9:** Local jurisdictions may coordinate controlled intersections so that traffic passes more efficiently through congested areas. Where traffic signals or streetlights are installed, may require the use of Light Emitting Diode (LED) technology.
- TR10:** Local jurisdictions may promote ride sharing programs e.g., by designating a certain percentage of parking spaces for high-occupancy vehicles, providing larger parking spaces to accommodate vans used for ride-sharing, and designating adequate passenger loading and unloading and waiting areas.
- TR11:** Local jurisdictions may encourage the use of car-sharing programs such as ZipCar. Accommodations for such programs include providing parking spaces for the car-share vehicles at convenient locations accessible by public transportation.
- TR12:** Project sponsors of a commercial use may submit to the Lead Agency (or other appropriate government agency) a Transportation Demand Management (TDM) plan containing strategies to reduce on-site parking demand and single occupancy vehicle travel. The sponsor may implement the approved TDM plan. The TDM may include strategies to increase bicycle, pedestrian, transit, and carpools/vanpool use. All four modes of travel may be considered. Strategies to consider include the following:

- Inclusion of additional bicycle parking, shower, and locker facilities that exceed the requirement
- Construction of bike lanes per the prevailing Bicycle Master Plan (or other similar document)
- Signage and striping onsite to encourage bike safety
- Installation of pedestrian safety elements (such as cross walk striping, curb ramps, countdown signals, bulb outs, etc.) to encourage convenient crossing at arterials
- Installation of amenities such as lighting, street trees, trash and any applicable streetscape plan.
- Direct transit sales or subsidized transit passes
- Guaranteed ride home program
- Pre-tax commuter benefits (checks)
- On-site car-sharing program (such as City Car Share, Zip Car, etc.)
- On-site carpooling program
- Distribution of information concerning alternative transportation options
- Parking spaces sold/leased separately
- Parking management strategies; including attendant/valet parking and shared parking spaces

TR13: Project sponsors and construction contractors may meet with the appropriate Lead Agency (or other government agency) to determine traffic management strategies to reduce, to the maximum extent feasible, traffic congestion and the effects of parking demand by construction workers during construction of this project and other nearby projects that could be simultaneously under construction. The project sponsor may develop a construction management plan for review and approval by the Lead Agency (or other government agency as appropriate). The plan may include at least the following items and requirements:

- A set of comprehensive traffic control measures, including scheduling of major truck trips and deliveries to avoid peak traffic hours, detour signs if required, lane closure procedures, signs, cones for drivers, and designated construction access routes.
- Notification procedures for adjacent property owners and public safety personnel regarding when major deliveries, detours, and lane closures will occur.
- Location of construction staging areas for materials, equipment, and vehicles at an approved location.

- A process for responding to, and tracking, complaints pertaining to construction activity, including identification of an onsite complaint manager. The manager may determine the cause of the complaints and may take prompt action to correct the problem. The Lead Agency may be informed who the Manager is prior to the issuance of the first permit.
- Provision for accommodation of pedestrian flow.
- As necessary, provision for parking management and spaces for all construction workers to ensure that construction workers do not park in on street spaces.
- Any damage to the street caused by heavy equipment, or as a result of this construction, may be repaired, at the project sponsor's expense, within one week of the occurrence of the damage (or excessive wear), unless further damage/excessive wear may continue; in such case, repair may occur prior to issuance of a final inspection of the building permit. All damage that is a threat to public health or safety may be repaired immediately. The street may be restored to its condition prior to the new construction as established by the Lead Agency (or other appropriate government agency) and/or photo documentation, at the sponsor's expense, before the issuance of a Certificate of Occupancy.
- Any heavy equipment brought to the construction site may be transported by truck, where feasible.
- No materials or equipment may be stored on the traveled roadway at any time.
- Prior to construction, a portable toilet facility and a debris box may be installed on the site, and properly maintained through project completion.
- All equipment may be equipped with mufflers.
- Prior to the end of each work-day during construction, the contractor or contractors may pick up and properly dispose of all litter resulting from or related to the project, whether located on the property, within the public rights-of-way, or properties of adjacent or nearby neighbors.

TR14: Local jurisdictions may encourage the use of public transit systems by enhancing safety and cleanliness on vehicles and in and around stations, providing shuttle service to public transit, offering public transit incentives and providing public education and publicity about public transportation services.

TR15: Local jurisdictions may encourage bicycling and walking by incorporating bicycle lanes into street systems in regional transportation plans, new subdivisions, and large developments, creating bicycle lanes and walking paths directed to the location of schools and other logical points of

destination and provide adequate bicycle parking, and encouraging commercial projects to include facilities on-site to encourage employees to bicycle or walk to work.

TR16: Transit agencies may encourage bicycling to transit facilities by providing additional bicycle parking, locker facilities, and bike lane access to transit facilities when feasible.

TR17: Project sponsors may ensure that prior to construction all necessary local and State road and railroad encroachment permits are obtained. As deemed necessary by the governing jurisdiction, the road encroachment permits may require the contractor to prepare a traffic control plan in accordance with professional engineering standards prior to construction. Traffic control plans may include the following requirements:

- Identification of all roadway locations where special construction techniques (e.g., directional drilling or night construction) would be used to minimize impacts to traffic flow.
- Development of circulation and detour plans to minimize impacts to local street circulation. This may include the use of signing and flagging to guide vehicles through and/or around the construction zone.
- Scheduling of truck trips outside of peak morning and evening commute hours.
- Limiting of lane closures during peak hours to the extent possible.
- Usage of haul routes to minimize truck traffic on local roadways to the extent possible.
- Inclusion of detours for bicycles and pedestrians in all areas potentially affected by project construction.
- Installation of traffic control devices as specified in the California Department of Transportation Manual of Traffic Controls for Construction and Maintenance Work Zones.
- Development and implementation of access plans for highly sensitive land uses such as police and fire stations, transit stations, hospitals, and schools. The access plans would be developed with the facility owner or administrator. To minimize disruption of emergency vehicle access, affected jurisdictions may be asked to identify detours for emergency vehicles, which will then be posted by the contractor. Notify in advance the facility owner or operator of the timing, location, and duration of construction activities and the locations of detours and lane closures.
- Storage of construction materials only in designated areas

- Coordination with local transit agencies for temporary relocation of routes or bus stops in work zones, as necessary.

- TR18:** Local jurisdictions may meet an identified transportation-related benchmark.
- TR19:** Local jurisdictions may adopt a comprehensive parking policy that discourages private vehicle use and encourages the use of alternative transportation.
- TR20:** Project sponsors may build or fund a major transit stop within or near the development.
- TR21:** Local jurisdictions and transit agencies may provide public transit incentives such as free or low-cost monthly transit passes to employees, or free ride areas to residents and customers.
- TR22:** Local jurisdictions and project sponsors may promote “least polluting” ways to connect people and goods to their destinations.
- TR23:** Local jurisdictions and project sponsors may incorporate bicycle lanes, routes and facilities into street systems, new subdivisions, and large developments.
- TR24:** Local jurisdictions may require amenities for non-motorized transportation, such as secure and convenient bicycle parking.
- TR25:** Local jurisdictions may ensure that the project enhances, and does not disrupt or create barriers to, non-motorized transportation.
- TR26:** Local jurisdictions may connect parks and open space through shared pedestrian/bike paths and trails to encourage walking and bicycling.
- TR27:** Local jurisdictions may create bicycle lanes and walking paths directed to the location of schools, parks and other destination points.
- TR28:** Local jurisdictions may work with the school districts to improve pedestrian and bike access to schools and to restore or expand school bus service using lower-emitting vehicles.
- TR29:** Local jurisdictions and transit agencies may provide information on alternative transportation options for consumers, residents, tenants and employees to reduce transportation-related emissions.
- TR30:** Local jurisdictions may educate consumers, residents, tenants and the public about options for reducing motor vehicle-related greenhouse gas emissions. Include information on trip reduction; trip linking; vehicle performance and efficiency (e.g., keeping tires inflated); and low-, and/or near zero- and/or zero-emission vehicles.

-
- TR31:** Local jurisdictions may purchase, or create incentives for purchasing, low- and/or near zero- and/or zero-emission vehicles.
- TR32:** Local jurisdictions may create local “light vehicle” networks, such as neighborhood electric vehicle systems.
- TR33:** Local jurisdictions may enforce and follow limits idling time for commercial vehicles, including delivery and construction vehicles.
- TR34:** Local jurisdictions may provide the necessary facilities and infrastructure to encourage the use of low-, and/or near zero- and/or zero-emission vehicles.
- TR35:** Local jurisdictions may reduce GHG emissions by reducing vehicle miles traveled and by increasing or encouraging the use of alternative fuels and transportation technologies.
- TR36:** Local jurisdictions may reduce VMT-related emissions by encouraging the use of public transit through adoption of new development standards that would require improvements to the transit system and infrastructure, increase safety and accessibility, and provide other incentives.
- TR37:** Project Selection: Local jurisdictions may give priority to transportation projects that would contribute to a reduction in vehicle miles traveled per capita, while maintaining economic vitality and sustainability.
- TR38:** Equal Pedestrian Access Local jurisdictions may include separated sidewalks whenever possible, on both sides of all new street improvement projects, except where there are severe topographic or natural resource constraints.
- TR39:** Public Involvement: Local jurisdictions may carry out a comprehensive public involvement and input process that provides information about transportation issues, projects, and processes to community members and other stakeholders, especially to those traditionally underserved by transportation services.
- TR40:** System Interconnectivity: Local jurisdictions may create an interconnected transportation system that allows a shift in travel from private passenger vehicles to alternative modes, including public transit, ride sharing, car sharing, bicycling and walking, by incorporating the following:
- Ensuring transportation centers are multi-modal to allow transportation modes to intersect;
 - Providing adequate and affordable public transportation choices, including expanded bus routes and service, as well as other transit choices such as shuttles, light rail, and rail;

- To the extent feasible, extending service and hours of operation to underserved arterials and population centers or destinations such as colleges;
- Focusing transit resources on high-volume corridors and high-boarding destinations such as colleges, employment centers and regional destinations;
- Coordinating schedules and routes across service lines with neighboring transit authorities;
- Supporting programs to provide “station cars” for short trips to and from transit nodes (e.g., neighborhood electric vehicles);
- Studying the feasibility of providing free transit to areas with residential densities of 15 dwelling units per acre or more, including options such as removing service from less dense, underutilized areas to do so;
- Employing transit-preferential measures, such as signal priority and bypass lanes. Where compatible with adjacent land use designations, right-of-way acquisition or parking removal may occur to accommodate transit-preferential measures or improve access to transit. The use of access management may be considered where needed to reduce conflicts between transit vehicles and other vehicles;
- Providing safe and convenient access for pedestrians and bicyclists to, across, and along major transit priority streets;
- Using park-and-ride facilities to access transit stations only at ends of regional transitways or where adequate feeder bus service is not feasible.

TR41: Transit System Infrastructure: Local jurisdictions may upgrade and maintain transit system infrastructure to enhance public use, including:

- Ensuring transit stops and bus lanes are safe, convenient, clean and efficient;
- Ensuring transit stops have clearly marked street-level designation, and are accessible;
- Ensuring transit stops are safe, sheltered, benches are clean, and lighting is adequate;
- Placing transit stations along transit corridors within mixed-use or transit-oriented development areas at intervals of three to four blocks, or no less than one-half mile.

TR42: Customer Service: Transit agencies may enhance customer service and system ease-of-use, including:

- Developing a Regional Pass system to reduce the number of different passes and tickets required of system users;
- Implementing “Smart Bus” technology, using GPS and electronic displays at transit stops to provide customers with “real-time” arrival and departure time information (and to allow the system operator to respond more quickly and effectively to disruptions in service);
- Investigating the feasibility of an on-line trip-planning program.

TR43: Transit Funding: Local jurisdictions may prioritize transportation funding to support a shift from private passenger vehicles to transit and other modes of transportation, including:

- Give funding preference to improvements in public transit over other new infrastructure for private automobile traffic;
- Before funding transportation improvements that increase roadway capacity and VMT, evaluate the feasibility and effectiveness of funding projects that support alternative modes of transportation and reduce VMT, including transit, and bicycle and pedestrian access.

TR44: Transit and Multimodal Impact Fees: Local jurisdictions may consider the use of transit and multimodal impact fees on new developments to fund public transportation infrastructure, bicycle infrastructure, pedestrian infrastructure and other multimodal accommodations.

TR45: Local jurisdictions may implement traffic and roadway management strategies to improve mobility and efficiency, and reduce associated emissions.

TR46: System Monitoring: Local jurisdictions may monitor traffic and congestion to determine when and where new transportation facilities are needed in order to increase access and efficiency.

TR47: Arterial Traffic Management: Local jurisdictions may modify arterial roadways to allow more efficient bus operation, including bus lanes and signal priority/preemption where necessary.

TR48: Signal Synchronization: Local jurisdictions may expand signal timing programs where emissions reduction benefits can be demonstrated, including maintenance of the synchronization system, and coordination with adjoining jurisdictions as needed to optimize transit operation while maintaining a free flow of traffic.

TR49: HOV Lanes: Local jurisdictions may encourage the construction of high-occupancy vehicle (HOV) lanes or similar mechanisms whenever necessary to relieve congestion and reduce emissions.

- TR50:** Delivery Schedules: Where operationally feasible, local jurisdictions may establish ordinances or land use permit conditions limiting the hours when deliveries can be made to off-peak hours in high traffic areas.
- TR51:** Local jurisdictions may reduce VMT related-emissions by implementing and supporting trip reduction programs.
- TR52:** Ride-Share Programs: Local jurisdictions may promote ride-sharing programs, including:
- Designate a certain percentage of parking spaces for ride-sharing vehicles;
 - Designate adequate passenger loading, unloading, and waiting areas for ride-sharing vehicles;
 - Provide a web site or message board for coordinating shared rides;
 - Encourage private, for-profit community car-sharing, including parking spaces for car share vehicles at convenient locations accessible by public transit;
 - Hire or designate a rideshare coordinator to develop and implement ridesharing programs.
- TR53:** Employer-based Trip Reduction: Local jurisdictions may support voluntary, employer-based trip reduction programs, including:
- Provide assistance to regional and local ridesharing organizations;
 - Advocate for legislation to maintain and expand incentives for employer ridesharing programs;
 - Require the development of Transportation Management Associations for large employers and commercial/ industrial complexes;
 - Provide public recognition of effective programs through awards, top ten lists, and other mechanisms.
- TR54:** Ride Home Programs: Local jurisdictions may implement a “guaranteed ride home” program for those who commute by public transit, ride-sharing, or other modes of transportation, and encourage employers to subscribe to or support the program.
- TR55:** Local Area Shuttles: Transit agencies may encourage and utilize shuttles to serve neighborhoods, employment centers and major destinations.
- TR56:** Local jurisdictions and transit agencies may create a free or low-cost local area shuttle system that includes a fixed route to popular tourist destinations or shopping and business centers.

- TR57:** Local jurisdictions may work with existing shuttle service providers to coordinate their services.
- TR58:** Low- and No-Travel Employment Opportunities: Local jurisdictions may facilitate employment opportunities that minimize the need for private vehicle trips, including:
- Amend zoning ordinances and the Development Code to include live/work sites and satellite work centers in appropriate locations;
 - Encourage telecommuting options with new and existing employers, through project review and incentives, as appropriate.
- TR59:** Local jurisdictions may support bicycle use as a mode of transportation by enhancing infrastructure to accommodate bicycles and riders, and providing incentives.
- TR60:** Development Standards for Bicycles: Local jurisdictions may establish standards for new development and redevelopment projects to support bicycle use, including:
- Amending the Development Code to include standards for safe pedestrian and bicyclist accommodations, by incorporating the following:
 - “Complete Streets” policies that foster equal access by all users in the roadway design;
 - Bicycle and pedestrian access internally and in connection to other areas through easements;
 - Safe access to public transportation and other non-motorized uses through construction of dedicated paths;
 - Safe road crossings at major intersections, especially for school children and seniors;
 - Adequate, convenient and secure bike parking at public and private facilities and destinations in all urban areas;
 - Street standards may include provisions for bicycle parking within the public right of way.
- TR61:** Local jurisdictions may require new development and redevelopment projects to include bicycle facilities, as appropriate with the new land use, including:
- Construction of weatherproof bicycle facilities where feasible, and at a minimum, bicycle racks or covered, secure parking near the building entrances;
 - Provision and maintenance of changing rooms, lockers, and showers at large employers or employment centers.

- Prohibit projects that impede bicycle and pedestrian access, such as large parking areas that cannot be safely crossed by non-motorized vehicles, and developments that block through access on existing or potential bicycle and pedestrian routes;
- Encourage the development of bicycle stations at intermodal hubs, with attended or “valet” bicycle parking, and other amenities such as bicycle rental and repair, and changing areas with lockers and showers;
- Conduct a connectivity analysis of the existing bikeway network to identify gaps, and prioritize bikeway development where gaps exist.

TR62: Bicycle and Pedestrian Trails: Local jurisdictions may establish a network of multi-use trails to facilitate safe and direct off-street bicycle and pedestrian travel, and provide bike racks along these trails at secure, lighted locations

TR63: Bicycle Safety Program: Local jurisdictions may develop and implement a bicycle safety educational program to teach drivers and riders the laws, riding protocols, routes, safety tips, and emergency maneuvers.

TR64: Bicycle and Pedestrian Project Funding: Local jurisdictions may pursue and provide enhanced funding for bicycle and pedestrian facilities and access projects, including, as appropriate:

- Apply for regional, State, and federal grants for bicycle and pedestrian infrastructure projects;
- Establish development exactions and impact fees to fund bicycle and pedestrian facilities;
- Use existing revenues, such as State gas tax subventions, sales tax funds, and general fund monies for projects to enhance bicycle use and walking for transportation.

TR65: Bicycle Parking: Local jurisdictions may adopt bicycle parking standards that ensure bicycle parking sufficient to accommodate five to 10 percent of projected use at all public and commercial facilities, and at a rate of at least one per residential unit in multiple-family developments (suggestion: check language with League of American Bicyclists).

TR66: Local jurisdictions may establish parking policies and requirements that capture the true cost of private vehicle use and support alternative modes of transportation.

TR67: Parking Policy: Local jurisdictions may adopt a comprehensive parking policy to discourage private vehicle use and encourage the use of alternative transportation by incorporating the following:

- Reduce the available parking spaces for private vehicles while increasing parking spaces for shared vehicles, bicycles, and other alternative modes of transportation;
- Eliminate or reduce minimum parking requirements for new buildings;
- “Unbundle” parking (require that parking is paid for separately and is not included in the base rent for residential and commercial space);
- Use parking pricing to discourage private vehicle use, especially at peak times;
- Create parking benefit districts, which invest meter revenues in pedestrian infrastructure and other public amenities;
- Establish performance pricing of street parking, so that it is expensive enough to promote frequent turnover and keep 15 percent of spaces empty at all times;
- Encourage shared parking programs in mixed-use and transit-oriented development areas.

TR68: Event Parking Policies: Local jurisdictions may establish policies and programs to reduce onsite parking demand and promote ride-sharing and public transit at large events, including:

- Promote the use of peripheral parking by increasing on-site parking rates and offering reduced rates for peripheral parking;
- Encourage special event center operators to advertise and offer discounted transit passes with event tickets;
- Encourage special event center operators to advertise and offer discount parking incentives to carpooling patrons, with four or more persons per vehicle for on-site parking;
- Promote the use of bicycles by providing space for the operation of valet bicycle parking service.

TR69: Parking “Cash-out” Program: Local jurisdictions may require new office developments with more than 50 employees to offer a Parking “Cash-out” Program to discourage private vehicle use.

TR70: Electric/Alternative Fuel Vehicle Parking: Local jurisdictions may require new commercial and retail developments to provide prioritized parking for electric vehicles and vehicles using alternative fuels.

TR71: Local jurisdictions may support and promote the use of low-, and/or near zero- and/or zero-emission vehicles, and alternative fuels, and other measures to directly reduce emissions from motor vehicles.

- TR72:** Low-, and/or near zero and/or Zero Emission Vehicles: Local jurisdictions may support and promote the use of low-, and/or near zero- and/or zero-emission vehicles, by doing the following:
- Develop the necessary infrastructure to encourage the use of low-, and/or near zero- and/or zero-emission vehicles and clean alternative fuels, such as development of electric vehicle charging facilities and conveniently located alternative fueling stations;
 - Encourage new construction to include vehicle access to properly wired outdoor receptacles to accommodate ZEV and/or plug in electric hybrids (PHEV);
 - Encourage transportation fleet standards to achieve the lowest emissions possible, using a mix of alternate fuels, PZEV or better fleet mixes;
 - Establish incentives, as appropriate, to taxicab owners to use alternative fuel or gas-electric hybrid vehicles.
- TR73:** Vehicle Idling: Local jurisdictions may enforce State idling laws for commercial vehicles, including delivery and construction vehicles.
- TR74:** Pedestrian and Bicycle Promotion: Local jurisdictions may work with local community groups and downtown business associations to organize and publicize walking tours and bicycle events, and to encourage pedestrian and bicycle modes of transportation.
- TR75:** Local jurisdictions may organize events and workshops to promote GHG-reducing activities.
- TR76:** Fleet Replacement: Local jurisdictions and agencies may establish a replacement policy and schedule to replace fleet vehicles and equipment with the most fuel efficient vehicles practical, including gasoline hybrid and alternative fuel or electric models.
- TR77:** Local jurisdictions may implement measures to reduce employee vehicle trips and to mitigate emissions impacts from municipal travel.
- TR78:** Trip Reduction Program: Local jurisdictions may implement a program to reduce vehicle trips by employees, including:
- Providing incentives and infrastructure for vanpooling and carpooling, such as pool vehicles, preferred parking, and a website or bulletin board to facilitate ride-sharing;
 - Providing subsidized passes for mass transit;
 - Offering compressed work hours, off-peak work hours, and telecommuting, where appropriate;

- Offer a guaranteed ride home for employees who use alternative modes of transportation to commute.

TR79: Bicycle Transportation Support: Local jurisdictions may promote and support the use of bicycles as transportation, including:

- Providing bicycle stations with secure, covered parking, changing areas with storage lockers and showers, as well as a central facility where minor repairs can be made;
- Providing bicycles, including electric bikes, for employees to use for short trips during business hours;
- Implementing a police-on-bicycles program;
- Providing a bicycle safety program, and information about safe routes to work.

TR80: Municipal Parking Management: Local jurisdictions may implement a Parking Management Program to discourage private vehicle use, including:

- Encouraging carpools and vanpools with preferential parking and a reduced parking fee;
- Institute a parking cash-out program;
- Renegotiate employee contracts, where possible, to eliminate parking subsidies;
- Install on-street parking meters with fee structures designed to discourage private vehicle use;
- Establish a parking fee for all single-occupant vehicles.

TR81: Travel Mitigation: Local jurisdictions may mitigate business-related travel, especially air travel, through the annual purchase of verified carbon offsets.

TR82: Transit Access to Municipal Facilities: Local jurisdiction and agency facilities may be located on major transit corridors, unless their use is plainly incompatible with other uses located along major transit corridors.

TR83: Local jurisdictions and development project sponsors may and are encouraged to coordinate and consult early with the Caltrans District Planning offices of Local Development Intergovernmental Review on any land use proposal that would be located within 500 feet of state transportation facilities to enable consideration of the site specific access and operational safety impacts.

WATER RESOURCES

- W1:** Local jurisdictions may encourage new development and industry to locate in those service areas with existing wastewater infrastructure and treatment capacity, making greater use of those facilities prior to incurring new infrastructure costs.
- W2:** Local jurisdictions may promote reduced wastewater system demand by: designing wastewater systems to minimize inflow and increase upstream treatment and infiltration to the extent feasible, reducing overall source water generation by domestic and industrial users, deferring development approvals for industries that generate high volumes of wastewater until wastewater agencies have expanded capacity.
- W3:** Wastewater treatment agencies are encouraged to have expansion plans, approvals and financing in place once their facilities are operating at 80 percent of capacity.
- W4:** Project sponsors may coordinate with the local wastewater provider in order to ensure that existing and/or planned sewer conveyance and treatment facilities are capable of meeting wastewater flow capacity requirements. Each project sponsor may identify specific on- and off-site improvements needed to ensure that impacts related to wastewater conveyance capacity are addressed prior to issuance of plans. Sewer capacity clearance from the local wastewater provider may be required at the time that a sewer connection permit application is submitted.
- W5:** As appropriate, confirmation of the capacity of the surrounding stormwater and sanitary sewer system and state of repair may be completed by a qualified civil engineer with funding from the project sponsor. The project sponsor may be responsible for the necessary stormwater and sanitary sewer infrastructure improvements to accommodate the proposed project. In addition, the sponsor may be required to pay any fees to improve sanitary sewer infrastructure as may be required by the applicable local agencies. Improvements to the existing sanitary sewer collection system may specifically include, but are not limited to, mechanisms to control or minimize increases in infiltration/inflow to offset sanitary sewer increases associated with the proposed project. To the maximum extent practicable, the sponsor may be required to implement Best Management Practices to reduce the peak stormwater runoff from the project site. Additionally, the project sponsor may be responsible for payment of any required installation or hook-up fees to the affected service providers.
- W6:** Wastewater treatment agencies may maximize efficiency of wastewater treatment and pumping equipment.

- W7:** Project sponsors with projects requiring the discharge of dredged or fill materials into U.S. waters, including wetlands, may comply with sections 404 and 401 of the Clean Water Act including the requirement to obtain a permit from the U.S. Army Corps of Engineers and the governing Regional Water Quality Control Board.
- W8:** Project sponsor may ensure that natural riparian conditions near projects are maintained, wherever feasible, to minimize the effects of stormwater flows at stream crossings. Where feasible, riparian areas may be restored or expanded to mitigate additional impervious surface and associated runoff.
- W9:** Prior to construction within the vicinity of a watercourse, the project sponsor may obtain all necessary regulatory permits and authorizations from the U.S. Army Corps of Engineers (Corps), Regional Water Quality Control Board (RWQCB), California Department of Fish and Game, California Coastal Commission, and local jurisdictions, and may comply with all conditions issued by applicable agencies. Required permit approvals and certifications may include, but not be limited to the following:
- U.S. Army Corps of Engineers (Corps): Section 404. Permit approval from the Corps may be obtained for the placement of dredge or fill material in Waters of the U.S., if any, within the interior of the project site, pursuant to Section 404 of the federal Clean Water Act.
 - Regional Water Quality Control Board (RWQCB): Section 401 Water Quality Certification. Certification that the project will not violate state water quality standards is required before the Corps can issue a 404 permit, above.
 - California Department of Fish and Game (CDFG): Section 1602 Lake and Streambed Alteration Agreement. Work that will alter the bed or bank of a stream requires authorization from CDFG.
- A qualified environmental consultant may be retained and paid for by the project sponsor to make site visits as necessary; and as a follow-up, submit to the Lead Agency a letter certifying that all required conditions have been instituted during the grading activities.
- W10:** Prior to issuance of a demolition, grading, or building permit within vicinity of a watercourse project sponsors may develop a final detailed landscaping and irrigation plan for review and approval by the appropriate local jurisdiction prepared by a licensed landscape architect or other qualified person. Such a plan may include a planting schedule, detailing plant types and locations, and a system for temporary irrigation of plantings.

- Plant and maintain only drought-tolerant plants on the site where appropriate, as well as native and riparian plants in and adjacent to riparian corridors. Along the riparian corridor, native plants may not be disturbed to the maximum extent feasible. Any areas disturbed along the riparian corridor may be replanted with mature native riparian vegetation and be maintained to ensure survival.
- All landscaping indicated on the approved landscape plan may be installed prior to the issuance of a Final inspection of the building permit, otherwise permitted.

All landscaping areas shown on the approved plans may be maintained in neat and safe conditions, and all plants may be maintained in good growing condition and, whenever necessary replaced with new plant materials to ensure continued compliance with all applicable landscaping requirements. All paving or impervious surfaces may occur only on approved areas.

W11: Project sponsors may comply with the State-wide construction storm water discharge permit requirements including preparation of Storm Water Pollution Prevention Plans for transportation improvement construction projects. Roadway construction projects may comply with the Caltrans storm water discharge permit. Best Management Practices may be identified and implemented to manage site erosion, wash water runoff, and spill control.

W12: Project sponsors may comply with the requirements of the National Pollutant Discharge Elimination System (NPDES) to address stormwater runoff. Detailed examples of potential mitigation activities that may be required by the Lead Agency are described below.

Project sponsors may submit with the application for a building permit (or other construction-related permit) a completed Construction-Permit-Phase Stormwater Supplemental Form. The project drawings submitted for the building permit (or other construction-related permit) may contain a stormwater management plan, for review and approval by the appropriate agency, to manage stormwater run-off and to limit the discharge of pollutants in stormwater after construction of the project to the maximum extent practicable. The post-construction stormwater management plan may include and identify the following:

- All proposed impervious surface on the site;
- Anticipated directional flows of on-site stormwater runoff; and
- Site design measures to reduce the amount of impervious surface area and directly connected impervious surfaces; and
- Source control measures to limit the potential for stormwater pollution;

- Stormwater treatment measures to remove pollutants from stormwater runoff; and
- Hydromodification management measures so that post-project stormwater runoff does not exceed the flow and duration of pre-project runoff, if required under the NPDES permit.

The following additional information may be submitted with the post-construction stormwater management plan:

- Detailed hydraulic sizing calculations for each stormwater treatment measure proposed; and
- Pollutant removal information demonstrating that any proposed manufactured/mechanical (i.e., non-landscape-based) stormwater treatment measure, when not used in combination with a landscape-based treatment measure, is capable of removing the range of pollutants typically removed by landscape-based treatment measures and/or the range of pollutants expected to be generated by the project.

All proposed stormwater treatment measures may incorporate appropriate planting materials for stormwater treatment (for landscape-based treatment measures) and may be designed with considerations for vector/mosquito control. Proposed planting materials for all proposed landscape-based stormwater treatment measures may be included on the landscape and irrigation plan for the project. The sponsor is not required to include on-site stormwater treatment measures in the post-construction stormwater management plan if he or she secures approval from an appropriate agency that an alternate approach is appropriate. The project sponsor may implement the approved stormwater management plan.

- W13:** Project sponsors may consult with the RWQCB and Storm Water Management Plan permit holders as projects are designed to ensure that projects protect the goals of the Clean Water Act and comply with federal storm water NPDES permits.
- W14:** Project sponsors may ensure that new facilities include structural water quality control features such as drainage channels, detention basins, oil and grease traps, filter systems, and vegetated buffers to prevent pollution of adjacent water resources by polluted runoff where required by applicable urban storm water runoff discharge permits.
- W15:** Structural storm water runoff treatment may be provided according to the applicable urban storm water runoff permit where facilities will be operated by a permitted municipality or county. Where Caltrans is the operator, the statewide permit applies.
- W16:** Project sponsors may ensure that operational best management practices for street cleaning, litter control, and catch basin cleaning are implemented to prevent water quality degradation in compliance with applicable storm

water runoff discharge permits. Efforts may be made to assure treatment controls are in place as early as possible, such as during the acquisition process for rights-of-way, not just later during the facilities design and construction phase.

- W17:** In compliance with applicable municipal separate storm sewer system discharge permits as well as Caltrans' storm water discharge permit, long-term sediment control may be affected through erosion control and revegetation programs designed to allow reestablishment of native vegetation on slopes and undeveloped areas.
- W18:** Drainage of roadway runoff may comply with Caltrans' storm water discharge permit. Wherever possible, roadways may be designed to convey storm water through vegetated median strips that provide detention capacity and allow for infiltration before reaching culverts.
- W19:** Treatment and control features such as detention basins, infiltration strips, and porous paving, other features to control surface runoff and facilitate groundwater recharge may be incorporated into the design of new transportation projects early on in the process to ensure that adequate acreage and elevation contours are provided during the right-of-way acquisition process.
- W20:** Project sponsors may assure projects mitigate for changes to the volume of runoff, where any downstream receiving water body has not been designed and maintained to accommodate the increase in flow velocity, rate, and volume without impacting the water's beneficial uses. Pre-project flow velocities, rates, and volumes must not be exceeded. This applies not only to increases in storm water runoff from the project site, but also to hydrologic changes induced by flood plain encroachment. Projects may not cause or contribute to conditions that degrade the physical integrity or ecological function of any downstream receiving waters.
- W21:** Impacts may be reduced to the extent possible by providing culverts and facilities that do not increase the flow velocity, rate, or volume and/or acquiring sufficient storm drain easements that accommodate an appropriately vegetated earthen drainage channel.
- W22:** Project sponsors of improvement projects on existing facilities may include upgrades to stormwater drainage facilities to accommodate any increased runoff volumes. These upgrades may include the construction of detention basins or structures that will delay peak flows and reduce flow velocities, including expansion and restoration of wetlands and riparian buffer areas. System designs may be completed to eliminate increases in peak flow rates from current levels.

W23: Local jurisdictions may encourage Low Impact Development and incorporation of natural spaces that reduce, treat, infiltrate and manage stormwater runoff flows in all new developments, where practical and feasible.

W24: Project sponsor may ensure that for sites less than one acre, project drawings submitted for a building permit (or other construction-related permit) contain a final site plan to be reviewed and approved by the appropriate local agency. The final site plan may incorporate appropriate site design measures to manage stormwater runoff and minimize impacts to water quality after the construction of the project. These measures may include, but are not limited to, the following:

- Minimize impervious surfaces, especially directly connected impervious surfaces;
- Utilize permeable paving in place of impervious paving where appropriate;
- Cluster buildings;
- Preserve quality open space; and
- Establish vegetated buffer areas.

The approved plan may be implemented and the site design measures shown on the plan may be permanently maintained.

W25: Project sponsors may implement BMPs to reduce erosion, sedimentation, and water quality impacts during construction to the maximum extent practicable. Plans demonstrating BMPs may be submitted for review and approval by the Lead Agency. At a minimum, the project sponsor may provide filter materials deemed acceptable to the Lead Agency at nearby catch basins to prevent any debris and dirt from flowing into the local storm drain system and creeks.

W26: Project sponsors for sites over one acre, may obtain coverage under the General Construction Activity Storm Water Permit (General Construction Permit) issued by the State Water Resources Control Board (SWRCB). The project sponsor may file a notice of intent (NOI) with the SWRCB. The project sponsor may be required to prepare a stormwater pollution prevention plan (SWPPP) and submit the plan for review and approval by the Lead Agency. At a minimum, the SWPPP may include a description of construction materials, practices, and equipment storage and maintenance; a list of pollutants likely to contact stormwater; site-specific erosion and sedimentation control practices; a list of provisions to eliminate or reduce discharge of materials to stormwater; BMPs, and an inspection and monitoring program. Prior to the issuance of any construction-related permits, the project sponsor may submit to the lead

agency a copy of the SWPPP and evidence of submittal of the NOI to the SWRCB. Implementation of the SWPPP may start with the commencement of construction and continue through the completion of the project. After construction is completed, the project sponsor may submit a notice of termination to the SWRCB.

W27: Project sponsors may ensure that project drawings submitted for a building permit (or other construction-related permit) contain a drainage plan to be reviewed and approved by the appropriate agency. The drainage plan may include measures to reduce the post-construction volume and velocity of stormwater runoff to the maximum extent practicable. Stormwater runoff may not be augmented to adjacent properties or creeks. The drainage plan may include and identify the following:

- All proposed impervious surface on the site;
- Anticipated directional flows of on-site stormwater runoff;
- Site design measures to reduce the amount of impervious surface area and directly connected impervious surfaces;
- Source control measures to limit the potential for stormwater pollution; and
- Stormwater treatment measures to remove pollutants from stormwater runoff.

W28: Project sponsors may submit an erosion and sedimentation control plan for review and approval by the appropriate government agency. All work may incorporate all applicable BMPs for the construction industry, including BMP's for dust, erosion and water quality. The measures may include, but are not limited to, the following:

- On sloped properties, the downhill end of the construction area must be protected with silt fencing (such as sandbags, filter fabric, silt curtains, etc.) and hay bales oriented parallel to the contours of the slope (at a constant elevation) to prevent erosion into the street, gutters, stormdrains.
- In accordance with an approved erosion control plan, the project sponsor may implement mechanical and vegetative measures to reduce erosion and sedimentation, including appropriate seasonal maintenance. One hundred (100) percent degradable erosion control fabric may be installed on all graded slopes to protect and stabilize the slopes during construction and before permanent vegetation gets established. All graded areas may be temporarily protected from erosion by seeding with fast growing annual species. All bare slopes may be covered with staked tarps when rain is occurring or is expected.

- Minimize the removal of natural vegetation or ground cover from the site in order to minimize the potential for erosion and sedimentation problems. Maximize the replanting of the area with native vegetation as soon as possible.
- Install filter materials acceptable to the appropriate agency at the storm drain inlets nearest to the project site prior to the start of the wet weather season (October 15); site dewatering activities; street washing activities; saw cutting asphalt or concrete; and in order to retain any debris flowing into the storm drain system. Filter materials may be maintained and/or replaced as necessary to ensure effectiveness and prevent street flooding.
- Ensure that concrete/granite supply trucks or concrete/plaster finishing operations do not discharge wash water into water courses, street gutters, or storm drains.
- Direct and locate tool and equipment cleaning so that wash water does not discharge into the street, gutters, or stormdrains.
- Create a contained and covered area on the site for storage of bags of cement, paints, flammables, oils, fertilizers, pesticides, or any other materials used on the project site that have the potential for being discharged to the storm drain system by the wind or in the event of a material spill. No hazardous waste material may be stored on-site.
- Gather all construction debris on a regular basis and place them in a dumpster or other container which is emptied or removed on a weekly (or other interval approved by the Lead Agency) basis. When appropriate, use tarps on the ground to collect fallen debris or splatters that could contribute to stormwater pollution.
- Remove all dirt, gravel, refuse, and green waste from the sidewalk, street pavement, and storm drain system adjoining the project site. During wet weather, avoid driving vehicles off paved areas and other outdoor work.
- As appropriate, broom sweep the street pavement adjoining the project site on a daily basis. Caked-on mud or dirt may be scraped from these areas before sweeping. At the end of each workday, the entire site may be cleaned and secured against potential erosion, dumping, or discharge to the street, gutter, and/or stormdrains.
- All erosion and sedimentation control measures implemented during construction activities, as well as construction site and materials management may be in strict accordance with the control standards listed in the latest edition of the Erosion and Sediment Control Field Manual published by the RWQB.

All erosion and sedimentation control measures may be monitored regularly by the project sponsor. If measures are insufficient to control

sedimentation and erosion then the project sponsor may develop and implement additional and more effective measures immediately.

- W29:** Project sponsors may ensure that projects requiring continual dewatering facilities implement monitoring systems and long-term administrative procedures to ensure proper water management that prevents degrading of surface water and minimizes, to the greatest extent possible, adverse impacts on groundwater for the life of the project. Construction designs may comply with appropriate building codes and standard practices including the Uniform Building Code.
- W30:** Project sponsors, lead agencies, and local jurisdictions may maximize, where practical and feasible, permeable surface area in existing urbanized areas to protect water quality, reduce flooding, allow for groundwater recharge, and preserve wildlife habitat. New impervious surfaces may be minimized to the greatest extent possible, including the use of in-lieu fees and off-site mitigation.
- W31:** Project sponsors may avoid designs that require continual dewatering where feasible.
- W32:** Where feasible, transportation facilities may be sited away from groundwater recharge areas, to prevent conversion of those areas to impervious surface.
- W33:** Project sponsors may reduce hardscape to the extent feasible to facilitate groundwater recharge as appropriate.
- W34:** Project sponsor may ensure that all roadbeds for new highway and rail facilities be elevated at least one foot above the 100-year base flood elevation. Since alluvial fan flooding is not often identified on FEMA flood maps, the risk of alluvial fan flooding may be evaluated and projects may be sited to avoid alluvial fan flooding. Delineation of floodplains and alluvial fan boundaries may attempt to account for future hydrologic changes caused by global climate change.
- W35:** Project sponsors of transportation improvements may comply with local, state, and federal floodplain regulations. Projects requiring federal approval or funding may comply with Executive Order 11988 on Floodplain Management, which requires avoidance of incompatible floodplain development, restoration and preservation of the natural and beneficial floodplain values, and maintenance of consistency with the standards and criteria of the National Flood Insurance Program.
- W36:** Local jurisdictions may, to the extent feasible and appropriate, prevent development in flood hazard areas that do not have appropriate protections, especially in alluvial fan areas of the region.

- W37:** Local water agencies may continue to evaluate future water demands and establish the necessary supply and infrastructure to meet that demand, as documented in their Urban Water Management Plans.
- W38:** Project sponsors, local jurisdictions, and water agencies may include conjunctive use as a water management strategy when feasible.
- W39:** Regional water agencies may consider, to the greatest extent feasible, potential climate change hydrology and attendant impacts on available water supplies and reliability in the process of creating or modifying systems to manage water resources for both year-round use and ecosystem health. As the methodology and base data for such decisions is still developing, agencies may use the best currently available science in decision-making. Local jurisdictions and water agencies may rely on current regional analyses when making local decisions regarding future water supply and reliability.
- W40:** Project sponsors and local jurisdictions may reduce exterior uses of water in public areas, and may promote reductions in private homes and businesses, by shifting to drought-tolerant native landscape plantings, using weather-based irrigation systems, educating other public agencies about water use, and installing related water pricing incentives. Local jurisdictions may also work with local retailers and vendors to promote the availability of drought resistant landscaping options and provide information on where these can be purchased. Use of recycled water especially in median landscaping and hillside landscaping may be implemented where feasible.
- W41:** Project sponsors may coordinate with the local water provider to ensure that existing and/or planned water supply and water conveyance facilities are capable of meeting water demand/pressure requirements. In accordance with State Law, a Water Supply Assessment may be required for projects that meet the size requirements specified in the regulations. In coordination with the local water provider, each project sponsor may identify specific on- and off-site improvements needed to ensure that impacts related to water supply and conveyance demand/pressure requirements are addressed prior to issuance of a certificate of occupancy. Water supply and conveyance demand/pressure clearance from the local water provider may be required at the time that a water connection permit application is submitted.
- W42:** Project sponsors may coordinate with the local fire service provider in order to ensure that existing and/or planned fire hydrants are capable of meeting fire flow demand/pressure requirements. The issuance of building permits may be dependent upon submission, review, approval, and testing of fire flow demand and pressure requirements, as established by the local fire service provider prior to occupancy.

W43: Project sponsors may implement water conservation measures in new development that may include but not be limited to the following:

- Installation of high-efficiency toilets (1.28 gallons per flush or less, includes dual flush.
- High-efficiency urinals (0.125 gallons per flush or less, includes waterless)
- Restroom faucet flow rate of 1.5 gallons per minute or less
- Public restroom faucet flow rate of 0.5 gallons per minute or less and self-closing
- Showerhead flow rate of 2.0 gallons per minute or less
- Limit of one showerhead per shower stall
- High efficiency clothes washers (water factor of 4.0 or less)
- High efficiency dishwashers (Energy Star rated)
- Domestic water heating system located in close proximity to point(s) of use, as feasible; use of tankless and on-demand water heaters as feasible
- Cooling towers must be operated at a minimum of 5.5 cycles of concentration
- Install on-site water recycling as feasible
- Use of recycled water (if available) for appropriate end uses (irrigation, cooling towers, sanitary)
- Single pass cooling may be prohibited (e.g., any vacuum pumps or ice machines)
- Irrigation may include:
 - Weather-based irrigation controller with rain shutoff
 - Flow sensor and master valve shutoff (for large landscaped areas)
 - Matched precipitation (flow) rates for sprinkler heads
 - Drip/microspray/subsurface irrigation where appropriate
 - Minimum irrigation system distribution uniformity of 75%
 - Proper hydro-zoning, turf minimization and use of native/drought tolerant plant materials
 - Use of landscape contouring to minimize precipitation runoff

W44: Project sponsors may consult with the local water provider to identify feasible and reasonable measures to reduce water consumption, including, but not limited to, systems to use recycled water for landscaping, drip

irrigation, re-circulating hot water systems, water conserving landscape techniques (such as mulching, installation of drip irrigation systems, landscape design to group plants of similar water demand, soil moisture sensors, automatic irrigation systems, clustered landscaped areas to maximize the efficiency of the irrigation system), water conserving kitchen and bathroom fixtures and appliances, thermostatically controlled mixing valves for baths and showers, and insulated hot water lines.

- W45:** Project sponsors may incorporate compliance with local drought measures as appropriate including prohibiting hose watering of driveways and associated walkways; requiring decorative fountains to use recycled water, and repairing water leaks in a timely manner.
- W46:** Project sponsors may incorporate automatic sprinkler systems that irrigate landscaping during morning hours or during the evening to reduce water losses from evaporation. Sprinklers may be required to reset to water less often in cooler months and during the rainfall season, so that water is not wasted in excessive landscape irrigation.
- W47:** Prior to issuance of building permits, project sponsors may pay any appropriate fees imposed by local water providers to off-set any fair share project costs as identified by the local water provider.
- W48:** As part of the general plan update process, local jurisdictions may coordinate with water providers to identify water budgets for development within their jurisdiction. Local water providers may provide for new water supply through a combination of water conservation (on and potentially off-site) and recycled water, such that the net increase in water demand (not including demand for recycled water) does not exceed the calculated demand anticipated in the most recent Urban Water Management Plan or other similar document.
- W49:** Project sponsors may create water-efficient landscapes.
- W50:** Project sponsors may install water-efficient irrigation systems and devices, such as soil moisture-based irrigation controls and use water-efficient irrigation methods.
- W51:** Project sponsors may incorporate water-reducing features into building and landscape design.
- W52:** Project sponsors may make effective use of graywater for landscape irrigation. (Graywater is untreated household wastewater from bathtubs, showers, bathroom wash basins, and water from clothes washing machines.)

W53: Project sponsors may implement low-impact development practices that maintain the existing hydrology of the site to manage storm water and protect the environment by doing the following:

- Devise a comprehensive water conservation strategy appropriate for the project and location.
- Design buildings to be water-efficient. Install water-efficient fixtures and appliances.
- Offset water demand from new projects so that there is no net increase in water use.
- Provide education about water conservation and available programs and incentives.

W54: Local jurisdictions may adopt and implement a comprehensive strategy to increase water conservation and the use of recycled water that includes similar measure to the following:

- **Water Consumption Reduction Target:** Regional water agencies may work together to set a target for to reduce per capita water consumption by 2020.
- **Water Conservation Plan:** Regional water agencies may establish a water conservation plan that may include such policies and actions as:
 - Tiered rate structures for water use;
 - Restrictions on time of use for landscape watering, and other demand management strategies;
 - Performance standards for irrigation equipment and water fixtures;
 - Requirements that increased demand from new construction be offset with reductions so that there is no net increase in water use.
- **Recycled Water Use:** Local jurisdictions and regional water agencies may establish programs and policies to increase the use of recycled water, including:
 - Create an inventory of non-potable water uses within the jurisdiction that could be served with recycled water;
 - Produce and promote the use of recycled water for agricultural, industrial, and irrigation purposes, including grey water systems for residential irrigation;
 - Produce and promote the use of treated, recycled water for potable uses where GHG emissions from producing such water are lower than from other potable sources.
- **Water Conservation Outreach:** Local jurisdictions and regional water agencies may implement a public education and outreach campaign to

promote water conservation, and highlights specific water-wasting activities to discourage, such as the watering of non-vegetated surfaces and using water to clean sidewalks and driveways.

- W55:** Local jurisdictions may ensure that building standards and permit approval processes promote and support water conservation.
- W56:** Local jurisdictions may establish building design guidelines and criteria to promote water-efficient building design, including minimizing the amount of non-roof impervious surfaces around the building(s).
- W57:** Local jurisdictions may establish menus and check-lists for developers and contractors to ensure water-efficient infrastructure and technology are used in new construction, including low-flow toilets and shower heads, moisture-sensing irrigation, and other such advances.
- W58:** Local jurisdictions may establish criteria and standards to permit the safe and effective use of gray water (on-site water recycling), and review and appropriately revise, without compromising health and safety, other building code requirements that may prevent the use of such systems.
- W59:** Local jurisdictions may establish programs and policies to ensure landscaping and forests are installed and managed to optimize their climate benefits.
- W60:** Project sponsors may install water efficient landscapes and irrigation, including:
- Planting drought-tolerant and native species, and covering exposed dirt with moisture-retaining mulch;
 - Installing water-efficient irrigation systems and devices, including advanced technology such as moisture-sensing irrigation controls; and/or
 - Installing edible landscapes that provide local food.
- W61:** Regional water agencies may maximize efficiency at drinking water treatment, pumping, and distribution facilities.
- W62:** Impacts to waters of the state (i.e., water bodies, drainages, and the beneficial uses they support) from proposed transportation (and/or development) projects -- or loss of beneficial uses from cumulative projects and their impacts, may be mitigated by enhancing or restoring water quality attributes and environmental values of water bodies impacted by previous transportation (and/or development) projects. For example, a new project could examine where an earlier project (preferably in close proximity to the new project area), created impairment to a riparian wildlife corridor, and then plan to remove this impairment as

mitigation. Alternatively a new project could remove an obstruction to sediment transport or remove a check dam currently preventing fish (for example, steelhead trout) migration.

via email: ssmith@aqmd.gov

Dear Mr. Smith:

The following comments from the Construction Industry Air Quality Coalition (CIAQC) are submitted to address the South Coast Air Quality Management District's Draft Program Environmental Impact Report (PEIR) for the 2012 Air Quality Management Plan dated September, 2012.

1-2

In the Draft PEIR, Chapter 6, Alternatives, Section 6.4 Project Alternatives to the 2012 AQMP, includes four alternatives to the proposed project (2012 Air Quality Management Plan) that the Program Environmental Impact Report will discuss and compare. Section 6.4.3 describes Alternative 3 - Greater Reliance on NOx Emissions Reductions. This alternative would rely on greater NOx emission reductions from the accelerated turnover and retirement of off-road construction equipment and on-road (trucks) mobile sources to achieve the federal 24-hour PM 2.5 standard while removing BCM-01 (Further Emission Reductions from Wood Burning Devices) from the 2012 Air Quality Management Plan.

1-3

The PEIR is to provide a discussion of alternatives to the proposed project as required by CEQA. Pursuant to the CEQA guidelines, alternatives should include realistic measures to attain the basic objectives of the proposed project and avoid or substantially lessen any of the significant effects of the project, and provide means for evaluating the comparative merits of each alternative (CEQA, Guidelines, §15126.6(a)).

1-4

CIAQC believes Alternative 3 does not meet the established criteria for analysis as required by CEQA as described on Page 1-35 of the Initial Study for the Draft PEIS that stated "The rationale for selecting alternatives rests on CEQA's requirement to present "realistic" alternatives; that is alternatives that can actually be implemented." While SCAQMD could contemplate accelerating the turnover of off-road construction vehicles and medium and heavy-duty trucks, any requirement that goes beyond those already required by the California Air Resources Board (CARB) is simply unrealistic and infeasible.

1-5

Off-road diesel-fueled equipment 25 horse power and greater used by the construction industry in California is strictly regulated under the CARB Off-Road Regulation. Idling limitations, written idling policies, equipment

Page Two

registration, disclosure for selling vehicles and equipment labeling requirements are already enforceable and fleet average targets established in the regulation begin in 2014. The fleet average targets effectively accelerate the turnover of older engines each year through 2023 to levels that are equal to Tier 4i (interim) or Tier 4 depending on the horsepower range for both large and medium sized fleets. For engines greater than 750 hp the final fleet average target is equivalent to an equal number of Tier 2 and Tier 4 engines (no Tier 3 standards established for this category). Small fleets, those less than 2,500 gross horsepower, are required to meet similar fleet average targets established for 2023 by 2028.

The Off-Road Regulation establishes very stringent NOx fleet average targets that will require fleet owners to sell older equipment, retire equipment, purchase new equipment or repower existing equipment with new engines (if possible) to remain in compliance. In order to achieve the fleet average targets described above, the current statewide fleet mix of equipment (engines) will need to change dramatically in the next ten years. Additionally, the economic and technological challenge the CARB regulation creates for contractors and equipment owners is further compounded by current federal policy under US EPA's Replacement Engine Regulation (40 CFR 1068.240) that prohibits the repowering of a machine with a previous tier engine unless the engine has prematurely failed. This policy increases compliance costs significantly.

According to CARB, as of September 2012, the current statewide construction fleet is comprised of approximately 27-percent Tier 0 engines, 23.3-percent Tier 1, 29-percent Tier 2, 13.6-percent Tier 3 and 6.8-percent Tier 4i (interim). These values demonstrate that the existing off-road construction fleet will experience a significant change (an estimated 80 to 85% turnover) by 2023.

The timeframe for fleets to replace and or repower equipment (if possible) is even more compressed than the Off-Road Regulation compliance dates might suggest in that Tier 4 engines become available in 2014 for those between 175 to 750 hp and 2015 for those 75 to 174 hp. These horsepower ranges encompass a large portion of construction equipment power systems. The accelerated implementation of CARB's Off-Road Regulation contemplated in Alternative 3 would require CARB to amend the regulation to require doubling the implementation rate of the regulation such that the emission reductions expected by 2021 would be realized by 2017. This is simply impossible for the construction industry.

Another important consideration is that off-road construction equipment is very expensive. A new dual-engine scrapper can cost more than one-and-a-quarter million dollars. For this reason, most contractors have historically purchased used equipment when it is needed for a specific job and the work to be performed. The equipment is then retained in the fleet after it has been paid for and becomes an integral asset to a company, giving it the ability to generate income throughout the useful life of the equipment. If a new equipment purchase is not possible because of cost, a company can rent equipment, but this results in additional costs that has to be absorbed by the contractor. Rental equipment can help satisfy a portion of the need for equipment in construction.

1-6

but certainly not a majority of it. Further, contractors are not likely to purchase lower tiered engines, such as Tier 3 to improve fleet averages, before the final Off-Road Regulation compliance date (even if it is used and less costly than a new machine) and then turn around a couple of years later and replace it by purchasing a Tier 4 or Tier 4I to achieve final fleet average targets. That approach would simply cost too much in what is still a down economy in southern California. Alternative 3 would effectively require the construction industry to turn over most of its equipment in only 2 or 3 years time. The economic strain on a fleet would be too great.

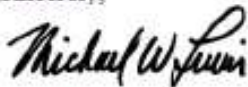

The Off-Road Regulation presents a significant change to the way companies must plan and purchase equipment. The fleet average targets are structured in such a way that older equipment in a fleet must be offset and replaced by newer, lower emitting engines to achieve the targets. The engine and equipment turnover needed to comply with the Off-Road Regulation will necessarily result in fleets with very few, if any, older lower-tiered engines that currently exist now remaining in fleets by 2023. For these reasons, CIAQC strongly maintains that it is simply unrealistic for the SCAQMD to consider a measure that accelerates the turnover of off-road construction vehicles to Tier 4 standards as Alternative 3 in the PEIR describes.

Additionally, Alternative 3 would require proposed control measure ONRD-03 to be modified to accelerate implementation of CARB's on-road truck and bus regulation, to double the compliance requirements currently in place by 2017. This requirement in addition to the accelerated turnover of construction equipment is not possible for contractors, many of which also own regulated trucks (approximately 70,000 in California).

For these reasons, CIAQC believes Alternative 3 is not a viable or realistic alternative and it should not be included in the final Draft PEIR or presented to the SCAQMD Governing Board as such.

Please do not hesitate to contact me if you have any questions or would like additional information.

Sincerely,

Michael W. Lewis,
Senior Vice-President

Responses to Comment Letter #1
Construction Industry Air Quality Coalition (CIAQC) –
Mike Lewis & Clayton Miller (10/23/2012)

- 1-1 This comment notifies the SCAQMD that a comment letter is attached to the email. No further response is necessary.
- 1-2 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Draft Program EIR for the 2012 AQMP. No further response is necessary.
- 1-3 This comment briefly describes Alternative 3 – Greater Reliance on NO_x Emissions Reductions, in Chapter 6 of the Draft Program EIR. No further response is necessary.
- 1-4 This comment identifies CEQA requirements for a discussion of alternatives in CEQA Guidelines §15126.6 (a). SCAQMD staff is aware of the requirements for an alternatives discussion in an EIR and the Draft Program EIR complies with all relevant requirements for preparing an alternatives analysis.
- 1-5 This comment suggests that Alternative 3 is not feasible. As noted in Chapter 6 of the Draft Program EIR, alternatives to the 2012 AQMP were developed by modifying the criteria and VOC reduction strategies. This approach has been used in the past for previous AQMPs. With regard to why the commenter believes Alternative 3 is infeasible, see responses to comments #1-6 through #1-11.
- 1-6 This comment summarizes the requirements of CARB’s existing On-road Truck & Bus Regulation and CARB’s existing Off-road Vehicle Regulation. No further response is necessary. The comment then goes on to say that complying with these existing regulations presents significant change in the way companies must plan and purchase equipment. The comment asserts that accelerating the compliance rate for both on-road and off-road mobile sources, as proposed in Alternative 3, means that Alternative 3 is not a “viable or realistic alternative.” CEQA Guidelines §15126 (a) states, “An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. An EIR need not consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives that will foster informed decision making and public participation.” Further, CEQA Guidelines §15364 defines feasible as, “...capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors.” Alternative 3 is considered to be a feasible alternative for the following reasons.
- Reasonable period of time – this alternative would require modifications to an existing regulation, which could be expeditiously implemented to ensure that the additional NO_x reductions from accelerating the turnover of vehicles are realized. These amendments would result in a modest increase in the average annual turnover rate of approximately three percent when compared to the current form of the regulation (from nine percent to 12 percent), which, while challenging, is not so extreme as to render the alternative unreasonable;

- Economic – the average annual turnover rate (and the costs of complying with the regulation) would increase by approximately 33 percent for the four-year timeframe of the alternative. While the cost increase is not insignificant, it is not so extreme as to eliminate the alternative from consideration. In addition, incentive funding such as the SOON and Moyer programs is available to alleviate some of the increased costs. Although Alternative 3 would result in greater compliance costs as indicated above, no physical effects of higher compliance costs have been identified as indicated in CEQA Guidelines §15131;
- Environmental – No environmental factors are identified that would make the alternative infeasible. In fact, the Alternative 3 would help make expeditious progress attaining the one-hour ozone standard (revoked) and the eight-hour ozone standard, which are included as project objectives. Impacts from Alternative 3 have been comprehensively analyzed in Chapter 6 of the Final Program EIR;
- Legal – No legal issues identified that would prevent implementing Alternative 3, although Alternative 3 does not reduce potential environmental impacts compared to the 2012 AQMP;
- Social – Alternative 3 primarily affects the penetration of new or retrofitted compliant on-road and off-road vehicles and retirement of old vehicles. For this reason Alternative 3 is not expected to create physical impacts to existing or planned land uses or physically divide established populations in the Basin that could result in adverse social impacts to places of worship or religious practices, cause urban blight, or limit or eliminate housing, especially low cost housing; and finally
- Technological – No technological impediments are identified as compliant vehicles and/or control technologies are readily available and would be in sufficient quantity to implement the alternative.

In summary, SCAQMD staff asserts that Alternative 3 is feasible as required by the CEQA Guidelines and the alternative should be included as one of the program alternatives.

- 1-7 This comment concludes the letter by repeating the assertion that Alternative 3 is unrealistic and infeasible. See response to comment #1-6, which addresses this comment.

Subject: Draft Program Environmental Impact Report: 2012 Air Quality Management Plan (AQMP)¹

Dear Mr. Inabinet:

The Consumer Specialty Products Association (CSPA)² appreciates the opportunity to offer comments on the South Coast Air Quality Management District (AQMD) Draft Program Environmental Impact Report (DPEIR) for the 2012 Air Quality Management Plan (AQMP), which was issued for comment on September 6, 2012.³ 2-2

CSPA submitted comments on the Initial Study for the Draft Program Environmental Impact Report on July 18, 2012. In addition, CSPA submitted comments on the draft 2012 AQMP on October 9, 2012. These documents are expressly incorporated herein by express reference. 2-3

In our earlier comments we expressed concerns that the 2012 AQMP should not include control measures for consumer products, and furthermore urged that AQMD remove all ozone control measures from this AQMP update, and proceed with only the PM 2.5 update. The numerous reasons supporting this include: 2-4

¹ The DPEIR for the 2012 AQMP is posted on the AQMD's website at: http://www.aqmd.gov/ceqa/documents/2012/aqmd/draftEA/2012AQMP/2012aqmp_dpeir.html.

² CSPA is a voluntary, non-profit national trade association representing approximately 240 companies engaged in the manufacture, formulation, distribution, and sale of products for household, institutional, commercial and industrial use. CSPA member companies' wide range of products includes home, lawn and garden pesticides, antimicrobial products, air care products, automotive specialty products, detergents and cleaning products, polishes and floor maintenance products, and various types of aerosol products. Through its product stewardship program Product Care[®], and scientific and business-to-business endeavors, CSPA provides its members a platform to effectively address issues regarding the health, safety, sustainability and environmental impacts of their products.

³ The DPEIR includes a project description and an analysis of potential adverse environmental impacts that could be generated by the proposed project. The AQMD explains that the 2012 AQMP identifies control measures that will be implemented to demonstrate attainment of the federal 24-hour standard for particulate matter less than 2.5 microns in diameter (PM 2.5) and provides Clean Air Act Section 182(e)(5) proposed implementation measures to make progress in attaining federal one-hour and eight-hour ozone standards.

CSPA Comments on the DPEIR for the 2012 AQMP

October 23, 2012

Page 2 of 7

- EPA has proposed an one-hour ozone SIP Call⁴ that will only be finalized after EPA receives, considers, and responds to all public comments. The final SIP Call will probably not be issued until sometime next year, and the final rule could differ from the proposal. The state will then have 12 months to respond. AQMD should therefore await the final SIP Call and move carefully to assure that its updated ozone AQMP is consistent with that rule. 2-5
- We have shown in previous comments that modeling studies (*see* Attachment A) have shown the further VOC reductions for consumer products contained in the 2007 AQMP are not necessary for ozone attainment, and therefore should be removed. AQMD needs to better evaluate its ozone attainment strategies, which requires more time. 2-6
- We have shown in previous comments that new environmental multimedia modeling data show that the low vapor pressure (LVP) compounds targeted for reduction in CTS-04 do not contribute significantly to ozone production. (*See* Attachment B.) That new measure is therefore ineffective and not appropriate for inclusion in the AQMP. 2-7
- Numerous other data have also been put on the record to show that the proposed control measures and ozone attainment demonstration for the 2012 AQMP are not appropriate, and work on updating the ozone portions of the AQMP need to be deferred. (*See* Attachment C.) 2-8

We therefore appreciate that the revised Draft Program Environmental Impact Report includes assessment of “Alternative 4: PM_{2.5} Emission Reduction Strategies Only.” Unfortunately, the flawed analysis of this alternative fails to consider the critical reasons we have provided for deferral of the ozone update. The assessment instead looks at the implementation of the Clean Air Act Section 182(e)(5) ozone attainment measures in the “black box” of the 2007 AQMP, including the vague and undefined “SCLTM-03” measure on Consumer Products—the very measure that we have shown in our 2007 ozone attainment modeling study to be unnecessary. (*See* Attachment A.) CSPA is not seeking to have the 2007 control measures implemented, but rather to have AQMD take time to consider the extensive data showing that more effective and cost effective measures can be adopted for ozone attainment. 2-9

The revised Draft Program Environmental Impact Report also includes assessment of “Alternative 3: Greater Reliance on NO_x Emissions Reductions.” Unfortunately, while the general concept would seem consistent with the evidence provided by CSPA in previous comments that NO_x reductions are more effective than VOC reductions for ozone attainment, the actual scenario assessed in Alternative 3 relates only to PM_{2.5} attainment, and eliminates only a wood burning measure. CSPA believes that this general concept should also be evaluated as an alternative for the ozone AQMP, substituting accelerated NO_x reductions for low-reactivity VOC reductions. 2-10

For reasons provided in our previous comments, and further detailed below, the 2012 AQMP should only include commitments for reductions in emission sources that are necessary for attainment of the federal PM_{2.5} standard. Moreover, to the extent that any future ozone AQMP contains Clean Air Act Section 182(e)(5) proposed implementation measures, the AQMD should 2-11

⁴ 77 Fed. Reg. 58072-58076 (September 19, 2012)

CSPA Comments on the DPEIR for the 2012 AQMP
October 23, 2012
Page 3 of 7

focus only on NO_x reductions for demonstrating progress in attaining federal one-hour and eight-hour ozone standards. In addition to being a PM 2.5 precursor, NO_x is also an ozone precursor. Thus, focusing on NO_x is consistent with the AQMD's efforts to continue making expeditious progress in attaining the federal one-hour and eight-hour ozone standards.

2-11
Con't

1. The Low Reactivity of VOCs in Consumer Products Make Further Reductions Unnecessary.

The low reactivity and low ozone impact of the VOC emissions from consumer products may make it *unnecessary* to further reduce the VOC content of consumer products to attain the federal ozone standard in the South Coast Air Basin. Therefore, for reasons detailed below, the 2012 AQMP should not include "black box" emission reduction measures for consumer products.

2-12

a. There are very significant differences between the relative ozone impacts of equal amounts of VOC emissions from various sources.

Scientific studies funded by our industry strongly suggest that a mass-based inventory approach overestimates the actual impact of consumer product VOC emissions on ozone attainment in the South Coast and other areas of California. In 2002, Sierra Research, Inc. conducted a research project to create a reactivity-weighted VOC emissions inventory for the South Coast. Sierra Research used the official emissions inventory for South Coast in 2000 and the official speciated emissions profiles, as well as the official ARB estimates for "maximum incremental reactivity" (MIR) for each species of VOC emission, to create an estimate of the maximum ozone formation potential attributable to each major category of anthropogenic emissions of organic gases in the region. This type of MIR-weighted inventory provides a much more scientifically accurate assessment of the relative ozone impact of various emissions sources than any mass-based VOC emissions inventory.

2-13

The results of that MIR-weighted VOC inventory project are presented in Attachment D to these comments. The study found significant differences between the total mass emissions and the ozone formation potential of those emissions, and these differences are due solely to the differing weighted MIR for the species of VOCs that make up the specific source emission. Some emissions sources therefore have a much higher ozone formation potential than their mass emissions suggest, while other emissions categories have a much lower ozone formation potential than suggested by their mass emissions. Consumer products are among the emissions categories with below average reactivity, and therefore lower ozone impact than would be expected based on mass of emissions alone.

The MIR scale provides an estimate of the maximum amount of ozone potentially formed from a VOC emission under the tropospheric conditions where ozone is most sensitive to VOCs. The conditions in the ozone attainment run are far less sensitive to VOC emissions, but although absolute VOC reactivity will decrease significantly, the relative reactivity differences between various VOCs will remain relevant.

As shown in the data in Attachment D, VOCs from consumer products have a weighted-average MIR of 1.5, well below the average for all emissions sources. Many mobile sources of VOCs have very high reactivity, including Aircraft (6.8), Farm Equipment (5.4), Heavy Duty Diesel Urban Buses (5.5), Heavy Duty Diesel Trucks (5.5), Light Duty Diesel Trucks (5.5), Medium

CSPA Comments on the DPEIR for the 2012 AQMP
 October 23, 2012
 Page 4 of 7

Duty Diesel Trucks (5.5), Ships and Commercial Boats (5.3) and Trains (5.5). VOC emissions from these sources cause three to five times as much ozone formation pound-per-pound as consumer product VOCs. The VOC sources with the largest potential ozone impacts in 2000 also exhibited very high reactivity profiles, including Light Duty Passenger Cars (3.7), Light Duty Trucks (3.8), and Off-Road Equipment (4.6).

The data from this study provide important evidence that very significant differences exist between the relative ozone impacts of equal amounts of VOC emissions from various sources. Generally speaking, mobile source VOC emissions create three to five times as much ozone as equal amounts of VOC emissions from most stationary and area sources, including consumer products. These significant differences in relative photochemical reactivity of various VOC sources must be taken into account in choosing and implementing effective, workable and cost-effective ozone attainment strategies.

- b. The U.S. Environmental Protection Agency's (EPA's) 2005 Interim Guidance on SIP development provides clear instructions that relative reactivity and ozone formation potential should be considered in SIPs, and that alternative fates and availability also should be considered.

EPA provided clear guidance to states in 2005 that differences in VOC reactivity should be considered in the development and implementation of SIPs. In its "Interim Guidance on Control of Volatile Organic Compounds in Ozone State Implementation Plans,"⁵ EPA "...encourages States to consider recent scientific information on the photochemical reactivity of volatile organic compounds (VOCs) in the development of State implementation plans (SIPs) designed to meet the national ambient air quality standard (NAAQS) for ozone."⁶ That guidance also states that, "By distinguishing between more reactive and less reactive VOCs, it should be possible to decrease ozone concentrations further or more efficiently than by controlling all VOCs equally."⁷ The Interim Guidance goes on to provide the specific guidance regarding factors that States should consider, including the following:

- The potential for alternative (non-atmospheric) fates and limited availability for ozone-forming photochemical reactions.
- Prioritizing control measures using reactivity metrics.
- Targeting emissions of highly reactive VOCs with control measures.
- The fate of VOC emissions and their availability for atmospheric reactions.

As we have demonstrated in previous comments, new data has shown that not only do LVPs have limited if any ability to contribute to VOC emissions and ozone formation, but many VOCs also have limited availability due to alternative environmental fates. (See Attachment B.) In regard to this important issue, the Interim Guidance, EPA instructs that:

⁵ 70 *Fed. Reg.* 54046-51 (Sept. 13, 2005).

States should also consider emerging research on the actual availability of VOCs for atmospheric reaction. In estimating VOC emissions, especially from coatings, solvents, and consumer products, it is often assumed that the entire volatile fraction is emitted and available for photochemical reaction, unless captured by specific control equipment. In some situations, however, otherwise volatile compounds may be trapped in liquid or solid phases or adhere to surfaces such that they are not actually released to the atmosphere. Once emitted into the atmosphere, VOCs may also be scavenged by rain, form particles, or deposit on surfaces. Taking this behavior into account should lead to more accurate VOC emissions inventories and photochemical modeling. It may also allow States to consider volatility thresholds or other approaches designed to reflect atmospheric availability in certain types of regulatory programs.

2-14
Con't

CSPA urges the AQMD to follow the 2005 Interim Guidance and consider the relative reactivity and ozone impacts and atmospheric availability of various compounds to determine which, if any, VOC control measures are considered for inclusion in any revised and updated ozone AQMP.

- c. Earlier scientific studies also document the fact that the low-reactivity of VOCs used in consumer products have negligible impacts on peak ozone levels.

Earlier studies also clearly demonstrated the minimal impact of consumer product VOCs on ozone non-attainment in California. Subsequent to the statewide revision of the California SIP in 1994, CSPA and another trade association funded an air quality modeling study to determine the specific role of consumer products in ozone attainment in both South Coast and in Sacramento regions. That study, "Impact of Consumer Products on California's Air Quality"⁸ used the exact Urban Airshed Model (UAM), inventories and meteorology utilized in the attainment demonstrations for the 1994 SIP. (See Attachment C.)

The study compared UAM outputs for two scenarios in the South Coast Air Basin:

- The attainment demonstration in the SIP, which included an 85 percent reduction in the VOC emissions from consumer products, and demonstrated attainment with the one-hour ozone standard in 2010; and,
- The exact same modeling run with only a 30 percent reduction in consumer products VOC emissions (the reduction already obtained by ARB regulations adopted prior to 1994).

2-15

The results showed that both scenarios demonstrated attainment of the one-hour ozone standard of 0.12 ppm in both South Coast and Sacramento. In both airsheds, the additional consumer product emissions, despite their very significant mass, had such small impacts on peak ozone formation that insufficient ozone was formed to cause non-attainment. This result was attributed to both the low reactivity of the consumer product emissions, and the geographic distribution of those emissions that lessened impacts on peak ozone levels. Aerosol consumer products exhibit especially low reactivity, since aerosol propellants tend to among the least reactive of all VOCs in the emissions inventory.

⁸ Sierra Research Report No. SR97-07-01 (July 1997) and addendum Report No. SR98-03-01 (March, 1998). See Attachment C.

CSPA Comments on the DPEIR for the 2012 AQMP

 Page 6 of 7

Unfortunately, CSPA was not able to obtain the underlying data from the AQMD to conduct a similar study using the computer model, inventories and meteorology utilized in the attainment demonstrations for the 2003 AQMP, but we believe that a similar result would have been obtained, especially considering that regulations promulgated by the ARB since 1994 provided additional reductions in consumer products VOC emissions.

The 1997 attainment remodeling study was conducted under 2010 attainment conditions that remained highly sensitive to overall VOC emissions. Therefore, the results of the study demonstrated that even under highly VOC-limited conditions where ozone formation is highly sensitive to overall VOC levels, ozone formation was *not* at all sensitive to consumer product VOC emissions. The attainment demonstration modeling for the 2007 AQMP, on the other hand, was under atmospheric conditions that are far more NO_x-limited, and far less sensitive to overall VOC emissions. We therefore had reason to expect that consumer product VOC emissions should have even less relative impact on ozone attainment in the 2023 attainment scenario.

CSPA believes that the results of these types of studies provide important information to support the development of effective ozone attainment strategies. It is important that the control measures in the SIP be focused primarily on those emissions sources (primarily NO_x) that play a significant role in ozone non-attainment in the South Coast.

The need to carefully consider the relative ozone impacts of various emission sources provides further reasons that the AQMD's commitment for future emissions reductions in the "black box" should not be allocated to consumer products. CSPA urges the AQMD to consider these data and adhere to the EPA 2005 Interim Guidance,⁹ which would result in only including commitments of for reductions in emissions sources that are actually necessary for ozone attainment in the South Coast Air Basin.

2-15
 Con't

SUMMARY AND CONCLUSIONS

CSPA appreciates the opportunity to comment on the DPEIR. We support the AQMD's goal of improving air quality in the South Coast Air Basin. However, the proposed VOC emission reduction measures for consumer products are neither necessary nor feasible. Moreover, these proposed measures would harm the consumers and businesses who rely on our products to provide a clean and healthy environment in which to live and work.

Additional reduction measures for consumer products or other low-reactivity sources are not needed for demonstrating attainment of the federal one-hour and eight-hour ozone standards. In addition, as documented in CSPA's earlier comments, reducing LVP materials in consumer products will have little or no impact in VOC emissions an ozone formation. Since the control measures impacting consumer products are *not* feasible, necessary or cost-effective, the AQMD should not include these measures in the final 2012 AQMP.

2-16

CSPA therefore urges AQMD to defer all ozone revisions in the 2012 AQMP until next year to allow time for a final EPA SIP Call rule to be issued, and to provide time to adequately address the numerous issues raised by CSPA and others in these comments. CSPA is willing to continue

⁹ 70 Fed. Reg. 54046-51 (Sept. 13, 2005).

Scientific Critique of South Coast Air Quality Management District Paper

“Non-Volatile, Semi-Volatile, or Volatile:

Redefining Volatile for Volatile Organic Compounds”

October 2012

ABSTRACT

A draft paper entitled “Non-Volatile, Semi-Volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds” authored by Uyên- Uyên T. Võ and Michael P. Morris is subjected to a scientific critique. The paper presents ambient evaporation data for organic compounds of varying volatility that is portrayed as drawing into question the regulatory criteria and test methods used to determine what low-vapor-pressure compounds are exempted from the regulatory definition of “Volatile Organic Compound” (VOC) for various uses. The paper fails to grasp the crucial differences between the technical term “volatile” and the regulatory term “VOC”, which relates to the ability to contribute significantly to formation of ozone in tropospheric ambient air through vapor-phase photochemistry. In this critique, the scientific concepts and studies are noted that limit the ability of low-volatility organic compounds to contribute significantly to tropospheric ozone formation and refute the arguments in the draft paper.

SCIENTIFIC CRITIQUE

“Non-Volatile, Semi-Volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds” authored by Uyên- Uyên T. Võ and Michael P. Morris was obtained from the authors in the form of a draft paper dated August 31, 2012, as well as a presentation dated June 21, 2012, that was presented at an Air & Waste Management Association meeting. This scientific critique was conducted by a number of chemists and environmental scientists in the consumer products industry.¹

¹ Scientists involved in developing this critique included representatives from the Consumer Specialty Products Association, Personal Care Products Council, American Chemistry Council, American Cleaning Institute, American Coatings Association, Automotive Specialty Products Alliance, National Aerosol Association, International Sanitary Supply Association, and International Fragrance Association North America.

Responses to Comment Letter #2
Consumer Specialty Products Association (CSPA) – Joe Yost (10/23/2012)

- 2-1 This comment notifies the SCAQMD that a comment letter with three attachments is submitted. No further response is necessary.
- 2-2 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Draft Program EIR for the 2012 AQMP. This comment and footnote #2 also provide background information describing the nature of the commenter’s business. Footnote #3 provides a general description of the contents of the Draft Program EIR for the 2012 AQMP. No further response is necessary.
- 2-3 This comment notifies the SCAQMD that previous comments submitted, relative to the Initial Study for the Draft Program EIR for the 2012 AQMP on July 18, 2012 [sic] and relative to the Draft Program EIR for the 2012 AQMP on October 9, 2012, should be incorporated by reference. (Note that the comment letter relative to the Initial Study for the Draft Program EIR for the 2012 AQMP was dated July 19, 2012.)
- 2-4 This comment reiterates previous comments suggesting that control measures for consumer products and ozone control measures should not be included in the 2012 AQMP. See response to comment #2-8.
- 2-5 With regard to the one-hour ozone SIP call, a requirement for the submittal of an attainment demonstration for the revoked one-hour ozone standard has been proposed by U.S. EPA, and the submittal will be due by early 2014. Since the emissions inventory and control strategy has already been developed for the 2012 AQMP, and because attaining the one-hour standard can rely on the same strategy as the federal eight-hour ozone Plan, SCAQMD staff was able to complete an attainment demonstration for the one-hour ozone standard as an Appendix to the 2012 AQMP. Moreover, no additional measures were identified. The comment expresses a preference to delay the submittal of the one-hour ozone attainment demonstration, taking the full one year time frame provided by U.S. EPA. However, SCAQMD staff believes that there is no reason to wait until the one-hour ozone attainment demonstration is due given that no new measures are being proposed and the work has been completed. Utilizing the current 2012 AQMP emissions inventory, modeling framework, and public process is the most efficient use of resources and time.
- 2-6 Reducing ozone precursor emissions, both NO_x and VOC emissions, is necessary to continue making progress in attaining the federal one-hour ozone standard (revoked) and the federal eight-hour ozone standard. The set of isopleths provided in the June 2012 STMPR meeting was based on the initial 2023 baseline inventory and preliminary modeling to illustrate the preferred path to attaining the ozone standard. Subsequent modeling sensitivity simulations that varied the VOC emissions by approximately 12 tons per day (across the board reductions) resulted in a 1.0 ppb movement in the eight-hour future design projection with lower VOC resulting in lower ozone. The current draft 2012 update to the 2007 AQMP eight-hour ozone projected 2023 future year design value placed several Basin sites within 1-2 ppb of the U.S. EPA threshold for demonstrating attainment. (U.S. EPA’s threshold was set at 84.4 ppb with rounding.) Far from being

insignificant, a 1.0 ppb change in the eight-hour ozone would jeopardize the attainment demonstration.

- 2-7 SCAQMD staff appreciates the efforts by CSPA to bring together a coalition of industry scientists to review the SCAQMD Paper “Non-Volatile, Semi-Volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds,” U. Vø and M. Morris, August 2012. Implementing Control Measure CTS-04 would require reevaluating the criteria established for LVP-VOCs by relying on scientific data and, therefore, the information provided in the critique supplements the scientific data available for consideration.

Although lower volatility compounds have limited vapor-phase availability, the study cited indicates that many LVP-VOC compounds are indeed non-volatile limiting their ability to contribute to ozone formation. However, the paper also demonstrates that many compounds that qualify as LVP-VOC under the existing criteria are volatile and semi-volatile, thus, available to participate in ozone formation and indeed participating in ozone formation due to their relatively higher Maximum Incremental Reactivity values.

Current U.S. EPA, CARB and SCAQMD emissions inventory and photochemical air quality models include speciation profiles that account for total organic gases (TOGs), including reactive compounds, unreactive and exempt compounds, as well as LVP-VOC compounds. Modeling results for ozone non-attainment areas have demonstrated that even compounds with low photochemical reactivity or LVP-VOCs contribute to photochemical ozone formation and not including these compounds would compromise the ozone attainment demonstrations. SCAQMD staff recognizes that some multi-media models that incorporate partitioning concepts such as “Atmospheric Availability” or “Environmental Fate” may have been recently developed; however, current peer-reviewed ambient ozone models used by CARB and SCAQMD do not include such partitioning concepts. SCAQMD staff will continue to work with USEPA and CARB staff on ozone model improvements, especially if additional peer-reviewed environmental fate and atmospheric availability studies justify incorporation into these predictive models.

The commenter attempts to justify the LVP-VOC exemption by noting that LVP-VOC compounds are predominantly partitioned into other environmental media (soil, water, etc.). The conclusion being that these products do not go into the air but instead are biodegraded. Yet this observation is true for nearly every chemical (LVP-VOC and non-LVP-VOC). Despite this partitioning, some fraction of the chemical enters the atmosphere and contributes to ozone formation. Contrary to the assertions made by the commenter, the critique does not provide evidence that LVP-VOC compounds are any different than traditional VOC compounds with respect to environmental partitioning. In fact, of the compounds studied (LVP-VOC and non-LVP-VOC) the highest predicted partitioning ratios into air are for some LVP-VOCs (22 percent for Light Distillate). It appears that there is no correlation between partitioning to air and LVP-VOC status. Furthermore, it is of concern that the current regulatory methodology may be requiring the transition from traditional VOC compounds (such as isopropanol) to LVP-VOCs (such as Light Distillate) with similar evaporation profiles, higher MIR values and more than four times higher predicted air partitioning factors.

SCAQMD staff concurs that the current VOC emissions inventory for consumer products should be reevaluated to more accurately and precisely determine their contribution to ozone formation using the best available scientific data and methodologies, including environmental chamber studies and evaporation studies using fully formulated products. However, because consumer products represent the largest single source of VOC emissions (under current methodologies), uncertainty about the inventory because of the LVP-VOC exemption, and the current regulatory structure may be limiting the environmental benefits sought after in the current CARB regulation, SCAQMD staff believes that it is imperative that Control Measure CTS-04 be included in the 2012 AQMP. Furthermore, Control Measure CTS-04 has been revised to include the commenter's suggestions pertaining to additional studies and refined emissions inventory.

It should be noted that Attachment B, cited in this comment, does not discuss Control Measure CTS-04 in any way, but instead critiques a paper prepared by SCAQMD staff regarding defining volatile compounds. It appears that this critique is included in an attempt to further demonstrate why VOC emission reductions are not necessary to attain the ozone standards (see also response to comment #2-19).

The comment does not explain why the ozone attainment demonstration is not appropriate. However, the comment states that working on the ozone part of the 2012 AQMP should be delayed. In light of the SIP call by U.S. EPA (see response to comment #2-5), SCAQMD staff disagrees.

- 2-8 Consistent with the previous AQMP, the current analysis shows that approximately 65 percent of additional NO_x emissions reductions, beyond already adopted rules and measures, will be needed to meet the eight-hour ozone standard of 80 ppb in 2023. The percent reduction in VOC emissions to meet the eight-hour ozone standard of 80 ppb in 2023, based on the 2007 AQMP carrying capacity projections, is approximately four percent. The Basin can only demonstrate attainment of the eight-hour standard by using the CAA §182 (e)(5) provision allowing for long-term measures that anticipate the development of new technologies or improving of existing control technologies. This CAA provision requires that these long-term measures be specifically identified at least three years prior to the attainment year (2020).

With less than eight years remaining to identify these so-called “black box” emissions reductions, it is imperative to move forward with the identification and development of all feasible specific measures to achieve these reductions as soon as possible. If progress is delayed, there will be even less time to develop and implement strategies before the looming deadlines, and thus the resulting necessary measures could be more burdensome and disruptive. Delaying progress will also provide less certainty and lead time to the regulated community for planning compliance with potential new regulatory requirements. The considerable time it takes for new technologies to be developed, assessed and implemented widely, especially in the mobile source sector, also underscores the need to begin immediately. Note that while this Plan commits to the adoption of several ozone measures in the near-term, the implementation date and emissions reduction commitments are deferred until 2020 or beyond.

Recent litigation regarding U.S. EPA approvals of previous SIPs has focused on the reliance on a relatively large “black box” to demonstrate attainment and the short time frame available to develop and deploy potential new technologies. The SCAQMD believes it is important to demonstrate progress towards ozone attainment by making commitments for additional emissions reductions that reduce the size of the “black box” commitments. In U.S. EPA’s comment letter on the Draft 2012 AQMP (August 30, 2012), they state that they “fully support the SCAQMD’s inclusion in the 2012 AQMP of updates on the implementation of control measures and emission reduction commitments relied upon in the South Coast 2007 AQMP to demonstrate expeditious attainment of the 1997 eight-hour ozone NAAQS. We urge the SCAQMD to continue working closely with EPA staff to identify the specific near-term and long-term control measures that will fulfill the NO_x and VOC emission reduction commitments contained in the SIP-approved South Coast 2007 eight-hour ozone plan, and to develop appropriate methodologies for calculating the emission reductions attributed to each such measure.”

Furthermore, U.S. EPA recently proposed to require a new one-hour ozone SIP for the Basin. In order to demonstrate attainment with this revoked standard by 2022, all feasible measures must be included in the SIP. Making enforceable emissions reductions commitments based on specific measures as they are identified is the best way to demonstrate that the SCAQMD is dedicated to realizing the emission reductions necessary to achieve the eight-hour and one-hour ozone standards. Future AQMPs would need to identify further specific measures and associated emissions reductions that will allow the “black box” commitments to shrink to zero by 2020.

Finally, it should be noted that Attachment C is an evaluation of consumer products on air quality prepared in 1997, so it does not provide comments specifically on either the 2012 AQMP or the Draft Program EIR. See response to comment #2-20 regarding the specific issues raised in Attachment C.

- 2-9 The commenter states that he appreciates the fact that the Draft Program EIR included Alternative 4 – PM_{2.5} Emissions Reduction Strategy Only, but states that it is flawed because, as asserted by the commenter, it does not include consideration of deferral of the ozone update CAA §182 (e)(5) block box measures from the 2007 AQMP (in particular 2007 AQMP Control Measure SCLTM-03 – Consumer Products. With regard to continued consideration of ozone reduction strategies, SCAQMD staff disagrees that Alternative 4 is flawed because, as explained in the description of Alternative 4, preparing a PM_{2.5} only plan means that the currently adopted 2007 AQMP, which is an ozone and one-hour PM_{2.5} Plan, remains in effect. This means that 2007 AQMP Control Measure SCLTM-03 continues to be a long-term control measure that could still be promulgated as a rule or regulation. By acknowledging that the ozone portion of the 2007 AQMP would remain in effect if Alternative 4 is ultimately adopted, the analysis presents a more realistic and conservative analysis of potential environmental impacts than would be the case by artificially ignoring the currently adopted 2007 AQMP. The SCAQMD cannot remove measures from the existing approved 2007 AQMP without substituting measures that would be equally effective. With regard to the need for further VOC emission reductions, see responses to comments #2-6 through #2-8. With regard to deferral of the one-hour ozone SIP submittal, see responses to comments #2-5 and #2-8.

- 2-10 The comment states that Alternative 3 - Greater Reliance on NO_x Emissions Reductions, only differs from the 2012 AQMP by eliminating Control Measure BCM-01, but the concept of accelerated NO_x reductions, instead of VOC reductions should be explored further. Although Alternative 3 does not include Control Measure BCM-01, the rest of the characterization of the alternative is incorrect. Alternative 3 includes a control measure that would include incentives for NO_x emission reductions from accelerated implementation of CARB's existing truck and bus regulation. The control measure assumes that the rate of compliance with the existing requirements by 2017 would be double the compliance rate estimated by CARB, which would be approximately an additional 5,000 compliant trucks. Similarly, Alternative 3 includes a NO_x control measure that would include incentives for accelerated compliance with CARB's off-road diesel vehicle regulation. The control measure assumes that the rate of compliance with the existing regulation by 2021 would occur in 2017, which is a doubling of the compliance rate estimated by CARB. The off-road control measure would result in approximately an additional 19,344 compliant off-road vehicles. For the emission effects of Alternative 3 compared to the 2012 AQMP, see Tables 6-14 through 6-16 in the Draft and Final Program EIRs. Based on the on-road and off-road control measures described here for Alternative 3, accelerated NO_x emission reductions have been explored as requested by the comment.
- 2-11 With regard to the comment relative to reasons for only going forward with PM_{2.5} reduction strategies, see response to comment #2-8 which provides the reasons to include ozone measures in the 2012 AQMP as required to demonstrate attainment of the 24-hour PM_{2.5} standard. The long-term ozone precursor reduction strategies demonstrate attainment of the ozone standards at all the air quality monitoring stations throughout the Basin by 2023. Modeling analysis shows that significant NO_x emissions reductions are the main path to attaining the eight-hour ozone standards in the Basin. Therefore, the ozone strategy focuses primarily on NO_x reductions. However, VOC emissions reductions can also be effective in improving the rate of progress towards attainment of the ozone standards, especially in the western portions of the Basin. Furthermore, there is a significant health benefit to meeting the ozone standards as soon as possible in as many areas of the Basin as possible. While the current eight-hour ozone design value site is at Crestline in the San Bernardino Mountains, projections for 2023 show that the design value site will be at Glendora in the San Gabriel Valley to the west. As shown in the 2023 baseline eight-hour ozone NO_x/VOC isopleths for Glendora and other western sites presented in the attachment to Appendix V, VOC reductions will help to lower ozone concentrations in the San Gabriel Valley and Western portions of the Basin. This is true near the level of the eight-hour ozone standards, but is even more significant along the path to attainment. This is due to the higher VOC/NO_x ratios projected to occur in future years, especially in the western Basin.

Based on the above information, short-term VOC controls (through 2020) will help offset the impact of the increased VOC/NO_x ratio in the impacted areas of the Basin, such as the San Gabriel Valley, that are immediately downwind of the primary emissions source areas. As such, a nominal amount of VOC reductions are proposed in the Draft 2012 AQMP. The proposed VOC control measures in the 2012 AQMP are based on implementing all feasible control measures through the application of available technologies and best management practices, while seeking a fair share reduction from

both mobile and stationary sources. As zero and near-zero technologies are implemented for mobile sources to reduce NO_x emissions, concurrent VOC reductions from mobile sources are expected. Thus, stationary sources must continue to achieve their fair share of VOC reductions in the future. This plan proposes a modest six tons per day of VOC emissions reductions out of a total 28 to 30 tons per day of VOC reductions needed for basin-wide attainment in 2023.

- 2-12 See responses to comments #2-6 and #2-7 for a discussion of the reasons for including consumer products as an ozone control measure and discussion on MIR control values of LVP-VOCs and VOCs found in consumer products, respectively. The paper, “Non-Volatile, Semi-Volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds,” U. Vø and M. Morris, August 2012, includes MIR values for the LVP-VOC samples studied. The MIR values for LVP-VOCs are comparable to traditional VOCs and widely used LVP-VOCs (benzyl alcohol, propylene glycol and ethylene glycol) have MIR values significantly higher than isopropyl alcohol and similar to 2-butoxyethanol, two traditional VOC chemicals for which the LVP-VOCs were meant to replace.
- 2-13 SCAQMD staff is concerned that reformulation of products by substituting LVP-VOCs for other solvents considered to be VOCs may not achieve the ozone reduction benefits anticipated by the Consumer Products Regulation (CPR). Further, considering the increasing use of LVP-VOCs used in formulations to comply with the CPR may offset any perceived benefits, especially since their relative evaporation rates under ambient conditions and maximum incremental reactivity (MIR) values can be much higher than ethane’s MIR value, the “bright line” used by U.S. EPA to distinguish between VOCs and negligibly reactive compounds.

The research project conducted in 2002 by Sierra Research did not include changes to the speciation of chemicals resulting from the last five amendments to the CPR, the adjustments made to MIR values over the last decade and may not have included LVP-VOCs in the inventory and speciation. However, even disregarding these factors and using the stated weighted-average MIR values cited in the comment letter, the MIR weighted inventory for consumer products still exceeds those from Passenger Vehicles, Light Duty Trucks and Medium Duty Trucks; all categories for which a host of control measures are included in the AQMP. Consumer product emissions, even when allowing for weighted-average MIR values cited by the comment, continue to be a major source of VOC emissions.

- 2-14 SCAQMD staff supports using recent scientific data and emerging research on the actual availability of VOCs for atmospheric reaction. The guidance document referenced by the commenter notes that a reactivity approach is more difficult to develop and implement than traditional mass-based approaches because reactivity-based programs carry the extra burden of characterizing and tracking the full chemical composition of VOC emissions. U.S. EPA encouraged all interested parties to continue to work through the Reactivity Research Working Group to improve the scientific foundation for reactivity-based regulatory approaches. SCAQMD staff committed to studying the effects of a reactivity-based approach by actively participating in the North American Research Strategy for Tropospheric Ozone (NARSTO) work related to reactivity. SCAQMD staff participated in the Reactivity Industry Working Group (RIWG) in 2009-2010 with leading scientists

from industry, government and public groups to identify issues surrounding reactivity-based regulatory strategies and consider multi-pollutant impacts in the hope of determining a path forward to addressing issues (Moore, B., U.S. EPA, Reactivity Summit Brief Summary, July 2009). However, despite these efforts, no resolution was reached regarding downwind impacts, toxics and particulate from secondary organic aerosols, and enforceability associated with limitations in analytical test methods capable of differentiating petroleum distillates. Lastly, the final RIWG meeting held in May 2010 resulted in U.S. EPA staff making a determination that additional review was necessary before any specific guidance or ‘toolkit’ can be made available to states and local agencies, and that this potential guidance is not designated as a high priority item for the Office of General Counsel of U.S. EPA. To date, no additional guidance has been issued by the U.S. EPA.

Factors (alternative fates and limited availability, using reactivity metrics, targeting highly reactive VOCs) cited in the 2005 U.S. EPA Guidance document referenced by the commenter, are in no way considered in the current LVP-VOC exemption in the CPR. CARB and SCAQMD staff will continue to work closely with interested stakeholders, including consumer product manufacturers, using the best scientific data to revise the LVP-VOC exemption. Moreover, given that the “black box” requires additional VOC reductions beyond those available with existing technology, SCAQMD needs to reduce VOCs from all feasible sources, even if their reactivity is low compared to high reactivity VOCs.

See response to comment #2-7 with regard to the relationship between reactivity and ozone production. For a discussion of the reasons for including consumer products as an ozone measure, see response to comment #2-6.

- 2-15 See response to comment #2-7 with regard to the relationship between reactivity and ozone production. For a discussion of the reasons for including consumer products as an ozone measure, see response to comment #2-6.
- 2-16 See responses to comments #2-6 and #2-7 regarding the necessity and feasibility of VOC reductions from consumer products.
- 2-17 See response to comment #2-5 regarding the need to adopt ozone reduction strategies in the 2012 AQMP.
- 2-18 This comment letter has the following document attached: Attachment A – Sierra Research, Inc. 2007, *Assessment of the Need for Long-term Reduction in Consumer Product Emissions in the South Coast Air Basin*, Prepared for the Consumer Specialty Products Association, September 12. The document evaluated control measures from the 2007 AQMP in an attempt to demonstrate why VOC emission reductions from consumer products are not necessary, so the information it contains is not the most current information available. This document does not specifically include comments on the 2012 AQMP, but attempts to demonstrate why VOC emission reductions are not necessary to attain the ozone standards. With regard to the need for VOC emission reductions, see responses to comments #2-6 and #2-7. In addition, there are no comments on the environmental analysis, mitigation measures, or the alternatives analysis in the Draft Program EIR for the 2012 AQMP. Therefore, no further response is necessary. Because this document does not provide comments or other information on

the 2012 AQMP or the Draft Program EIR for the 2012 AQMP, the full text of this document has not been included in Appendix G; instead, only the cover page is included. The full document comprising Attachment A to this letter, however, is available upon request.

- 2-19 This comment has the following document attached: Attachment B – *Scientific Critique of the South Coast Air Quality Management District Paper, “Non-volatile, Semi-volatile, or Volatile: Redefining Volatile for Volatile Organic Compounds*. No authors are listed for this critique, but footnote #1 on page 1 states that the scientists involved in the critique include representatives from CSPA, Personal Care Products Council, etc. This document does not comment on the 2012 AQMP, but critiques a paper prepared by SCAQMD staff regarding defining volatile compounds. It appears that this critique is included in an attempt to further demonstrate why VOC emission reductions from consumer products are not necessary to attain the ozone standards. With regard to the need for VOC emission reductions, see responses to comments #2-6 and #2-7. In addition, there are no comments specifically on the environmental analysis, mitigation measures, or the alternatives analysis in the Draft Program EIR for the 2012 AQMP. Therefore, no further response is necessary. Because this document does not provide comments or other information on the 2012 AQMP or the Draft Program EIR for the 2012 AQMP, the full text of this document has not been included in Appendix G; instead, only the cover page is included. The full document comprising Attachment B to this letter, however, is available upon request.

- 2-20 This comment letter also has the following document attached: Attachment C – Sierra Research, Inc. 1997, *Impact of Consumer Products on California’s Air Quality*, Prepared for the Chemical Specialties Manufacturers Association and the Cosmetic, Toiletry, and Fragrance Association, July 19. This document was prepared in 1997 and makes many of same points already expressed in the comment letter as indicated in the following paragraphs.

The paper concludes that VOC emissions are overestimated in the 1994 SIP. The implication is that VOC emissions from consumer products are overestimated in the current inventory. See response to comment #2-7 which indicates that consumer products represent the largest single source of VOC emissions. Response to comment #2-7 notes, however, that there is uncertainty about the VOC inventory for consumer products because of the current LVP-VOC exemption. Finally, evidence is accumulating that compared to VOC emissions from other sources, VOCs from consumer products have similar evaporation profiles, higher MIR values and more than four times higher predicted air partitioning factors.

The paper also asserts that VOC emissions from consumer products are less photochemically reactive. See response to comment #2-7.

The paper asserts that VOC emissions from consumer products have far less impact on air quality in California than VOC emissions from other sources. See response to comment #2-7.

The paper asserts that no further regulations of consumer products are necessary. See responses to comments #2-6 and #2-7 for a discussion of the reasons for regulating consumer products.

Finally, due to its size, the full text of this document has not been included in Appendix G; instead, only the cover page is included. The full document comprising Attachment C to this letter, however, is available upon request.

Re: *Comments on Draft Environmental Impact Report for 2012 Air Quality Management Plan*

Dear Mr. Inabinet:

This letter is submitted on behalf of the County of Orange ("County") in its capacity as the owner and operator of John Wayne Airport, Orange County ("JWA"). This letter contains the County's written comments on the Draft Program Environmental Impact Report ("Draft PEIR") for the proposed 2012 Air Quality Management Plan ("2012 AQMP"), issued by the South Coast Air Quality Management District ("SCAQMD" or "District"). The County appreciates the opportunity to provide comments on the Draft PEIR.¹

3-2

Our comments on the Draft EIR are intended to serve the following principal objectives:

1. First, we appreciate the opportunity to continue to work constructively and cooperatively with the SCAQMD in evaluating and developing realistic airport emissions inventories and aviation forecasts for the proposed 2012 AQMP and analyzing the potential environmental impacts of the proposed measures. We hope that our past comments, our comments in this letter, and our continued cooperation in this process will allow us to make meaningful contributions toward resolving and addressing the difficult and complex airport regulatory issues associated with air quality in the Basin.
2. Second, we are concerned with a number of the responses that the SCAQMD provided to our July 27, 2012, comment letter on the Notice of Preparation and Initial Study ("NOP/IS") for the proposed 2012 AQMP. These responses warrant further comment and discussion at this time.

3-3

3-4

¹ The County has previously submitted comment letters on the Notice of Preparation of a Draft Program EIR, the draft 2012 AQMP and The Integra Report. Please see enclosed comment letters to Mr. Steve Smith from Ms. Lori Ballance, dated July 27, 2012, to SCAQMD from Mr. Alan Murphy, dated August 31, 2012, and to SCAQMD from Mr. Alan Murphy, dated September 28, 2012.

Mr. Jeff Inabinet
 South Coast Air Quality Management District
 October 23, 2012
 Page 2

3. Third, there are important questions and issues which must be addressed in the EIR which have not been addressed, including the accuracy of the baseline emissions inventory, whether the lack of clarity regarding the proposed emission control measures prevents the EIR from meeting CEQA's informational disclosure standards, whether this lack of clarity renders the project description so uncertain that the impact analysis is speculative, and whether emission reductions associated with these measures can actually be quantified because their parameters are so uncertain. Without careful attention and response to these important issues, the District will be unable to provide an EIR that meets the CEQA requirements and will be unable to structure appropriate and effective air quality regulations which might affect the operations of the air carrier airports in the Basin while minimizing the environmental impacts of those regulations. 3-5
4. Fourth, and finally, we continue to have a number of concerns and questions regarding Control Measures MCS-03 and ADV-07 as well as the long term black box measures and the proposed regulation of ultrafine particles that require further comment and discussion. 3-6

GENERAL COMMENTS

EMISSION INVENTORY

The draft AQMP provides an emission inventory using 2008 as the baseline year. In our July 27, 2012, written comments to the District on the NOP/IS, JWA expressed concern regarding the accuracy of the baseline emissions inventory assumptions utilized in the CEQA analysis for the 2012 AQMP.² In order to help ensure the accuracy of the baseline emissions inventory assumptions for JWA, JWA provided the District with aircraft activity data and airport specific data for JWA for incorporation into the 2012 AQMP and requested that the baseline emissions inventory be updated and modified to incorporate this new information. In response to the County's request, the District indicated that staff "... will consider the request ... and determine the magnitude of the change from the information provided in the Draft 2012 AQMP." We want to confirm by this letter that staff will include all of the information provided by JWA to the District with respect to the aircraft activity data and airport specific data for JWA, including, but not limited to, the recent information the County provided after reviewing the Integra Environmental Consulting, Inc. Report which provides the assumptions utilized in preparing the 2012 AQMP's emissions inventories relative to the aviation sector. 3-7

We are particularly concerned with this issue because the baseline year is not only used to determine future year air quality emissions projections, but also appears to be used in the development of AQMP control measures. As we have stated in our previous comments to the

² A copy of the District's response to this letter is included in Appendix B to the Draft EIR.

Mr. Jeff Inabinet
 South Coast Air Quality Management District
 October 23, 2012
 Page 3

District, the District needs to be seriously concerned about both the accuracy and completeness of the existing data that it relied upon for the emission inventory. Revision is required to accurately reflect the baseline and projected future activity levels at JWA. These revisions should be presented in the 2012 AQMP and the County recommends that the Draft EIR be revised to accommodate such a discussion, as well.

3-7
 Con't

DISTRICT’S LACK OF REGULATORY AUTHORITY RELATIVE TO AIRCRAFT EMISSIONS

In our July 27, 2012, written comments on the NOP/IS, we requested that the District clearly inform the public and decision makers of the District’s lack of regulatory purview relative to aircraft emissions. Although the District’s response to this request acknowledges that “the Clean Air Act expressly preempts state and local agencies from adopting or enforcing any standard respecting emissions of any air pollutant from any aircraft or engine thereof unless such standard is identical to a standard [adopted by EPA and FAA] applicable to aircraft ...”, the District’s response also indicates that “...the term standard ... does not include in-use or operational requirements [and that] whether any individual measure, which does not constitute a standard preempted under the CAA, would be preempted by any other law would need to be decided on the facts of each case.”

3-8

We continue to have a fundamental disagreement with the District regarding the extent of the District’s authority to regulate aircraft emissions. Specifically, we continue to believe that, to the extent the District attempts to regulate aircraft related emissions, directly or indirectly (through in-use or operational requirements), any such regulation would constitute a constitutionally impermissible local intrusion into a federally preempted field of regulation. *People of State of Cal., v. Dept. of Navy* (1977) 431 F.Supp. 1271, 1281; *Washington v. General Motors Corp.* (1972) 405 U.S. 109, 92 S.Ct. 1396, 31 L.Ed.2d 727. The District’s attempted indirect regulation of airport related emissions through in-use or operational requirements would be an impermissible and unconstitutional intrusion into an area which is pervasively and exclusively controlled by federal law and federal authority. *City of Burbank v. Lockheed Air Terminal, Inc.* (1973) 411 U.S. 624, 633.

SPECIFIC COMMENTS ON FAILURE TO MEET CEQA REQUIREMENTS

PERFORMANCE STANDARDS

The Draft EIR is a program EIR that attempts to examine the environmental effects of the proposed control measures that we understand will ultimately be issued as rules or regulations and promulgated as part of a continuing regulatory program for the District. Although a program EIR may properly focus on “broad policy alternatives and program wide mitigation measures,” as well as “regional influences, secondary effects, cumulative impacts, broad alternatives and other factors that apply to the program as a whole,” the District should adopt performance

3-9

Mr. Jeff Inabinet
South Coast Air Quality Management District
October 23, 2012
Page 4

standards or objectives that can then be translated into specific measures or regulations when a project specific CEQA analysis is prepared. The Draft PEIR fails to comply with this requirement.

Although the 2012 AQMP has identified a number of control measures, the EIR, in many cases, fails to discuss any performance standards for these measures. For example, proposed Control Measure MCS-03 includes as a methodology “diverting or eliminating process streams that are vented to flares, and installing redundant equipment to increase operational reliability.” (EIR, p. 4.2-4). However, the District has not provided any performance standards that it feels are appropriate – the EIR must address any performance targets that have been established so that they can be translated into specific control measures. Similarly, proposed Control Measure ADV-07 includes measures “to continue the development of cleaner aircraft engines and work with the airlines and local airport authorities to develop mechanisms to route the cleanest aircraft to serve the South Coast Air Basin.” (EIR, p. 2-28). Again, the EIR must address any performance targets that the District has established independent from the FAA’s CLEEN Program so that they also can be translated into specific control measures for the airline and airport industry.

3-9
Con’t

CEQA’S INFORMATIONAL DISCLOSURE STANDARDS

The lack of clarity regarding the proposed control measures also prevents the EIR from meeting CEQA’s informational disclosure standards and arguably renders the project description so uncertain that the impact analysis borders on speculation. As stated above, the proposed control measures must be revised to include performance standards and objectives to provide an adequate basis for the impact analysis.

3-10

EMISSION REDUCTION CREDITS

In addition, because of the uncertain parameters of the proposed control measures, the EIR should not indicate that emission reductions will be associated with these measures. Only once the parameters of each of the control measures are better defined can the analysis provide a meaningful discussion of possible emission reductions that may result from implementation of the control measures.

3-11

AREAS OF CONTROVERSY

CEQA Guidelines require an EIR to contain a discussion of the areas of controversy known to the lead agency, including issues raised by agencies and the public and issues to be resolved. Cal.Code Regs. 15123(b)(2)(3). Although the draft PEIR provides a brief discussion, this discussion is incomplete and must be revised. Specifically, this section must include those issues raised by the County in connection with its comment letters submitted on both the NOP and the

3-12

Mr. Jeff Inabinet
South Coast Air Quality Management District
October 23, 2012
Page 5

Draft 2012 AQMP including, but not limited to, issues relating to the accurateness of the baseline data used and the cost effectiveness of the measures proposed.

3-12
Con't

SPECIFIC COMMENTS ON PROPOSED CONTROL MEASURES

CONTROL MEASURE MCS-03

With respect to Control Measure MCS-03, although we appreciate the District's response to our comment letter on the NOP/IS which acknowledges that "operational, technological and economic variables will be among the key variables to be consider[ed] ..." during the second phase of implementation, there is little, if any, discussion in the Draft PEIR regarding these constraints and how they will be taken into account when designing the measure's parameters and predicting associated emission reductions. The Draft PEIR should be revised to include a discussion relative to the fact that controlling emissions during start-up and shutdown is constrained by operational, technological and economic limitations and provide an analysis of how these limitations may impact the projected emission reductions for this Measure.

3-13

CONTROL MEASURE ADV-07

Relative to Control Measure ADV-07, as indicated in our comment letter on the Draft 2012 AQMP, we continue to be concerned about the extent to which ADV-07 is intended to impose affirmative obligations on the District or local airport authorities to regulate the aircraft fleet mix serving the South Coast Air Basin. Although we continue to have no immediate objection to the District providing support for FAA's Continuous Lower Energy, Emissions and Noise ("CLEEN") Program, JWA objects to any measure that requires local airport authorities to regulate the aircraft fleet mix serving the South Coast Air Basin on the grounds that such affirmative obligation would be incompatible with the jurisdictional authorities and powers of airport owners/operators. The Draft PEIR should be revised to provide additional information on the ultimate intent of ADV-07.

In addition to the concern addressed above, we are also concerned that the EIR fails to discuss any performance standards for this Control Measure ADV-07. As indicated on page 2-28 and 4.2-37 of the Draft PEIR, the proposed Measure includes the development of cleaner aircraft engines; however, the only performance standard provided for this Measure is based on FAA's CLEEN Program, which has as a goal the development of new aircraft engines that are up to 60 percent cleaner in NOx emissions than current aircraft engines. Is this the performance target that the District has established for this Measure and, if so, will this performance target be used to develop additional specific control measures for the airline industry? The Draft PEIR must clarify any performance targets that have been established for this Control Measure, whether this Control Measure is intended to merely provide support for the CLEEN program, and discuss

3-14

Mr. Jeff Inabinet
South Coast Air Quality Management District
October 23, 2012
Page 6

whether any additional affirmative obligations will be imposed on the District or local airport authorities with respect to the regulation of the aircraft fleet mix serving the Basin.

3-14
Con't

The proposed Control Measure also includes working with the airlines and local airport authorities to develop mechanisms to route the cleanest aircraft to serve the South Coast Air Basin. As we have discussed with the District on many occasions in the past, neither the District nor airport operators can ensure that only the "cleanest aircraft" operated by commercial airlines serve the Basin; such a requirement would trigger federal preemption and interstate commerce implications. In addition, we have serious doubt, particularly after adoption of the Airport Noise and Capacity Act of 1990 (49 USCA 2151, et seq.), as to whether airport proprietors generally have sufficient residual authority to act effectively as the agencies working with the District and the airlines in developing, implementing and enforcing a program that requires the cleanest aircraft to serve the Basin. At a minimum, the District should receive adequate assurances from the Federal Aviation Administration, the Department of Transportation, and any other relevant federal authorities that airport proprietors do, in fact, have sufficient regulatory authority to allow them to make meaningful implementation choices which would allow them to enforce local regulations to achieve whatever mandates are imposed on them by the District.

3-15

LONG-TERM (BLACK BOX) CONTROL MEASURES FROM THE 2007 AQMP

Table 6-2 in the Draft PEIR shows the black box measure strategies from the 2007 AQMP and also shows the proposed control measures from the 2012 AQMP that affect the same emissions sources. It is unclear from this Table and the discussion provided whether the methods of emissions control from the 2007 AQMP are still being considered for implementation. Specifically, the method of emissions control for aircraft from the 2007 AQMP is as follows: "More stringent emission standards for jet aircraft (engine standards, clean fuels, retrofit controls); Airport bubble."

It is unclear from the discussion whether the District is still considering implementation of an "airport bubble" concept in connection with the proposed 2012 AQMP control measures. The EIR must clarify whether this method of emission control is still being considered and whether this concept will be translated into specific control measures for the airport and airline industry.

3-16

We have discussed at length with the District our concern regarding the role of the airport proprietor relative to the administration of air quality emission strategies at airports in the Basin. As you know, we have expressed strong opposition to the "airport bubble" concept previously proposed by the District and will continue to oppose any measure that requires an airport to become the air quality "enforcer" for airport users.

Mr. Jeff Inabinet
South Coast Air Quality Management District
October 23, 2012
Page 7

REGULATION OF ULTRAFINE PARTICLES

As indicated in the District's response to the County's comment letter on the NOP/IS for the 2012 AQMP, the District is continuing to include a discussion of the evaluation of ultrafine particles as a "subset of PM_{2.5}." This is neither necessary nor appropriate for the following reasons. First, while the federal Clean Air Act requires submittal of a plan by December 14, 2012 outlining how the District will achieve the National Ambient Air Quality Standards (NAAQS) for PM_{2.5} in the South Coast Air Basin, there is no such deadline for ultrafine particles which are not regulated by NAAQS. Second, by including control measures specific to ultrafine particles in connection with their status as a subset of PM_{2.5}, the District is addressing issues beyond the current regulatory framework established by the U.S. Environmental Protection Agency via the NAAQS program. Third, and finally, it is impossible to determine how the PM_{2.5} control measures may regulate ultrafine particles as a "subset of PM_{2.5}."

3-17

As indicated in our comment letter on the Draft 2012 AQMP, the County/JWA supports a bifurcated approach to 2012 AQMP which focuses on attention on NAAQS achievement; other air quality related issues relating to ultrafine particles can, and should, be addressed via a separate and subsequent process.

CONCLUSION

In closing, the County/JWA thanks the District again for this opportunity to comment on the Draft PEIR for the 2012 AQMP. We look forward to continuing to engage in an open, thorough and responsive public process on the 2012 AQMP and assisting the District with its efforts to improve air quality in the South Coast Air Basin. If you have any questions regarding the issues addressed in this letter, please do not hesitate to contact us at your convenience.

3-18

Very truly yours,

A handwritten signature in cursive script that reads "Lori D. Ballance".

Responses to Comment Letter #3
Gatzke Dillon & Balance Representing Orange County – Lori Balance (10/23/2012)

- 3-1 This comment notifies the SCAQMD that a comment letter submitted on behalf of John Wayne Airport is attached. No further response is necessary.
- 3-2 This comment notifies the SCAQMD that the comment letter on the Draft Program EIR is submitted on behalf of Orange County in its capacity as the owner and operator of the John Wayne Airport is attached. No further response is necessary. The comment also provides a general statement that the comments serve a number of principal objectives. With regard to the principal objectives stated and SCAQMD staff's responses to these principal objectives, see responses to comments #3-3 through #3-6.
- 3-3 The comment requests that past comments, current comments, and continued cooperation in this process will allow the County to continue contributing to complex airport regulatory issues associated with air quality in the Basin. The SCAQMD welcomes participation in AQMP development from all stakeholders including, but not limited to, public agencies, affected industries, environmental organizations, and other interested parties. To the extent that AQMP control measures affect a specific stakeholder group, it is important that the group affected participate in crafting control measures, as well as any resulting rules or regulations. Currently, the 2012 AQMP contains Control Measure ADV-07 – Actions for the Deployment of Cleaner Aircraft Engines. This control measure describes the actions needed to develop, demonstrate, and commercialize advanced technologies, procedures, and sustainable alternative jet fuels that could be deployed in the 2020 to 2030 timeframe, so no emission reductions are associated with it as part of this AQMP process. The control measure recognizes that state and local aircraft emission regulations are preempted by the Clean Air Act, which gives that responsibility to U.S. EPA in consultation with the Federal Aviation Administration (FAA). However, emission reductions are needed from all emissions sources, including those regulated by the federal government. Therefore, it is important that the County participated in any future control measure development relative to emission reductions from aircraft to ensure the most effective and cost-effective measures are identified.
- 3-4 This comment expresses general concern regarding SCAQMD responses to comments regarding the NOP/IS for the 2012 AQMP, although the comment does not identify the specific responses of concern. The SCAQMD provided responses to all comments received relative to the NOP/IS. However, it is important to keep in mind that responses to comments made at the NOP/IS stage often result in changes that get incorporated into the Draft Program EIR. Further, at the NOP/IS stage, the environmental analysis is not complete, so detailed responses were not always possible.
- 3-5 With regard to the accuracy of the baseline emissions inventory, see response to comment #3-7.

The comment also states that, without consideration of the baseline issue identified in the first part of the comment, the Draft Program EIR is prevented from meeting CEQA's disclosure requirements and the SCAQMD would be unable to structure appropriate and effective air quality regulations affecting airports while minimizing environmental impacts of those regulations. SCAQMD staff disagrees with the assertion that the

Program EIR does not comply with CEQA's disclosure requirements. The Program EIR complies with all relevant CEQA requirements for preparing an EIR (CEQA Guidelines §§15120 through 15131) and for preparing a program CEQA document (CEQA Guidelines §15168). Regarding the comment on disclosure requirements and the project description, see response to comment #3-10.

It is also unclear what is meant by the phrase structure appropriate and effective air quality regulations. Among other requirements, one of the primary purposes of the Program EIR is to evaluate adverse environmental impacts from the control measures in the 2012 AQMP as written. Some of the control measures, especially long-term and advanced control measures, cannot at this stage identify specific control technologies anticipated to be used to comply with any future regulatory requirements or include emission reduction targets. As a result, assumptions had to be made to provide a comprehensive and conservative environmental analysis. The Program EIR describes all 2012 AQMP control measures to the extent they have been developed. Further development would occur in the future when the control measures are promulgated as rules or regulations. Control measures will be promulgated as rules, regulations, or other mechanisms in the future through an open public process. At that time, a project-specific NEPA and/or CEQA document would be prepared by the appropriate public agency based on the actual regulatory requirements.

- 3-6 This comment expresses general concerns regarding several control measures in the 2012 AQMP. See responses to comments #3-9 and #3-13 regarding a discussion of Control Measure MCS-03 and responses to comments #3-9 and #3-14 regarding a discussion of Control Measure ADV-07.
- 3-7 The 2012 AQMP baseline inventory was developed incorporating all information submitted by John Wayne Airport and SCAQMD staff will revise the Integra Report to reflect the updated information provided by the airport authority. SCAG's growth information was used to estimate the future airport activity listed in Table 3.3 of the Integra Report and is further described in their Aviation and Ground Access Appendix of the 2012 Regional Transportation Plan (http://rtpscs.scag.ca.gov/Documents/2012/final/SR/2012fRTP_Aviation.pdf).

The emission estimates for 2035 listed in Table 2.4 of the Integra Report were generated using the airport activity as estimated by SCAG's RADAM model and FAA's Emissions and Dispersion Modeling System (EDMS) airport model. For John Wayne Airport the activity was capped at the authorized limit of 10.8 MAP. The emission estimates for John Wayne Airport are not inconsistent with the expected improvement in engine technology and growth in airport activity in that increased activity resulted in increased emissions with the exception of NO_x, which has been and will continue to be the main focus of emissions improvements from aircraft engines.

The projected 2035 fleet mix was provided by SCAG and is included in their recently adopted 2012–2035 RTP/SCS. The estimates were generated by the Regional Airport Demand Allocation Model (RADAM) an approved model used by SCAG staff since 1994 to project growth in aircraft activity in the region. While SCAQMD staff recognizes that operations at the airport do not include some aircraft types today, there is nothing limiting the use of these types in the future and we believe it is appropriate to use

information that is consistent with SCAG’s 2012–2035 RTP/SCS and other growth assumptions used in the AQMP. (The one exception would be a physical characteristic that would not allow operation of an aircraft type at the airport such as the B737-900 craft referenced as too long to operate at John Wayne Airport. However the engine type is the same as the other B737 classes that would likely be used in lieu of the 900 series and we would expect the estimated emissions would be similar).

- 3-8 The comment repeats a concern that an attempt by the SCAQMD to regulate airport related emissions, even through in-use or operational requirements, would be federally preempted. As identified in NOP/IS response to comment #4-7 (see Appendix B of this Program EIR), the Clean Air Act generally preempts state and local agencies from adopting or enforcing any standard respecting emissions of any air pollutant from any aircraft or engine. [42 U.S.C. §7573.] The term “standard”, however, does not include in-use or operational requirements. [*Engine Manufacturers’ Association v. EPA*, 88 F.3d 1075 (D.C. Cir. 1996).]

In any event, Control Measure ADV-07 does not purport to seek regulation of aircraft emissions. The control measure does not take credit for emissions reductions, does not identify cost effectiveness and recognizes that the implementing agencies are the SCAQMD, U.S. FAA, U.S. EPA, and CARB (see AQMP Appendix IV-B, page IV-B-86). Rather, ADV-07 is intended to develop and demonstrate new technologies for improved efficiency and reduced emissions through the FAA initiated Continuous Lower Energy, Emissions and Noise (CLEEN) program and through other incentive-based or demonstration-based projects (see AQMP Appendix IV-B, page IV-B-86). If, through the development of these projects, it is determined that feasible regulatory action exists, the SCAQMD may elect to pursue that path after determining whether such action, while not preempted under the CAA, would be preempted by any other law.

- 3-9 The comment states that the SCAQMD should adopt performance standards or objectives that can be translated into specific measures or regulations when a project-specific CEQA analysis is prepared. It is assumed here that, since the terms performance standards and objectives refer specifically to the control measures, the comment is requesting specific emission reduction targets for each control measure, which will be addressed in the following paragraphs. However, CEQA does not require “performance standards” for control measures in an AQMP. If objectives refer to project objectives defined pursuant to CEQA Guidelines §15124, then the commenter is referred to Section 2.9 in Chapter 2 of the Program EIR, which clearly identifies the objectives of the 2012 AQMP.

While some of the control measures have performance standards or emission reduction expectations, each control measure varies in inventory, targeted pollutant, affected sources, and ability to generate emission reductions. For these reasons, a standardized objective for all measures is not possible. The primarily goal is to reduce emissions but the methods of achieving reductions can vary, for example modifying operating processes, upgrading/replacing equipment, or lowering emission rates. The goal of Control Measure MCS-03 is to establish procedures to better quantify emission impacts from start-up, shutdown and turnarounds. Secondly, an analysis will be conducted to identify improved operating procedures that minimize emissions. The target emission reductions from this control measure have not yet been determined because the analysis

that will take place during rule development has not been completed to reach that conclusion.

The advanced control technology (ADV) measures are designed to deploy the cleanest control technologies as early as possible, but many of these actions will need time to develop. Specific amount of expected reduction from future proposed requirements will be determined during the rule development phase and after control technology is deployed.

It should be noted that the development of control strategies for the 2012 AQMP and selection of emission reduction measures are based on a list of criteria. The criteria include technological feasibility, cost effectiveness, emission reduction potential, rate of emission reduction, enforceability, public acceptability and legal authority. For further discussion of the criteria, see Table 4-1 in Chapter 4 of the 2012 AQMP. For the 2012 AQMP, other goals were considered such as promoting fair share responsibility and maximizing private/public partnerships.

The comment acknowledges that the CEQA document for the 2012 AQMP is a Program EIR and a Program EIR properly focuses on broad policy alternatives and program wide mitigation measures.” The comment states that the EIR must address performance targets established independent from FAA’s CLEEN Program so they can be translated into specific control measures for the airline and airport industry. As noted in response to comment #3-3, Control Measure ADV-07 describes actions that could be deployed in the 2020 to 2030 timeframe, so no emission reductions are associated with it as part of this AQMP process. There is no requirement that a particular control measure must include emission reduction targets. Among other requirements, the AQMP must demonstrate attainment with the applicable ambient air quality standards for the non-attainment pollutants. In the case of the 2012 AQMP, it is specifically a PM2.5 SIP that demonstrates attainment of the federal 24-hour PM2.5 standard by 2015, as required by the CAA and contains additional ozone control measures to partially fulfill the 2007 SIP commitment. SCAQMD staff is also proposing a one-hour ozone demonstration to comply with U.S. EPA’s proposed SIP call. This demonstration is included in 2012 AQMP Appendix VII. As noted in response to comment #3-5, one of the main purposes of the Program EIR is to analyze environmental impacts from the control measures as written, which it does.

- 3-10 The comment states that there is a lack of clarity regarding the 2012 AQMP control measures because, in part, they do not include performance standards and objectives. As a result, the Program EIR does not meet CEQA’s disclosure standards, the project description is uncertain and the impact analysis is speculative. With regard to performance standards and objectives, see response to comment #3-9. The Program EIR includes a comprehensive description of the proposed project in Chapter 2, which includes summaries of all stationary and mobile source control measures. Similarly, Appendix F identifies all transportation control measures provided by SCAG. Further, the actual 2012 AQMP and associated appendices describing the control measures were available concurrently with the Draft Program EIR. The Program EIR complies with all relevant CEQA requirements for preparing a project description (see CEQA Guidelines §15124). The environmental analysis in the Program EIR includes examinations of potential secondary impacts from emission reduction technologies, as well as impacts

from other types of compliance approaches and is, therefore, not speculative. CEQA recognizes that preparing an EIR involves some degree of forecasting, and must use its best efforts to find out and disclose all that it reasonably can (CEQA Guidelines §15144). The Program EIR was prepared consistent with CEQA Guidelines §15144 and has disclosed all impacts that it reasonably can. Chapter 4 of the Program EIR includes robust analyses of potential adverse impacts to each of the environmental topics analyzed. Further, the analyses of environmental impacts in the Program EIR are commensurate with the level of detail of the 2012 AQMP and, therefore, cannot be as detailed as the environmental analysis for a specific construction project. The subchapters clearly identify control measures that could potentially contribute to impacts to that environmental topic; provides a quantitative or qualitative analysis of all control measures and PM2.5 control measures separately from the ozone control measures, depending on the information available for that control measure; and provides significance determinations for the 2012 AQMP overall and separately for impacts from PM2.5 and ozone control measures.

- 3-11 As noted in response to comment #3-9, criteria are followed in the development of the control measures. Some source categories already have established inventories and proposed methods of future control that enabled SCAQMD staff to determine an anticipated range of emission reductions from implementation of the proposed control strategy. Other measures, however, require further evaluation of inventory, available control technology, etc., that can only be established with a technological assessment and public participation during the rule development process. Estimated emission reductions will be determined at that time.
- 3-12 This comment requests the areas of controversy discussion in the Draft Program EIR to be revised to reflect issues previously raised on behalf of John Wayne Airport. While it is correct that CEQA Guidelines §15123 (b)(2) requires a public agency to identify the areas of controversy in the CEQA document, including issues raised by agencies and the public, no areas of controversy were identified at the time of release of the NOP/IS relative to the environmental analysis so no discussion was included in the NOP/IS. In response to this comment, however, an areas of controversy discussion has been added to the Final Program EIR. The issue of cost-effectiveness of the AQMP control measures is not an environmental topic required to be analyzed in a CEQA document because it did not result in a chain of cause and effect resulting in physical effects. Cost effectiveness is a topic discussed in the Socioeconomic report. With regard to the issue raised in this comment relative to the baseline, the 2012 AQMP baseline inventory was developed incorporating all information submitted by John Wayne Airport. Consequently, because the baseline inventory incorporates the data provided by the John Wayne Airport, this issue does not constitute an area of controversy as defined by CEQA. As explained in Section 1.3 in Chapter 1, no areas of controversy were identified in this comment letter or other comment letters on the Draft Program EIR received by the SCAQMD.
- 3-13 All control measures identified in the 2012 AQMP may be subject to constraints specific to the emission sources being controlled. Control measures are general blueprints for reducing emissions from affected sources, including sources that would be regulated by Control Measure MCS-03. Determining potential operational, technical and economic constraints more appropriately takes place during the rule development process when a

thorough evaluation of the source category is performed. Similarly, during the rule development process input from, and participation by affected industry, stakeholders, and the public would help identify potential constraints and strategies for overcoming these constraints, such as tiered compliance dates, compliance exemptions, and program incentives. Control measure MCS-03 is expected to initially include an evaluation of emission reductions from a number of sources, refineries in particular.

The analysis in the Draft Program EIR takes a conservative approach to analyzing environmental impacts from control measures such as MCS-03. Reasonable assumptions were made regarding potential types of control technologies or approaches that could be used to reduce emissions from this source category and secondary environmental impacts were analyzed accordingly.

- 3-14 Control Measure ADV-07 includes recognition of the efforts associated with the CLEEN Program to develop cleaner aircraft engines. However, in order to route cleaner aircraft to region, there is a need to determine if there are mechanisms such as incentives that will bring cleaner aircraft to the region. SCAQMD staff recognizes that this effort will involve local airport authorities, state and federal agencies and the airlines. It is premature at this point to determine the “performance target” for this measure since specific mechanisms have not been developed. The measure will be further developed as part of the next AQMP development.
- 3-15 The commenter asserts that a control measure that would have the SCAQMD work with the airports and airlines to develop mechanisms to route the cleanest aircraft to serve the South Coast Air Basin would necessarily be federally preempted, particularly in light of the Airport Noise and Capacity Act of 1990 (49 U.S.C. §2151 et seq.). SCAQMD staff disagrees. The measure involves working together with the affected parties. SCAQMD staff notes that the relevant preemption provision, 49 U.S.C. §41713, preempts regulations that “have the force and effect of law related to a price, route, or service of an air carrier...” Thus, it would not include, for example, incentive programs not having the force and effect of law. Moreover, the statute expressly provides that it does not limit a state or political subdivision of a state “from carrying out its proprietary powers and rights.” [49 U.S.C. §41713 (b)(3).] Thus, the airports may be able to exercise their authority as “municipal proprietors” in this area. The Airport Noise and Capacity Act (now reorganized at 49 U.S.C. §47521 et seq.) does not seem to be relevant since it deals with noise restrictions, and should not be interpreted to apply to air pollution issues. But even if it applied, it still allows restrictions on noisier aircraft in certain cases. [49 U.S.C. §47524.] The SCAQMD will work with the airports and other stakeholders to implement this measure to the extent legally feasible and not preempted.
- 3-16 As indicated in the text of Chapter 6 in the Draft Program EIR, Alternative 1 – No Project Alternative, consists of not adopting the 2012 AQMP. In this situation, the currently adopted AQMP, which is the 2007 AQMP, would remain in effect. Similarly, adopting Alternative 4 – PM_{2.5} Emissions Reduction Strategy Only, nevertheless means the ozone portion of the 2007 AQMP would still remain in effect. Table 6-2 identifies the remaining measures from the 2007 AQMP that could be implemented under these two scenarios. If Alternative 1 or Alternative 4 is adopted, then the airport control measure from the 2007 AQMP could be promulgated as a rule in the future based on the fact that it is also a control measure from the 2007 AQMP. Since the airport control measure in

the 2007 AQMP includes the bubbling concept, this could be considered in any future rule that is promulgated. Control measure ADV-07 in the 2012 AQMP does not identify airport bubbling as a proposed method of control.

The black box control measures in the 2007 AQMP are concepts that require further development. These concepts will be further developed with input from all affected stakeholders. Concepts included in the 2007 AQMP black box measures but not discussed in ADV-07 should not be interpreted as being removed from further consideration. Ultimately, some concepts may require actions on the federal level to implement, while other actions may potentially be incentives based that could be implemented at the local level.

- 3-17 Although it is correct that no national ambient air quality standards have been established for ultrafine particles, they are not part of demonstration of attainment of the 24-hour PM_{2.5} standard as analyzed in Chapter 5 and Appendix V of the 2012 AQMP. In addition, ultrafine particulates are not characterized in the emissions inventory data and were not considered in the development of the control strategy. Thus, no commitments to reduce ultrafine particles are submitted in the 2012 AQMP. Finally, the PM_{2.5} control measures in the 2012 AQMP do not specifically regulate ultrafine particles. As discussed in Chapter 9 of the 2012 AQMP, in most urban environments, vehicular fossil fuel combustion constitutes the major contributing sources of ultrafine particles. The PM_{2.5} control strategy in the 2012 AQMP is the curtailment of wood burning, thus, targeting PM_{2.5} emissions and not ultrafine particles. Reference to ultrafine particulates as a subset of PM_{2.5} in the 2012 AQMP is meant to inform the public that PM_{2.5} control measures would potentially provide ultrafine emission reductions. Although ultrafine particulates are included in the PM_{2.5} category, there are not control measures specific to ultrafine particulates in the 2012 AQMP.
- 3-18 The comment reiterates the County's desire to continue working with the SCAQMD with its efforts to improve air quality in the Basin. No further response is necessary.
- 3-19 This comment letter has the following documents attached as enclosures.
1. Copy of a July 27, 2012 comment letter from Ms. Lori Ballance on the June 28, 2012 NOP/IS for the 2012 AQMP. Responses to these comments were prepared and have been included in Appendix B of the Draft and Final Program EIR. Since this document is in Appendix B, it has not been included in Appendix G of the Final Program EIR.
 2. Copy of the August 31, 2012 comment letter from Ms. Lori Ballance on the Draft 2012 AQMP. This comment letter and responses to these comments have been prepared by AQMP staff and will be made available prior to the adoption hearing. Since this comment letter and responses to comments will be included as part of the 2012 AQMP documentation, it is not included here.
 3. Copy of the September 28, 2012 comment letter from Mr. Alan Murphy on the Draft 2012 AQMP. This comment letter and responses to these comments have been prepared by AQMP staff and will be made available prior to the adoption hearing. Since this comment and responses to comments will be included as part of the 2012 AQMP documentation, it is not included here.

The main focus of the above three documents is ensuring that the 2012 AQMP baseline includes up to date information on emissions from the John Wayne Airport. See response to comment #3-7, which addresses this topic.

Dr. William A. Burke, Chairman
Members of the SCAQMD Governing Board
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765

RE: Draft Program EIR for the 2012 Air Quality Management Plan

Dear Chairman Burke and Governing Board Members:

As representatives of Southern California's broader business community, we appreciate the opportunity to provide comments on the 2012 Air Quality Management Plan (AQMP), and, here in particular, on the Draft Program Environmental Impact Report (DPEIR)¹.

Our group is comprised of leaders from many of Southern California's largest regional business entities and associations. The final 2012 AQMP, and the rule making that will eventually stem from it, will directly affect many of these businesses' interests. Our highest priority is to work with SCAQMD to develop a well-balanced strategy that addresses federal requirements through an economically feasible compliance program. To that end, we offer the following comments on the DPEIR:

4-2

1. A PM2.5-Only Plan as an alternative to the project currently proposed.

We requested² that the District include a PM2.5-only alternative in its CEQA evaluation and we very much appreciate the fact that such a Plan has been included as Alternative 4 in the DPEIR. We also want to acknowledge three specific conclusions about Alternative 4 in the DPEIR:

- A PM2.5-only Plan was not rejected as infeasible as were two other potential Alternatives³.
- A PM2.5-only Plan "... is considered to be a legally viable alternative ..." because, with this 2012 Plan submission, the District is only required to demonstrate attainment of the 24-hour PM-2.5 standard⁴.
- Alternative 4 - again, a PM2.5-only Plan - would generate fewer adverse environmental impacts or less severe impacts than the Project (i.e., the draft AQMP)⁵.

4-3

We strongly support these findings.

¹ The DPEIR was released on Thursday, September 8th.

² Comment letter on the CEQA Initial Study, July 27, 2012, comment letter on the Draft AQMP, August 31, 2012, and verbally at workshops and other venues.

³ DPEIR Section 6.3.

⁴ DPEIR Section 6.4.4.

⁵ DPEIR Section 6.8.

2. The summaries of some of the stationary source control measures in the DPEIR⁶ remain at odds with the draft proposed control measures themselves.

As was noted in our letter on the CEQA Initial Study, there were discrepancies between the descriptions of some of the stationary source control measures and the language of the actual measures. Notwithstanding the explanation that the DPEIR examines "... impacts from secondary effects that may not be directly stated in the control measure,"⁷ there are still a few fundamental differences in the descriptions (DPEIR compared to the Revised AQMP).

- CMB-01, NO RECLAIM, Phase I. Whereas the control measure itself has been made a contingency measure, there is no mention of that fact in the summary of the measure in the DPEIR.
- CMB-01, NOx RECLAIM, Phase II. There is no mention in the DPEIR of the contingency status of Phase I. Further, the actual control measure speaks of implementation beginning in 2020 while the summary in the DPEIR states that the control measure would seek further reductions by 2020.
- FUG-01, Vacuum Trucks. The summary in the DPEIR states that the "... control measure seeks to reduce emissions from the further venting of vacuum trucks." It is not known what is meant by "further venting", and there is no such discussion in the control measure itself.
- FUG-02, LPG Transfer and Dispensing. The expansion of the applicability of this control measure to is not a given. As is clearly stated in the control measure, with Rule 1177 having been adopted as Phase I, the intended next phase (Phase II) will be an evaluation of the potential for further emissions reductions.

4-4

3. DPEIR, Appendix F.

The Coalition is concerned that the current title of Appendix F, RTP/SCS Mitigation Measures Table, might be misinterpreted to imply that these are required mitigation measures. The title on the first page of the appendix, "Examples of Measures That Could Reduce Impacts from Planning, Development, and Transportation Projects," accurately conveys the proper meaning. In fact, the wording was carefully crafted by SCAG's Regional Council in response to concerns from local governments and the business community. The title of Appendix A should be changed to agree with the title on page F-1.

4-5

Finally, our July 27th comment letter on the CEQA Initial Study raised our concerns with the non-timely release of documents related to the 2012 AQMP. The District, in its response⁸ to our concerns, noted that four regional hearings had been scheduled in order to provide more opportunity for public comment. However, the late release dates of the DPEIR and the Revised AQMP (September 6th⁹, and September 8th¹⁰,

4-6

⁶ DPEIR Section 2.8.1.1

⁷ Responses to comments number 6-6, DPEIR.

⁸ Responses to comments number 6-4, DPEIR.

⁹ E-mail from CEQA Administration, SCAQMD.

¹⁰ E-mail from Mr. Michael Krause, SCAQMD.

respectively) effectively precluded meaningful review of the documents or presentation of appropriate comments at the regional hearings. We are now aware of the second round of regional hearings (scheduled for November 13th through 15th), and we sincerely hope that there will not be any further changes to the documents prior to these new hearings.

4-6
Con't

As the AQMP process moves forward, the individuals and organizations who have signed onto this letter look forward to our continued partnership with SCAQMD. Please know that the business community remains committed to helping develop a balanced, workable 2012 AQMP that provides for both environmental and economic success. We join here, however, to express our unity in finding that the Draft Program EIR for the 2012 AQMP is in need of additional improvement and correction - especially in regard to the issues outlined above. Also, please note that, in addition to supporting this joint letter, some of our members may wish to submit a comment letter of their own.

4-7

We welcome further discussion of these comments; please contact Tracy Rafter, CEO of BizFed (Tracy.rafter@bizfed.org) or Matt Petteruto, Vice President of Economic Development for the Orange County Business Council (mpetteruto@ocbc.org).

Sincerely,

Tracy Rafter

**Responses to Comment Letter #4
BizFed – David Englin (10/23/2012)**

- 4-1 This comment notifies the SCAQMD that a comment letter is attached to the email. No further response is necessary.
- 4-2 This comment provides a general description of groups represented by the comment letter. No further response is necessary. The comment also states that the groups' priority is to work with the SCAQMD to develop a well-balanced strategy that addresses federal requirements economically. The SCAQMD welcomes participation in the AQMP from all stakeholders including, but not limited to, public agencies, affected industries, environmental organizations, and other interested parties. To the extent that AQMP control measures affect a specific stakeholder group, it is important that the group affected participate in crafting control measures, as well as any resulting rules or regulations.
- 4-3 The comment indicates appreciation for including a PM2.5 only alternative (Alternative 4) in the Program EIR for the 2012 AQMP. The comment also lists three conclusions about Alternative 4 from Chapter 6 and supports the conclusions listed. No further response is necessary.
- 4-4 The comment notes that there were some discrepancies in the description of three control measures in the 6/28/12 NOP/IS compared to the Draft 2012 AQMP. Based on comments received regarding this inconsistency, the NOP/IS was revised to accurately describe the control measures and recirculated for an additional 30-day comment period. No comments were received.

The comment also states that there are fundamental differences in the descriptions in the Draft Program EIR compared to the Revised Draft EIR. SCAQMD staff disagrees with this assertion. As noted in the comment, the text in the Program EIR is a summary, so it does not track the text in the control measure word for word.

The Draft Program EIR does not mention that Phase I of Control Measure CMB-01 is now a contingency measure. In response to public comment, the emission reductions for Control Measure CMB-01 are now included as a contingency measure, which would be implemented if the emission reductions are needed to demonstrate attainment. This minor change has been included in the Final Program EIR as follows. “This proposed control measure will seek further reductions of 2 tpd of NO_x allocations by 2014. The proposed Phase I reductions are designed to serve as a contingency measure. It will be implemented if the Basin does not attain the federal 24-hr PM_{2.5} standard by 2014. If necessary, Phase I is expected to be adopted in 2013 and the shave will be implemented/triggered for compliance year 2015 if the attainment of 24-hr PM_{2.5} standard is not met by 2014.” If Phase I of Control Measure CMB-01 is not triggered or implemented, Phase II would target a cumulative three to five tons per day of NO_x emission reductions. These modifications are noted in the Final Program EIR, were evaluated by SCAQMD staff, and do not affect the environmental analysis in any way because, regardless of whether or not Phase I is implemented, potential adverse impacts would be at most the same as those analyzed in the Draft Program EIR because the same types of secondary environmental impacts from the same types of control equipment

would occur to achieve NOx emission reductions of three to five tons per day. As a result, changing Phase I of Control Measure CMB-01 to a contingency measure does not affect the environmental analysis or change any significance determinations.

The comment also notes that Control Measure CMB-01 states that Phase II would be implemented in 2020, whereas the Draft Program EIR states that Phase II of Control Measure CMB-01 would seek NOx reductions by 2020. Implementation means that the control requirements would be in effect and that emission reductions would be occurring, so the two phrases are not inconsistent. However, the text in the Final Program EIR has been modified to as follows, “This proposed NOx control measure would seek further reductions in NOx allocations by the year is expected to be adopted by 2015 for implementation between 2017 and 2020 to be consistent with the 2012 AQMP. If Control Measure CMB-01, RECLAIM Phase I, contingency measure emission reductions are not triggered and implemented, Phase II will target a cumulative three to five tons per day of NOx emission reductions.”

The comment indicates that the summary of Control Measure FUG-01 in the Draft Program EIR states that the control measure would seek to reduce emissions from further venting from vacuum trucks, whereas, the control measure does not include this exact phrase. To further clarify the summary of Control Measure FUG-01, the text has been modified as follows, “This control measure will primarily focus on high-emitting seeks to reduce emissions from the further venting of vacuum trucks operations, such as those found in petrochemical industries and other operations that include the transfer of volatile liquids such as gasoline.”

The comment also states that the text in the Draft Program EIR does not indicate what the applicability of Control Measure FUG-02 would be expanded to. The summary of Control Measure FUG-02 in Chapter 2 of the Program EIR states, “The purpose of Control Measure FUG-02 is to further reduce fugitive VOC emissions associated with the transfer and dispensing of LPG by expanding rule applicability to include LPG transfer and dispensing at currently exempted facilities such as refineries, marine terminals, natural gas processing plants and pipeline transfer stations, as well as facilities that conduct fill-by-weight techniques.” This sentence clearly states the applicability of Control Measure FUG-02. However, for the full text of Control Measure FUG -02, the commenter is referred to 2012 AQMP Appendix IV-A.

Finally, it should be noted that the Draft Final 2012 AQMP was available for public review and comment during the same time period as the Draft Program EIR was available, so the public had access to the actual description of the 2012 AQMP control measures in addition to the summaries in the Draft Program EIR. As is apparent in the comment, the commenter had a copy of the Draft Final 2012 AQMP control measures to be able to make the comparisons with the summaries in the Draft Program EIR.

- 4-5 The comment requests that the cover page title of Appendix F be changed to match the title on the first page of the appendix. This requested change has been made.
- 4-6 This comment reiterates a previously submitted comment on the NOP/IS from July 27, 2012 regarding the difficulties of not having a sufficient amount of time to review the NOP/IS relative to the scheduling of the regional hearings. The comment also indicates that the timing of releasing the Draft Program EIR and the Revised Draft 2012 AQMP

relative to the scheduling of the four regional hearings held in September precluded meaningful review of the documents and presentation materials. Lastly, this comment acknowledges that additional regional hearings will be held in November and requests that no additional changes to the documents will be made prior to the hearings.

SCAQMD staff, while aware of the compressed time frame for the 2012 AQMP development, is also committed to providing sufficient time for public comment. It is important to note that the development schedule was constrained by the availability of input data from SCAG's 2012 RTP and CARB's emissions inventories as well as U.S. EPA's submittal deadline of December 2012. Nonetheless, SCAQMD staff continues the enhanced outreach efforts to all stakeholders and SCAQMD staff has made every effort to provide all data and information to the public as soon as it became available.

SCAQMD staff believes that there have been ample opportunities for the public to review and comment on the 2012 AQMP and supporting documents, including the NOP/IS and Draft Program EIR as demonstrated in the following timeline of events regarding the 2012 AQMP development process:

- The NOP/IS was released for a 30-day public review and comment period from June 28, 2012 to July 27, 2012. Five public workshops/CEQA scoping meetings were held regarding the NOP/IS on July 10, 2012, July 11, 2012 (two meetings), July 12, 2012 and July 24, 2012.
- The Draft 2012 AQMP (with Appendices I-IV and VI) was released for public review and comment on July 18, 2012. Appendix V of the Draft 2012 AQMP was released for public review and comment on August 2, 2012. Comments were encouraged to be submitted by August 31, 2012 for inclusion of possible modifications into the Revised Draft 2012 AQMP.
- The Recirculated NOP/IS was released for a 30-day public review and comment period from August 2, 2012 to August 31, 2012. Two public workshops/CEQA scoping meetings were held regarding the Recirculated NOP/IS on August 9, 2012 and August 12, 2012.
- The Draft Program EIR was released for a 47-day public review and comment period from September 7, 2012 to October 23, 2012.
- The Revised Draft 2012 AQMP was also released for public review and comment on September 7, 2012.
- Four Regional Hearings for the Revised Draft 2012 AQMP were held between September 11, 2012 and September 13, 2012.
- The Socioeconomic Report was released for a 45-day public review and comment period from September 28, 2012 to November 12, 2012.
- Four additional Regional Hearings for the Revised Draft 2012 AQMP will be held between November 13, 2012 and November 15, 2012.

Further, while comments on the 2012 AQMP can be received up to the date of the Governing Board hearing scheduled for December 7, 2012, SCAQMD staff continues to strongly encourage comments to be submitted as early as possible to allow staff time to

respond and make any necessary modifications to the document. In addition, so that all stakeholders can keep current with issues raised in the comments, all comment letters submitted to the SCAQMD on the 2012 AQMP have been made available online when received (<http://www.aqmd.gov/aqmp/2012aqmp/commentletters/commentlist.html>) and responses to these comments will be released prior to the Governing Board Hearing for consideration during the adoption hearing. Lastly, all comments submitted relative to the Draft Program EIR and their responses have been included in Appendix G of this Final Program EIR.

As demonstrated by the timeline outlined above, the review period for most of the documents has been extended, additional workshops and regional public hearings have been added, and the scheduled Governing Board hearing date has been delayed until December 2012. Further, an additional 45 days were provided when the Socioeconomic Report was released on September 28, 2012.

Thus, SCAQMD staff believes that with such additional review time, adequate time has been provided. For example, the total public review and comment period for both the Draft and Revised Draft 2012 AQMP will be over 100 days.

With regard to the comment about making changes to the documents prior to the regional hearings, there have been minor edits to the Revised Draft 2012 AQMP due to the comments received that have been reflected in the Draft Final 2012 AQMP released November 7, 2012, before the Regional Hearings starting on November 13, 2012. In addition, the Final Program EIR has been modified accordingly. Thus, because of the multiple opportunities for submitting comments, SCAQMD staff could not guarantee that the documents will not be revised again prior to the regional hearings scheduled in November.

Finally, when converting the Draft Program EIR to a Final Program EIR, changes are often made to the text based on public comments received on the environmental analysis. Changes in the text may also be made in response to modifications of the 2012 AQMP resulting from updated information, public testimony or other public comments. Any changes to the Program EIR are evaluated to determine whether or not they provide substantial new information or result in new significant impacts or substantially increase the severity of existing significant impacts, pursuant to CEQA Guidelines §15088.5. If changes to the Program EIR do not trigger any of the conditions identified in CEQA Guidelines §15088.5, recirculation is not required.

- 4-7 This comment states that members of the business community remain committed to helping develop a balanced and workable 2012 AQMP. However, the business community believes that the Program EIR needs improvement and correction, especially with regard to the issues outlined in the comment letter. As noted in response to comment #4-2, the SCAQMD welcomes participation in the AQMP development process from all stakeholders. Further, the Program EIR complies with all relevant CEQA requirements and includes responses to all issues raised in the comment letter. Most requested changes have been made. The changes to the Program EIR suggested in the comments have been evaluated and do not trigger any of the conditions in CEQA Guidelines §15088.5 requiring recirculation.

Subject: Draft 2012 AQMP Program Environmental Impact Report

Dear Mr. Inabinet:

The Port of Long Beach (POLB) and Port of Los Angeles (POLA) appreciate the opportunity to comment on the Draft Program Environmental Impact Report (Draft EIR) developed for the 2012 Air Quality Management Program (AQMP). The ports appreciate that AQMD staff took steps to address the scoping comments provided by the ports, specifically the inclusion of a transportation and traffic impact analysis as part of the Draft EIR.

5-2

However, the ports must reiterate their concerns relating to AQMP Control Measure IND-01 (Backstop Measures for Indirect Sources of Emissions from Ports and Port-Related Sources). As the AQMD knows from prior comment letters submitted by the ports (please see AQMP comment letters dated August 30, 2012; July 10, 2012; and May 4, 2010), the ports believe that Measure IND-01 exceeds the AQMD's authority and should not be included in the AQMP for the reasons set forth in the referenced letters.

5-3

Measure IND-01 also contains various flaws which contribute to the inadequacy of the Draft EIR and failure to comply with the California Environmental Quality Act (CEQA). First, Measure IND-01, as described in the project description of the Draft EIR and in the AQMP itself, is unconstitutionally vague and lacks sufficient description of exactly what it proposes to impose on the ports or substantial evidence in support. The Draft EIR's failure to describe the project fully makes it impossible for AQMD, the ports, or the public to assess its environmental impacts. An EIR must describe the whole of the action, or the entirety of a project, including reasonably foreseeable actions that are part of a project, and must analyze the impacts of those reasonably foreseeable actions. Because of the importance and consequences of the AQMP to the State of California's State Implementation Plan (SIP) if adopted by California Air Resources Board (ARB), and to the Federal Clean Air Act enforcement if approved by the U.S. Environmental Protection Agency (EPA), the AQMD is required to fully disclose the details of Measure IND-01 before adoption, and CEQA requires a full disclosure and discussion, which AQMD has failed to do.

The San Pedro Bay Ports Clean Air Action Plan was developed with the participation and cooperation of the staff of the US Environmental Protection Agency, California Air Resources Board and the South Coast Air Quality Management District.

Jeff Inabinet
October 22, 2012
Page -2-

Second, to the extent the AQMD intends to approve the Draft EIR and AQMP containing the vague current version of Measure IND-01, and later, as a part of future rulemaking, provide details regarding its proposed actions against the ports including an environmental assessment, that would be segmentation or piecemealing of its CEQA analysis.

5-5

Third, Measure IND-01 has serious problems of infeasibility which the Draft EIR has failed to analyze at all. Measure IND-01 in effect attempts to convert the ports' various aspirational goals, set forth in their voluntary Clean Air Action Plan (CAAP), into enforceable regulation against the ports. However, the CAAP goals depend upon future technology advancement which has not yet occurred, all of which are beyond the control of the ports. Therefore, there are technology feasibility issues with the AQMD making the ports' goals into required emissions limits. Further, as the ports are not air regulators and they do not themselves own, operate, or control the emissions equipment operated by the port industry, there are legal feasibility questions over the ports' ability to exercise authority to carry out the actions of Measure IND-01. There are also serious legal feasibility questions including federal preemption asserted by railroads in connection with locomotive specifications and rail operations, and international preemption asserted over ocean vessels. The Draft EIR is flawed in its failure to discuss these infeasibility issues, and had it done so, it would lead to the conclusion that Measure IND-01 should be removed from the AQMP.

5-6

5-7

Fourth, the AQMD has concluded in the air quality analysis that specific measures associated with Measure IND-01 "are unknown, and therefore the impacts are speculative," (see page 4.2-7 of Draft EIR). This is yet another reason why the Draft EIR is flawed. CEQA Guidelines Section 15145 specifies that if, after thorough investigation, a Lead Agency finds that a particular impact is too speculative for evaluation the agency should note its conclusion and terminate discussion of the impact. Instead, the AQMD proceeded to analyze secondary impacts to air quality that are based on speculative assumptions regarding construction emissions, energy demand, and operations.

5-8

Lastly, to the extent that Measure IND-01 proposes to impose upon the ports a form of enforcement for port industry's failure to meet the CAAP's target emissions reduction goals, when the ports do not own, operate, or control the emissions sources, it violates constitutional limitations requiring that exactions imposed on a party must be proportional to the party's contribution, when it fails to include all parties involved in the CAAP, including the actual emissions sources.

5-9

Given these deficiencies and speculation under CEQA and with the AQMP rulemaking, Measure IND-01 should be removed from the final EIR and the AQMP, and the analysis should be revised accordingly. With this change, the ports can support the revised AQMP and can continue to work with AQMD, other agencies, and the port industry in the collaborative manner that has made the ports' voluntary CAAP a success.

5-10

**Responses to Comment Letter #5
Ports of Long Beach and Los Angeles –
Richard Cameron & Christopher Cannon (10/23/2012)**

- 5-1 This comment notifies the SCAQMD that a comment letter pertaining to the Draft Program EIR for the 2012 AQMP is attached. No further response is necessary.
- 5-2 The comment states that the ports appreciate the opportunity to comment on the Draft Program EIR. No further response is necessary. The comment also expresses appreciation that SCAQMD staff took steps to address scoping comments provided by the ports, specifically by including a transportation and traffic analysis in the Program EIR.
- 5-3 The comment reasserts the commenters' position that the SCAQMD lacks legal authority to adopt Control Measure IND-01. The SCAQMD has responded to the commenters' previous letters. In brief, the SCAQMD has authority to regulate indirect sources under existing law. Health & Safety Code §§40716 (a)(1); 40440 (b)(3). The Ports satisfy the definition of indirect source because they are a "facility, ...installation...[or] real property...which attracts, or may attract, mobile sources of air pollution. 42 U.S.C. §7410 (a)(5)(C). Air districts may regulate indirect sources even though the regulation is intended to reduce emissions from the mobile sources associated with the indirect source, and although the district would be preempted from setting emission standards for those mobile sources. See *Nat'l Ass'n of Home Builders v. San Joaquin Valley APCD*, 627 F. 3d 730 (9th Cir. 2010)
- 5-4 The comment asserts that Control Measure IND-01 is unconstitutionally vague and that the Draft Program EIR's analysis fails to sufficiently describe the project so as to allow the public to comment on it. The doctrine against unconstitutionally vague laws is designed to assure that a penal statute defines "the criminal offense with sufficient definitiveness that ordinary people can understand what conduct is prohibited, " and to ensure that the statute establishes "minimal guidelines to govern law enforcement." *Kolender v. Lawson*, 461 U.S. 352, 357-58 (1983). Control measure IND-01 does not violate this doctrine because it has not yet been developed into a rule and hence cannot subject anyone to criminal enforcement.

The Draft Program EIR provides an overall project description as well as a general description of each control measure, including IND-01. The document analyzes the types of technologies and processes that would be used to reduce emissions from port-related sources and evaluates the potential environmental impacts of such methods. Since it is not known at this date exactly which technology or technologies will be selected, this description is all that can feasibly be provided. The CEQA document is a Program EIR because it covers a series of actions that can be characterized as one large project and is being prepared in connection with the issuance of rules, regulations, plans or other general criteria to govern the conduct of a continuing program (CEQA Guidelines §15168 (a)(3)). As such, CEQA expressly contemplates that future activities under the program will be evaluated as they are individually approved to determine if further environmental analysis is needed (CEQA Guidelines §15168 (c)). A program EIR may properly focus on "broad policy alternatives and programwide mitigation measures" as well as "regional influences, secondary effects, cumulative impacts...and other factors

that apply to the program as a whole” (CEQA Guidelines §15168 (b)(4) and (d)(2)). Therefore, a program EIR “... need not be as precise as an EIR on the specific projects which might follow.” *Rio Vista Farm Bureau Center .v County of Solano*, 5 Cal. App. 4th 351, 374 (1992) Program EIRs are frequently used in conjunction with the process of tiering, which is expected to be the case when preparing project-specific CEQA documents for control measures promulgated as rules or regulations. Tiering is “the coverage of general matters in broader EIRs (such as on general plans or policy statements) with subsequent narrower EIRs...” (CEQA Guidelines §15385). As stated by the California Supreme Court: “An agency that chooses to tier may provide analysis of general matters in a broader EIR, then focus on narrower project-specific issues in later EIRs.” *In re Bay-Delta Programmatic Environmental Impact Report Coordinated Proceedings*, 43 Cal. 4th 1143, 1173(2008). The Draft Program EIR for the 2012 AQMP analyzed the potential environmental impacts of various types of technologies and processes that could be used to reduce emissions from sources such as those found at the ports. The exact impacts resulting from the particular methods that will be used under Control Measure IND-01 can only be determined in the future as the measure is developed into a rule or regulation and adopted. As held by the California Supreme Court, this approach is proper where the details of future projects that are part of the overall program will be developed in the future.

The comment states that Control Measure IND-01 contains various flaws that contribute to the inadequacy of the Draft Program EIR, including a vague project description, which makes it difficult to assess environmental impacts. SCAQMD staff disagrees with the assertion that the Draft Program EIR is flawed and does not comply with CEQA. The Draft Program EIR complies with all relevant CEQA requirements for preparing an EIR (CEQA Guidelines §§15120 through 15131) and for preparing a program CEQA document (CEQA Guidelines §15168). The Program EIR includes a comprehensive description of the proposed project in Chapter 2, which includes summaries all stationary and mobile source control measures. Similarly, Appendix F identifies all transportation control measures provided by SCAG. Consequently, the Program EIR complies with all relevant CEQA requirements for preparing a project description (see CEQA Guidelines §15124). It should also be noted that the Draft Final 2012 AQMP was available for public review and comment during the same time period as the Draft Program EIR was available, so the public had access to the actual description of the 2012 AQMP control measures in addition to the summaries in the Draft Program EIR. Finally, Chapter 4 of the Program EIR includes comprehensive analyses of potential adverse impacts to each of the environmental topics analyzed. The subchapters clearly identify control measures that could potentially contribute to impacts to that environmental topic; provides a quantitative or qualitative analysis of all control measures and PM2.5 control measures separately from the ozone control measures, depending on the information available for that control measure; and provides significance determinations for the 2012 AQMP overall and separately for impacts from PM2.5 and ozone control measures. The Program EIR was prepared consistent with CEQA Guidelines §15144 and has disclosed all impacts that it reasonably can.

SCAQMD staff disagrees with the commenter that 2012 AQMP lacks sufficient description of Control Measure IND-01. As described in Chapter 4 of the 2012 AQMP, Control Measure IND-01 is a backstop measure whose implementation is triggered if

emission levels projected to result from the current regulatory requirements and voluntary reduction strategies specified by the Ports are not realized. These reductions are considered in the baseline emissions inventory, so if not achieved, the control strategy and attainment demonstration in the 2012 AQMP would not be accurate. A detailed description of Control Measure IND-01 can be found in Appendix IV-A which includes source category background, emission inventory, regulatory history, proposed method of control, rule compliance, cost effectiveness and implementing agency. Under the “Elements of the Backstop Rule” is a description of the phases of implementation such as a determination if: 1) reported emissions for 2014 exceed the 2014 target milestone; 2) Basin fails to meet the 24-hour PM_{2.5} standard by 2014; and, 3) further emission reductions from port-related sources are feasible. The discussion continues regarding the submittal of an Emission Control Plan if the backstop rule is triggered and details as to what should be included in the plan, for instance sufficient control measures to bring back into compliance with 2014. Any further details regarding the future requirements will be determined more appropriately during the rule development process.

- 5-5 The comment states that if the SCAQMD certifies the Program EIR and approves the 2012 AQMP, which includes Control Measure IND-01, future rulemaking, including the preparation of an environmental analysis would be piecemealing the CEQA analysis. As indicated, the CEQA document for the 2012 AQMP is a Program EIR prepared pursuant to CEQA Guidelines §15168 because the 2012 AQMP constitutes a series of actions that can be characterized as one large project and are related in the connection with the issuance or rules, regulations, plans, or other criteria to govern the conduct of a continuing program. In addition, preparation of a Program EIR allows an agency to consider broad policy alternatives and program-wide mitigation measures at an early time when the agency has greater flexibility to deal with basic problems or cumulative impacts. Further, CEQA recognizes that preparation of more than one CEQA document may occur for projects that contain a series of related actions or ongoing programs. Specifically, CEQA Guidelines §15152 describes the concept of tiering which refers to using the analysis of general matters contained in a broader EIR (such as one prepared for a general plan or policy statement) with later EIRs and negative declarations on narrower projects; incorporating by reference the general discussions from the broader EIR; and concentrating the later EIR or negative declaration solely on the issues specific to the later project. Any subsequent environmental analysis for Control Measure IND-01 would likely tier off of the 2012 AQMP Program EIR and, therefore, would not constitute piecemealing.

With regard to the comment that Control Measure IND-01 is vague, see response to comment #5-4 regarding details of the control measure.

- 5-6 SCAQMD staff considers the Control Measure IND-01 to be feasible for the following reasons. The control measure trigger is based on emission reduction targets from port-related sources, and “backstops” those emission reductions already expected from existing air quality rules, regulations, and commitments (such as the CARB/Class 1 Railroads MOUs). These emission reductions are part of the SIP’s future baseline emissions inventory for port-related sources, so nothing in the CAAP that isn’t already being implemented to meet existing and future reductions required by state and federal law, is required to meet the targets in the control measure. If the “backstop” rule is

triggered, the Ports would submit an Emission Control Plan to the District. The plan should include measures sufficient to bring the Ports back into compliance with the 2014 emission targets (Phase I) and to further reduce their emissions to the new target based on their contribution to the total inventories, necessary in meeting the 24-hr PM_{2.5} standard through a SIP amendment (Phase II). The “backstop” rule would be triggered if it is later determined that there is a shortfall in the original target or a change occurs in the Basin-wide carrying capacity for the 2014 federal 24-hr PM_{2.5} ambient air quality standard. In response to the statement that the measure makes the ports responsible for voluntary goals under the CAAP, the SCAQMD staff believes it can regulate Port sources under its existing authority under current state law. As stated in Control Measure IND-01, the SCAQMD has the authority to adopt rules to control emissions from indirect sources under existing law. The Clean Air Act defines an indirect source as a “facility, building, structure, installation, real property, road or highway which attracts, or may attract, mobile sources of pollution.” [42 U.S.C. §7410 (a)(5)(C); CAA §110 (a)(5)(C).] Under this definition, the Ports are an indirect source. As specified in the California State Air Pollution Control Laws, codified in the California Health & Safety Code, districts are further authorized to adopt rules to “reduce or mitigate emissions from indirect sources” of pollution. (Health & Safety Code §40716 (a)(1)). The SCAQMD is also required to adopt indirect source rules for areas where there are “high-level, localized concentrations of pollutants or with respect to any new source that will have a significant impact on air quality in the South Coast Air Basin,” (Health & Safety Code §40440 (b)(3)).

- 5-7 The comment asserts that there are serious legal feasibility questions regarding Control Measure IND-01, including federal preemption asserted by railroads, an international preemption asserted by ocean vessels, and because the ports do not own or operate the sources. The SCAQMD recognizes the preemption arguments raised by various industries but does not believe that these arguments establish that there can never in any case be a state or local rule affecting such sources. For example, a state rule affecting foreign-flagged vessels, even outside the three-mile state boundary, was upheld by the Ninth Circuit, and the US Supreme Court declined to review the case. *Pacific Merchant Shipping Ass’n. v. Goldstene*, 639 F. 3d 1154 (9th Cir. 2011). And the Ninth Circuit has held that when a state or local air pollution rule affecting railroads has been approved by U.S. EPA into the State Implementation Plan, the courts will harmonize the purposes of the Clean Air Act with the Interstate Commerce Commission Termination Act to determine whether the state or local rule is preempted. Preemption is not automatic. *Ass’n. of American Railroads v. South Coast AQMD*, 662 F. 3d 1094(9th Cir. 2010).

For a discussion of the issue relative to the ports not owning the polluting sources, see response to comment #5-9.

- 5-8 The comment refers to footnote “a” to Table 4.2-1, which states, “The specific actions associated with the control measure are unknown and, therefore, the impacts are speculative.” This footnote references Control Measure IND-01 among other control measures. The comment states that because impacts are speculative, Control Measure IND-01 should not have been further analyzed. However, footnote “a” goes on to say, “In order to provide a conservative analysis, it is assumed that the control measure could require air pollution control technologies that are similar to those that are currently required (e.g., SCR, electrification, use of alternative fuels, etc., and would have the

potential to require construction activities that would generate noise).” This approach was taken to provide a conservative analysis of environmental impacts from all control measures, including IND-01.

- 5-9 The comment asserts that Control Measure IND-01 violates constitutional limits requiring that exactions imposed on a party be proportional to the party’s contribution, because the ports do not own, operate, or control the emissions sources, when it fails to include all parties involved in the CAAP, including the actual emissions sources. The basic concept of indirect source contemplates that the emissions to be controlled are from sources not owned or operated by the indirect source. For example, Rule 2202 applies to employers of 250 or more employees and focuses on emissions from employee vehicles which are not owned or operated by the source. The concept of an “exaction” generally refers to a requirement that, as a condition of a development approval, a developer must dedicate sites for public or common facilities, or make payments to defray the costs of land or facilities or otherwise provide public amenities. Abbott, et al. *“Exactions and Impact Fees In California”* (Solano Press 2001), p. 15. Therefore, a regulation to reduce air pollution would not normally be considered an exaction. Moreover, the principle of proportionality referred to by the commenter was established by the United States Supreme Court which decided that a land dedication requirement must bear a “rough proportionality” to project impacts. *Dolan v. City of Tigard*, 512 U.S. 374(1994). In this case, all of the impacts of concern are ultimately the result of the fact that the two major ports operate here in the district, so the concept of proportionality to impacts is not violated. Finally, the state and the SCAQMD are also seeking to impose all feasible emission reduction measures on all types of mobile sources found within the ports, so the regulatory program does not fail to include all parties.
- 5-10 With regard to the deficiencies in the Program EIR asserted by the commenters, see responses to comments #5-4 and #5-5. With regard to the comments on speculation, see response to comment #5-8.
- See response to comment #5-4 regarding the reasons for keeping Control Measure IND-01 as part of the PM2.5 control strategy that relies on the emission reductions projected to be achieved from the current regulatory requirements and voluntary reduction strategies specified by the Ports. The SCAQMD intends to continue to work with the Ports in a collaborative manner to strive not to trigger Control Measure IND-01, but if a backstop rule is necessary, the SCAQMD will work cooperatively with the Ports to develop a feasibility analysis and implementation schedule.
- 5-11 The comment thanks SCAQMD staff for considering the comments in the letter and provides a contact person and phone number in case of questions. No further response is necessary.

Re: Comments to 2012 Air Quality Management Plan (AQMP) Draft Program Environmental Impact Report (DPIER)

Dear Mr. Inabinet:

Southern California Gas Company ("SoCalGas") appreciates the opportunity to review and comment on the DPEIR for the AQMP. SoCalGas supports the South Coast Air Quality Management District's ("SCAQMD") comprehensive control strategies towards attainment of the Federal 24-hour PM2.5 ambient air quality standard, while making expeditious progress towards attainment of State PM standards, as currently outlined in the AQMP and the DPEIR. We encourage SCAQMD to continue along this path towards attainment. SoCalGas has no points of contention with DPEIR and applauds SCAQMPD for its work to date. In continued support of SCAQMD's efforts, SoCalGas offers the following comments to the DPEIR.

6-2

1. Subchapter 4.3 Project Specific Impacts - Energy

Section 4.3.4.2 states that control measures in the 2012 AQMP may result in an increase in demand for natural gas associated with stationary sources. In particular, the DPEIR asserts that demand for natural gas in Southern California is expected to increase by approximately .20 percent from 2010 to 2020 (DPEIR p. 4.3-13). However, SoCalGas' 2012 California Gas Report (CGR) predicts that our service area within Los Angeles, Riverside, Orange and San Bernardino Counties should expect to see a .13 percent decline in demand over the same period. Based on the 2012 CGR predictions, the overall statewide natural gas demand is projected to decrease by .25 percent.

6-3

Section 4.3.4.2 also identifies mitigation measures required for potentially significant impacts to natural gas resources associated with the AQMP. Mitigation Measure E-8 would focus on requiring project sponsors to pursue incentives to promote energy efficient equipment and promote energy conservation. SoCalGas supports this measure, as energy efficiency naturally leads to lower fuel consumption, which in turn reduces overall greenhouse gas

6-4

emissions as secondary pollutant. In addition, SoCalGas' efforts have also encouraged our industrial and commercial customers to utilize natural gas stationary sources during peak hours to reduce their electric demand and lower their electric bill, especially for those customers under a Time-Of-Use (TOU) contract. Further, SoCalGas encourages SCAQMD to require mitigation measures that include analysis of energy usage with the goal of conserving energy through the efficient use of energy. As part of the mitigation measures, SCAQMD should encourage project proponents to consider the potential for reducing energy peak demand by utilizing natural gas stationary sources during off-peak hours. Finally, SCAQMD should recognize that California natural gas utilities are subject to the California Public Utilities Commission's ("CPUC's") Evaluation, Measurement and Verification (EM&V) Policy framework. The EM&V objectively values the energy efficiency savings of the IOUs. For your reference, I am including an attachment that summarizes the CPUC's EM&V policy as we understand how it applies to SoCalGas.

6-4
Con't

Once again, SoCalGas recognizes the importance of this DPEIR and appreciates continued collaboration with SCAQMD on the AQMP. If you have any questions to these comments, please free to contact Noel Muyco at (213) 244- 5514 or via email at NMuyco@semprautilities.com

6-5

Sincerely,

Albert J. Garcia
Senior Counsel

cc: Lee Wallace
Noel Muyco
Daniel McGivney
Alison Smith
Vince Gonzales
Colby Morrow

Summary of CPUC's EM&V Policy as applicable to SoCalGas

Energy Efficiency

Energy Efficiency and Demand Response are the first priority in California's loading order for energy resources. Pursuant to applicable Public Utilities Code sections, the CPUC regulates the IOUs' energy efficiency programs. Energy efficiency typically refers to the installation of energy efficient technologies or measures to reduce energy usage and eliminate energy losses in homes, businesses, and new construction. An energy efficient home or business can help consumers reduce energy usage while maintaining comparable service, thereby saving money on utility bills. On September 24, 2009, the CPUC approved funding and programs for the 2010-2012 energy efficiency program cycle. These energy efficiency programs are projected to save 7000GWh, 3460MW, and 150 MMTherms and follow the 2006-2008 program cycle, which resulted in savings of over 6000GWh, 1175MW, and 84MMTherms. The funding is 42% higher than the prior three-year cycle (2006-2008) and will support programs designed to produce deeper and more comprehensive savings that the Commission believes California's utilities can and will achieve. These programs and related energy savings are a key component of California's broader energy policies and greenhouse gas mitigation strategies. Energy Division's Demand-side Management (Evaluation, Measurement and Verification and Integrated Demand-side Analysis), and Residential and Non-Residential Programs sections work with the IOUs to develop and evaluate these energy efficiency programs.

Background

In 2003, the Commission, in collaboration with the California Energy Commission (CEC) and the now defunct California Consumer Power and Conservation Financing Authority developed California's first Energy Action Plan (EAP). The EAP sets forth a loading order that prioritizes which energy resources California will use to meet its future energy needs. The loading order stipulates that energy efficiency is California's "resource of first choice." Since the loading order issued, the Commission has invested in energy efficiency programs designed to displace or defer costly supply-side alternatives.

It is in the context of energy efficiency as a resource that the Commission's existing EM&V policy framework took shape. Decision (D.) 05-01-055 returned California's Investor Owned Utilities (IOUs)³ to the role of energy efficiency program administrators and tasked the Commission's Energy Division with EM&V of the utility programs. D.05-01-055 defined the objectives of EM&V as follows:

- 1) measure and verify energy and peak load savings for individual programs, groups of programs, and at the portfolio level;
- 2) generate data for savings estimates and cost-effectiveness inputs;
- 3) measure and evaluate the achievements of energy efficiency programs, groups of programs and/or the portfolio in terms of the "performance basis" established under Commission-adopted EM&V protocols: and

6-6

4) evaluate whether programs or portfolio goals are met. (D.05-01-055, at 12.)

Evaluation, Measurement, and Verification (EM&V) of California Utility Energy Efficiency Programs

http://docs.cpuc.ca.gov/PUBLISHED/FINAL_DECISION/125983.htm#P84_3093

The EM&V Methodological Framework

Two documents contain the Commission's methods and best practices to date: the California Evaluation Framework (Evaluation Framework) and the California Energy Efficiency Protocols (Protocols). The Evaluation Framework was developed through the collaborative work of the IOUs, Energy Division and TecMarket Works. Teams of professional evaluators offered recommendations for consistent methods and best practices for a wide range of evaluation questions outlined options for a cyclical approach to planning and conducting evaluations of energy efficiency programs. The Protocols were initially adopted by an Administrative Law Judge (ALJ) ruling in April 2006 as a follow up to the Evaluation Framework and were offered as a more prescriptive guide for conducting evaluation and allocating resources. Minor updates were adopted by ruling in January 2007. The Protocols were developed by TecMarket Works specifically to guide evaluation of the 2006-2008 IOU energy efficiency program cycles. The Protocols specify in detail acceptable approaches and procedures for the evaluation of IOU energy efficiency portfolios. The content of these documents has remained largely unchanged since 2006.

Responses to Comment Letter #6
Southern California Gas Company – Albert Garcia (10/23/2012)

- 6-1 The email informs the reader that the comments are included as an attachment and that the commenter is available to answer questions about the comment letter. No further response is necessary.
- 6-2 This comment states that SoCalGas supports the control strategies in the 2012 AQMP and encourages the SCAQMD to continue along this path towards attainment. Further, SoCalGas has no points of contention with the Draft Program EIR for the 2012 AQMP. No further response is necessary.
- 6-3 The commenter states that the Draft Program EIR presents a future increase in natural gas demand of 0.2 percent in southern California, but the SoCalGas *2012 California Gas Report* predicts a 0.13 decrease in natural gas demand over the same period.

Review of the *2012 California Gas Report*, indicates SoCalGas projects total gas demand to grow at an annual rate of 0.12% from 2011 to 2030. Over the forecast period 2012-2030, demand is expected to exhibit annual decline (of 0.13%) from the level in 2012 due to modest economic growth, CPUC-mandated energy efficiency (EE)s and renewable electricity goals, decline in commercial and industrial demand, and continued increased use of non-utility pipeline systems by enhanced oil recovery customers and savings linked to advanced metering modules. The Report states that although the forecast covers an 18-year natural gas demand and forecast period, from 2012 through 2030; only the consecutive years 2012 through 2014 and the point years 2015, 2020, 2025, and 2030, “These single point forecasts are subject to uncertainty, but represent best estimates for the future, based upon the most current information available.”

The future increase in natural gas demand in the Program EIR was obtained from the CEC’s *California Energy Demand 2012-2022 Final Forecast*. This report includes the following natural gas demand forecast.

“For the high demand scenario, consumption in the pure econometric forecast was almost 2 percent lower and peak demand 0.60 percent higher in 2022 compared to high demand CED 2011 Final statewide results shown in this chapter. The mid demand econometric scenario yielded projected 2022 consumption almost identical to CED 2011 Final, while peak demand was 1.8 percent higher. In the low econometric demand scenario, statewide consumption was projected to be 0.3 percent higher and peak 1.9 percent higher versus CED 2011 Final in 2022.”

Based on the above information, using the CEC’s natural gas demand forecast for the analysis of potential natural gas demand impacts in the Draft Program EIR provides a conservative estimate of future natural gas demand. Further, since future natural gas demand impacts were concluded to be significant, it is not necessary to revise the analysis. However, a footnote will be added to Subchapter 4.3, reporting the SoCalGas Report natural gas demand projections.

- 6-4 The commenter states that SoCalGas supports Mitigation Measure E-8 – Project sponsors should pursue incentives to encourage the use of energy efficient equipment and vehicles and promote energy conservation. The commenter states that SoCalGas encourages the

SCAQMD to require mitigation measures that include analysis of energy usage with the goal of conserving energy through the energy efficiency and consider the potential for reducing energy peak demand by utilizing natural gas stationary sources during off-peak hours. When promulgating 2012 AQMP control measures as SCAQMD rules or regulations, additional project-specific CEQA analyses will be prepared. To the extent that energy impacts from the subsequent projects need to be analyzed, if impacts are significant the SCAQMD would likely include energy conservation measures such as those suggested in the comment.

The commenter states that SCAQMD should recognize that natural gas utilities in the state are subject to the California Public Utilities Commission's Evaluation, Measurement and Verification (EM&V) Policy framework. The commenter states that the EM&V objectively values the energy efficiency savings of the investor-owned utilities (IOUs). The commenter prepared and provided an attachment to the comment letter that summarizes the policy as it applies to SoCalGas. SCAQMD staff recognizes that the EM&V policy appears to apply to the four largest IOUs in California with regard to implementing energy efficiency programs.

- 6-5 The concluding paragraph provides information on SoCalGas contacts. No further response is necessary.
- 6-6 As mentioned in comment #6-4, the commenter prepared and included an attachment that summarizes the EM&V policy as it applies to SoCalGas. SCAQMD staff may consider the EM&V policy, as appropriate, when evaluating projects with potential energy impacts. As already noted, the EM&V policy appears to apply specifically to the four largest IOUs in California with regard to implementing energy efficiency programs.

Cc: Adams, Greg
Subject: LACSD 2012 AQMP CEQA COMMENTS

Hello Steve Smith and Mike Krause:

You and your staff have done a great job on this document. Our thoughts are as follows:

} 7-1

On Page 1-13, last paragraph of Section 1.4.5, I think you are confusing agencies and the facilities that they operate. I suggest the following re-write or something close to it:

} 7-2

"Much of the urbanized areas of Los Angeles and Orange Counties are serviced by three agencies that operate coastal facilities: the City of Los Angeles Bureau of Sanitation's Hyperion Treatment Plant in El Segundo and Terminal Island in San Pedro, the Los Angeles County Sanitation Districts' Joint Water Pollution Control Plant (JWPCP) in Carson and two Orange County Sanitation District treatment plants, one in Huntington Beach and one in Fountain Valley."

On Page 1-15, first sentence of Section 1.4.8, I checked and the two transformation (waste-to-energy) facilities located within the district have a long term combined average daily capacity of about 1600-1700 tons per day, not 3240 tons per day, depending on BTU content of the post-recycled waste stream they manage.

} 7-3

On Page 1-20, Section 1.5.5, wastewater treatment facilities can probably manage a reasonable increase in wastewater flows generated from air pollution control equipment scrubbers but not the SOx RECLAIM shave impacts (~ 2 billion gallons per day), for example.

} 7-4

On Page 3.3-8, LADWP operates Haynes (not Los Angeles County) and LADWP in cooperation with DWR operates the Castaic Pumped Storage Facility and not Los Angeles County.

} 7-5

On Page 3.3-20, Section 3.3.4.3.3 Anaerobic Digestion, it is amusing that you cite a small operation in Tulare operating two engines under a 100KW each, while right here in your back yard LACSD operates a combined cycle turbine facility in Carson using digester gas that produces around 20 MW and a landfill gas Rankine cycle steam plant at the Puente Hills Landfill that produces around 48 MW net, to mention a few. In the third paragraph, it is misleading to say that there are 132 "waste-to-energy" plants in California because of the term's very specific historical meaning. "Renewable energy" plants might be more appropriate.

} 7-6

6. In Subchapter 4.2 Air Quality, it is difficult for us to make intelligent comments on the CEQA-related aspects of the MCS-01 control measure, mentioned several times throughout this chapter, due to the almost complete lack of specificity on the measure. Many subtleties involved in the control measures can never be aired via this CEQA review process in absence of that detail. One example concern is our Rule 1134-governed digester gas fired combustion turbines mentioned above. Notwithstanding the fact that LACSD spent approximately \$3.5MM in the 1995-98 timeframe, under a SCAQMD variance, attempting to make Steuler GmbH post-combustion SCR catalysts work, there are several CEQA related aspects to upgrading to BARCT levels that should that be discussed now. These include the disposal of substantial quantities of gas-pretreatment media, whatever they may be, because of the near-zero siloxane tolerance of the catalysts; additional hydrogen sulfide sulfur removal capital systems and chemicals again for catalyst protection, and effects of non-optimum mixing length downstream of ammonia injection grids on particulate matter formation and ammonia slip plus the usual construction related emissions and additional electrical parasitic load considerations. The present CEQA document discusses SCR issues as ammonia slip in detail and a little about ammonium bisulfate formation and the construction emissions and additional electrical loads, but other project aspects are presumably left for rule-specific CEQA documents that accompany the formal rulemaking. Having certainty over the scope of the proposed control measure is only what we ask.

7-7

All in all, this is a comprehensive and well-crafted document. Again, you and your staff have done a commendable job and are to be congratulated.

Responses to Comment Letter #7
Los Angeles County Sanitation Districts – Greg Adams (10/23/2012)

- 7-1 This comment compliments SCAQMD staff on the work performed for the Draft Program EIR. No further response is necessary.
- 7-2 This comment recommends clarifications to the description of the agencies that operate POTWs and the actual facility names of the POTWs in the hydrology and water quality discussion in Chapter 1. The Final Program EIR has been modified accordingly in the hydrology and water quality discussions in Section 1.5.5 of Chapter 1 and in Section 3.5.7 of Subchapter 3.5.
- 7-3 This comment recommends a correction to the capacity of the two transformation facilities in the solid and hazardous waste discussion from 3,240 tons per day to an average daily capacity of 1,600 to 1,700 tons per day. While the comment did not include a reference to support the suggested revision, according to CalRecycle, the permitted capacities of the Southeast Resource Recovery Facility and the Commerce Refuse-To-Energy Facility are 2,240 tons per day¹ and 1,000 tons per day², respectively. Thus, the combined permitted capacity of these two transformation facilities is correctly stated at 3,240 tons per day. For clarity, the Final Program EIR has been modified to reflect the CalRecycle citations in the solid and hazardous waste discussions in section 1.5.8 of Chapter 1 and in section 3.8.2 of Subchapter 3.8.
- 7-4 This comment suggests that wastewater treatment facilities can handle a reasonable increase in wastewater generated from air pollution control equipment such as scrubbers as part of implementing the 2012, but not to the extent of the wastewater projections previously analyzed under the 2010 amendments to Regulation XX - RECLAIM for the SOx shave of RTCs. Based on the analysis in the Final Program Environmental Assessment (PEA) prepared for the 2010 amendments to the SOx RECLAIM program, which involved air pollution control equipment that utilize water and generate wastewater, SCAQMD staff also believes that wastewater treatment facilities should be able to accommodate a moderate increase in wastewater generation. However, it is important to note that Control Measure CMB-01 would call for a NOx shave of RTCs, not a SOx shave. Because control equipment installed to control NOx emissions is not typically water intensive, implementation of Control Measure CMB-01 would not be expected to have the same magnitude of wastewater impacts as was analyzed in the Final PEA for the 2010 amendments to the SOx RECLAIM program.
- 7-5 This comment recommends a correction to the name of the operator of the Haynes Natural Gas Power Plant to be changed from Los Angeles County to the LADWP. This comment also recommends a correction to the name of the operator of the Castaic Pump-Storage Power Plant to be changed from Los Angeles County to the LADWP and to note that the LADWP operates this plant in cooperation with the DWR. The Final Program EIR has been revised to reflect both of these corrections.

¹ Permitted capacity of Southeast Resource Recovery Facility,
<http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AK-0083/Detail/>.

² Permitted capacity of Commerce Refuse-To-Energy Facility,
<http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AA-0506/Detail/>.

- 7-6 This comment recommends including a reference to the LACSD’s combined cycle turbine facility in Carson and the landfill gas Rankine cycle steam plant at the Puente Hills landfill as examples of operations that also utilize anaerobic digestion. The Final Program EIR has been revised to reflect this recommendation in the discussion regarding anaerobic digestion in Subchapter 3.3.

This comment also recommends changing the phrase “waste-to-energy” to “renewable energy” because the phrase “waste-to-energy” has a specific historical meaning. While the comment did not include a reference to support the suggested revision, according to the California Energy Commission discussion of waste-to-energy facilities, the statement that there are 132 “waste-to-energy” plants in California is accurate³. Thus, the Final Program EIR will not be revised to reflect this recommendation.

- 7-7 The intent of Control Measure MCS-01 – Application of All Feasible Measures Assessment, is to focus on new technology developed in the future subsequent to the approval of the 2012 AQMP, so the specific description of the future actions under the control measure is not possible at this time. However, triggering requirements of the control measure would likely occur when new feasible cost-effective best available retrofit control technology is developed and made available. Implementation of Control Measure MCS-01 could take place in two phases if a technology study is warranted. However, if an assessment of the feasibility, cost effectiveness, and availability of new technology has already been prepared and properly demonstrated, a two-phase approach might not be necessary.

This comment remarks on the difficulty of commenting on the potential air quality impacts of implementing Control Measure MCS-01 due to the lack of specificity of elements in the control measure and requests certainty over the scope of the control measure. This comment also provides examples of potential environmental impacts pertaining to implementing BARCT requirements for digester gas fire combustion turbines subject to Rule 1134 and suggests including these examples in the Program EIR. This comment also recommends a modification to the CEQA document that reflects a discussion of ammonium bisulfate formation, construction and additional electrical loads. Lastly, this comment recognizes that several project aspects are left for rule-specific CEQA documents that accompany the formal rulemaking process.

Because Program EIRs analyze broad policies and not project-specific details, the analysis of Control Measure MCS-01 in the Final Program EIR for the 2012 AQMP is commensurate with the level of specificity of the project. However, as the comment acknowledges, when Control Measure MCS-01 undergoes the rule making process, the specifics of implementing the control measure and the individual environmental impacts will be fully analyzed to a much greater level of detail during the rule development process. For this reason, the Final Program EIR does not contain the same level of detail as suggested in the comment’s example of the environmental impacts relative to implementing Rule 1134.

- 7-8 This comment again compliments SCAQMD staff on the work performed for the Draft Program EIR. No further response is necessary.

Letter #8

Comments by Sierra Club Angeles Chapter on
 Draft South Coast Air Quality Management Plan (AQMP) and
 Draft Program Environmental Impact Report (PEIR)

October 23, 2012, Sent to: 2012aqmpcomments@scqmd.gov

Dear South Coast Air Quality Management District,

For over a decade, the top priority of the Sierra Club has been stopping global warming to protect life on this planet. We are pleased with the emphasis placed in both the AQMP and PEIR on analyzing and reducing GHG emissions.

8-1

However, there are numerous examples in the PEIR of where opportunities to stake out a clear position to reduce GHG emissions are ignored.

For example, p. 1-11 states, "One of the key areas of concern in the energy sector is reducing the amount of petroleum-based fuels in the District. Consumption of these fuels is a major factor in the amount of criteria pollutants in southern California. Alternative fuels play an important role in the strategy to reach attainment in the region. Renewable energy resources include biomass, hydro, geothermal, solar and wind."

It is incorrect to talk about "alternative fuels" as a group. In fact, it is very misleading to have the sentence immediately following the use of the term "alternative fuels" be a definition of "renewable energy resources." A layman might conclude that "alternative fuels" only include "renewable energy resources." The PEIR should clearly specify that, compared to gasoline and diesel, there are some small criteria pollutant reductions from "alternative fuels" such as natural gas and methanol, but much larger reductions from "alternative fuels" such as electric cars, especially those powered by renewable energy resources.

8-2

In fact, the term "alternative fuels" is so misleading as to be obsolete. The term "alternative fuels" is widely misconstrued to include natural gas, especially by proponents and beneficiaries of that industry. Wind, solar, biomass and geothermal sources, moreover, are now fully "mainstream" fuels increasingly competitive with most fossil fuels. They are not "alternative" or second-class to anything else and are now as solidly established—in terms of legitimacy and need—as traditional fuels. SCAQMD should henceforth avoid the term and use instead terms that specify more precisely what is being referred to, such as renewable energy sources. In addition, energy efficiency and energy conservation, the cheapest and most abundant sources of clean energy—"negawatts"—should not be ignored or neglected in any discussion of "clean energy sources." Again, energy efficiency and conservation are not "alternative" sources but fully-accepted mainstream contributors to greenhouse gas reduction and air quality improvement.

Even more of a problem on p. 1-11 is ignoring the importance of GHG emissions from natural gas. We request the sentence be reworded as follows (bold added):

8-3

“One of the key areas of concern in the energy sector is reducing the amount of petroleum consumption of fossil based fuels in the District. Consumption of these fuels is a major factor in the amount of criteria pollutants and GHG emissions in southern California. Alternative fuels play an important varying roles in the strategy to reach attainment in the region. There are some small criteria pollutant reductions from “alternative fuels” such as natural gas and methanol, but much larger reductions in both criteria pollutants and GHG emissions using “alternative fuels” such as electric cars, especially those powered by renewable energy resources.” Then continue with the definition of renewable energy resources. ¶

8-3
Con’t

¶
In addition, we do not see any mention in the PEIR of the fact that much of the imported natural gas (which is 88% of the natural gas used in California) is produced by fracking of shale gas, which has been documented to have greater GHG impact than burning coal to make electricity. In fact, the latest analyses state, “Using all available information and the latest climate science, we conclude that for most uses, the GHG footprint of shale gas is greater than that of other fossil fuels on time scales of up to 100 years. When used to generate electricity, the shale gas footprint is still significantly greater than that of coal at decadal time scales but is less at the century scale. We reiterate our conclusion from our April 2011 paper that shale gas is not a suitable bridge fuel for the 21st Century.” – from “Venting and leaking of methane from shale gas development,” by Robert W. Howarth, Renee Santoro & Anthony Ingraffea, Climatic Change (2012) 113:537–549. ¶

¶
To summarize the latest science: ¶

1. Unless leakage rates for new methane can be kept below 2%, substituting gas for coal is not an effective means for reducing the magnitude of future climate change. ¶
2. Fugitive methane emissions from conventional natural gas wells are estimated at 2–5% of well production and thus conventional wells are major contributors to global warming, beyond even burning coal for electricity. ¶
3. Fugitive methane emissions from natural gas fracked wells are estimated at least 2% more than a conventional natural gas wells, and thus are significantly greater contributors to global warming. ¶
4. Industry admits that fugitive methane emissions from conventional natural gas wells are likely 2%. However, the only scientific study has found fugitive methane emissions of 4%. ¶
5. We can’t slow global warming with natural gas; the only hope is ‘rapid and massive deployment’ of clean energy technologies (with zero-carbon emissions). ¶
6. Therefore, fracked shale gas is not a suitable fuel for the 21st Century. ¶

8-4

¶
This means the PEIR must be amended to state the GHG emissions from the use of natural gas, for vehicles, power generation, and perhaps other uses, are significant and require strong mitigation measures, such as those listed below. ¶

8-5

¶
In addition, as the PEIR correctly reports, “Executive Order S-3-05 . . . established emission reduction . . . goals to . . . reduce GHG emissions . . . to 80 percent below 1990 levels by 2050.” The SCAQMD is legally bound to comply with Executive Order S-3-05. Therefore the AQMP and PEIR must show how they are supporting reduction of “GHG emissions . . . to 1990 levels by 2020, and to 80 percent below 1990 levels by 2050.” ¶

8-6

¶
Since there are many sources of GHG emissions in addition to fossil fuels, such as industrial processes, to achieve 80 percent below 1990 levels by 2050 means that essentially all use of fossil fuels for combustion (such as natural gas for electricity and hot water) must end by 2050. Since most large natural gas power plants have life expectancies of 40 years, it is past time for AQMP to state its policy is not to support construction of any new large natural gas plants. This would support reductions of both NOx and GHG emissions. ¶

¶
A simple straight-line extrapolation from 1990 levels by 2020 to 80 percent below 1990 levels by 2050 yields 40% percent below 1990 levels by 2035. Thus this AQMP and PEIR must show how they are on track to reduce GHG emissions to 40% percent below 1990 levels by 2035, the final target date in this plan (and the SCAG RTP). ¶

8-6
Con't

¶
Thus it is time for SCAQMD to end support for natural gas, whether it is for large natural gas power plants, hot water heaters, or even some industrial uses, which could be supplied by solar hot water, especially concentrating solar. State goals are zero net energy new buildings (residential by 2020 and commercial by 2030). SCAQMD should support this by all feasible control measures, plus investigate how to require this on sales. ¶

¶
We also call to SCAQMD's attention Sierra Club California's formal opposition to new licensing of all new natural gas-fired electrical generation power plants (larger than 50 MW). The only exceptions are permitting of certain technologies using natural gas fuel (such as cogeneration plants, renewables with natural gas backup, large fuel cell facilities, biogas wheeling) only if they significantly reduce fossil fuel consumption and carbon emissions and protect air quality. ¶

¶
This discussion has important implications for control measures, especially those that must begin now, because of the extremely slow turnover of residential, commercial, and government buildings. Some examples of such control measures would be as follows: ¶

- Requiring solar PV electricity generation for new, major remodels, and sales of residences, commercial, industrial, and government buildings. ¶
- Requiring solar thermal hot water generation for new and major remodels of residences, commercial, industrial and government buildings. ¶
- Requiring solar thermal hot water generation for new swimming pools. ¶
- Requiring industrial processes to install energy efficiency measures and convert as rapidly as possible to solar thermal hot water generation wherever feasible. ¶
- Requiring all new and major remodels of all large commercial, industrial and government buildings to install additional solar thermal generation to supply heat in the winter and operate absorption chillers for cooling in the summer. ¶
- Requiring district heating and cooling wherever feasible. ¶
- Requiring use of waste heat and co-generation where feasible from fuel cells or other sources of heat in large commercial, industrial and government buildings. ¶
- Requiring fleets to go to zero emission vehicles, such as battery electric vehicles charged by solar panels, or fuel cells fueled by hydrogen produced by solar electricity. ¶
- Requiring electric vehicles charging stations to be installed in all businesses and commercial buildings above a minimum size. ¶

8-7

¶
Mitigations for GHG effects of the use of natural gas need to be expanded. For example, Control Measure INC-01 must be amended to include efficiency and solar thermal for hot water and industrial processes. There also need to be additional control measures mandating implementation of the above requirements. ¶

8-8

¶
Thank you for the opportunity to comment. ¶

8-9

Responses to Comment Letter #8
Sierra Club – Jim Stewart (10/23/2012)

8-1 This comment provides background information describing the nature of the commenter’s organization and states that there are numerous examples in the Draft Program EIR where opportunities to stake out a clear position to reduce GHG emissions are ignored. The commenter’s examples are addressed in responses to comments #8-1 through #8-6.

8-2 The commenter states that it is incorrect to discuss “alternative fuels” as a group. The commenter states that readers of the Program EIR may conclude alternative fuels only include renewable resources. The commenter states that the SCAQMD should avoid using the term alternative fuels and instead use terms that specify more precisely the energy source, such as, renewable energy resources. The commenter states that energy efficiency and energy conservation should not be neglected in any discussion of clean energy sources.

SCAQMD is fuel neutral and SCAQMD supports technologies that reduce criteria, toxic and GHG emissions. SCAQMD promotes energy efficiency and energy conservation. As stated in the Draft Program EIR, the 2012 AQMP is not expected to result in the use of fuel or energy resources in a wasteful manner.

8-3 The commenter requests modifying the last paragraph on page 1-11 of the Draft Program EIR to explicitly state that combustion of natural gas also generates GHG gases. The section in question is simply a summary of the energy existing setting. The proposed changes were not made as they specifically reference air quality impacts, not energy.

SCAQMD is fuel neutral and SCAQMD supports technologies that reduce criteria, toxic and GHG emissions. SCAQMD agrees that natural gas, as well as other combustion fuels, generates GHGs; however, the replacement of diesel and gasoline fueled sources under the 2012 AQMP with natural gas fueled sources would reduce criteria pollutant, air toxic, and GHG emissions.

8-4 The commenter states that much of the imported natural gas is produced by fracking of shale gas. The commenter states that fracking of shale gas has greater GHG impact than burning coal to make electricity. The 2012 AQMP does not include measures requiring fracking. In addition, based on discussions with natural gas utilities, it is not possible for them to distinguish what portion of the natural gas imported is from a specific source. Once natural gas is placed into the pipelines it is indistinguishable from all other natural gas in the pipeline. SCAQMD has no jurisdiction over natural gas sources outside of California.

SCAQMD staff appreciates the information on the fugitive releases of methane from the natural gas wells and transport system along with the environmental impacts from hydraulic fracturing. SCAQMD staff has been monitoring, tracking carefully, providing updates to the SCAQMD’s Governing Board, providing information to the public, and contacting representatives from academia and the oil and gas industry regarding hydraulic fracturing. Recently, the SCAQMD held a forum providing information on what hydraulic fracturing is, while focusing on potential environmental impacts of hydraulic fracturing and policy level implications. In addition, SCAQMD staff is

working with both the state and federal government in developing regulations. SCAQMD staff will also be developing hydraulic fracturing regulations in accordance with the SCAQMD's regulatory authority, if feasible and appropriate. Finally, any fugitive release of natural gas from wellheads or during transport does not affect in any way attainment of the federal 24-hour PM_{2.5} standard in the Basin.

- 8-5 The commenter states GHG emission from the use of natural gas for vehicles, power generation and other uses are significant and require strong GHG mitigation measures. The 2012 AQMP does not promote fracking (see response to comment #8-4). The comment also does not provide any qualitative data supporting the statement that GHG emissions are significant. The Program EIR includes a comprehensive analysis of GHG emission impacts, which were concluded to be less than significant.
- 8-6 SCAQMD staff recognizes the clean air benefits renewable energy provides to both the electric power grid and other services such as hot water heating. Chapter 10 of the 2012 AQMP addresses California's Renewable Portfolio Standard, requiring a 33 percent increase in the use of renewable energy generation, and the benefits that increased energy efficiency provides in reducing fuel and energy demands. The SCAQMD is exploring all options to reduce GHG emissions, while still meeting its mandates to attain the criteria pollutant standards and reduce exposures to air toxics. For example, the SCAQMD is working with the State in helping achieve the goals of S-3-05. The jointly developed document between SCAQMD, San Joaquin APCD, and the ARB *Vision for Clean Air: A Framework for Air Quality and Climate Planning* shows pathways on how we can achieve 2050 GHG reduction levels. As shown in the document there is not a single pathway that can be taken to meet the GHG goals and further development and implementation of transportation technologies is needed.

Chapter 10 shows that total energy consumption in southern California was nearly 2.1 quads⁴ in 2008 and is expected to show a slight 0.1 quad increase by 2023. However, the slight increase in projected energy use in southern California is expected to be met with a disproportionate increase in energy prices; in 2008 almost \$54 billion were spent on energy, while the projected cost of energy consumption in 2023 is expected to be \$74 billion. Overall the projected five percent increase in energy consumption is expected to be met with a 27 percent increase in energy prices. As also mentioned in Chapter 10, a large increase in the use of renewable energy coupled with the expanding mass transit systems would help lower emissions, including GHG emissions, reduce impacts from volatile energy prices, help localize dollars spent on energy, and provide some isolation from increasing energy costs.

The SCAQMD endorses solar power as a clean air solution to help provide emission-free electricity to residences and businesses. The SCAQMD has been an early supporter of implementing new solar technologies. For example, SCAQMD headquarters currently has over 180kW of solar panels installed that are being used to demonstrate three different solar technologies. Additionally, the SCAQMD is funding and participating in several technology demonstration projects that help address the limitations of solar energy, such as, coupling solar power production with energy storage to help with

⁴ A quad is a unit of energy equal to 10¹⁵ (a short-scale quadrillion) Btus, or 1.055 × 10¹⁸ joules (1.055 exajoules or EJ) in the international system (SI) of units.

intermittency (i.e., subject to interruption or periodic stopping). The SCAQMD is also promoting the benefits electrification technologies would provide to further reduce emissions, such as electric vehicles, and as mentioned earlier, promote electricity generation from clean sources such as renewable fuels.

The prices of solar panels having come down nearly a third in the past couple of years due to less expensive ways to manufacture polysilicon, an increase in solar manufacturers, and expiring solar incentives in other countries. Resulting price declines have made PV solar very competitive with conventional generating technologies. This decline in prices has helped implement solar technologies in southern California as there are now many solar installation companies that employ thousands in this sector. The recent increase in rooftop solar PV installations does not show any indication of slowing down in the near future since financing mechanisms have become available along with local incentives and federal tax credits. Additional incentives for solar installations are also likely in the near future as a portion of the revenues utilities start to receive from the Cap and Trade program under AB 32.

Unfortunately, solar power does not currently provide a standalone solution to providing all the electrical generation needs for Southern California. Until the intermittency, large storage technologies, and increased panel efficiencies become more cost effective existing generating natural gas-fired power generating technologies are required to provide base loads, ramp rates, and other ancillary services such as frequency regulation. Additionally, the clean air benefits renewable energy sources such as solar power provide in southern California would be best realized as transportation technologies, such as electrification, are implemented at a faster rate.

The *Vision* document also presented biofuels as a potential pathway among several to meet the GHG reduction mandates and goals of California. The use of biofuels does not typically provide an advantage in reducing criteria pollutants if they are combusted from standard internal combustion engines (ICEs) such as diesel ICEs. Therefore in the *Vision* document it is stated “In the longer-term, to meet the greenhouse gas targets, any combustion-based heavy-duty trucks would rely predominantly on efficiency and renewable and biofuel solutions. However, to achieve the air quality standards in the South Coast, a technology transition to zero- and near-zero emission trucks (e.g., electric, fuel cell, or hybrid with all electric range) to reduce NOx emissions is also needed.” In summary, SCAQMD staff supports the development and implementation of solar energy technologies to the maximum extent feasible and cost-effective. These technologies are not needed to attain the PM2.5 standards, but SCAQMD staff will continue to support solar technologies for attaining the ozone standards in the future.

The comment states that the 2012 AQMP and the Program EIR must show how they are on track to reduce GHG levels 40 percent by 2035. As noted earlier, the jointly developed document between SCAQMD, San Joaquin APCD, and the CARB *Vision for Clean Air: A Framework for Air Quality and Climate Planning* shows pathways on how we can achieve 2050 GHG reduction levels. Further, the purpose of the Program EIR for the 2012 AQMP is to evaluate potential environmental impacts from the proposed project. As indicated in Subchapter 4.2, potential GHG impacts from implementing the 2012 AQMP is expected to result in reducing GHG emissions approximately 0.477

million metric tons of CO₂e. Since GHG emission would be reduced from implementing the 2012 AQMP, GHG emission impacts were concluded to be insignificant and, therefore, measures to mitigate GHG emissions are not required.

- 8-7 The commenter states that the Sierra Club opposes the licensing of all new natural gas power plants, but lists exceptions. The commenter requests that the 2012 AQMP include a suggested list of control measures. Some of the alternative technologies mentioned in the comment include using natural gas in cogeneration, using biogas, and large fuel cells. Currently the SCAQMD is funding demonstration projects with many of these technologies and alternative sources of fuel. Biogas can provide a good replacement for natural gas and has GHG benefits, but currently has limited supply sources with high upfront costs to develop new sources. Generation sources using natural gas for fuel cells have many applications to provide a generation source and waste heat recovery for a building. The SCAQMD is currently installing a demonstration fuel cell to further investigate potential power generating and heating benefits. However, large fuel cells are currently very costly and the efficiency of the system with waste heat recovery is similar to a combined cycle power plant. As the costs of these systems come down they can be more widely implemented and have criteria pollutant emission benefits over large power generating facilities.

Some of the proposed control measures are covered under the Title 24 building standards. CEQA staff has referred this comment to the 2012 AQMP staff. In general, the SCAQMD supports measures such as these if and when they are feasible. The SCAQMD will consider these suggestions, as appropriate, in future rule development efforts.

See response for comment #8-6 regarding the use of solar power to replace current power generation sources.

- 8-8 The primary objective of Control Measure INC-01 is to develop programs that promote and encourage adoption and installation of cleaner, more-efficient combustion equipment with a focus on zero and near-zero emission technologies. The commenter's request to include "efficiency and solar thermal for hot water and industrial processes" in Control Measure INC-01 is not necessary as those example are in concert with the goals of Control Measure INC-01.
- 8-9 This comment concludes the letter. No further response is necessary.

 Diamond Bar, CA 91765

Subject: Comments of the Draft 2012 Air Quality Management Program Environmental Impact Report

Dear Dr. Wallerstein:

The Orange County Council of Governments (OCCOG) welcomes its responsibility to comment on the Draft 2012 Air Quality Management Plan Program Environmental Impact Report (AQMP/PEIR). As you will recall, OCCOG shared comments on the Draft 2012 Air Quality Management Plan in our August 31, 2012 letter to you.

9-1

As with our previous comment letter, given the timing of the comment period, the comments below have not been considered by the full OCCOG Board of Directors. The OCCOG Technical Advisory Committee has formed an ad-hoc subcommittee to review AQMP documents and their input formed the basis of our comments.

1. PEIR Appendix F: "RTP/SCS Mitigation Measures Table". The appendix title page should be revised to reflect the more accurate title "Examples of Measures That Could Reduce Impacts from Planning, Development, and Transportation Projects." This needed change will make the document consistent with the adopted Southern California Association of Governments 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy.

9-2

2. It appears that the demographic and socio-economic data included in the analysis of the PEIR is outdated and is not the most recent data prepared for the Center for Demographic Research and used in the Orange County Sustainable Communities Strategy and the Southern California Association of Governments 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy. The analysis should be revised to include the demographic and socio-economic data contained in the Orange County Sustainable Communities Strategy.

9-3

Dr. Barry Wallerstein
October 23, 2012

3. There are significant errors in describing Orange County in Subchapter 3.6 – Land Use and Planning and Subchapter 3.2 – Climate Change. Corrections need to be made in the final draft of the PEIR. These errors are included as an attachment to this letter.

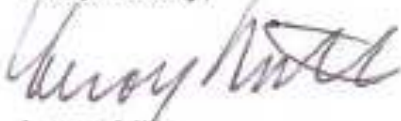

9-4

Again, OCCOG appreciates the opportunity to provide further comments on the 2012 AQMP/PEIR. At this time, we anticipate providing further comment on the overall AQMP plan and the recently released socio-economic report.

9-5

We look forward to receiving your response to our comments and would be pleased to work with your staff on the noted technical corrections.

Respectfully,

Leroy Mills
OCCOG Chairman

cc: OCCOG Board of Directors

Dr. Barry Wallerstein
October 23, 2012

**Errors Noted Orange County Data in Subchapters 3.6 and 3.2
Land Use and Planning and Climate Change**

Subsection 3.6.3.2 Orange County (page 3.6-7): The Orange County General Plan is only applicable to areas of unincorporated Orange County and does not supersede the General Plans of the 34 independent local jurisdictions. Therefore, it is erroneous and misleading to state policies identified in the County of Orange General Plan and generalize that these policies are applicable to the 34 local Orange County jurisdictions. The PEIR should either be revised to clearly state that the County of Orange General Plan is only applicable to those unincorporated areas of the County of Orange and each local jurisdiction has their own governing General Plan or remove the text in its entirety.

9-6

Subsection 3.6.3.2.2 Commercial (page 3.6-8): There are errors in describing the commercial areas within Orange County that need to be revised in the final version of the Program Environmental Impact Report. 1) The commercial area located within close proximity to the intersection of Interstate 5, State Route 22, and State Route 57 is not known as the "Orange Crush" as noted in the draft PEIR. The "Orange Crush" is used to describe the intersection of the three transportation corridors, not the commercial/office area. 2) The area surrounding John Wayne Airport and the University of California, Irvine is known as the Irvine Business Complex or IBC not the Irvine Spectrum. 3) The terminology "El Toro Y" is used to describe the intersection of two transportation corridors, Interstate 405 and Interstate 5, not the commercial/office center. That is the Irvine Spectrum.

9-7

Subsection 3.6.3.2.3 Industrial (page 3.6-8): The paragraph is erroneous in referencing the Orange County General Plan, which is only applicable to the unincorporated areas of the County of Orange. Every local jurisdiction has their own governing General Plan that may identify areas of industrial use. The paragraph needs to be revised for the final PEIR.

9-8

Subsection 3.6.3.2.5 Open Space (page 3.6-8): The Orange County Sustainable Communities Strategy identifies the preservation/open space programs located throughout all of Orange County, including the individual efforts of the County of Orange and the 34 local jurisdictions. This paragraph should be revised to generally reflect the open space policies outlined in the Orange County Sustainable Communities Strategy.

9-9

Dr. Barry Wallerstein
October 23, 2012

Table 3.2-1A and Table 3.2-1B (pages 3.2-13 and 3.2-14): It is unclear how certain calculations were made in both tables due to the rounding of the values. The Final PEIR should include the non-rounded values to ensure reviewers are able to confirm the calculations and assumptions. In addition, any reference to these numbers in the text of the document should be corrected for consistency. For example on Table 3.2-1A, under Waste Disposal NOx, the 2007 AQMP value is 2 and the draft 2012 AQMP is 2, yet the percent change is calculated at -24%. In Table 3.2-1B, under Fuel Consumption Sox, the 2007 AQMP value is 2 and the draft 2012 AQMP value is 2, yet the percent change is -3%. The Petroleum Production and Marketing Sox 2007 AQMP value is 1 and the draft 2012 AQMP value is 1, yet the percent change is -32%. The Petroleum Production and Marketing PM 2.5 2007 AQMP value is 1 and the draft 2012 AQMP value is 2, yet the percent change is 68%. The Cleaning and Surface Coatings PM 2.5 2007 AQMP value is 1 and the draft 2012 AQMP value is 2, yet the percent change is 53%.

9-10

Responses to Comment Letter #9
Orange County Council of Governments – Leroy Mills (10/23/2012)

- 9-1 This comment notifies the SCAQMD that the comments contained in the letter pertain to the Draft Program EIR for the 2012 AQMP but that the comments were not considered by the full OCCOG Board of Directors. Instead the comments were prepared by the OCCOG Technical Advisory Committee. Lastly, this comment notifies the SCAQMD that a previous comment letter was submitted relative to the Draft 2012 AQMP on August 31, 2012. No further response is necessary.
- 9-2 This comment recommends the title of Appendix F to be changed from “RTP/SCS Mitigation Measures Table” to “Examples of Measures That Could Reduce Impacts From Planning, Development, and Transportation Projects” for consistency with the SCAG 2012-2035 RTP/Sustainable Communities Strategy. The title of Appendix F of the Final Program EIR has been revised accordingly.
- 9-3 This comment states that the demographic and socioeconomic data included in the analysis of the Draft Program EIR is outdated and that the analysis should be revised to reflect the most recent data contained in the Orange County Sustainable Communities Strategy. Because the comment does not specifically state what data are obsolete, SCAQMD staff is unable to identify what data needs to be updated. Further, since Orange County’s SCS was incorporated into SCAG’s 2012-2035 RTP/SCS, which forms the basis of the 2012 AQMP’s socioeconomic forecasts, it is not necessary to update the CEQA document to include socioeconomic data.
- 9-4 This comment states that there are errors in the description of Orange County in Subchapter 3.6 – Land Use and Planning and Subchapter 3.2 – Air Quality and that the errors are described in more detail in an attachment to the comment letter. For responses to the individual described errors, see responses to comments #9-6 through #9-10.
- 9-5 This comment concludes the letter. No further response is necessary.

Responses to comments attached to Letter #9

- 9-6 This comment recommends the Land Use and Planning discussion that pertains to the Orange County General Plan be clarified to explain that the plan is only applicable to unincorporated areas within Orange County and that each of the 34 cities within Orange County has its own General Plan. Section 3.6.3.2 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.
- 9-7 This comment recommends the Land Use and Planning discussion that pertains to the commercial areas within Orange County General Plan to be clarified to explain that the commercial area located within the proximity of Interstate 5, State Route 22, and State 57 is not the “Orange Crush” transportation corridor. This comment also recommends the Land Use and Planning discussion that pertains to the area surrounding John Wayne Airport and the University of California – Irvine to be described as the Irvine Business District and not the Irvine Spectrum. This comment also recommends the Land Use and Planning discussion that pertains to the intersection of Interstate 5 and Interstate 405 to be described as the “El Toro Y” and the commercial/office center in the vicinity of this

intersection to be described at the Irvine Spectrum. Subsection 3.6.3.2.2 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.

- 9-8 This comment recommends the Land Use and Planning discussion that pertains to the Orange County General Plan be clarified to explain that the plan is only applicable to unincorporated areas within Orange County and that each of the 34 cities within Orange County has its own General Plan. Subsection 3.6.3.2.3 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.
- 9-9 This comment recommends the Land Use and Planning discussion that pertains to open space should be revised to reflect the open space polices outlined in the Orange County Sustainable Communities Strategy. Subsection 3.6.3.2.5 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.
- 9-10 The commenter has identified several typos in Tables 3.2-1A and 3.2-1B (in Chapter 3.2 of the Draft Program EIR). These typos have been corrected in the Final PEIR to match the actual, correct values as provided in Tables III-2-1A and III-2-1B in Appendix III of the 2012 AQMP, which have been available since July in both a draft (<http://www.aqmd.gov/aqmp/2012aqmp/draft/Appendices/AppIII.pdf>) and revised draft version (<http://www.aqmd.gov/aqmp/2012aqmp/RevisedDraft/appIII.pdf>).

The commenter has also suggested that the values provided in the tables should be provided in non-rounded numbers so that reviewers can confirm the calculations and assumptions. SCAQMD staff disagrees with this suggestion as the data provided in the table is a straight comparison between the emissions data in the 2007 AQMP and the 2012 AQMP, so other than the footnotes provided for certain entries, no assumptions were made when compiling this table. Further, based on the data compiled, the calculations can be confirmed as currently presented. Thus, other than the corrections made to the typos, no other changes to these tables are necessary.

Letter #10
Greg Nord, OCTA

Potential Conflicts with the 2012-2035 RTP/SCS PEIR ¶

Several sections of the PEIR for the 2012 AQMP include language along the following lines: ¶

¶

Mitigation measures are not required for the 2012 AQMP because implementation of the 2012 AQMP is not expected to result in potentially significant adverse _____ impacts and does not contribute to the impacts identified in the 2012-2035 RTP/SCS Final Program EIR. However, because implementation of the 2012-2035 RTP/SCS is expected to result in significant impacts, mitigation measures were identified in the 2012-2035 RTP/SCS Program EIR. The 2012-2035 RTP/SCS Program EIR mitigation measures are included in Appendix F, as part of the 2012 AQMP Program EIR. ¶

¶

The “legal standing” of Appendix F with respect to the 2012 AQMP PEIR is not explicitly stated anywhere within the document. Thus, circulation of Appendix F as part of the 2012 AQMP PEIR could be construed as an invitation to re-open the 2012-2035 RTP/SCS PEIR. It is recommended that language be included within the 2012 AQMP PEIR to clarify that Appendix F is provided for informational purposes only. ¶

¶

If additional mitigation to address the 2012 AQMP’s cumulative contribution is available, it should be included in the AQMP PEIR. For example, the 2012 AQMP could call for cleaner fuels and higher energy efficiency standards (regulations that would be introduced at the state and/or federal level). ¶

¶

Proposed Expansion of MM-TR-29 ¶

The following language is included on page 1-23 under the heading “Implementation of Control Measures” and is repeated later in the document: ¶

¶

SCAQMD recommends that mitigation measure MM-TR29 from SCAG’s 2012-2035 RTP/SCS PEIR (which generally requires a traffic management plan) be implemented for all [word(s) missing] that have the potential to impact roadways. ¶

¶

MM-TR29 addresses temporary construction-related traffic impacts and says project sponsors should develop construction management plans for review and approval by the lead agency. The AQMP PEIR should clarify what “all” refers to and ensure that the recommendation is reasonable for any project that would fall within the definition of “all”. (For instance, it might not be reasonable to require a comprehensive construction management plan for a small project, such as parking lot resurfacing or tree trimming that might disrupt traffic for only a few days.) ¶

¶

Site-Specific Air Quality Mitigation ¶

Page 4.2-18 of the AQMP PEIR ¶

¶

The proposed requirements AQ-1 through AQ-7 (especially the AQ-1 requirement to submit a Construction Emission Management Plan to SCAQMD/CEQA for approval prior to the start of construction) will add cost, time and complexity to the project delivery process. It is recommended (a) that appropriate thresholds be developed to distinguish which projects would be subject to these requirements and (b) that a self-certification process is implemented for compliance with them. ¶

10-1

10-2

10-3

Responses to Comment Letter #10
Orange County Transportation Authority – Greg Nord (10/23/2012)

- 10-1 This comment includes a statement from Chapter 5 in the Program EIR that addresses cumulative impacts. The statement indicates that mitigation measures are not required for specified environmental impact areas where the 2012 AQMP does not contribute to significant adverse impacts. This statement is made under two scenarios. The first scenario is where the 2012 AQMP does not create any impacts to an environmental topic area as indicated in the Initial Study and was not further analyzed in the Draft Program EIR. Under this scenario, project-specific mitigation measures are not required as no impacts are expected to be generated that could contribute to cumulative impacts, thus, cumulative impact mitigation measures would not be required.

The second scenario where this statement is made is when analysis of project-specific impacts to an environmental topic indicated that impacts would be less than significant. In this situation, impacts are not concluded to be cumulatively considerable as defined by CEQA Guidelines §15064 (h)(1) and, therefore, are not cumulatively significant. In the situation where impacts from the 2012 AQMP are not cumulatively significant, mitigation measures would not be required.

Finally, where project-specific impacts from the 2012 AQMP are concluded to be significant, the analysis concludes that project-specific impacts contribute to significant adverse cumulative impacts. For all environmental topic areas where project-specific impacts were concluded to be significant, feasible mitigation measures were identified. These measures would also serve to mitigate significant adverse cumulative impacts.

The comment also requests clarification on the “legal standing” of Appendix F, which includes mitigation measures from SCAG’s 2012–2035 RTP/SCS Final Program EIR. As recognized in the comment Appendix F is for informational purposes only. To make it clearer that Appendix F is for information purposes only, the following footnote has been added to page 5-1 in Chapter 5 of this Final Program EIR. “In addition to summarizing impacts from the 2012-2035 RTP/SCS, this document includes a list of all measures identified in the 2012-2035 RTP/SCS Program EIR to mitigate environmental impacts from that project for informational purposes only. The Program EIR for the 2012-2035 RTP/SCS, which includes all of the mitigation measures in Appendix F, was previously certified in April 2012.

As described in Chapter 4 and Appendix IV-B of the 2012 AQMP, 17 mobile source measures are being proposed that focus on accelerated retrofits or replacement of existing vehicles or equipment, acceleration of vehicle turnover, and greater use of cleaner fuels in the near-term. In the longer term, there is a need to increase the penetration and deployment of near-zero and zero-emission vehicles such as plug-in hybrids, battery-electric, fuel cells, and further use of cleaner fuels (either alternative fuels or new formulation of gasoline and diesel fuels). However, as noted by the commenter, regulating these sources would require state or federal involvement. The cost to incentivize the implementation of these mobile source measures are provided in the individual write-ups for each measure found in Appendix IV-B. Because these mobile measures already call for more efficient vehicle performance and cleaner fuels, and, thus, part of the proposed project, they are not classified as mitigation measures under CEQA.

- 10-2 This comment notes that there are words missing in a sentence in Chapter 1 on page 1-23 and requests clarification of the sentence. The sentence identified in the comment has been modified as follows:

SCAQMD recommends that mitigation measure MM-TR29 from SCAG’s 2012-2035 RTP/SCS Program EIR (which generally requires a traffic management plan) be implemented for all projects resulting from Control Measures ONRD-05 and/or ADV-01 that have the potential to impact roadways.

- 10-3 The comment recommends developing appropriate thresholds for identifying projects that would be subject to construction air quality mitigation measures AQ-1 through AQ-7 and that a self-certification process be implemented to demonstrate compliance with the referenced mitigation measures. With regard to the comment about thresholds, the SCAQMD has developed construction air quality thresholds, both regional and localized significance thresholds that are recommended for use by public agencies when preparing an environmental analysis pursuant to CEQA or NEPA. For those lead agencies that use the SCAQMD’s recommended construction significance thresholds, if projects for which they are lead agencies exceed the recommended construction air quality significance thresholds as part of complying with 2012 AQMP control measures promulgated as rules or regulations in the future, they would be required to implement mitigation measures AQ-1 through AQ-7. Projects with construction emission less than the SCAQMD’s suggested significance threshold would not be required to implement the mitigation.

It is unclear what is meant by “self-certification process.” However, when the SCAQMD imposes mitigation measures on an affected facility, it is typically the responsibility of the facility owner/operator to implement applicable mitigation measures. Further, the owners/operators are typically required to keep records documenting implementation of applicable mitigation measures that must be kept onsite for a specified period of time and be available for review by SCAQMD inspectors.

Subject: FW: Comments to AQMD Draft EIR-2012 Air Quality Management Plan AQMP due 10.23.2012

From: Joyce Dillard [mailto:dillardjoyce@yahoo.com]
Sent: Tuesday, October 23, 2012 2:25 PM
To: 2012 AQMP Comments
Subject: Comments to AQMD Draft EIR-2012 Air Quality Management Plan AQMP due 10.23.2012

Federal Register Docket EPA-R09-OAR-2012-0721-0001 titled Finding of Substantial Inadequacy of Implementation Plan; Call for California State Implementation Plan Revision; South Coast and dated August 30, 2012 states:

Our proposed SIP call is based on the evidence submitted by California in the form of the 2003 South Coast 1-Hour Ozone Plan that the approved 1997/1999 South Coast 1-Hour Ozone SIP was substantially inadequate to provide for attainment of the 1-hour ozone standard by the applicable attainment date of November 15, 2010.

Federal Register EPA-R09-OAR-2012-0713-0001 titled Disapproval of Implementation Plan Revisions; State of California; South Coast VMT Emissions Offset Demonstrations and dated September 19, 2012 states:

EPA is proposing to withdraw its final approvals of state implementation plan revisions submitted by the State of California to meet the vehicle-miles-traveled emissions offset requirement under the Clean Air Act for the Los Angeles-South Coast Air Basin 1-hour and 8-hour ozone nonattainment areas. EPA is also proposing to disapprove the same plan revisions. EPA is proposing the withdrawal and disapproval actions in response to a remand by the Ninth Circuit Court of Appeals in Association of Irrigated Residents v. EPA.

Are you figures reflective of that criteria and how does it effect the facts, assumptions, and mitigations of this plan.

You base the plan on the following components:

- 1) the SCAQMD's Stationary and Mobile Source Control Measures;
- 2) suggested State Mobile Source Control Measures; and
- 3) Regional Transportation Strategy and Control Measures provided by SCAG.

Not taken into consideration for emission projections, monitoring and mitigation are increases in density, planned by the municipalities, not SCAG and major projects that generate VMT such as an NFL Football Stadium and related sports such as Major League Baseball, whether it be in the City of Los Angeles, City of Industry or the Rose Bowl in Pasadena (temporary) and its related entertainment activities affect Air Quality such as tailgating (barbeques) and fireworks. Also, the effects of increase in Metrolink traffic, maintenance and maintenance yard usage are not addressed. The increase of hotels for tourism is not addressed nor any increase in airplane traffic and in port traffic (supplies). These are regional factors that should be reflected in your Emission Growth Factors.

11-1

11-2

In my prior comments, you ducked the question of Ozone and Signage. Though you may not be the permittees of signage, you need to take into consideration the growth effects of the region, especially 24/7 digital signage.

11-3

These factors MUST be considered in any Mitigation for the 2012 AQMP. This Draft EIR is flawed.

11-4

Under **Aesthetics**, you state:

These general plans establish local policies related to aesthetics and the preservation of scenic resources within their communities or sub-planning areas, and may include local scenic highway programs.

11-5

You also fail to list the Caltrans Arroyo Seco Scenic Byway within the District borders. This Byway should be considered for mitigation in any NFL Stadium in Los Angeles or temporary site at the Rose Bowl in Pasadena in all measures of the EIR.

Under **Hydrology and Water Quality**, you state:

2012-2035 RTP/SCS impacts associated with hydrology and water quality would be reduced following the implementation of the 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation for water quality, wastewater, riparian habitats and waters of the U.S. runoff/drainage, groundwater, flooding, and water supply.

Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would contribute to cumulatively considerable impacts following mitigation to water demand impacts. The cumulative impacts of other hydrology and water quality impacts associated with the 2012 AQMP are less than significant.

11-6

Omitted are effects on the Watersheds and Sub-Watersheds and the compliance issue of pollutants generated from emissions. This is extremely significant as the LA County Flood Control District LACFCD is implementing a parcel task to pay for watershed mitigation and maintenance under Watershed Management Areas, as guided by the LA Regional Water Quality Control Board.

The cost is extremely high for this execution, compounded by other local and state taxpayer-backed funding mechanisms.

Under **Land Use and Planning**, you state:

Implementation of the 2012 AQMP would not result in any significant impacts associated with land use or planning. Potential land use and planning impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures.

However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would contribute to inconsistencies with general plans, disruption or division of established communities, changes to land uses by changing concentrations of development throughout SCAG, change patterns of growth and urbanization beyond the SCAG region, and cumulatively considerable changes to land use and the intensity of land use. Short-term construction related impacts and long-term or permanent displacement or offsite impacts from new facilities would also potentially occur as a result of implementation of the 2012-2035 RTP/SCS.

11-7

Moreover, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable land use and planning impacts requiring mitigation.

11-7
Con't

Under State law, there should be no inconsistencies with the General Plans and their Elements. Guidance is issued by the Governor's Office of Planning including COMPLETE STREETS AND THE CIRCULATION ELEMENT and COMMUNITY AND MILITARY COMPATABILITY PLANNING.

Under **Noise**, you state:

The 2012 AQMP control measures associated with construction of overhead catenary lines could result in significant noise and vibration impacts after mitigation due to the geographic proximity of sensitive receptors. Although impacts would be reduced following implementation of noise mitigation measures identified in the 2012 AQMP Program EIR, noise and vibration impacts associated with the construction of catenary lines would remain significant in areas where sensitive receptors are located near transportation corridors.

2012-2035 RTP/SCS impacts associated with noise would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation for noise and vibration during construction activities and operational activities. Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would contribute to cumulatively considerable construction noise and vibration impacts following mitigation.

11-8

You fail to recognize destruction, damage and possible emissions from underground pipes due to these factors. You have not even addressed the types of emissions from the various underground pipe infrastructure.

Under **Solid/Hazardous Waste**, you state:

The 2012 AQMP control measures would not result in significant impacts on solid or hazardous waste. Solid and hazardous waste impacts associated with the 2012-2035 RTP/SCS would remain significant following mitigation because the demand for solid waste services in the SCAG region and the resulting need to move solid waste large distances, potentially out of the region, would remain. Based on the above information, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable solid or hazardous waste impacts following mitigation

11-9

You fail to recognize attempts by municipalities to place solid waste recycling operations within the region. You fail to neither analyze landfill usage increase nor identify the landfills that would accommodate waste. All these factors contribute emissions themselves and require more mitigation than addressed.

Under **Transportation and Traffic**, you state:

The 2012 AQMP control measures that could result in the construction of overhead catenary lines are expected to remain a significant construction impact to traffic after mitigation. Such construction activities would generate traffic associated with construction worker vehicles and trucks delivering equipment, materials and supplies to the project site during the duration of the construction activities.

11-10

Similarly, transportation infrastructure improvements pertaining to overhead catenary electrical lines could require the dedication of an existing lane exclusive to vehicles using the overhead catenary electrical lines or fixed guideway systems. Thus, a reduction in the number of available lanes could result in significant adverse operational traffic impacts.

According to the 2012-2035 RTP/SCS PEIR, implementation of the RTP/SCS would result in several significant and several less than significant impacts after mitigation. The 2035 VMT and 2035 heavy-duty truck VHD would be substantially greater than the existing conditions and as such would result in a significant impact in spite of implementing mitigation measures. As the population increases through 2035, the number of trips originating and ending in Santa Barbara, San Diego and Kern counties to and from the SCAG region would increase. And the transportation demand from growth, in combination with the accommodating projects in the 2012-2035 RTP/SCS would contribute to a cumulatively considerable transportation impact.

Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, would contribute to cumulatively considerable construction impacts following mitigation and, since no mitigation measures were identified that reduce potential operation-related traffic impacts, these remain significant.

You fail to recognize increased VMT in relationship to conversion timetables and any emission factors sustained before conversion.

Under Biological Resources, you state:

The 2012 AQMP is not expected to result in significant biological resources impacts. 2012-2035 RTP/SCS impacts associated with biological and open space resources would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation due to significant disturbance and removal of natural vegetation that may be utilized by sensitive species, habitat fragmentation and the associated decrease in habitat quality, litter, trampling, light pollution and road noise in previously undisturbed natural areas, displacement of riparian and wetland habitat, siltation of streams and other water bodies during construction, and the loss of prime farmlands, grazing lands, open space and recreation lands. The increased urban development anticipated by the 2012-2035 RTP/SCS would also result in similar impacts. However, since the 2012 AQMP was not identified as creating any adverse biological resources impacts, it would not create cumulatively considerable impacts, so adverse cumulative biological resources impacts from the 2012 AQMP are concluded to be less than significant.

You have not taken into consideration ecosystems, endangered wildlife and vegetation, wetlands and watershed management issues.

Under Cultural Resources, you state:

The 2012 AQMP is not in itself expected to result in significant cultural resources impacts. The development of transportation facilities as part of the 2012-2035 RTP/SCS may affect historical resources because many projects could be located in older urban centers where structures of architectural or historical significance are likely to be located. In addition, 2012-2035 RTP/SCS transportation projects would significantly affect archaeological and paleontological resources because projects could be located in previously undisturbed areas.

You fail to even mention Tribal issues or Disadvantaged Communities.

11-10
Con't

11-11

11-12

Under **Geology and Soils**, you state:

Implementation of the 2012 AQMP would not in itself result in significant geological or soil impacts. Potential geologic and soil resources impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS is expected to result in potential damage to transportation infrastructure through surface rupture, ground shaking, liquefaction, and landsliding, as well as long term soil erosion and/or loss of top soil, subsidence, and slope failure. Moreover, the 2012 AQMP would not contribute to geologic and soil resources impacts associated with transportation projects projected in the 2012-2035 RTP/SCS and, therefore, would not be expected to contribute to a cumulatively considerable impact requiring mitigation.

11-13

and under **Mineral Resources**, you state:

Implementation of the 2012 AQMP would not result in any significant impacts associated with mineral resources. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of 2012-2035 RTP/SCS would result in increased demand driven by growth and the large number of projects anticipated in the 2012-2035 RTP/SCS. The 2012 AQMP, when combined with past, present, and reasonably foreseeable activities and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable mineral resources impacts following mitigation.

You are now addressing the Fracking issue under your October 12, 2012 press release. The issue is omitted in the Draft EIR as are emissions from subsidence factors.

Under **Population and Housing**, you state:

The 2012 AQMP control measures would not result in population and housing impacts. The policies included in the 2012-2035 RTP/SCS seek to direct growth in a way that is efficient for both mobility and land consumption. Implementation of the RTP/SCS would help induce growth to certain vacant areas of the region, a substantial number of residences and businesses would likely be displaced, and the mobility benefits from the RTP/SCS may shift population, households, and employment. This may generate potentially significant adverse cumulative population and housing impacts in spite of implementing mitigation measures.

11-14

Therefore, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, would not be expected to produce a cumulatively considerable impact following mitigation

You fail to recognize density issues in COMMUNITY PLANS of the GENERAL PLANS and the high density planned with consequences in Health Risk Assessments being underplayed.

Under **Public Services**, you state:

The 2012 AQMP control measures would not result in significant public services impacts. The public service impacts from the 2012-2035 RTP/SCS associated with police, fire, and emergency response were concluded to be significant in spite of implementing mitigation measures. Impacts to wildfire threats would also remain significant because development would occur in areas that have a high threat of fire. In addition, the region's demand to accommodate an additional 453,000 school children

11-15

would remain a significant impact on public services following implementation of 2012-2035 RTP/SCS mitigation measures.

Based on the above information, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and with 2012-2035 RTP/SCS projects in particular, is not expected to produce cumulatively considerable impacts to public services following mitigation

You fail to recognize sea-level rise with emissions and possible flooding factors. Emergency services and their need for equipment and vehicles have not been addressed in relationship to population and density increase.

Under **Recreation**, you state:

The 2012 AQMP control measures would not result in significant impacts on recreation resources. Impacts associated with recreation resources remain significant following mitigation because the 2012-2035 RTP/SCS would contribute to the loss and disturbance of open space and recreational lands. Based on the above information, the 2012 AQMP, when combined with past, present, and reasonably foreseeable activities, and in particular with the 2012-2035 RTP/SCS transportation projects, would not be expected to contribute to cumulatively considerable recreation impacts following mitigation.

You have not addressed pollution effects on warming of the air and atmosphere and its effects on plants, wildlife and birds in parks, open spaces, forests and wetlands.

Under **Agricultural Resources**, you state:

The 2012 AQMP is not expected to result in significant agriculture resources impacts, as evaluated in the NOP/IS.

For the 2012-2035 RTP/SCS, agricultural resource impacts are expected to remain significant following mitigation as the 2012-2035 RTP/SCS is expected to contribute to the loss and disturbance of agricultural lands as up to 74,300 new lane miles could be developed, some of which could disturb or consume agricultural lands. Potential agricultural resources impacts associated with the 2012-2035 RTP/SCS would be reduced following the implementation of 2012-2035 RTP/SCS Program EIR mitigation measures. However, 2012-2035 RTP/SCS impacts would remain significant following mitigation because implementation of the 2012-2035 RTP/SCS would contribute to significant loss and disturbance of agricultural lands. Moreover, the 2012 AQMP would not contribute to these impacts, so adverse cumulative operational agricultural resources impacts are concluded to be less than significant.

You have not addressed pollution effects on warming of the air and atmosphere and its effects on agriculture.

Will you be able to obtain **OVERALL ATTAINMENT STRATEGY** with this flawed and understated Draft EIR or have a Federal Implementation Plan exercised over the State Implementation Plan?

Joyce Dillard

11-15
Con't

11-16

11-17

11-18

Responses to Comment Letter #11
Ms. Joyce Dillard (10/23/2012)

- 11-1 As noted in the comment the U.S. EPA published a “SIP call” on September 19, 2012, finding the existing approved one-hour ozone SIP substantially inadequate to provide for attainment of the revoked one-hour ozone standard (<http://www.aqmd.gov/aqmp/2012aqmp/EPA/FederalRegister-SIPcall.pdf>). This action was in response to the decision of the Ninth Circuit Court of Appeals in *Association of Irrigated Residents, et al, v. United States Environmental Protection Agency, et al.*, 686 F. 2d 668 (Amended January 12, 2012). As a result, SCAQMD staff prepared Appendix VII of 2012 AQMP for the purpose of providing an attainment demonstration of the one-hour ozone standard. Appendix VII is composed largely of summaries or replication of information, such as air quality, emission inventory and ozone control strategy, presented in the main volume and appendices of the 2012 AQMP, so there is no effect on the 2012 AQMP. The only new information presented in Appendix VII is the discussion demonstrating attainment with the one-hour ozone standard. Because the one-hour ozone standard demonstration does not require that additional control measures be identified, the one-hour ozone standard attainment demonstration has no effect on the 2012 AQMP, which also demonstrates the attainment of the federal 24-hour PM_{2.5} standard.

As also indicated in the comment, in response to a decision of the Ninth Circuit Court of Appeals in *Association of Irrigated Residents v EPA*, (9th Cir., reprinted as amended on January 27, 2012, 686 F. 3d 668), EPA withdrew its approval of, and then disapproved, the vehicle miles travelled (VMT) emissions offset demonstrations in the 2003 one-hour ozone SIP and the 2007 one-hour ozone plan (“Disapproval of Implementation Plan Revisions; State of California; South Coast VMT Emissions Offset Demonstrations”, September 19, 2012 (77 Fed. Reg. 58067)). In August 2012, the U.S. EPA issued guidance entitled “Implementing Clean Air Act Section 182 (d)(1)(A): Transportation control measures and Transportation Control Strategies to Offset Growth in Emissions Due to Growth in Vehicle Miles Travelled.” The U.S. EPA guidance recommended a calculation methodology that could be done to determine if sufficient transportation control strategies and TCMs have been adopted and implemented to offset the growth in emissions due solely to growth in VMT. SCAQMD staff conducted a VMT emissions offset analysis pursuant to U.S. EPA guidance and concluded that actual emissions with controls and VMT growth were substantially less than emissions assuming no new measures and no VMT growth (“ceiling”). Based on this conclusion, no new TCMs are required for the one-hour ozone SIP. SCAQMD staff has prepared the *VMT Offset Requirement Demonstration* (2012 AQMP Appendix VIII) to provide the results of the VMT emissions offset analysis to the public. Consequently, the VMT offset demonstration in Appendix VIII does not affect the emission reduction strategies in the 2012 AQMP.

- 11-2 SCAG has the responsibility of preparing and approving the portions of the AQMP relating to regional demographic projections and integrated regional land use; housing; employment; and transportation programs, measures, and strategies using a “bottom up” approach. This means that the local municipalities provide the above types of information to SCAG, which in turn develops regional and subregional forecasts. The

transportation strategy and transportation control measures (TCMs) are also included in SCAG’s adopted 2012-2035 RTP/SCS that links regional transportation planning to air quality planning. The 2012-2035 RTP/SCS considers every component of regional multimodal transportation system, including transit, passenger rail, high-speed rail, goods movement, aviation, airport ground access, highways, arterials, operation and maintenance. In addition, in developing the 2012-2035 RTP/SCS, SCAG worked with dozens of public agencies, 191 cities, hundreds of local, county, regional and state officials, business community, environmental groups, as well as various nonprofit organizations. Future VMT activity is determined through SCAG’s transportation demand model based on the socioeconomic growth demographics and land use developments.

- 11-3 The comment states that the SCAQMD needs to take into consideration the effects of the growth of digital signage light pollution in the region on air quality. This comment is similar to a comment previously submitted by this commenter. The previous comment letter included an attachment entitled “City Light Pollution Affects Air Pollution,” which asserts that light pollution has the potential to affect ozone concentrations. The 2012 AQMP is required by law to demonstrate attainment with the federal eight-hour PM2.5 ambient air quality standard, although it contains control measures to reduce ozone precursors to continue making progress in attaining the federal eight-hour ozone standard. A comprehensive ozone SIP will be prepared in 2015, so consideration of the effects of light pollution on ozone concentrations can be considered and evaluated as part of the future federal eight-hour ozone plan.

As indicated in response to comment #11-1 above, the U.S. EPA published in the Federal Register a proposed “SIP call” which, if finalized, would require the SCAQMD to prepare a demonstration of attainment of the one-hour ozone standard, with attainment required by ten years from the date the SIP call is finalized. In response to the U.S. EPA’s “SIP call” and in anticipation that it will be finalized, SCAQMD staff has prepared the *One-hour Ozone Attainment Demonstration*, which demonstrates attainment of the federal one-hour (revoked) ozone standard by the year 2022. Therefore, it relies on the same ozone control measures as the eight-hour ozone plan to respond to the U.S. EPA’s “SIP call.”

- 11-4 This comment states that these factors [see comments #11-1 through #11-3] must be considered in any mitigation for the 2012 AQMP and the Draft Program EIR is flawed. The factors in comments #11-1 through #11-3 have been addressed. See responses to comments #11-1 through #11-3. SCAQMD staff disagrees with the assertion that the Draft Program EIR is flawed. The Draft Program EIR complies with all relevant CEQA requirements for preparing an EIR (CEQA Guidelines §§15120 through 15131) and for preparing a program CEQA document (CEQA Guidelines §15168). No evidence has been provided in the comment that supports the assertion that the Draft Program EIR is flawed.
- 11-5 The comment states that the Draft Program EIR fails to list the CalTrans Arroyo Seco Scenic Byway within the district. Subchapter 3.1 of the Draft Program EIR contains existing setting information relative to aesthetics resources. Table 3.1-2 identifies designated scenic highways within the district and Table 3.1-2 identifies highways within the district eligible for scenic highway designation. The Arroyo Seco Parkway is not a

designated scenic highway nor is it a highway listed as eligible for designation, although it is listed as an historic highway⁵. Regardless of its designation, no control measures were identified that would adversely affect this roadway. The only roadways identified that could be adversely affected by Control Measures ONRD-01, ADV-01, and ADV-02, were existing transportation corridors in areas within and adjacent to the Port of Los Angeles (e.g., Navy Way, and Port of Long Beach), around container transfer facilities (truck/train) near the Terminal Island Freeway and East Sepulveda Boulevard intersection, along the Alameda Corridor, as well as the railyards near downtown Los Angeles (East Washington Boulevard in the City of Commerce, which are located within three miles of the northern terminus of the Alameda Corridor and east of I-710). As indicated in Subchapter 4.1, based on current information regarding the possible future location of catenary lines, they would likely be located near cargo transfer facilities or on existing heavily used cargo transport corridors. The Arroyo Seco Parkway does not fit these categories. For the reasons given here, aesthetics impacts to scenic highways were concluded to be less than significant.

The comment also states that the Arroyo Seco Parkway should be considered for mitigation in any NFL Stadium in Los Angeles, temporary site at the Rose Bowl, and in all measures of the EIR. It is unclear what this comment means. The CEQA document for the NFL stadium in Los Angeles was prepared and recently certified by the City of Los Angeles. It is the responsibility of the lead agency to identify and impose feasible measures, as necessary, to mitigate aesthetics impacts from this project. As a single purpose agency responsible for air quality, the SCAQMD has no authority to impose measures to mitigate aesthetics impacts in a CEQA document prepared by another public agency. The Rose Bowl is an existing facility that currently hosts college football games as well as other events, so it unclear what mechanism would be used to require aesthetics mitigation measures. Finally, as noted in the first part of this response, control measures in the 2012 AQMP are not expected to affect in any way aesthetic resources along the Arroyo Seco Parkway or any other scenic highways in the district, so mitigation measures are not required.

- 11-6 The comment cites text regarding potential cumulative hydrology and water quality impacts from the 2012–2035 RTP/SCS. The comment then states that the Draft Program EIR does not take into consideration the effects of implementing the 2012 AQMP on watersheds and sub-watersheds and the compliance issue of pollutants generated. The comment mentions the Los Angeles County Flood Control District (LACFCD) is implementing an expensive parcel tax to cover costs for watershed mitigation and maintenance.

Implementation of the 2012 AQMP does not require the construction of structures that would affect watersheds or sub-watersheds. Further, the comment does not identify any specific effects of the project on hydrology and water quality nor does the comment provide any evidence that ecosystems would be adversely affected by implementing the 2012 AQMP. Lastly, the implementation of LACFCD's parcel tax project is unrelated to the implementation of the 2012 AQMP.

⁵ California Scenic Highway Mapping System. http://www.dot.ca.gov/hq/LandArch/scenic_highways/index.htm.

- 11-7 In addition to citing text from the cumulative impacts chapter, the comment also states that under state law, there should be no inconsistencies between general plans and their elements. The 2012 AQMP is not a general plan with the various elements associated with general plans so it is not subject to general plan requirements. As discussed in response to comment #11-2, growth forecasts are provided by local jurisdictions as developed in their detailed general plans.
- 11-8 The comment cites text regarding potential cumulative biological resources impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not take into consideration potential noise impacts to underground pipes or emissions from underground pipes. It is assumed that this comment refers to the 2012 AQMP. As noted in response to comment #11-5, the only roadways identified that could be adversely affected by Control Measures ONRD-01, ADV-01, and ADV-02, were existing transportation corridors in areas within and adjacent to the Port of Los Angeles (e.g., Navy Way, and Port of Long Beach), around container transfer facilities (truck/train) near the Terminal Island Freeway and East Sepulveda Boulevard intersection, along the Alameda Corridor, as well as the railyards near downtown Los Angeles (East Washington Boulevard in the City of Commerce, which are located within three miles of the northern terminus of the Alameda Corridor and east of I-710). These roadways are already heavily travelled roadways and the control measures that propose installation of catenary lines do not increase traffic and, therefore, would not increase noise from traffic. Further, to the extent heavy-duty trucks operate on catenary lines, they have the potential to be quieter than heavy-duty diesel trucks. For these reasons, operational noise impacts were concluded to be less than significant.

Project construction could involve equipment and activities that may have the potential to generate groundborne vibration. In general, demolition of structures during construction generates the highest levels of vibration. The FTA has published standard vibration levels and peak particle velocities for construction equipment operations. The FTA uses vibration decibels (abbreviated as VdB) to measure and assess vibration amplitude. In the United States, vibration is referenced to one micro-inch/sec (25.4 micro-mm/sec) and presented in units of Vd.

As noted above noise and vibration impacts from ONRD-01, ADV-01, and ADV-02 as a result of installing catenary lines would occur along existing transportation corridors and right-of-ways where few structures, if any, would be located. Since, demolition would be the primary cause of vibrations and demolition is expected to be minimal, damage to underground pipes and any resulting emissions are not anticipated. Finally, because no specific projects are currently proposed, any noise or vibration impacts would be speculative.

- 11-9 The comment cites text regarding potential cumulative solid waste impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not recognize attempts by municipalities to place solid waste recycling operators within the region. It is assumed that this comment refers to the 2012 AQMP. The 2012 AQMP does not include any control measures that would require or result in construction and operation of solid waste recycling operations in the district. The SCAQMD has no land use authority so would not be able to require solid waste recycling facilities in any municipalities in the district. Land use decisions are made by the public agencies with general land use

authority, i.e., cities or counties. The decision by local municipalities to develop such facilities is also independent from the 2012 AQMP. If local municipalities plan to locate solid waste recycling facilities in their jurisdictions, they would be subject to CEQA, requiring a separate environmental analysis of the project.

The comment also states that the Draft Program EIR does not analyze landfill usage increase or identify landfills that would accommodate waste. The CEQA Guidelines indicate that the degree of specificity required in a CEQA document depends on the type of project being proposed (CEQA Guidelines §15146). The detail of the environmental analysis for certain types of projects cannot be as great as for others. Since the 2012 AQMP is a broad planning document the level of detail of the control measures is not as great as it would be for a specific construction project. As a result, a Program EIR is the appropriate CEQA document because it allows the analysis to properly focus on broad policy alternatives and program wide mitigation measures. The analysis of solid waste impacts in Subchapter 4.8 is commensurate with the level of detail of the 2012, which means that specific landfills that might be affected by 2012 AQMP cannot be identified. Based on that analysis, solid waste impacts were concluded to be less than significant so mitigation is not required.

- 11-10 The comment cites text regarding potential cumulative transportation and traffic impacts from the 2012–2035 RTP/SCS. The comment then states that the Draft Program EIR does not recognize a potential increase in VMT in relation to conversion timetables and any emission factors sustained before conversion. Contrary to the comment, there is no increase in VMT from converting from conventionally fueled vehicles to alternative clean fuel vehicles.
- 11-11 The comment cites text regarding potential cumulative biological resources impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not take into consideration ecosystems, endangered wildlife and vegetation, wetlands and watershed management issues. It is assumed that this comment refers to the 2012 AQMP. As is indicated in both the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 Recirculated NOP/IS, all of the topics mentioned in the comment were evaluated to determine whether or not the 2012 AQMP has the potential to adversely affect biological resources (see the discussions under “IV. Biological Resources” in the 8/2/12 recirculated IS, which can be found in Appendix A of this Final Program EIR). As indicated in the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 Recirculated NOP/IS, it was concluded that the 2012 AQMP would not generate any biological resources impacts. No comment letters were received that refuted this conclusion and no information or other data are provided that indicate in any way that the 2012 AQMP could adversely affect biological resources.
- 11-12 The comment cites text regarding potential cumulative cultural resources impacts from the 2012–2035 RTP/SCS. The comment then states that the Draft Program EIR fails to mention tribal issues or disadvantaged communities. The topic of cultural resources was concluded in the NOP/IS for the 2012 AQMP to have less than significant cultural resources impacts and no comments were received disputing this conclusion. Further, the comment does not provide any evidence to support the implication that Native American tribes or disadvantaged communities would be adversely affected by implementing the 2012 AQMP.

11-13 The Draft Program EIR did not evaluate hydraulic fracturing because the 2012 AQMP does not include any control measures that would require hydraulic fracturing. However, SCAQMD staff is currently assessing current SCAQMD regulations to determine if they adequately cover oil and gas production activities when hydraulic fracturing is used. Additional regulatory actions may include additional controls as well as reporting and public notification requirements for hydraulic fracturing. See also response to comment #8-4 for additional information on hydraulic fracturing.

11-14 The comment cites text regarding potential cumulative population and housing impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not recognize density issues in community plans of general plans, high planned density or the potential for health risk assessments being underplay. It is assumed that this comment refers to the 2012 AQMP. As is indicated in both the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, potential impacts to land use and housing were evaluated to determine whether or not the 2012 AQMP has the potential to adversely affect these areas (see the discussions under “XIII. Population and Housing” in the 8/2/12 recirculated IS, which can be found in Appendix A of this Final Program EIR). As indicated in the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, it was concluded that the 2012 AQMP would not generate any impacts to population or housing in the district. No comment letters were received that refuted this conclusion and no information or other data are provided that indicate in any way that the 2012 AQMP could adversely affect biological resources.

With regard to density, the 2012 AQMP projects future emissions in the Basin using growth projections provided by SCAG, which in turn are provided from the local land use agencies. See response to comment #11-2 for additional information on density information provided to the SCAQMD by SCAG.

It is unclear what the comment about health risk assessments (HRA) “being underplayed” refers to. An HRA is an analysis of toxic air contaminants (TACs) from an institutional, commercial, or industrial facility on local sensitive receptors. New or existing facilities that have the potential to emit or currently emit TACs may be required to prepare an HRA pursuant to SCAQMD Rule 1401 or Rule 1402. If the comment implies that increases in density may increase the number of sensitive receptors affected by a new or existing facility, there is no evidence or data provided to support such an assertion. First, as already noted, the 2012 AQMP is not expected to affect population growth in any way. Second, the 2012 AQMP takes into consideration future growth as discussed in response to comment #11-2. Although the 2012 AQMP is a PM_{2.5} attainment plan, some of the ozone control measures in the plan promote replacing diesel fueled mobile sources with alternative clean fuels and accelerated compliance with existing CARB regulations that reduce diesel PM emissions. Diesel PM is classified as carcinogenic, so measures to reduce diesel PM emissions would serve to reduce exposure by sensitive receptors to TAC emissions. Finally, future projects involving air toxics emissions from stationary sources would still be subject to SCAQMD air toxics control Rules 1401, 1401.1 or Rule 1402.

11-15 The comment cites text regarding potential cumulative public services impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not consider sea level rise and flooding, which could increase demand for emergency services, equipment

and vehicles, relative to population and density increases. It is assumed that this comment refers to the 2012 AQMP. It is assumed that the reference to sea level rise and flooding refer to global climate change impacts, specifically global warming, from GHG emissions. An analysis of GHG emission impacts from the 2012 AQMP was prepared and is included in Subchapter 4.2 in the Program EIR. The analysis concluded that implementing some of the mobile source control measures would actually reduce GHG emissions compared to the baseline year (2008) levels. Consequently, potential GHG emission impacts were concluded to be less than significant so impacts to emergency service described in the comment would not be an effect of adopting the 2012 AQMP. Similarly, as previously noted, the AQMP is not expected to affect population growth in any way, so adverse impacts to emergency services from increasing population and density growth is not an effect of adopting the 2012 AQMP.

- 11-16 The comment cites text regarding cumulative recreation resources impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD has not addressed pollution effects on warming of the air and atmosphere and resulting effects on plants, wildlife and birds in parks, open spaces, forests, and wetlands. It is assumed that this comment refers to the 2012 AQMP. The environmental checklist used to perform the analysis of potential impacts from the 2012 AQMP in the IS identifies two types of recreation impacts: would a project increase the use of neighborhood and regional parks resulting in substantial use and accelerated deterioration; and projects that included or require construction of parks that could have adverse environmental effects (see also CEQA Guidelines Appendix G). As is indicated in both the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, potential recreation impacts were evaluated to determine whether or not the 2012 AQMP has the potential to adversely affect recreational resources (see the discussions under “XV. Recreation” in the 8/2/12 recirculated IS, which can be found in Appendix A of this Final Program EIR). As indicated in the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, it was concluded that the 2012 AQMP would not generate any recreational resources impacts. No comment letters were received that refuted this conclusion and no information or other data are provided that indicate in any way that the 2012 AQMP could adversely affect recreational resources.

With regard to the comment about warming the air and atmosphere, it is assumed this refers to global warming impacts from GHG emissions. As indicated in response to comment #11-15, some of the mobile source control measures would actually reduce GHG emissions compared to the baseline year (2008) levels, so GHG emission impacts were concluded to be less than significant.

With regard to the 2012 AQMP’s effects on plants, wildlife and birds in parks, open spaces, forests, and wetlands, these are actually biological resources impacts, so see response to comment #11-11.

- 11-17 The comment cites text regarding cumulative agricultural resources impacts from the 2012–2035 RTP/SCS. The comment then states that the SCAQMD does not take into consideration warming of the air and atmosphere and its effects on agricultural resources. It is assumed that this comment refers to the 2012 AQMP. As is indicated in both the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, agricultural resources were evaluated to determine whether or not the 2012 AQMP has

the potential to adversely affect agricultural resources (see the discussions under “II. Agriculture and Forest Resources” in the 8/2/12 recirculated NOP/IS, which can be found in Appendix A of this Final Program EIR). As indicated in the original 6/28/12 NOP/IS for the 2012 AQMP and the 8/2/12 recirculated NOP/IS, it was concluded that the 2012 AQMP would not generate any agriculture or forest resources impacts. No comment letters were received that refuted this conclusion and no information or other data are provided that indicate in any way that the 2012 AQMP could adversely affect biological resources.

With regard to the comment about warming the air and atmosphere, it is assumed this refers to global warming impacts from GHG emissions. As indicated in response to comment #11-15, some of the mobile source control measures would actually reduce GHG emissions compared to the baseline year (2008) levels, so GHG emission impacts were concluded to be less than significant.

- 11-18 The 2012 AQMP demonstrates attainment of the 24-hour PM_{2.5} national ambient air quality standard by 2014 (see Chapter 5 of the 2012 AQMP) with the implementation of the PM_{2.5} control strategy outlined in Chapter 4 of the 2012 AQMP. In addition, 2012 AQMP Appendix VII includes an attainment demonstration for the one-hour ozone standard by 2022 through implementing: the eight-hour ozone reduction strategy, carryover measures from the 2007 SIP, and the §182 (e)(5) (“black box”) measures. In addition to the one-hour ozone demonstration, the control strategies and emissions inventory can also be found in Appendix VII of the 2012 AQMP. If the 2012 AQMP is not approved by the U.S. EPA, then consequences can occur including a Federal Implementation Plan. The U.S. EPA approval of the 2012 AQMP or consequences if not approved does not have any bearing on the environmental analysis.

Letter #12

 Subject: Steve Smith Comments DEIR New +11 paGES 6/17/17.12 Harvey Eder & PSPC 10/23
 Attachments: COMMENT LETTER.docx

Howdy SSmith AQMD,

I am incorporating the comments of the Angeles Chapter Sierra Club in the Deir and AQMP as well as the 11 pates submitted to you and the district July 17 &18 2012.

12-1

Also EDU 01 needs to include GHG green House Gases and education in the form including but not limited to public service announcements and kl-14 + education plans for teachers for various grades about how solar is cost effective now and the ghg problems from natural gas being 100 times the gwp compared to co2 etc.(co2e)

12-2

Any other public methods that the district or carb or epa used or that may be effective to educate about the costs of fosswel fuel ghgs vs solar electricity /batteries for vehicles and or solar hydrogen direct or through fuel cells for vehicles should be covered as well etc. Pro solar problems of ghg etc criteria pollution etc especially ghg of methane/natural gasw etc.

Thanks, take care

Harvey Eder 10/23/12

Responses to Comment Letter #12
Mr. Harvey Eder (10/23/2012)

- 12-1 The comment states that the comment letter submitted by the Sierra club is incorporated by reference. See Comment Letter #8 and responses to comments #8-1 through #8-9. The comment also states that previous comments submitted on July 17 and 18, 2012, by this commenter and attached to the e-mail are incorporated by reference. The attached comments, which were also submitted to the SCAQMD were previously evaluated and it was concluded that they did not include any comments on the environmental analyses, mitigation measures, or project alternatives in the Draft Program EIR. As a result, the comments were treated as AQMP comments and were forwarded to SCAQMD staff responsible for preparing the 2012 AQMP. The attached comments and responses to these comments have been prepared by AQMP staff and will be made available prior to the adoption hearing. As a result, the attachment to this letter is not included in this appendix.
- 12-2 The education components requested to be added into Control Measure EDU-01 are in concert with the goals of this measure and the lifecycle analysis of different energy sources and combustion processes will be included.

SCAQMD staff is aware of the larger GWP potentials of climate forcers with shorter atmospheric lifetimes, such as methane, when looking at a 20- or 10-year time horizon. Referencing these larger GWPs on a shorter timeframe has no affect on the Basin achieving PM2.5 standards. SCAQMD staff is also working on identifying ways to assess the forcing impacts of other components such as the black carbon emitted within the Basin.

SUBJECT: Draft Program environmental Impact Report for 2012 Air Quality Management Plan (AQMD)

Dear Mr. Smith:

The County of Orange has reviewed the Draft Program environmental Impact Report for 2012 Air Quality Management Plan (AQMD) and offers the following comments:

Advance Planning:

- 1. DEIR Appendix F: "RTP/SCS Mitigation Measures Table". The appendix title page shall be revised to reflect the more accurate title "Examples of Measures That Could Reduce Impacts from Planning, Development, and Transportation Projects", which is consistent with the adopted Southern California Association of Governments 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy.
2. It appears that the demographic and socio-economic data included in the analysis of the Program Environmental Impact Report (PEIR) is outdated and is not the most recent demographic and socio-economic data prepared for the Center for Demographic Research and used in the Orange County Sustainable Communities Strategy and the Southern California Association of Governments 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy. The analysis should be revised to include the demographic and socio-economic data contained in the Orange County Sustainable Communities Strategy.
3. There are mischaracterizations in describing Orange County in Subchapter 3.6 – Land Use and Planning. These should be revised in the final draft of the Program Environmental Impact Report.
a. Subsection 3.6.3.2 Orange County (page 3.6-7): The County of Orange General Plan is only applicable to areas of unincorporated Orange County and does not supersede the General Plans of the 34 independent local jurisdictions. Therefore, it is erroneous and misleading to state policies identified in the County of Orange General Plan and

13-1

13-2

13-3

13-4

generalize that these policies are applicable to the 34 local Orange County jurisdictions. The Program Environmental Impact Report should either be revised to clearly state that the County of Orange General Plan is only applicable to those unincorporated areas of the County of Orange and each local jurisdiction has their own governing General Plan or remove the text in its entirety.

13-4
Con't

b. Subsection 3.6.3.2.2 Commercial (page 3.6-8): There are inaccuracies in describing the commercial areas within Orange County that should be revised in the final version of the Program Environmental Impact Report. 1) The commercial area located within close proximity to the intersection of Interstate 5, State Route 22, and State Route 57 is not known as the "Orange Crush" as noted in the draft PEIR. The "Orange Crush" is used to describe the intersection of the three transportation corridors, not the commercial/office area. 2) The area surrounding John Wayne Airport and the University of California, Irvine is known as the Irvine Business Complex or IBC, not the Irvine Spectrum. 3) The terminology "El Toro Y" is used to describe the intersection of two transportation corridors, Interstate 405 and Interstate 5, not the commercial/office center. That is the Irvine Spectrum.

13-5

c. Subsection 3.6.3.2.3 Industrial (page 3.6-8): The paragraph is erroneous in referencing the County of Orange General Plan, which is only applicable to the unincorporated areas of the County. Every jurisdiction has their own governing General Plan that may identify areas of industrial use. The paragraph should be revised for the final DEIR.

13-6

d. Subsection 3.6.3.2.5 Open Space (page 3.6-8): The Orange County Sustainable Communities Strategy identifies the preservation/open space programs located throughout all of Orange County, including the individual efforts of the County of Orange and the 34 local jurisdictions. This paragraph should be revised to generally reflect the open space policies outlined in the Orange County Sustainable Communities Strategy.

13-7

Sincerely,

Michael Balsamo
Manager, OC Community Development
OC Public Works/OC Planning
300 North Flower Street
Santa Ana, California 92702-4048

Responses to Comment Letter #13
Orange County Public Works – Michael Balsamo (10/24/2012)

- 13-1 The comment requests that the cover page title of Appendix F be changed to match the title on the first page of the appendix. This requested change has been made.
- 13-2 The comment states that it “appears” that the demographic and socioeconomic data included in the Program EIR is outdated and that the analysis should be revised to reflect the most recent data contained in the Orange County Sustainable Communities Strategy. Because the comment does not specifically state what data are obsolete, SCAQMD staff is unable to identify what data need to be updated. Further, since Orange County’s SCS was incorporated into SCAG’s 2012-2035 RTP/SCS, which forms the basis of the 2012 AQMP’s socioeconomic forecasts, it is not necessary to update the CEQA document to include socioeconomic data. Without further clarification of what data do not appear to be the most recent, no further response is possible.
- 13-3 This comment is a general assertion that the Program EIR contains inaccurate descriptions of Orange County. See responses to comments #3-4 through #3-7 for responses to comments on each topic mentioned.
- 13-4 This comment states that discussion regarding the Orange County General Plan be clarified to explain that the plan is only applicable to unincorporated areas within Orange County and that each of the 34 cities within Orange County has its own General Plan. Section 3.6.3.2 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.
- 13-5 This comment states that there are inaccuracies in Subsection 3.6.3.2.2 regarding the descriptions of commercial areas in Orange County. This comment recommends the Land Use and Planning discussion that pertains to the commercial areas within Orange County General Plan to be clarified to explain that the commercial area located within the proximity of Interstate 5, State Route 22, and State 57 is not the “Orange Crush” transportation corridor. This comment also recommends the Land Use and Planning discussion that pertains to the area surrounding John Wayne Airport and the University of California – Irvine to be described as the Irvine Business District and not the Irvine Spectrum. This comment also recommends the Land Use and Planning discussion that pertains to the intersection of Interstate 5 and Interstate 405 to be described as the “El Toro Y” and the commercial/office center in the vicinity of this intersection to be described at the Irvine Spectrum. Subsection 3.6.3.2.2 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.
- 13-6 This comment recommends the Land Use and Planning discussion that pertains to the Orange County General Plan be clarified to explain that the plan is only applicable to unincorporated areas within Orange County and that each of the 34 cities within Orange County has its own General Plan. Subsection 3.6.3.2.3 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.

- 13-7 This comment recommends the Land Use and Planning discussion that pertains to open space should be revised to reflect the open space polices outlined in the Orange County Sustainable Communities Strategy. Subsection 3.6.3.2.5 of Subchapter 3.6 in the Final Program EIR has been revised to reflect these recommended changes. None of these changes to the Final Program EIR, however, will alter the conclusions.

PREFACE

Since the release of the Draft Socioeconomic Report in September 2012, the AQMD has added two scenarios on transportation control measures (TCMs) in the 2012 Regional Transportation Plan (RTP) that are committed to the 2012 AQMP. The congestion relief benefit analysis beyond 2014 in the Draft Socioeconomic Report was based on all TCMs in the 2012 RTP. The two scenarios focus on only those committed to the 2012 AQMP. The No TCM Scenario in Appendix G shows costs of TCMs and their associated job impacts by industry separately from other control measures; and removes the congestion relief benefit from the analysis. The TCM Benefit at 2014 Level Scenario in Appendix H assumes that the congestion relief benefit would stay constant at the 2014 level.

Appendix I is added to facilitate approximation of 2005 constant dollars to various other years' dollars. Other changes to the Draft Report are in underlines and strikeouts. Responses to comments on the Draft Socioeconomic Report received after its release have been incorporated into the Responses to Comments to the 2012 AQMP.

EXECUTIVE SUMMARY

EXECUTIVE SUMMARY

As Southern Californians seek to fulfill our legal duties under the Clean Air Act, and to meet standards for air that is healthful to breathe, we are challenged by the need to consider social, economic, and environmental factors while also complying with federal attainment requirements. The socioeconomic impact assessment is designed to help decision-makers and stakeholders arrive at a clean air blueprint that lays out a strong path toward reduced public health damages while at the same time maintaining economic strength, social fairness, and long-term sustainability.

The Draft [Final](#) Socioeconomic Report for the Draft [Final](#) 2012 Air Quality Management Plan (AQMP or Plan) is a rigorous application of statistical analysis and computer modeling to assess the aggregate potential impacts of the overall suite of control measures. Competitiveness of individual businesses ~~sectors~~ will be analyzed in detail during ensuing rulemaking processes. The Draft [Final](#) Report has undergone external peer-review (See Appendix F for a list of peer-review economists) to improve information for the 2012 AQMP and seek suggestions for enhancement of future analysis.

[The \\$7.7 billion congestion benefit in the September 2012 release of the Draft Socioeconomic Report is for all TCM-type projects in the 2012 Regional Transportation Plan \(RTP\). The benefit for the SIP-committed TCMs, which is comprised of the first two years of TCM-type projects in the 2012 RTP, is estimated to be \\$519 million \(See Appendix H\).](#)

Overall, there are two main conclusions in the Report:

- The Draft [Final](#) 2012 AQMP is not expected to result in dramatic impacts on the region's competitiveness as measured by share of national jobs, cost of production, relative delivered prices, and exports and imports.
- The estimated \$10.7 billion ~~in~~ quantifiable benefits—[including congestion relief benefits for all the TCMs](#)—(21 percent of which are health benefits) of the Draft [Final](#) 2012 AQMP [is are](#) greater than the estimated \$448 million in average annual costs. Still there is a net modest job gain due to cleaner air.

The Draft [Final](#) 2012 AQMP has been prepared to meet the challenge of achieving healthful air quality in the South Coast Air Basin (Basin) and the Coachella Valley. This report accompanies the Draft [Final](#) 2012 AQMP and presents the potential socioeconomic impacts resulting from implementation of this Draft [Final](#) Plan. The information contained herein is considered by the South Coast Air Quality Management District (District) Governing Board when taking action on the Draft [Final](#) Plan.

PM_{2.5} levels have improved dramatically over the past two decades. In 2011, both the annual PM_{2.5} standard and the 24-hour PM_{2.5} standard were exceeded at only one air monitoring station, Mira Loma, in northwestern Riverside County. The primary focus of this Draft [Final](#) 2012 AQMP is to bring the Basin into attainment with the 24-hour PM_{2.5} standard.

The Draft [Final](#) 2012 AQMP control strategy is comprised of a traditional command-and-control approach, voluntary/incentive programs, and advanced technologies. Short- and near-

term control strategies are proposed and will be implemented by the District, local and regional governments (e.g., transportation control measures provided in the 2012 Regional Transportation Plan), and the California Air Resources Board (CARB). These strategies include basin-wide short-term PM_{2.5} measures, episodic control measures for high PM_{2.5} days, measures to partially implement the Section 182(e)(5) commitment in the 2007 ozone SIP toward meeting the 8-hour ozone standard by 2024, and transportation control measures (TCM) adopted by the Southern California Association of Governments (SCAG). Many of the measures require behavioral changes and voluntary participation through outreach, incentive, and education. Implementation of these control strategies has potential effects on the region's economy.

The District relies on a number of methods, tools, and data sources to assess the impact of proposed control strategies on the economy. The involved applications include: integration of air quality data and concentration-response relationships to estimate benefits of clean air; capital, operating and maintenance expenditures on control devices and emission reductions to assess the cost of the Draft [Final](#) Plan; and REMI (Regional Economic Models, Inc.) model to assess potential employment and other socioeconomic impacts (e.g., population and competitiveness). The Draft [Final](#) Socioeconomic Report attempts to answer the following important questions.

What Is the Total Implementation Cost of the Draft [Final](#) 2012 AQMP?

The projected annual average implementation cost of the Draft [Final](#) Plan is \$448 million annually, on average, between 2013 and 2035 to correspond to SCAG's long-term projection period. The PM_{2.5} strategy, including transportation control measures (TCM) proposed by the Southern California Association of Governments (SCAG), is projected to cost \$326.6 million. The cost of TCMs alone is \$326.4 million. The projected cost for all the ozone measures is approximately \$122 million annually, of which \$40 million is attributable to stationary source controls.

Technological advancements may reduce costs over time. However, actual costs could be higher than projected costs. Compliance costs will be further refined at individual facilities and evaluated during rulemaking.

What Are the Benefits of the Draft [Final](#) 2012 AQMP?

Over the years, there has been an overall trend of steady improvement in air quality in the Basin. Additional emission reductions are still needed in order to bring the Basin into compliance with the federal 24-hour PM_{2.5} standard. Complying with the air quality standard would allow the District to avoid potential sanctions that could increase offset ratios for major sources and result in suspension of highway transportation funding. The benefits of better air quality through implementation of the Draft [Final](#) 2012 AQMP include reductions in morbidity and mortality, visibility improvements, reduced expenditures on refurbishing building surfaces, and reduced traffic congestion.

The Draft 2012 Plan is projected to comply with the federal PM_{2.5} standard with an average annual benefit of \$10.7 billion between 2014 and 2035. The \$10.7 billion includes approximately \$7.7 billion for congestion relief [for all TCMs in the 2012 RTP](#), \$2.2 billion for

averted illness and higher survival rates, \$696 million for visibility improvements, and \$14 million for reduced damage to materials.

~~The total benefit of the Draft Plan is expected to exceed the analyzed \$10.7 billion annually since n~~Not all of the benefits associated with the implementation of the Draft Final Plan can be quantified. For example, the quantified health benefits only account for reduced exposure from PM_{2.5}, while those from decreased exposure to ozone and nitrogen dioxides are not included. In addition, reductions in vehicle hours traveled for personal trips and damages to plants, livestock, and forests have not been quantified. Further research is needed before these benefits can be quantified.

What Are the Costs of the Draft Final 2012 AQMP Compared to the Benefits?

The analysis contained herein estimates that the benefits for the Draft Final Plan significantly outweigh the anticipated costs. The measurement of clean air benefits is performed indirectly since clean air is not a commodity purchased or sold in a market. This often results in incomplete and underestimated benefits. The benefits of clean air (based on the total emission reductions required for attainment) for which a monetary figure can be applied are estimated to be \$10.7 billion (including congestion relief benefits for all the TCMs) as compared to the estimated costs of \$448 million on an average annual basis. There are, however, many benefits which are still unaccounted for, such as reductions in chronic illness and lung function impairment in human beings, reduced damage to livestock and plant life, erosion of building materials, and the value of reduced vehicle hours traveled for personal trips.

What Potential Effects Will the Draft Final Plan Have on Employment?

Both control costs and clean air benefits impact regional employment. The employment impact analysis was performed separately for PM_{2.5} and ozone control measures, clean air benefits, and a combination of the two resulting from the attainment of air quality standards. Clean air benefits, including congestion relief benefits for all the TCMs, are projected to result in a gain of 42,174 jobs annually over the period of 2014-2035. Conversely, implementation of control measures would result in 3,257 jobs forgone annually. Clean air benefits and control measures would result in a gain of 37,043 jobs annually.

Many industries would experience additional jobs created due to cleaner air based on the assumptions in the REMI model that the amenity resulting from cleaner air would attract immigration and increase business competitiveness. The sectors that are projected to have relatively large shares of jobs created are accommodation and food services, government, retail trade, and real estate/rental/leasing. The retail trade sector and government would experience larger shares of jobs forgone from implementation of control measures. The District recognizes that every actual job is important.

The socioeconomic analysis herein is designed to identify operations and sectors that are subject to control measures and assess their impacts on these sectors. The Plan can affect small businesses as they spread in every sector of the economy. The potential small business impacts of individual control measures will be further examined in the rule development process when specific elements of these measures are developed. ~~The employment impacts associated with~~

~~unquantified measures will be examined further as the affected industries of these measures are defined in more detail.~~ In addition, as measures are developed into rules, their potential employment impacts will be specifically assessed.

What Are the Potential Impacts on Socioeconomic Groups and Local Communities?

The Draft [Final](#) Plan is designed to bring northwest Riverside (the Mira Loma area), the only area in exceedance of the federal PM_{2.5} standard, into attainment. However, PM_{2.5} air quality benefits occur throughout the Basin. The San Fernando Valley, southern Los Angeles County, and the northwest Riverside County would experience the highest shares of air quality benefits. The western portions of Los Angeles and Orange Counties and the eastern and northern portions of San Bernardino County are projected to have the highest shares of health benefits.

Implementation of PM_{2.5} and ozone measures would impose costs on various communities. The sub-regions with the highest costs are the central, southeast, and San Fernando areas of Los Angeles County. These three areas are projected to have the highest cost shares from SCAG TCMs and relative higher cost shares from ozone measures.

All sub-regions are projected to have additional jobs created from cleaner air. The eastern, southern, and San Fernando sub-regions in Los Angeles County and Riverside County are projected to have more jobs created than other sub-regions resulting from clean air benefits. Implementation of quantified control measures would result in jobs forgone between 2013 and 2035. Orange County is projected to have the highest share of jobs forgone from implementation of control measures. This is because the majority of SCAG transportation control measures (TCM) in Orange County would be financed by development fees, which would have a heavy burden on one single sector of the economy—the construction sector. For the entire Draft [Final](#) Plan, all sub-regions would show positive job impacts as the four-county area becomes more competitive and attractive with the progress in clean air.

Job gains from cleaner air would benefit all wage groups. Conversely, all five groups would experience jobs forgone from control measures. However, there is no significant difference in impacts expected for high- versus low-paying jobs. The same is observed for impacts on the price of consumption goods from one income group to another. These findings will be further evaluated during individual rule development.

What Potential Effect Will the Draft [Final](#) Plan Have on Competitiveness of Local Industries?

The Draft [Final](#) Socioeconomic Report examines competitiveness of local industries in four areas: the Basin's share of national jobs, cost of production, relative delivered prices, and exports and imports. The quantified measures and benefits of the Draft [Final](#) 2012 AQMP are not expected to result in discernible differences in the four-county region's share of national jobs. The impacts on product prices of nearly all the sectors are projected to be less than one percent of their respective baseline indices. The impacts on imports and exports are relatively small as well.

The competitiveness analysis of the Draft [Final](#) Plan focuses on its impact on various sectors of the local economy. Individual control measures could obviously result in impacts on individual companies. Competitiveness at the company level will be analyzed during individual rule development efforts to the extent feasible.

The actual effects of the Draft [Final](#) 2012 AQMP on regional competitiveness could vary from the projected effects. First, the analysis assumes that all control costs are "extra" costs when compared to air pollution control costs in other regions. This ignores the fact that some competing regions tend to follow the District's lead and adopt control measures with objectives similar to those proposed in the District or at a minimum have some level of control with its consequent costs. For example, a number of eastern states have adopted the California vehicle exhaust standards. The Draft [Final](#) Socioeconomic Report underestimates the benefits from clean air that would increase regional attractiveness.

Does This Analysis Affect the Selection of Possible Alternatives to the Draft [Final](#) 2012 AQMP?

It may. The Draft [Final](#) Socioeconomic Report can affect the selection of alternatives to the proposed Plan as identified in the Environmental Assessment for the Draft [Final](#) 2012 AQMP. In considering whether to adopt the Draft [Final](#) Plan or one of the alternatives, the District Governing Board will seek the best balance of greatest socioeconomic and environmental benefits and least adverse environmental and socioeconomic impacts, while ensuring compliance with all legal requirements and attainment as expeditiously as practicable.

The No Project Alternative, which is the 2007 AQMP, cannot be meaningfully compared with the Draft [Final](#) Plan since the No Project Alternative would not comply with the 24-hour PM_{2.5} standard until 2019, which is not the earliest practicable date, while the Draft [Final](#) Plan would comply with the 24-hour PM_{2.5} standard in 2014 and implement part of the 2007 ozone SIP 'black box' commitment [Clean Air Act Section 182(e)(5) measures].

The Draft [Final](#) Plan has a higher cost than the PM_{2.5} Strategy Only Alternative but would achieve ozone benefits and also higher PM_{2.5} air quality benefits due to the co-benefit from ozone measures. The Localized PM Control Alternative is projected to have lower air quality benefits than the Draft [Final](#) 2012 AQMP and the Greater Reliance on NO_x Reductions Alternative. Both the Localized PM Control and Greater Reliance on NO_x Reductions Alternatives would not meet the federal PM_{2.5} standard until 2017. The Greater Reliance on NO_x Reductions Alternative would benefit broader areas than the Draft [Final](#) Plan as NO_x is more prevalent than PM_{2.5}. Therefore, the Greater Reliance on NO_x Reductions Alternative has the highest clean air benefits among all the alternatives.

What Are the Key Areas of Uncertainty and Caveats in This Assessment?

As with any complex analysis, some uncertainty is inherent in the methodology employed. Consequently, caveats need to be applied in interpreting the results. The key areas of uncertainty and caveats in this socioeconomic assessment are described as follows:

- Air Quality Change: Air quality modeling used the most current estimates of emissions, prognostic meteorological models, multilayered dispersion platforms (i.e., CMAQ), and

sophisticated chemistry modules. The key areas of uncertainty impacting the estimation of future year health benefits arise from emission estimates, model layer structure, boundary specifications, and dispersion assumptions.

- Exposure ~~estimates~~Estimates: Exposure estimates are based on extrapolations to census boundaries. There is uncertainty in how well this captures actual population exposures.
- Health Impact Functions: There are several health effects estimates of dose-response functions in the literature for a given health effects. There are uncertainties and variability in these estimates. For example, the premature mortality estimate used in this analysis was taken from a study conducted in Southern California. Using the mortality function from this study gives estimates of premature mortality that are somewhat higher than those based on national multi-city studies.
- Health Benefits: The health benefit analysis in this report is limited by the availability of health studies that quantify health effects associated with exposure to various pollutants and their economic valuation. Not all the known adverse health effects caused by air pollution have been quantified. Similarly, not all other clean air benefits such as congestion relief related to personal trips are quantifiable at this time.
- Socioeconomic Model: The REMI model, which was used to analyze the impacts of the Draft Final 2012 AQMP, projects possible impacts on jobs, distribution of jobs, income, cost of production, relative delivered prices, exports, and imports based upon cost data for control measures and the benefit data for each effect of clean air. The projections are based on national and local statistics for a cluster of economic actors such as industries and population by age and cohort. These statistics reflect the net changes of all the events on these actors and cannot be segregated into gross changes of individual events.

What Efforts Will Be Taken to Refine the District's Socioeconomic Report?

Previous AQMPs have identified actions that would further enhance the ability to quantify and evaluate the benefits and costs of the proposed Plan. This Socioeconomic Report has accomplished several of these actions and identified others for still future assessment. Enhancements to this Socioeconomic Report include finer geography for more detailed assessments of distributional impacts, incorporation of new concentration and response health functions for a range of health effects, and greater use of the American Community Survey (ACS) 5-year estimates from the U.S. Census Bureau.

The following enhancements are recommended for future AQMPs:

- Conduct a review of the District's socioeconomic analysis; ~~methods~~ to update methods and approaches, as appropriate;
- Quantification of uncertainty through sensitivity analysis and/or probabilistic confidence intervals;
- Include the value of a statistical life (VSL) related to health risks in future years of an individual's life and illness-specific VSLs;

- Incorporate health benefits resulting from reductions in air toxic pollutants such as diesel particulates;
- Expand sub-regional analyses to include environmental justice (EJ) areas. These areas may be classified by income or race;
- Evaluate potential social ramifications of migration and job losses;
- Analyze the impact of highly polluted areas on property values and rents and the ensuing impacts on the concentration of lower-income households; ~~and~~
- Perform a periodic assessment of projections relative to reality to track the performance of various models that are used for socioeconomic analyses; ~~and~~
- Explore scenarios where other regions may adopt controls similar to AQMD's for the competitive analysis.

Future enhancements on health benefit assessments would also include the impact of exposure to pollutants on life expectancy, differential impacts on various segments of the population, and identification of significant pollutant thresholds.

The socioeconomic analysis will continue to evolve to reflect changes in regulatory structure such as greater reliance on incentive programs and public financing strategy. Building a time series database would enhance the assessment of specific segments of an industry, facilitate the alignment with published governmental statistics, and enhance the analysis of competitiveness impacts. The effort would include the use of different databases to track existing facilities and new facilities, review of inspectors' reports for annotated information on firm turnover and closure, and identification of start-up companies in high tech disciplines with the assistance of the District's Technology Advancement Office.

[Responses to comments on the Draft Socioeconomic Report for the Draft 2012 AQMP can be found in the Responses to Comments to the 2012 AQMP.](#)

CHAPTER 1

INTRODUCTION

Introduction

Draft [Final](#) 2012 AQMP

Legal Requirements

Draft [Final](#) 2012 AQMP Socioeconomic Issues

Assessment Methodology

INTRODUCTION

The Draft [Final](#) 2012 Air Quality Management Plan (AQMP or Draft [Final](#) Plan) is designed to meet the challenge of achieving clean air in southern California. The Draft [Final](#) Plan proposes strategies and programs aimed at both a healthy environment and economy. The projected costs of implementing the Draft [Final](#) Plan and the associated benefits of achieving clean air standards are the subject of this report. The purpose of this assessment is to define and present the potential socioeconomic impacts related to the Draft [Final](#) 2012 AQMP.

DRAFT [FINAL](#) 2012 AQMP

The Draft [Final](#) 2012 AQMP is a plan designed to achieve the federal 2006 24-hour PM_{2.5} standard by 2014 and partially implement commitment in the 2007 ozone State Implementation Plan (SIP) for the 1997 8-hour ozone standard by 2024 for the South Coast Air Basin (Basin) and those portions of the Salton Sea Air Basin that are under the District's jurisdiction (namely the Coachella Valley). This revision began with the remaining control strategies in the 2007 State Implementation Plan (SIP) approved by U. S. EPA in 2011, and was then expanded to include new strategies. These new control strategies focus on reducing emissions from directly emitted PM_{2.5}, ammonia and PM_{2.5} precursors—NO_x and VOC.¹

The Draft [Final](#) 2012 AQMP is comprised of a traditional command-and-control approach, voluntary/incentive programs, and advanced technologies. Short- and near-term control strategies are proposed and will be implemented by the District, local and regional governments (e.g., transportation control measures provided in the 2012 Regional Transportation Plan), and the California Air Resources Board (CARB). These strategies include basin-wide short-term PM_{2.5} measures, episodic control measures for high PM_{2.5} days, measures to partially implement Section 182(e)(5) commitment in the 2007 ozone SIP toward meeting the 8-hour ozone standard by 2024, and transportation control measures (TCM) proposed by the Southern California Association of Governments (SCAG). Many of the measures require behavioral changes and voluntary participation through outreach, incentive, and education.

As with the previous AQMPs, the District has proposed to expand its control program for mobile sources by proposing additional mobile source control strategies to supplement CARB's existing mobile source regulations. All the proposed District mobile source measures would require public funding assistance to achieve NO_x reductions through accelerated fleet turnover or the use of the cleanest off-road engine standards.

The implementation of short- and near-term measures will produce both direct and secondary impacts on the community and economy of the 21 sub-county regions. Direct impacts include costs such as expenditures on pollution control equipment, transportation infrastructure, and reformulated products. Direct impacts also include benefits such as decreased medical costs due to better air quality and reduced repainting and resurfacing costs on building materials. Secondary impacts are the spillover impacts of direct costs and benefits as a result of interactions between industries and consumers in the 21 sub-county regions.

¹ The majority of PM_{2.5} emissions in the Basin are secondarily formed.

LEGAL REQUIREMENTS

The District's socioeconomic analyses of air quality rules are subject to two types of requirements. One is District Governing Board's resolutions and the other is the California Health and Safety Code. Both apply to future rulemaking for control measures that are included in an approved AQMP. As part of the 1989 AQMP approval, the District Governing Board passed a resolution that called for District staff to prepare an economic analysis of emission reduction rules proposed for adoption or amendment. Elements to be included in the analysis include identification of affected industries, cost effectiveness of control, and public health benefits.

In addition, Health and Safety Code Section 40440.8, which took effect on January 1, 1991, requires a socioeconomic analysis of each District rule that has significant emission reduction potential. In addition to the elements required under the District's resolution, Section 40440.8 requires the District to estimate employment impacts and to perform socioeconomic analyses of the project alternatives developed pursuant to the California Environmental Quality Act (CEQA).

Health and Safety Code Section 40728.5 requires that the Governing Board actively consider any socioeconomic impacts in its rule adoption proceedings. Health and Safety Code Section 39616 requires the District to ensure that any market incentive strategies it adopts result in lower or equivalent overall costs and job impacts, (i.e., no significant shift from high-paying to low-paying jobs), when compared with command-and-control regulations. Health and Safety Code Section 40920.6, which became effective on January 1, 1996, requires that incremental cost effectiveness (difference in costs divided by difference in emission reductions) be performed whenever more than one control option is feasible to meet control requirements.

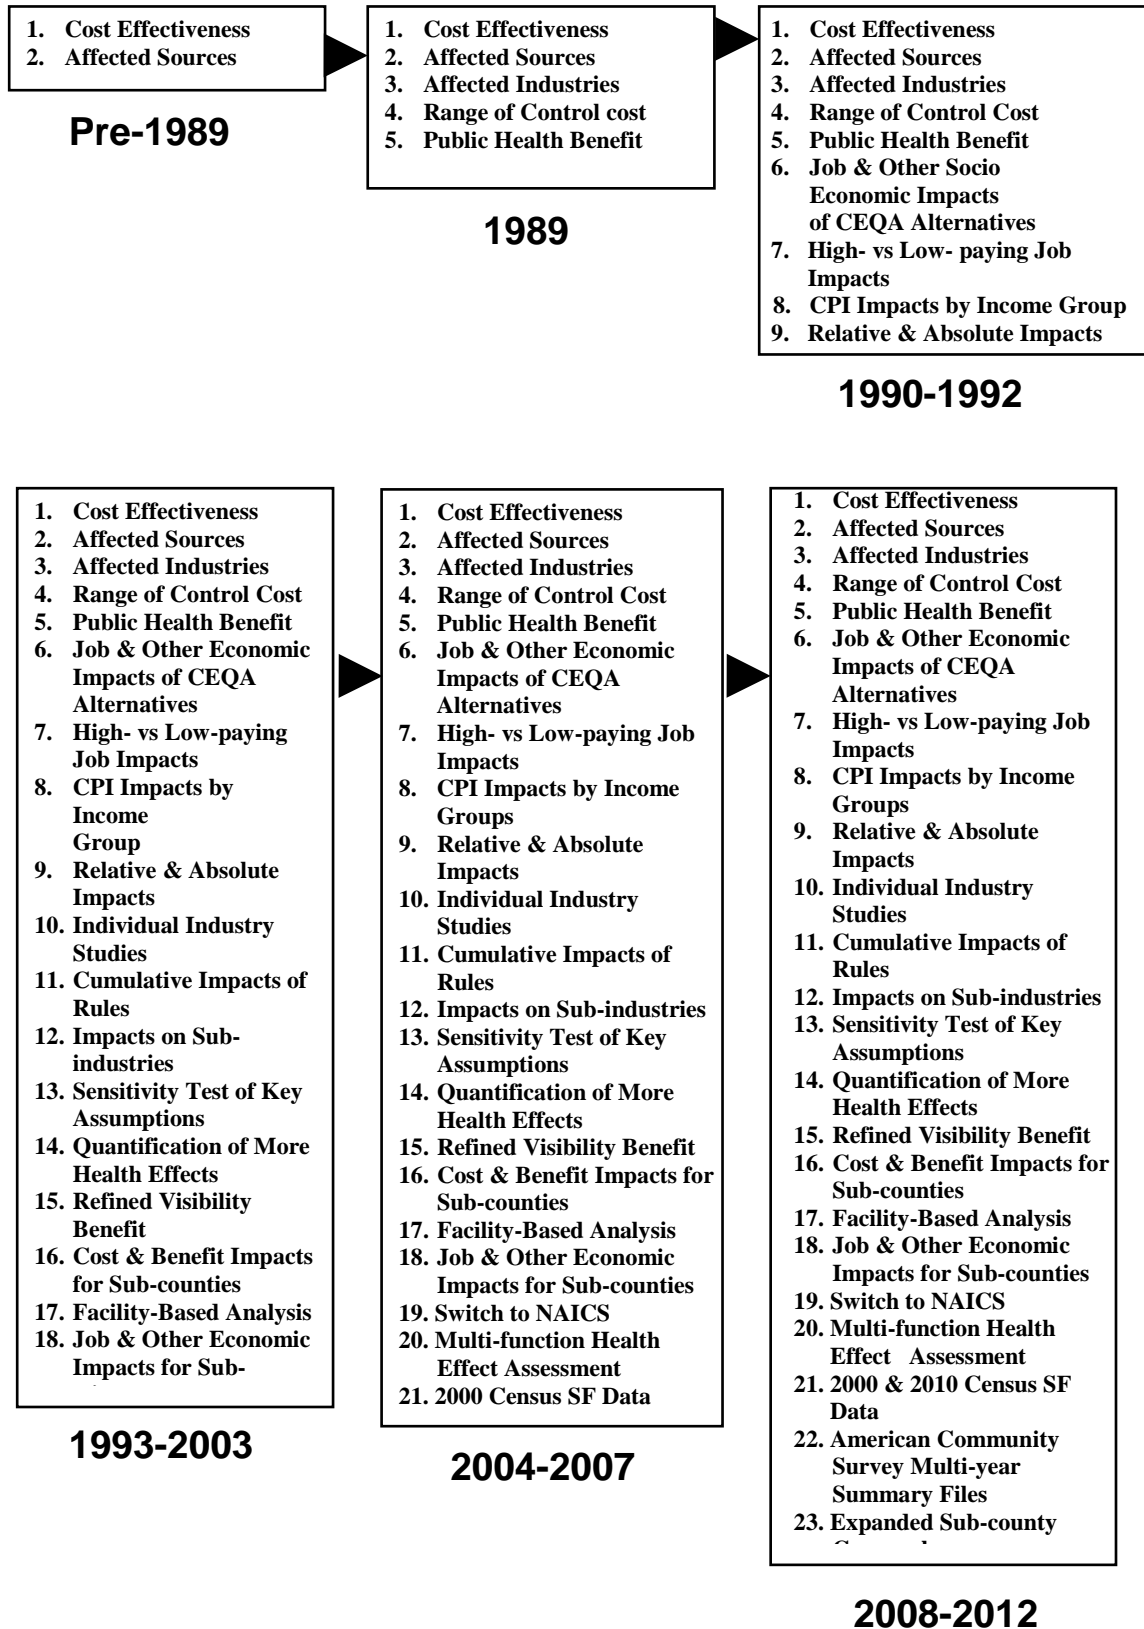

None of these requirements apply to the preparation of the AQMP. However, the District staff performs a socioeconomic analysis of the Draft [Final](#) Plan in order to further inform public discussions and the decision making process of the Draft [Final](#) Plan.

Current Socioeconomic Analysis Program

District staff continually seeks to improve its analysis of socioeconomic impacts by expanding its methods and tools. Over the years, the District's socioeconomic analyses have diversified and evolved as shown in Figure 1-1. The District relies on both quantitative and qualitative analyses, describes impacts in absolute and relative terms, and has continually refined its analysis to a more detailed level. In addition, the District has used facility-based and sub-industry data to better identify the underlying socioeconomic characteristics of various sizes of affected industries. Such analysis becomes an important analytic tool in situations where proposed regulations disproportionately impact small or minority owned businesses.

The Massachusetts Institute of Technology (MIT) conducted an audit of the District's socioeconomic impact analysis program (Polenske et al., 1992). This audit found that the District surpassed most other agencies in analytical methods. The audit did, however, recommend that the District use alternative approaches and work with the regulated community and socioeconomic experts to refine its socioeconomic assessments. The AQMP Advisory

FIGURE 1-1
Evolution of Socioeconomic Analysis

Group, Scientific, Technical and Modeling Peer Review Advisory Group (STMPRAG), the Ethnic Community Advisory Group (ECAG) and the Local Government, and Small Business Assistance Advisory Group (LGSBAAG) have been involved in providing input and refinements to the socioeconomic assessments. STMPRAG is composed of leading experts in the socioeconomic and air quality modeling fields, representatives from the regulated community, and participants from public interest groups. ECAG, the predecessor of the Environmental Justice Advisory Group, consists of representatives from community groups, small businesses, and grass roots organizations who work extensively with their communities. LGSBAAG is made up of representatives from local governments and small businesses.

In 1998, the District co-funded a visibility study with the most recent property sales data and census data for the four-county area (Beron et al., 2001). Results indicated that a strong relationship existed between the marginal willingness to pay for improved visibility (price of visibility) and educational level and household net income.

In 2000, towards the goal of expanding its analysis tools, District staff commissioned BBC Research and Consulting to examine approaches to assessing impacts of proposed regulations on a spectrum of facilities and to evaluating impacts of rules after their adoption. The study results indicated the need to employ a variety of external data sources, construct internal time series data, and explore data sharing opportunities with other governmental agencies.

Beginning in 2000, published economic statistics at the industry level have moved away from the Standard Industrial Classification (SIC) system to the North American Industrial Classification System (NAICS) to include new and emerging industries such as information technologies, among others. In 2006, all the potentially affected point source facilities in the 2002 emission inventory were re-designated with appropriate NAICS codes.

Since 2007, the District has been using a U. S. EPA approved health benefit assessment model—BenMAP—to assess health benefits associated with reductions in exposure to criteria pollutants. BenMAP is a GIS-based system and integrates epidemiological studies with air quality and demographic data, as well as economic valuation methodologies to quantify health effects associated with pollutant concentration and economic values associated with these effects. The District also uses the model to conduct sensitivity analyses on several issues related to the health benefit assessment; and the allocation of costs of individual control measures to sub-county areas.

The American Community Survey (ACS) continuously samples population to provide up-to-date demographic statistics to supplement information not provided by decennial censuses. There are ACS 1-year, 3-year, and 5-year estimates for various purposes. The 2006-2008 estimate was used to expand the four-county geography to 21 sub-regions from the previous 19 regions. The 2005-2009 and 2006-2010 estimates that provided 60 months of collected data at the census tract level were used to compile statistics on age cohorts, race, ethnicity, housing, and household characteristics to support the assessments of health, visibility, and material benefits.

In preparation for work for the Draft [Final](#) 2012 AQMP, District staff has consulted with the AQMP Advisory Group, STMPRAG, and independent consultants to discuss possible and future refinements to data collection, modeling, and socioeconomic processes.

DRAFT [FINAL](#) 2012 AQMP SOCIOECONOMIC ISSUES

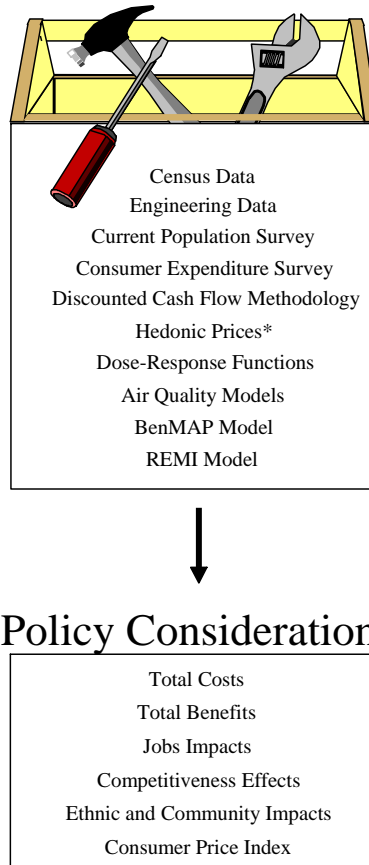

In addition to covering all the topics listed under the legal mandates for rulemaking that were previously described, this assessment addresses the following issues and provide estimates of:

- ACS 5-year estimates on race and ethnicity distribution of population;
- Benefits of the Draft [Final](#) 2012 AQMP;
- Total implementation cost of the Draft [Final](#) 2012 AQMP;
- Cost of the Draft [Final](#) 2012 AQMP as compared to the benefits;
- Effect of quantifiable measures and benefits of the Draft [Final](#) Plan on employment;
- Potential impacts on sub-county areas and socioeconomic groups;
- Effect of the Draft [Final](#) Plan on industrial competitiveness;
- Potential economic effects of the CEQA alternatives to the Draft [Final](#) 2012 AQMP; and
- Key areas of uncertainty in this assessment.

ASSESSMENT METHODOLOGY

To assess the socioeconomic impacts of the Draft [Final](#) 2012 Plan, District staff has relied on a variety of data sources, methods, and tools (Figure 1-2). The analysis is divided into a number of segments whose interrelationship is shown in Figure 1-3. The analysis is performed at the sub-county level by grouping contiguous census tracts that have similar political, geographical, and social characteristics. Los Angeles County is sub-divided into 11 regions, Orange County into four regions, and Riverside and San Bernardino Counties into three regions each.

FIGURE 1-2
Assessment Tool Kit

*See Glossary

The socioeconomic analysis period is from 2013 to 2035 to address various implementation dates of control measures and the resulting air quality benefits. The socioeconomic impacts of the Draft [Final](#) 2012 AQMP are evaluated with respect to a baseline condition, which assumed that the four-county region would continue [receiving federal highway funding to making-make](#) the necessary infrastructure investments [for implementation of the 2012 Regional Transportation Plan \(RTP\) in air-quality and transportation improvements order](#) to keep ~~it~~ [the region](#) competitive nationally and globally. [However, the funding hinges on achieving the air quality standard that is the primary goal of the Draft Final 2012 AQMP.](#) For this reason, the baseline forecast provided by SCAG includes ~~the 2012 Regional Transportation Plan (RTP) and~~ the 2012 [AQMP RTP](#). The socioeconomic analysis herein attempts to address any deviations from the baseline when the Draft [Final](#) 2012 AQMP is fully implemented in terms of benefits of cleaner air, costs of control measures, and spillover impacts of direct benefits and costs. These deviations represent the impact of the Draft [Final](#) 2012 AQMP.

Benefit Analysis

A two-step process is utilized to estimate the benefits expected from attaining the federal PM_{2.5} standard. The first step involves translating the improvements in air quality expected to result from the Draft [Final](#) Plan into dollar values. Benefit categories with quantified relationships with air quality include improved human health, the public's willingness to pay for improved visibility, reduced damage to building materials, and reduced vehicle miles and vehicle hours traveled.

Established concentration-response relationships from recent research and air quality data from different air quality models are used to assess the benefits. The second step involves qualitatively describing the remaining types of benefits that would result from implementing the Draft [Final](#) Plan, but for which monetary benefit estimates are unavailable.

Cost Analysis

A two-step process is also employed to estimate the costs of the Draft [Final](#) Plan. The first step involves the quantification of each control measure based on engineering cost estimates that can be developed at this time and identification of directly affected entities. Based on the proportions of emission reductions, the second step was to allocate the total cost of each control measure to affected sub-county regions. For stationary sources, facility emission reductions are aggregated by sub-region and industry according to the location of facilities. For area and mobile sources, emission reductions are assigned to air quality modeling grids with various surrogates. For example, population was used for VOC reductions from reformulated consumer products and housing units were used for VOC reductions from reformulated architectural coatings. For the mobile sources, emission factors from the ARB EMFAC 2011 as well as Vehicle Miles Traveled (VMT) from SCAG's transportation model were used. These emission reductions are then aggregated to 21 sub-regions according to the correspondence between grid cells and sub-regions. Population at census tracts from the 2010 Census is used to split a grid cell that may be divided into more than one sub-region.

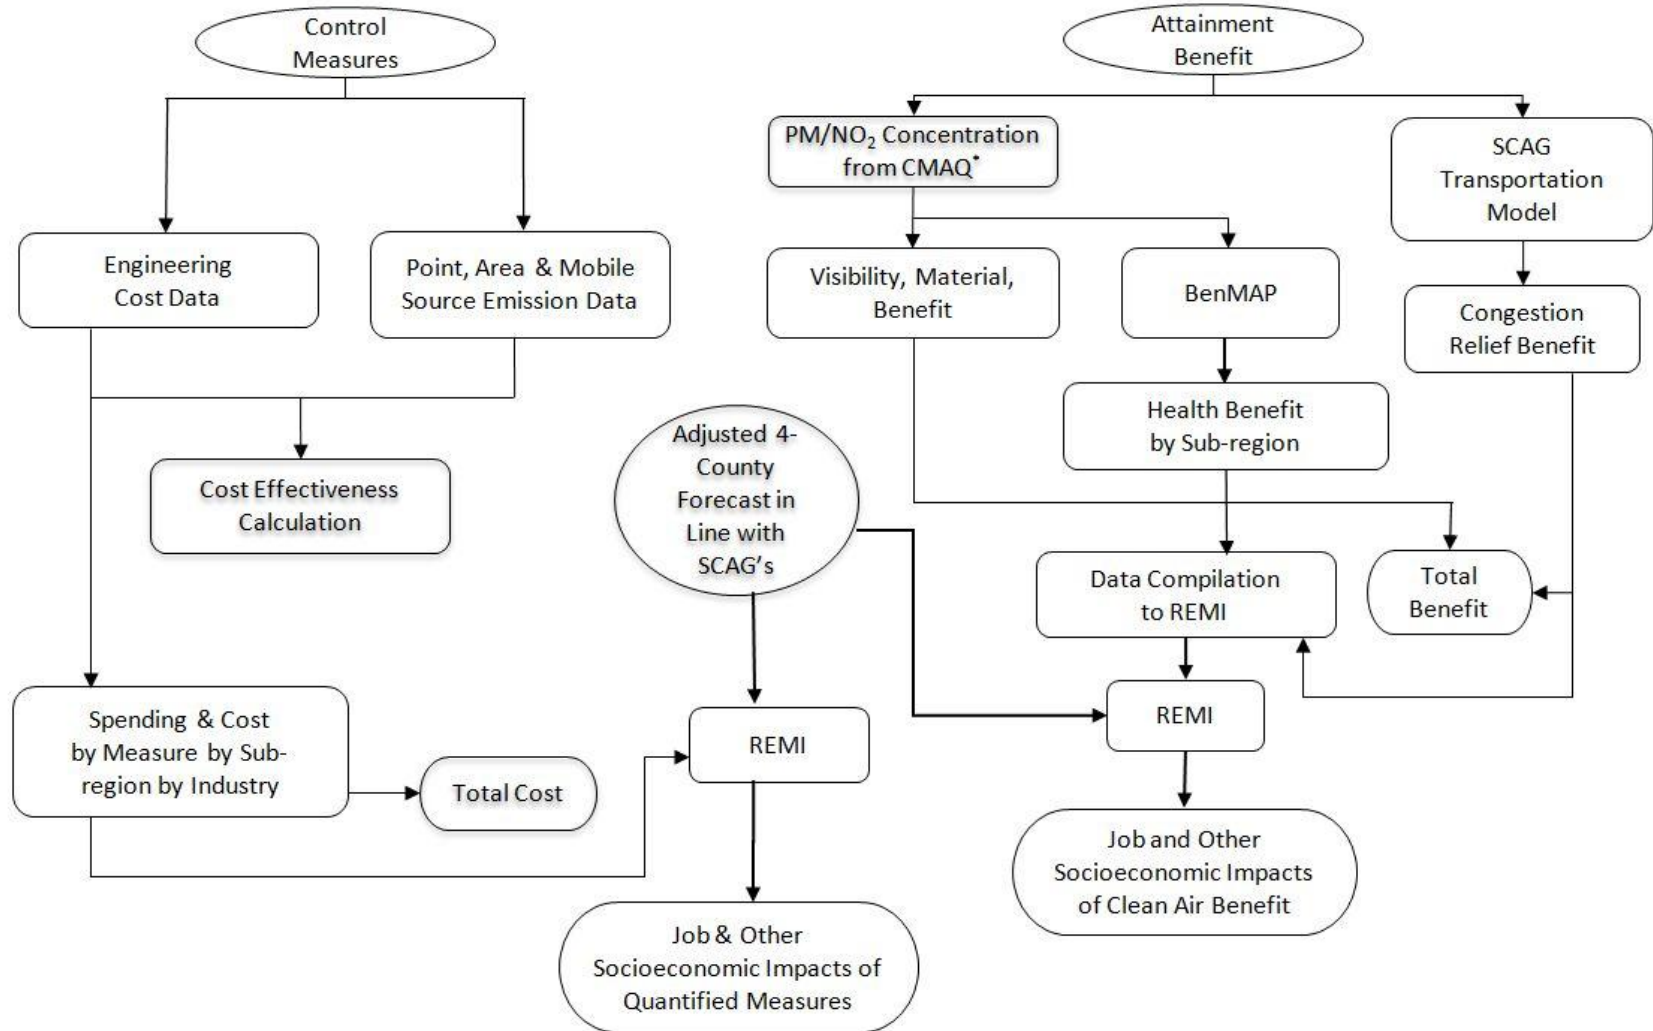

Job and Other Socioeconomic Impact Analysis

To estimate job impacts and other socioeconomic impacts that may result from the quantifiable measures and clean air benefits, the REMI (Regional Economic Models, Inc.) 18-region 70-sector model is utilized. The REMI model incorporates state-of-the-art modeling techniques and the most recent economic data. The MIT report conducted on the District's socioeconomic assessments found that the REMI model is "technically sound." Figure 1-4 shows an example of how the REMI model can be used to assess the socioeconomic impact of a policy. Both the cost and benefit impacts are developed outside of the REMI model and are used as input to the REMI model.

To assess the impacts on socioeconomic groups, the impacts on product prices from the REMI model are overlaid on consumption patterns of various income groups to examine the changes in consumer price indices of these income groups. The data on consumption patterns are from the Bureau of Labor Statistics' Consumer Expenditure Survey.

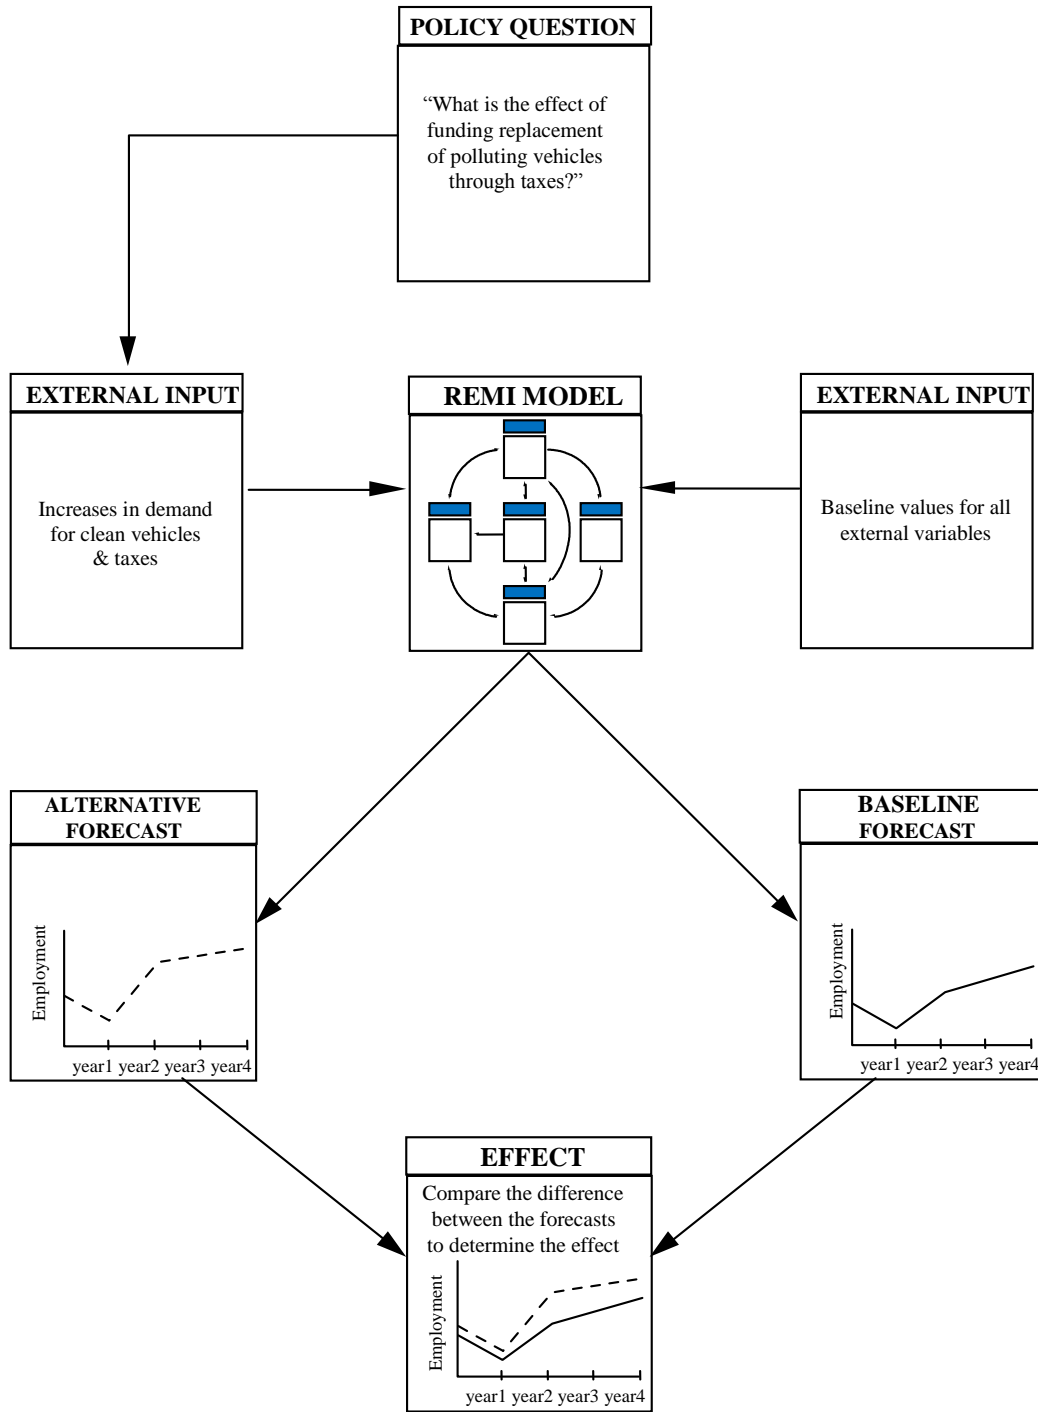

To assess the impacts on competitiveness of the four-county area, the following were considered: the region's share of national jobs in those industries whose products are also

FIGURE 1-3
AQMP Socioeconomic Analysis

*CMAQ = Community Multiscale Air Quality Model

FIGURE 1-4
Use of the REMI Model

| sold in the national market; the impacts of the Draft [Final](#) Plan on product prices by industry; and the changes in imports and exports as a result of implementing the Draft Final Plan's control measures. These factors are selected based on a review of effects of past public policies on a region's competitiveness.

CHAPTER 2

ECONOMY AND AIRQUALITY

Introduction

Demographics

Four-County Economy

Other Economies

Air Quality and Economy

Future Growth

INTRODUCTION

Los Angeles, Orange, Riverside, and San Bernardino Counties collectively constitute one of the largest regional economies in the United States. The jurisdiction of the SCAQMD includes all or the majority of the populated portions of these four counties. In 2010, the four-county area's gross domestic product (GDP) was \$768 billion (2005 dollars), which was 5.9 percent of the US GDP and 45 percent of the California GDP (U. S. BEA, 2012). These counties had 17.1 million people in 2010, which was 45.8 percent of California's total population or 5.5 percent of the U.S. population. In addition, there were 6.3 million wage and salary workers in the four-county area in 2011, a 44 percent share of the state's total wage and salary workforce (EDD, 2012b).

The South Coast Air Basin (SCAB), which is part of the four-county area, has the worst ozone in the nation along with San Joaquin Valley and Houston, and is classified as an extreme non-attainment area for the 8-hour federal ozone standard. The SCAB is also in nonattainment for the 24-hour PM_{2.5} Standard. As such, stringent control measures have to be proposed in order to meet the standard. The four-county area has the most diversified economy in the nation, and the business community has expressed concerns about the impact of air quality regulations on the local economy, in particular, on the manufacturing sector. In what follows, characteristics of the local economy are presented and compared to other local economies.

DEMOGRAPHICS

Population of the four-county area is expected to grow from its 2008 level of 16.9 million to 18.6 million in 2020, and 20.9 million in 2035 (REMI, 2011). This represents an annual population growth rate of 0.79 percent over the 2008-2035 period and between 2020 and 2035.

According to the 2010 census, 45 percent of the 17.1 million residents in the four-county area were Hispanic, followed by 33 percent White, 12 percent Asian, seven percent African American, and three percent were of other races or multiple races. Hispanics are people of Hispanic origins regardless of their races. Los Angeles County was the most racially and ethnically diverse county in the region with 28 percent Whites and 48 percent Hispanics. Los Angeles and Orange Counties had the highest percentage of Asians. Orange and Riverside Counties had the highest percentage of Whites. In all four counties, Whites and Hispanics were the two largest ethnic groups. Table 2-1 shows the ethnic distribution of population by county.

TABLE 2-1
Distribution of Race and Ethnicity in Four Counties

County	Hispanic	White	Asian	African-American	Other
Los Angeles	48%	28%	14%	8%	3%
Orange	34%	44%	18%	1%	3%
Riverside	45%	40%	6%	6%	3%
San Bernardino	49%	33%	6%	8%	3%
Total	45%	33%	12%	7%	3%

Sources: U.S. Census Bureau. 2010 SF1 100% Data [Data Files QT-P3 and QT-P4]. Retrieved June 2012 from <http://factfinder2.census.gov/faces/nav/jsf/pages/searchresults.xhtml?ref=geo&refresh=t>

Based on census tract boundaries with consideration of topographical features and city boundaries, the four-county area was divided into 21 sub-regions. The counties of Riverside and San Bernardino were divided into three sub-regions each: two more urbanized areas and a more sparsely populated area. Los Angeles County was divided into 11 sub-regions and Orange County was divided into four sub-regions. Figures 2-1 shows the ethnic distribution of population in each of these sub-regions, respectively, based on the 2010 census.

Socioeconomic characteristics of the sub-regions were compiled using the 2010 Census data. These data were aggregated to the sub-region level by apportioning census tracts to the appropriate sub-region. Spatial allocation of census tracts were assigned to sub-regions using ArcGIS. The 21 sub-regions showed considerable variation as measured by several socioeconomic indices (Table 2-2).

Sub-regions in Riverside and San Bernardino Counties had relatively higher share of youth population while the western area of Los Angeles County had the lowest percentage of youth among all sub-regions. The non-urbanized portion of Riverside County had the highest percentage of elderly population. Newly developed sub-regions and those in urban centers had the lowest share of the elderly. The poverty rates ranged from a low of seven percent in the southern part of Orange County to 29 percent in the south central area of Los Angeles County according to the 2006-2010 American Community Survey.

TABLE 2-2
Socioeconomic Characteristics of County Sub-areas

Sub-area	Population (thousands)	Percent (%)		
		Poverty ¹	Youth ²	Elderly ³

¹Poverty data are based on the U.S. Census Bureau’s 2006-2010 American Community Survey. For 2010, the federal poverty threshold for a family of four is \$22,314 (Census, 2012).

²Youth = 18 years old or younger.

³Elderly = 65 years old or above.

FIGURE 2-1
2010 Census: Ethnic Distribution of Population

FOUR-COUNTY ECONOMY

The four-county region is built around the nation's largest port complex and entertainment and tourism sectors; and has a diversified manufacturing center. The ports of Los Angeles and Long Beach have the highest container traffic (a combined total of more than 14 million TEUs in 2011) among all U.S. ports.

The four-county economy has a strong and well diversified economic base. Of the total \$768 billion GDP in 2010 in the four-county area, the sector of real estate, rental, and leasing had the biggest share (19 percent), followed by manufacturing (10 percent), and government and information (nine percent each). The manufacturing share of GDP had been between nine and 10 percent of the local economy since 2001; in the recessionary year 2008, its share went up to 11 percent. Contribution of the information sector had risen from seven percent of GDP in 2001 to nine percent in 2010.

More than 8.9 million jobs supported the \$768 billion GDP in 2010. The sectors that had the highest shares of jobs were government (12 percent), retail trade (10 percent), health care and social assistance (10 percent), professional, scientific, and technical services (8 percent), manufacturing (7 percent), accommodation and food services (7 percent), and administrative and waste management services (7 percent). Table 2-3 shows the contribution of top 10 major sectors in terms of GDP and jobs in 2010, respectively. Figure 2-2 shows the manufacturing trend from 2001 to 2010 in terms of GDP and jobs in the four-county region, which was commensurate with the national trend. In 2010, the U.S. manufacturing sector produced \$100 billion more of goods than China but used only one-tenth the labor due to increases in productivity through automation. Goods that required 1,000 workers to produce in 1950 need only 177 workers today (WSJ, 2012).¹

TABLE 2-3
Percentage Contribution to South Coast Economy by Sector in 2010

Industry	Share of Jobs	Share of GDP
Government	12%	9%
Retail Trade	10%	6%
Health Care and Social Assistance	10%	6%
Professional, Scientific and Technical Services	8%	8%
Accommodation and Food Services	7%	2%
Administrative and Waste Management Services	7%	3%
Other Services	7%	2%
Manufacturing	7%	10%
Finance and Insurance	5%	6%
Real Estate, Rental and Leasing	5%	19%
Wholesale Trade	5%	8%
Information	3%	9%

Industries are based on the NAICS codes.

¹“Notable & Quotable.” (WSJ) Wall Street Journal. February 1, 2012. sec A, p. A14.

FIGURE 2-2
Four-county Manufacturing Trend (2001 to 2010)

Over the 2001-2010 period, shares of the retail trade sector in the total jobs had remained at 10 percent while the sector's GDP shares had declined slowly from seven to six percent. There had been a slight increase in shares of the real estate, rental, and leasing sector in the total jobs (four to five percent) commensurate with its slight increase in the GDP shares (18 to 19 percent). The government sector had been slightly trending up in recent years in terms of job shares (11 to 12 percent), while trending down in terms of GDP shares (10 to nine percent). Job shares of the information sector had gone down from four to three percent. However, its GDP shares had been trending up from seven to nine percent.

Because the four-county economy is made up of four counties, strengths of economies in separate counties will differ from one another and from the overall four-county economy.

Green Jobs

Based on a survey conducted by the California Labor Market Information Division, green jobs (as defined in the footnote below) spread across nearly all industries (EDD, 2010).² The four-county region had 41.3 percent of the total 432,840 green jobs in California. Approximately 2.9 percent of the total jobs in southern California were green jobs. Among all the regions in California, northern California had the highest share of green jobs in its total jobs (8.1 percent). Green jobs in southern California were concentrated in existing materials recycling (29 percent), all phases of energy efficient products from construction to maintenance (26 percent), and natural and sustainable product manufacturing (20 percent).

Three industries had the highest share of all green jobs in California: manufacturing (20.5 percent), construction (14.2 percent), and professional, scientific, and technical services (9.7 percent). The share of green jobs as a percentage of all jobs was the highest in utilities (27.8 percent), followed by mining, quarrying, and oil and gas extraction (18.3 percent), and

²As detailed in the EDD survey summary, green jobs herein are defined as those workers engaging in generating and storing renewable energy; recycling existing materials; constructing, producing, installing, and maintaining energy efficient products; educating and complying with green business practices; and manufacturing natural and sustainable products.

construction (11 percent). Many occupations have benefited from green jobs. The top green job occupations were carpenters, hazardous materials removal workers, and sustainable farmers and farm workers.

Over the years, the AQMD has been in partnership with private entities to provide funding to businesses that promote commercialization of and demonstrate the successful use of clean fuels and technologies. For every dollar that the AQMD contributes, there is, on average, a \$3 investment by the AQMD partners. Many of these projects result in creation of green jobs. In 2011, approximately \$200 million funding (from Proposition 1B, the Carl Moyer Program, the Clean Fuel Program, and earmarked U.S. EPA and DOE funds) was provided by the AQMD.

Occupational Wage and Employment

Based on the May 2010 occupational employment and wage estimates for the four-county area, 29 percent of 6.3 million wage and salary jobs were in sales, office, and administrative support occupations with average annual wages between \$37,000 and \$40,000. Except for management positions, higher wage occupations included legal, engineering, computer, healthcare, and other highly skilled profession. Los Angeles and Orange Counties paid higher wages in almost all occupations but community and social services, and transportation and material moving occupations. Table 2-4 has the number of jobs and mean annual wage by occupation in the four-county area. Many of the top-paying occupations are skilled positions in the scientific, technical, and professional fields. Goods movement related jobs are not separately tracked, but are spread among all occupations.

TABLE 2-4
Number of Jobs and Mean Annual Wage by Occupation

Occupation Title	Jobs*		Mean Annual Wage	
	LA-OR	RS-SB	LA-OR	RS-SB
All Occupations	5,191,880	1,140,830	\$ 50,120	\$ 42,930

Farming, Fishing, and Forestry Occupations	4,550	5,840	\$ 23,870	\$ 21,400
Food Preparation and Serving Related Occupations	436,980	111,450	\$ 21,540	\$ 21,310

*Exclude self-employed.

Bureau of Labor Statistics, Department of Labor, May 2010 Metropolitan and Nonmetropolitan Area Occupational Employment and Wage Estimates [Data File], <http://www.bls.gov/oes/2010/may/oesrcma.htm>.

OTHER ECONOMIES

Due to its air quality status, the four-county region has a complex air quality program which has included various local and state regulations over decades. Although air quality control programs alone do not define the underlying economy, they are an integral part of the general environment under which people live and businesses operate. The section below examines other regions where air quality problems are less severe to ascertain whether their economic profiles are different from the four-county area.

The Bay Area is an anchor to the northern California economy. The San Diego economy is ranked fourth in California, following the Los Angeles-Long Beach-Santa Ana, San Francisco-Oakland-Fremont, and San Jose-Sunnyvale-Santa Clara metropolitan statistical areas (MSA). The Houston-Sugar Land-Baytown MSA, of which the Houston-Galveston-Brazoria area is a part, is the fifth largest MSA in the nation in terms of GDP in 2010. The Bay Area AQMD (BAAQMD), San Diego Air Pollution Control District (SDAPCD), and

the Houston-Galveston-Brazoria area are in compliance with the PM2.5 standard. The BAAQMD and SDAPCD have also attained the federal 8-hour ozone standard. Not only do the strengths of these economies differ from the South Coast economy, but their air quality status is also dissimilar to that of the South Coast economy.

The BAAQMD had 7.2 million people in 2010 and is comprised of nine counties, Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano, and Sonoma. The BAAQMD economy had over 4.3 million jobs.³ Three sectors had the largest share of jobs: professional, scientific, and technical services (12.5 percent), government (11 percent), and healthcare and social assistance (9.4 percent). The share of manufacturing workforce in the BAAQMD economy was 7.6 percent in 2010, a decline from 10.6 percent in 2001. Table 2-5 shows the contribution of the top 10 major sectors in terms of jobs in 2010.

TABLE 2-5
Percentage Contribution to Bay Area Economy
by Sector in 2010

Industry	Share of Jobs
Professional, Scientific, and Technical Services	12.50%
Government	11.00%
Health Care and Social Assistance	9.40%
Retail trade	8.90%
Manufacturing	7.60%
Accommodation and food services	7.00%
Administrative and waste management services	6.00%
Other services	5.40%
Construction	4.50%
Wholesale trade	3.20%

San Diego had 3.1 million people in 2010. The total GDP of the San Diego economy was \$15.5 billion (in 2005 dollars) in 2010, which was dominated by the real estate/rental/leasing sector (19.8 percent), followed by the government (16.7 percent), professional, scientific, and technical services (9.8 percent), as well as manufacturing (9.4 percent) sectors. The share of manufacturing in the San Diego economy had been on the rise over the years from 7 percent in 2001 to 9.4 percent in 2010. In 2010 the San Diego economy supported 1.8 million jobs, most of which were in the sectors of government (18.8 percent), professional, scientific, and technical services (10.3 percent), retail trade (9.1 percent), and health care and social assistance (8.3 percent). Manufacturing jobs were 5.7 percent of the total San Diego jobs in 2010, a steady decline from 7.4 percent in 2001. Table 2-6 shows the contribution of the top 10 major sectors in terms of GDP and jobs in 2010, respectively.

³ GDP data is available for states and metropolitan statistical areas (MSA); however, it is not available at the county level. Both the BAAQMD and Houston-Galveston-Brazoria areas have geography which includes portions of MSAs; published GDP data cannot be readily constructed for these areas.

TABLE 2-6
Percentage Contribution to San Diego Economy by Sector in 2010

Industry	Share of Jobs	Share of GDP
Government	18.8%	16.7%
Professional, Scientific, and Technical Services	10.3%	9.8%
Retail Trade	9.1%	5.8%
Health Care and Social Assistance	8.3%	5.4%
Accommodation and Food Services	7.7%	3.00%
Administrative and Waste Management Services	6.1%	2.70%
Other Services	5.8%	2.10%
Manufacturing	5.7%	9.4%
Real Estate and Rental and Leasing	5.4%	19.8%
Finance and insurance	4.9%	4.7%
Construction	4.5%	3.4%
Wholesale Trade	2.8%	4.7%
Information	1.7%	6.6%

The Houston-Galveston-Brazoria area (hereafter Houston economy) is comprised of eight counties: Brazoria, Chambers, Fort Bend, Galveston, Harris, Liberty, Montgomery, and Waller. In 2010, the Houston economy had over 5.9 million people. Its 3.4 million jobs were dominated by the following sectors: government (11.2 percent), retail trade (9.4 percent), and health care and social assistance (9 percent). The manufacturing sector had declined to 6.7 percent of the total jobs in 2010 from 8.5 percent in 2001. The construction sector's employment continued to decline from its height in 2007. Table 2-7 shows the contribution of the top 10 major sectors in terms of jobs in 2010.

TABLE 2-7
Percentage Contribution to Houston Economy
by Sector in 2010

Industry	Share of Jobs
Government	11.20%
Retail trade	9.40%
Health Care and Social Assistance	8.90%
Professional, Scientific, and Technical Services	8.10%
Construction	7.50%
Administrative and Waste Management Services	7.40%
Manufacturing	6.70%
Accommodation and Food Services	6.70%
Other services	5.80%
Finance and insurance	5.50%

As with the South Coast economy, the economies in the Bay Area AQMD, San Diego Air Pollution Control District, and Houston-Galveston-Brazoria area had shown a decline of the share of manufacturing jobs over the years and the government sector is the highest share of

total local jobs. On the air quality front, population, industry makeup, emission profile, transportation, weather, and geography as a whole have made southern California more susceptible to air quality problems than San Diego, the Bay Area, and Houston.

AIR QUALITY AND ECONOMY

Growth is a potential impediment to progress in air quality. As such, improvements in air quality must be sufficiently large to offset increases in population and economic activities in order to achieve air quality standards.

The South Coast Air Basin (SCAB) is close to meeting the federal annual standard for PM_{2.5}, 15 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). As of the end of 2011, the AQMD had been experiencing an annual reduction of 6.8 percent in PM_{2.5} concentration since its 2001 peak. The AQMD still has the most number of days exceeding the federal 8-hour ozone standard despite a downward trend. During 2001-2010, the number of days exceeding the federal 8-hour ozone standard was reduced at an annual rate of 2.82 percent. There had been significant improvements in air quality within the SCAB despite significant growth in GDP, employment, and population, as shown in Figure 2-3. In fact, economic growth is needed to support investment in cleaning the air. The business community has made great stride in complying with some of the most stringent controls in the nation while remaining competitive. The South Coast economy was hit hard during the 2007-2009 Great Recession and the 1990-1991 recession, and experienced a slowdown during the early 2000s. However, air quality continued to show steady progress.

FIGURE 2-3
Air Quality, Economic and Demographic Trends in South Coast*

*Economic and demographic data was from REMI Insight®. 18 Area Model for the South Coast Economy, Version 1.3.13, 2011.

Future Growth (Baseline Forecast)

The recent Great Recession ended in the second quarter of 2009, according to the Business Cycle Dating Committee of National Bureau of Economic Research (NBER). Since then the South Coast economy has been on a slow recovery. As with any other recovery after a recession, job recovery often lags. However, the lag is more pronounced and protracted at this time due to a slumping housing market.

According to the California State University, Long Beach, short-term forecast, the four-county region’s jobs would grow by one and one-half percent in 2012 from 2011. Job growth in a number of sectors would exceed two percent. The leisure & hospitality services sector is expected to add jobs at a pace of 3.1 percent in 2012 after a 2.1 percent gain in 2011, reflecting growing demand in the restaurant, hotel and amusement sectors. The professional & business services sector that includes accounting, management consulting and computer systems design is expected to experience job growth of 2.9 percent in 2012. The retail trade sector would add jobs at a pace of 2.3 percent. Anticipated job growth for 2012 in the health and private education sector is 2.2 percent. In 2012, both the durable and

nondurable manufacturing sectors would likely have small, but positive, job growth. Most of this growth is likely to occur in Riverside, San Bernardino and Orange Counties. Government employment is expected to decline in both federal and state and local government employment (CSULB, 2012).

Los Angeles County from 2012 to 2014 is forecasted to grow one and one-half percent in non-farm payroll jobs. Riverside and San Bernardino Counties are expected to experience job growth similar to that of Los Angeles County from 2012 to 2014. Employment in Orange County is projected to grow in the range of two percent over the same period (CSULB, 2012).

Projections by the REMI (Regional Economic Models, Inc.) model that were modified to reflect SCAG projections; indicate that from 2008 to 2035; the four-county region is expected to gain 2.03 million jobs at an annual growth rate of 0.72 percent (REMI, 2012). There are small differences in the job forecast methodology and U.S. projections between REMI and SCAG forecasts. However, these differences do not affect the results reported herein as the REMI forecast was adjusted to reflect the growth rates in the SCAG regional growth forecast (See Appendix C for details).

SCAG projections (which form the baseline projections for the Draft Final 2012 AQMP) assumed ~~that continuation of federal highway funding that would be necessary for~~ the four-county area ~~would continue to making make~~ the ~~necessary~~ infrastructure investments ~~for implementation of the 2012 RTP in air quality and transportation improvements order~~ to keep ~~it the region~~ competitive nationally and globally. For this reason, SCAG projections reflect the full implementation of the 2012 RTP. The highway funding hinges on the Basin's and the necessary air quality programs that would be in compliance with the federal Clean Air Act (CAA). In other words, the baseline forecast does not ~~represent a scenario of no further air quality control regulations or programs beyond what is already adopted,~~ ~~or include~~ the potential consequences of not meeting the federal air quality standard (e.g., 2 to 1 offset ratio for new and modified major sources and withheld highway funding under the CAA).

Total employment in Los Angeles County is projected to increase by 0.68 million jobs at a 0.41 percent annual growth rate, while Orange County is projected to increase by 0.18 million jobs at a 0.31 percent annual growth rate. Similar to population growth, total employment in Riverside County is projected to increase by 0.73 million jobs at a 2.31 percent annual growth rate, and San Bernardino County is projected to increase by 0.44 million jobs at a 1.53 percent annual growth rate.

The fastest growth would occur in the construction (NAICS 23), services (NAICS 54-56, 61-62, 71-72, 81), and finance, insurance, and real estate (NAICS 52-53) sectors. The construction sector's jobs are anticipated to grow at 0.95 percent annually, followed by the services and finance, insurance, and real estate sectors at 0.84 percent each. Job growth in the retail and wholesale trade (NAICS 44-45, 42) sector is expected to reach an annual rate of 0.48 percent. In the manufacturing, transportation, and utilities (NAICS 31-33, 48-49, 22) sectors, employment is projected to decline at 0.01 percent annually over the 2008-2035 period.

Figure 2-4 shows historical (2008) and projected sectoral share of employment for 2020 and 2035. The four-county economy, which is composed of a large non-manufacturing sector, is becoming modestly more service-based. Shares of employment in the services (NAICS 54-56, 61-62, 71-72, 81); finance, insurance, and real estate; construction; and government sectors are projected to increase over time between 2008 and 2035. Slightly smaller shares of total jobs in the four-county area are anticipated to occur in the information (NAICS 51), manufacturing, and retail and wholesale trade sectors in 2035 as these sectors become more productive.

The baseline forecast is used as a benchmark against which the impacts of the Draft [Final](#) | 2012 AQMP are evaluated.

CHAPTER 3

COSTS AND BENEFITS

Introduction

Costs

Benefits

Summary

INTRODUCTION

Public policies are often examined relative to their overall costs and benefits, providing a general indication of the net economic impact of the policy. Applying that approach to the AQMP preferably would involve the full quantification of costs and benefits in monetary terms, i.e., dollars.¹ Equipment and materials which are required by control measures are purchased and sold in markets, and their prices can thus be used to measure the costs of implementing control measures. Cost quantification becomes more uncertain when control technologies cannot be specifically identified at the planning stage. Cheaper options may be deployed and marginal costs could be on the rise for the last few tons of emission reductions in order to reach attainment. On the other hand, the possibility of technology advancement and large-scale production due to regulatory requirements may drive down control costs.

There is no direct way to measure benefits of clean air because clean air is not a market commodity. Placing a monetary value on reduced incidence of illness or loss of life is also difficult and more subjective than determining control equipment costs. This often results in incomplete assessments and underestimation of benefits.

This chapter presents aggregate benefits and costs for either the four-county area or by county. Chapter 5 has more detailed results for 21 sub-regions.

COSTS

The cost of attaining clean air in the four-county area includes expenditures on control equipment, low-polluting materials, and infrastructure investments. To quantify these costs, the two-step methodology described in Chapter 1 was applied. The majority of these costs are estimated based on currently available technology.

For each point source control measure, cost data was developed for the entire District and then allocated to the industries and sub-regions to which the affected point sources belong based on the projected emission reductions in the Draft [Final](#) 2012 AQMP and the 2008 emissions inventory data.² Figure 3-1 shows the distribution of point sources in the 2008 emission inventory. Point sources include stationary, identifiable sources of emissions that release over four tons or more of VOC, NO_x, SO_x, or PM or emitting more than 100 tons of CO per year. For area, on-road, and off-road sources, the cost for each measure was assessed for affected industries in the District and then allocated to the 21 sub-regions based on emission reductions at each air quality grid and the correspondence between grids and sub-regions.³ The cost of each control measure is comprised of the annual operating and maintenance expenditure and

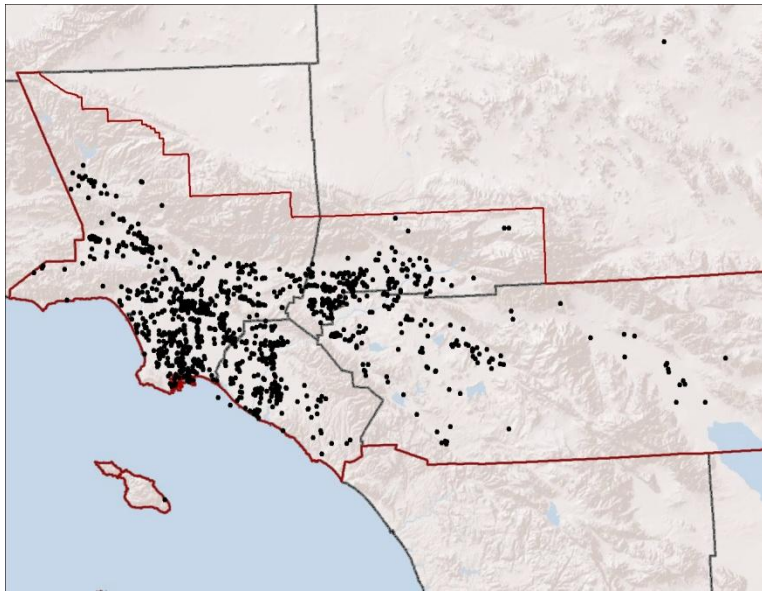

¹All the dollars in this report are expressed in constant 2005 dollars, which removes the effects of general price changes. Changes in constant dollars over time reflect changes in quantity only, which is a better barometer of the standard of living. Currently, all federal statistics in constant dollars are denominated in 2005 dollars. [Appendix I—CPI and Cost Indices—provides consumer price indices \(CPIs\) from 2005 to 2011 and the Marshall & Swift Equipment Cost Indices from 2005 to 2011.](#)

²In cases where facilities are owned by companies headquartered elsewhere, costs may not be incurred in the four-county area. Therefore, the cost burden in the four-county area may be lessened.

³For area and off-road sources, emission reductions were distributed based on CARB's emission surrogate profiles at the gridded level. For on-road sources, information at the transportation zone level from SCAG was used to distribute emission reductions to grids.

capital expenditure annualized over the economic life of equipment at the 4-percent real interest rate. The cost of stationary source control measures does not include construction costs associated with the re-design of a facility to accommodate the new required device and permitting. The cost associated with these categories will be considered during the rulemaking process.

FIGURE 3-1
Point Source Location in the 2008 Emission Inventory

A total of 143 public and private projects with multiple implementation years associated with [the SIP-committed TCMs in the 2012 AQMP](#) were quantified. [The SIP-Committed TCMs](#) were derived from the first two years of the 2011 Federal Transportation Improvement Program (FTIP), which is a multimodal list of capital improvement projects to be implemented over a six-year period. TCMs provide mobility, increase efficiency and safety of the transportation system, and reduce transportation-related air pollution. TCMs are part of the 2012 RTP and have approximately a [fourthree](#)-percent share of the total RTP cost. Appendix E has a list of TCMs along with funding sources, completion dates, and types of costs that were used for the analysis herein. Affected sub-regions are identified according to the description of each project. Annualized capital cost and annual operating and maintenance costs were calculated for each project within its implementation period and converted to 2005 constant dollars based on an annual inflation rate of 3.2 percent. SCAG also identified public funding sources for these public projects such as local sales tax, state or federal sales tax on gasoline sales, alternative fuel tax, and motor vehicle tax.⁴ Private funding includes development fees. The cost burden was distributed to each sub-region according to the proportion of sub-region population in the county in most cases. Furthermore, it was assumed that engineering and right-of-way expenditures would occur immediately upon funding. Construction expenditures were allocated evenly from an initial funding year to the completion date of a project.

⁴Based on TCM data from SCAG, only 4.9 percent of TCM funding (\$15.9 million annually) was assumed from federal sources.

The average annual control cost of all PM_{2.5} and ozone control measures in the Draft [Final](#) 2012 AQMP is projected to be approximately \$448 million from 2013 to 2035, of which TCMs have an annualized cost of \$326 million. [Table 3-1 in Appendix G—No TCM Benefit Scenario—shows costs by industry for TCMs and the District’s portion of PM_{2.5} strategy, respectively.](#) Figure 3-2 shows the annual cost trend of these measures. The high costs in 2026 are from TCMs as public funding for two construction projects is unleashed at once. Table 3-1 shows the distribution of control costs for PM_{2.5} measures (including TCMs), ozone measures, and the Draft [Final](#) Plan, respectively, among various industries. Approximately, 84 percent of the TCM cost is borne by consumers, as shown at the end of Table 3-1. The \$43 million cost borne by the construction sector under the PM_{2.5} strategy is mainly due to the TCM development agreements. The government sector would incur a \$10 million cost as its general funds are used to finance TCM projects. Of the total \$122 million cost for the ozone strategy, sectors that are projected to bear the highest costs are consumers (\$40 million), followed by petroleum and coal products where refineries belong (\$12 million), construction (\$8.3 million), and government, and truck and rail transportation (approximately \$7 million each). Incentive funding from vehicle license fees that is assumed to partially finance the implementation of on-road measures and one off-road measure is allocated to consumers as a reduction in their expenditures. The \$12 million cost borne by the refineries is mainly from Phase II NO_x reductions of RECLAIM. The relatively high costs associated with the sectors of construction, government, and truck and rail transportation are mainly due to Control Measures ONRD-03 (Accelerated Penetration of Partial Zero-Emission and Zero-Emission Light-heavy- and Medium-heavy-duty Vehicles), ONRD-04 (Accelerated Retirement of Older On-road Heavy-duty Vehicles), or OFFRD-01 (Extension of the Surplus Off-road Opt-in for NO_x Provision for Construction Industrial Equipment). All the sectoral costs are less than 0.32 percent (32 hundredths of one percent) of each sector’s average annual output from 2013-2035.

*Average output from 2013 to 2035 in 2005 dollars.

**\$326.44 million are TCM costs.

Cost by County

Table 3-2 shows how the potential control costs are distributed among the four counties for the quantifiable measures. Los Angeles County could incur an annual cost of about \$328 million, or approximately 73 percent share of the total cost. This is because most of the affected emission sources are located in Los Angeles County.

TABLE 3-2
Average Annual Control Cost by County
(millions of 2005 dollars)

County	Control Cost	% Share
Los Angeles	\$328	73%
Orange	72	16%
Riverside	24	5%
San Bernardino	23	5%
Total*	\$448	100%

*The sum of individuals does not add to the total due to rounding.

BENEFITS

Despite the uncertainty of assigning dollar figures to the benefits of attaining the federal PM_{2.5} standard in 2014, it is apparent that clean air will result in significant benefits to the four-county region. Partial assessments can be made for the impact of better air quality on mortality, morbidity, visibility, and materials. However, the full assessment of air quality benefits in dollar terms is not possible until advances occur in human health, physical science, and

economic disciplines, which will allow monetary estimates to be made for currently unquantifiable areas.

Quantified Benefits

Air quality continues to improve due to previously adopted regulations and implementation of many control measures from the 2007 AQMP. Implementation of PM_{2.5} measures would lead to attainment of the federal 24-hour PM_{2.5} standard in 2014. Implementation of ozone measures would bring the Basin toward compliance with the federal ozone standard in 2023.

Although each attainment demonstration is performed with respect to the worst air quality site, the benefit assessment (except for the material benefit) herein is analyzed with respect to the changes in the projected year-long air quality concentrations between the expected control based on adopted regulatory programs and the Draft [Final](#) 2012 AQMP for the benchmark years in each air quality modeling grid (4 kilometer by 4 kilometer). The total average annual quantifiable benefits associated with implementing the Draft [Final](#) 2012 AQMP are projected to be \$10.7 billion, which represents the currently quantifiable benefit of moving beyond today's regulations to the level needed to meet the federal PM_{2.5} standards. A breakdown of these benefits is shown in Table 3-3. The benefit ranges from \$14 million for reduced expenditures resulting from less damage to building materials and less frequent cleaning to \$7.7 billion for reductions in congestion related to [all the TCMs proposed by SCAG in its 2012 RTP, of which the corresponding benefit for the SIP-committed TCMs in the 2012 AQMP is estimated to be \\$519 million](#). It is appropriate to consider the congestion relief benefit and SCAG TCMs because these measures are largely adopted for their congestion relief benefit as well as air quality improvements. [Based on the \\$519 million benefit for the SIP-committed TCMs, the total quantifiable benefit for the 2012 AQMP is projected to be \\$3.5 billion, as shown in Appendix H—TCM Benefit at 2014 Level](#). The detailed components of each benefit category and related assumptions are discussed in the remaining pages of this chapter.

TABLE 3-3
 Quantifiable Benefits of Draft [Final](#) 2012 AQMP
 (millions of 2005 dollars)

Benefit	Average Annual (2014 to 2035)
Reduction in Morbidity	\$23
Reduction in Mortality	2,225
Visibility Improvement	696
Reduced Materials Expenditures	14
Congestion Relief	7,712
Total	\$10,670

Health Benefit

It is well-documented that smog can result in short-term and chronic illness. Figure 3-3 illustrates mostly short-term smog effects. Numerous studies have demonstrated an association between illness and ambient air pollutants. [Since 2007 the Basin's residents have experienced significant health benefits due to improvements in PM_{2.5} levels from continuous implementation](#)

of PM controls and slowdown in economy. In 2011, the federal PM_{2.5} standards were exceeded at only one air monitoring station. Based on published epidemiological studies, demographic and projected air quality data, and economic valuation of health effects, the quantifiable health benefits of achieving the federal PM_{2.5} standard is estimated to be \$4.1 billion in 2014. The proposed PM_{2.5} strategy is also projected to result in co-benefits from reductions in exposure to NO₂, which is not included in the analysis due to resource constraints. Nor are co-benefits from ozone reductions because the ozone strategy in the Draft Final Plan represents a partial implementation of the Black Box whose full implementation is needed for the ozone attainment. Health effects of PM_{2.5} and other criteria pollutants are shown in Figure 3-4.

FIGURE 3-3
Effects of Smog

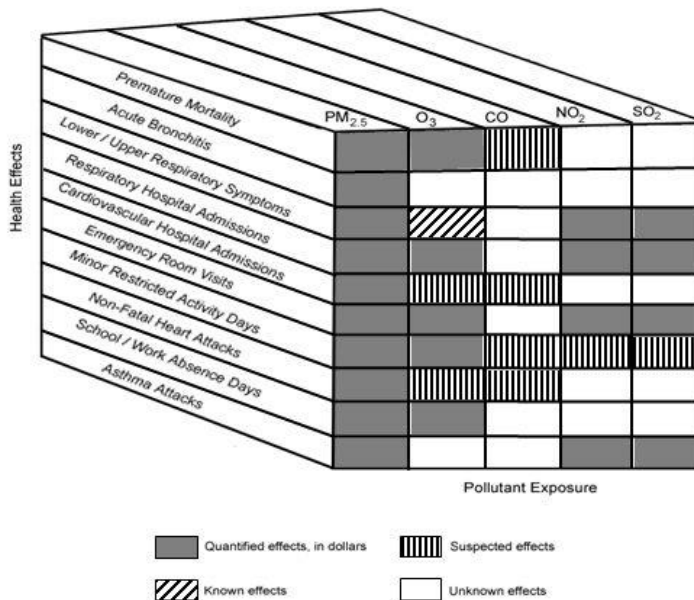

FIGURE 3-4
Health Effects of Criteria Pollutants

Quantification of health benefits requires the establishment of concentration-response functions for various symptoms and translation of health endpoints into dollar values. The latter step is needed in order to monetize known effects. Additional epidemiological studies are needed for unknown and suspected effects before developing concentration-response functions. Based on a thorough review of epidemiological literature, concentration-response functions for various health endpoints for PM_{2.5} were selected. A health benefit model, BenMAP, was used to pool population, air quality data, and economic values of health effects for the health benefit analysis.

Air quality is expected to improve due to the implementation of the existing control strategy. The analysis herein focuses on the degree of improvement in future years due to the implementation of control measures in the Draft [Final](#) 2012 AQMP by comparing the future baseline air quality (at the current level of regulations) to the future controlled air quality for the same year.

The majority of the region's population is currently exposed to unhealthful air. PM_{2.5} causes effects as extreme as premature death, as well as increased respiratory infection, asthma attacks, and other related health effects. Groups that are most sensitive to the effects of PM_{2.5} are children, the elderly, and people with certain respiratory and heart diseases. Assessments were made for reductions in premature deaths resulting from reductions in annual average PM_{2.5} concentrations; and reductions in respiratory and cardiovascular hospital admissions, emergency room visits, asthma attacks, minor restricted activity days (MRAD) from acute respiratory symptoms, and non-fatal heart attacks from reductions in daily PM_{2.5} concentration for the benchmark years 2014 and 2023.⁵ The PM_{2.5} benefit assessment herein has no threshold employed, i.e., it is assumed that there are health benefits for all reductions in emissions, even to levels below the current national ambient air quality standard (NAAQS).

Table 3-4 shows the number of avoided cases (or person-days) by health effect when the Basin attains the PM_{2.5} standard in 2014 and in 2023. The mortality impact (premature deaths) was analyzed based on the kridging model for the Los Angeles Metro Area in the 2009 Krewski et al. study (with a relative risk factor of 1.17). The elderly are more susceptible to premature deaths than other age groups. Reductions in health effects are translated into monetary terms based on the cost of illness (medical costs and work loss) or willingness-to-pay associated with each effect. The unit value of each health effect may vary by age, year, symptom, and/or county. The willingness-to-pay amount for avoiding a premature death was based on the value of a statistical life (VSL) in Kochi et al. (2006) adjusted to 2005 dollars and 2010 real income. The range of \$6.1 to \$6.7 million reflects variations in real income across sub-regions. For non-fatal heart attacks, the lower end of the range represented the average of four newer studies ([Zanobetti et al., 2009](#); [Pope et al., 2006](#); [Zanobetti and Schwartz, 2006](#); and [Sullivan et al., 2005](#)) from 2005 to 2009 and the higher end came from Peters et al. (2001).

A sensitivity analysis indicates that in 2014, eight percent of the adult (30 years old or above) avoided premature deaths would be attributed to evaluating the PM_{2.5} mortality benefit only to the NAAQS. However, there is no clear PM_{2.5} exposure threshold below which no adverse health effects are observed. In fact, California has lower PM_{2.5} standards than the federal standards. Furthermore, the U.S. EPA is in the process of proposing a more stringent annual

⁵ The health function was applied daily and aggregated to 365 days for each benchmark year.

PM_{2.5} standard based on several health studies (See Appendix I to the Draft [Final](#) 2012 AQMP for more details). The estimates in Table 3-4 assumed no existence of any health threshold below which benefits would not occur.

TABLE 3-4
Changes in Number of Symptoms for Future Years *

Health Effect	Number of Avoided Cases		Unit Value
	2014	2023	
Mortality (Adult & Infant)	668	275	\$6.1 - \$6.7 million

*Changes reflect differences in base and control cases for a given year. Positive numbers are reductions in symptoms due to the Draft [Final](#) 2012 AQMP.

**Person-days.

Table 3-5 shows the quantifiable health benefit of improved air quality associated with the 2012 Draft [Final](#) AQMP for PM_{2.5} morbidity and mortality relative to air quality without the Draft [Final](#) Plan. The total annual health benefit is projected to reach \$1.7 billion in 2023. Assuming that the 2023 benefit continues into the future, the projected average annual health benefit from 2014 to 2035 is approximately \$2.2 billion. Reductions in health expenditures may benefit low-income households more since they devote more of their out-of-pocket income to health expenditures than high-income households. Although the latter tend to consume more health care, the majority of their care expenses are paid for by private insurance under employer coverage (Holahan & Zedlewski, 1992).

TABLE 3-5
Clean Air Health Benefits
(millions of 2005 dollars)

Category	2014	2023	Average Annual (2014-2035)
PM _{2.5} Morbidity	45	16	23
PM _{2.5} Mortality	4,075	1,680	2,245
Total*	\$4,120	\$1,696	\$2,247

PM_{2.5} benchmark years are 2014 and 2023. Benefits for between 2014 and 2023 were linearly interpolated based on benchmark year estimates. Benefits beyond 2023 were assumed to be the same as those in 2023.

*[The sum of individuals may not add to the total due to rounding.](#)

Visibility Aesthetic Benefit

It has been shown that visibility—the ability to see distant vistas—has an impact on property values. To examine this relationship, researchers correlated sales prices of owner-occupied single-family homes between 1980 and 1995 with socioeconomic and housing characteristics of these homes and visibility data at the census tract level to arrive at a willingness-to-pay value for visibility (Beron et al., 2001).⁶ The research was performed for Los Angeles, Orange, Riverside, and San Bernardino Counties. Results indicated that the marginal willingness to pay for visibility (or price of visibility) was related to the percentage of college degrees for people 25 years or older, net income (household income minus housing cost), and visibility (in miles) at each location.⁷

Using visibility data for the benchmark years 2014, 2023, and 2030 and the projected net income and percentage of the college degree population (age 25 and above) at the sub-region level based on the growth rates between the 2005-2009 and 2006-2010 American Community Survey (ACS) estimates for these two variables, the average monetary value of visibility improvements per household from the Draft [Final](#) 2012 AQMP was calculated for each sub-region.⁸ These values were then annualized over a 50-year period at the four-percent real interest rate, which was then multiplied by the number of households to arrive at total values of visibility benefits. These totals were further adjusted downward by 55 percent to reflect visibility aesthetics only to avoid the potential aggregation of health and visibility embedded in the willingness to pay (Loehman et al., 1994).

The benefit for visibility improvements in 2035 was estimated using visibility data in 2030 and projected 2035 net income and percentage of the college degree population. Benefits for visibility improvements during non-benchmark years were linearly interpolated based on the benefits for benchmark years. The average annual visibility aesthetic benefit between 2014 and 2035 is projected to be \$696 million. Table 3-6 shows the visibility aesthetic benefit by county.

⁶ Property prices were used as a conduit to arrive at the willingness to pay for improved visibility, which is a function of visibility, the percentage of college degree of people over 25 years old, and net income. The recent fluctuations in property prices may or may not change the relationship between these independent variables and the willingness-to-pay amount for visibility. Additional research is required to arrive at a definitive conclusion.

⁷ The marginal willingness-to-pay (MWTP) equation used for this assessment is:

$$MWTP = 9032.42 + 0.09Y + 200.73 (COLLEGE) - 425.33V$$

Where Y stands for net income, COLLEGE for percentage of population with a college degree, and V for visibility.

The total willingness-to-pay (TWTP) for a specific reading of visibility is arrived at by integrating the above equation with respect to V:

$$TWTP = 9032.43V + 0.09YV + 200.73 (COLLEGE)V - (\frac{1}{2}) 425.33V^2$$

⁸ Adjustments of the growth rates to county averages were made in those sub-regions where growth rates of the ACS 5-year estimates were negative or unreasonably large.

TABLE 3-6
 Visibility Aesthetic Benefit by County
 (millions of 2005 dollars)

County	2014	2023	Average Annual (2014-2035)
Los Angeles	\$671	\$285	\$341
Orange	247	158	147
Riverside	187	115	113
San Bernardino	168	91	97
Total*	\$1,274	\$649	\$696

*The sum of individuals may not add to total due to rounding.

Material Benefit

Total suspended particulate matter (TSP) causes accelerated wear and breakdown of painted wood and stucco surfaces of residential and commercial properties (Murray et al., 1985). In addition, TSP will lead to additional household cleaning costs (Cummings et al., 1985).

The annual average PM_{2.5} concentrations at seven locations (three in Los Angeles County, two in Riverside County and one in each of the remaining two counties) were used to calculate the avoided household cleaning and damage to wood and stucco surfaces of residential properties that were projected to grow proportionately with the growth of housing units.⁹ The avoided damage to commercial properties was assessed at three percent of that to residential properties. The 4.81 ratio of TSP to PM_{2.5} was used to convert PM_{2.5} to TSP, which was used in the original material benefit assessment (Murray et al., 1985). The analysis was performed at the county level for the benchmark years 2014, 2023, 2030, and 2035. The 2035 avoided damage was assessed based on the 2030 PM_{2.5} data. The total avoided damage from all sources was linearly interpolated for interim years between 2014 and 2035 and allocated to each sub-region according to its proportion of households within a county in the 2006-2010 ACS.

The total benefit associated with the decrease in costs for repainting stucco and wood surfaces, and cleaning is projected to be \$35 million in 2014 and \$13 million in 2023. Table 3-7 shows material benefits by county for selected years.

⁹The household cleaning coefficient was adjusted downward by multiplying the proportion of soiling in the total contingency valuation (0.088).

TABLE 3-7
Material Benefit by County
 (millions of 2000 dollars)

County	2014	2023	2030	Average Annual (2014-2035)
Los Angeles	\$16.8	\$6.3	\$0.9	\$6.5
Orange	9.2	1.8	0.3	2.9
Riverside	5.0	2.9	1.7	2.9
San Bernardino	4.0	1.9	1.0	2.0
Total	\$35.0	\$12.9	\$3.9	\$14.3

PM_{2.5} benchmark years are 2014, 2023, and 2030. Benefits for non-benchmark years are linearly interpolated numbers based on benchmark year estimates.

Traffic Congestion Relief Benefit

Los Angeles is ranked as the most congested city in the nation. An estimated 62 percent of the lane miles are congested, resulting in the loss of fuel, time, and productivity (Texas Transportation Institute, 2011).

Traffic congestion relief benefits herein for 2014 were for the committed TCMs in the 2012 AQMP whereas the benefits for 2020 and 2035 in this section were for all the TCMs in the 2012 RTP. In order to analyze the benefit from the SIP-committed TCMs between 2014 and 2035 and due to the data constraint, it was assumed that the congestion relief benefit would stay constant at the 2014 level. This estimate is conservative because

- Only those projects that will be operational in the first two years are included in the 2014 benefit, and
- Some of the SIP-committed TCM projects will not be fully completed and operational in the first two years.

The 2014 congestion relief benefit from the SIP-committed TCMs is estimated to be \$519 million in 2014 and would continue from 2015 to 2035.

Implementation of SCAG transportation control measures (TCM) will reduce daily vehicle miles traveled (VMT) and daily vehicle hours traveled (VHT) in the four-county region, amounting to an average annual benefit of \$7.7 billion from 2014 to 2035 (Tables 3-8 and 3-9). TCMs include a wide variety of transportation projects such as arterials, grade crossing improvements, high occupancy vehicle lanes, mixed flow lanes, hot lanes/toll ways, transit, intelligent transportation systems, truck lanes, commuter rail, high speed rail, and others. These projects have a combination of public and private funding.

Traffic congestion relief benefits were assessed for reductions in daily VMT for the period between 2014 and 2035. Reductions were calculated as the difference between baseline (without SCAG TCMs) and control (with SCAG TCMs) conditions for the benchmark years

2014, 2020, and 2035.¹⁰ Reductions in VMT were distributed to the 4 kilometer x 4 kilometer grid cell level using brake and tire wear in grams per mile and then aggregated up to the sub-regions in the four-county area. Daily VMT reductions were converted to an annual reduction by multiplying by 250 working days per year.

Implementation of the TCMs is projected to reduce VMT by 3.3 million miles in 2014, ~~13.3 billion-million~~ miles in 2020, and 2.3 ~~billion-million~~ miles in 2035. VMT changes were allocated to two types of vehicles: autos (93 percent) and trucks (seven percent) according to the 2008 base year VMT associated with each type of vehicle. VMT reductions (or increases) for each vehicle type were allocated to each sub-region, which was then multiplied by the operating and maintenance cost per mile of that vehicle type to arrive at the benefit of reduced travel. The operating and maintenance costs for passenger and light duty vehicles were assumed to be 19.6¢ per mile (AAA, 2012). Operating and maintenance costs for medium-duty and heavy-duty trucks were assumed to be 61¢ per mile (ATRI, 2011).

In the year 2014 an estimated \$161 million of savings on vehicle operation and maintenance is expected, as shown in Table 3-8. By the year 2035, the estimated savings would rise to \$739 million.

TABLE 3-8
Reduced Vehicle Operating and Maintenance Costs by Type of Vehicle
(millions of 2005 dollars)

Type of Vehicle	2014	2020	2035	Average Annual (2014-2035)
Autos	\$130	523	901	598
Trucks	31	123	212	141
Total	161	646	1,113	739

Implementation of TCMs is projected to reduce VHT for business and commute trips by ~~over 66123,500-000~~ hours in 2014 and over ~~2.64.7~~ million hours in 2035. For the purpose of this analysis, it was assumed that 81 percent of VHT reductions were for business and commute trips and 19 percent were for other trips (SCAG, 2012a). Only VHT reductions for business and commute trips were included in the benefit assessment. Of the 81 percent reductions in business and commute trips, it was further assumed that 8 percent was for business and 73 percent was for commute trips (SCAG, 2012a).

The benefit of VHT reductions for the sub-regions was calculated by multiplying the share of VHT within the sub-region by the appropriate hourly wage rate. Daily VHT reductions associated with commute trips were multiplied by an annual conversion rate of 250 and an hourly wage rate of \$10.78, which is one-half of the average wage rate of all workers in Los Angeles County (EDD, 2012), to arrive at the annual benefit of spending less time on commuting. One-half of the average wage (\$10.78) provides an estimate of the value of commuters' time consistent with recent research (Steimetz and Brownstone, 2005) involving Southern California transportation data and the average length of work-home trips in the four-

¹⁰Impacts on VMT and VHT from TCM were available only in 2014. For 2020 and 2035, TCM impacts on VMT and VHT were calculated by applying the ratio of TCM to RTP impacts in 2014 to 2020 and 2035 RTP impacts, respectively, since TCM is a subset of RTP.

county area (SCAG, 2012a). Daily VHT reductions from business trips were also multiplied by an annual conversion rate of 250 and an hourly wage rate of \$21.84 for truck drivers (ATRI, 2011) to arrive at the annual benefit from VHT reductions for business trips. Savings from reduced travel time for business and commute trips is estimated at \$358 million for 2014 and at \$13.8 billion for 2035, respectively, as shown in Table 3-9.

TABLE 3-9
Savings from Reduced Travel Time by Trip Type
(millions of 2005 dollars)

Type of Trip	2014	2020	2035	Average Annual (2014-2035)
Business	\$59	\$657	\$2,291	\$1,156
Commute	299	3,305	11,529	5,817
Total	\$358	\$3,962	\$13,820	\$6,973

Unquantified Benefits

Areas in which benefits from improved air quality have been identified but not fully quantified include human health, building materials, plant life and livestock, and reductions in vehicle hours traveled for personal trips. Each of these areas is discussed below.

Health Benefit

The quantifiable health benefits associated with improved air quality were assessed relative to reduced morbidity and mortality from PM_{2.5}. The present state of knowledge does not allow all adverse health effects that have been identified to be measured and valued in dollars. It should be noted that many health effects cannot be valued in dollars mainly because sufficient data are not available to establish a quantitative relationship between pollutant level and health effect. Hence quantification of health effects may be underestimated.

Material Benefit

In addition to the quantifiable materials damage caused by ozone and PM_{2.5}, a link exists between several pollutants (ozone, sulfur dioxide, PM_{2.5}, and nitrogen oxides) and ferrous metal corrosion; erosion of cement, marble, brick, tile, and glass; and the fading of fabric and coated surfaces. The damages and conversely the potential benefits from reducing the exposure currently cannot be quantified and valued in dollars.

Traffic Congestion Relief Benefit

Implementation of TCMs is projected to reduce daily VHT by 28,833 hours in 2014 for personal trips, relative to the 2014 baseline projections for VHT. Savings resulting from reduced travel time for personal trips are difficult to quantify due to the variation of the value of time from one individual to another and were not included in this benefit calculation. Based on one-half of the average hourly wage rate (\$10.78), savings from reduced travel time for personal trips is

estimated at \$78 million (2005 dollars) for the year 2014. This could bring the total traffic congestion relief benefit to approximately \$597 million in 2014.

SUMMARY

The Draft [Final](#) 2012 AQMP projects the attainment of the federal air quality standards of PM_{2.5} in 2014 and implements progress toward the ozone standard via additional measures which reduce the remaining “black box” measures. The total quantified benefit in 2014 is estimated to be \$948 million and increases to \$9 billion in 2023 (Table 3-10). [Based on the \\$519 million benefit for the SIP-committed TCMs, the total quantifiable benefit for the 2012 AQMP is projected to be \\$2.7 billion in 2023 and \\$3.5 billion annually, on average, from 2014 to 2035.](#) The quantified health benefits have not accounted for the reduction in all adverse health effects due to the implementation of the Draft [Final](#) 2012 AQMP. In addition, benefits have not been quantified for reductions in vehicle hours traveled for personal trips; and reductions in damages to plants, livestock, and forests as a result of implementing the Draft [Final](#) 2012 AQMP. If all these factors were considered, the estimated benefits would be higher than the estimates presented in this analysis.

TABLE 3-10
Total Costs and Benefits of the Draft [Final](#) Plan
(millions of 2005 dollars)

	2014	2023	Average Annual
Total Costs	\$510	\$357	\$448
Total Benefits	\$5,948	\$9,031	\$10,670

The total cost of the Draft [Final](#) Plan is projected to be at \$510 million in 2014 and decrease to \$357 million in 2023. The cost of measures was based on the prices of equipment and materials that would be required for the implementation of these measures.

As the District comes closer to its attainment goals for various pollutants, the cost in achieving the final increment towards attainment might actually result in higher costs than projected. However, technological advancements may reduce costs over time. However, actual costs could be higher than projected costs if modifications to existing plant structure are required. Impacts on individual facilities or more refined socioeconomic impact analysis will be conducted during the AQMD future rulemaking when regulated requirements and affected facilities are more defined.

Further research is needed relative to quantifying the known health effects. Relative to costs, additional efforts will be made to work with the CARB and U. S. EPA to quantify the costs associated with long-term measures where technologies are better defined.

CHAPTER 4

EMPLOYMENT IMPACTS

Introduction

Job Impacts ~~from~~ of Draft Final 2012 AQMP

Summary

INTRODUCTION

The employment impacts of control measures and clean air benefits were analyzed by utilizing the Regional Economic Model, Inc. (REMI) model. This model contains 18 sub-regions within the four-county area. Each sub-region is comprised of 70 public and private sectors. The structure of each sub-region's economy is represented through production, sales, and purchases between sectors; demand and supply of products in each sector; expenditures made by consumers, businesses, and governments; and product flows between one sub-region, the rest of the sub-regions, and the rest of the U.S.

The employment impact analysis was performed separately for control measures, clean air benefits, and both combined. The employment impacts in this chapter represent changes from the baseline regional jobs. [The assessments herein for clean air benefits, and combined measures and benefits beyond 2014 were based on the congestion relief benefit for all the TCMs in the 2012 RTP. Employment impacts based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

JOB IMPACTS ~~FROM OF~~ DRAFT FINAL 2012 AQMP

Implementation of the Draft Final 2012 AQMP will reduce morbidity and mortality; improve visibility; decrease expenditures on household cleaning and refurbishing building surfaces; and provide relief from congestion, as discussed in Chapter 3. The total quantifiable benefit of the Draft Final 2012 AQMP amounts to approximately \$5.95 billion in 2014 and \$9.1 billion in 2023. The PM_{2.5} and ozone measures would result in an annual cost of approximately \$510 million in 2014 and \$357 million in 2023. Both benefits and costs will affect the employment base in the four-county economy.

The four-county economy will expand from the effects of two major forces resulting from cleaner air. First, the substitution of imports [general consumer purchases (which would increase due to the reduction in health care expenditures)] for local production (reduced health care services related to improved air quality) leads to jobs not created.¹ Second, the improvement in the quality of life will make the area more attractive so that more people will move in until the expected real earnings rate is reduced sufficiently to compensate for the estimated effect of the increased amenities (Greenwood et al., 1991).² This influx will increase labor force and local demand. On the other hand, the local economy will also experience relative slowdown from implementing control measures. This is because the increased cost of doing business leads to fewer jobs created and the resulting higher product price would lower consumer purchasing power. Table 4-1 shows the average annual job impacts, as well as job impacts with respect to the years 2014 and 2023, for quantified benefits and control measures,

¹ General consumer purchases can be satisfied by local production and imports. Health care services are locally produced goods.

² Because of cleaner air, economic migrants are willing to move into the Basin in exchange for lower earnings (wage and salary) than what the Basin would otherwise be. Currently, there is no systematic approach to evaluating migration of retired persons as they do not belong to the labor force. Therefore, their willingness to pay (and non-wage generated income stream) for avoided morbidity and mortality is not accounted for in the migration functions that were used only for economic migrants in the labor force.

respectively. Figure 4-1 shows the trends of job impacts from clean air benefits, control measures, and both combined from 2013 to 2035, respectively.

TABLE 4-1
Job Impacts of Quantified Clean Air Benefits and Measures

Category	2014	2023	2035	Average Annual
Clean Air Benefits & Measures (2013-2035)*	2,988	28,187	96,968	37,043
Clean Air Benefits (2014-2035)*	2,262	30,146	100,016	42,174
Congestion Relief*	348	20,371	87,843	32,986
Visibility Improvements	1,008	5,313	6,445	4,947
Reduced Materials Expenditures	133	191	181	179
Health Benefits	774	4,146	5,214	3,910
Control Measures (2013-2035)	731	-1,929	-2,955	-3,257
TCMs	715	537	-813	-1,611
District PM _{2.5}	7	-10	-3	-4
Ozone Strategy	26	-2,457	-2,142	-1,639

Results from modeling all the categories are slightly different from the sum of results from modeling each category one at a time because of nonlinearity of the REMI model.

*Based on all the TCMs in the 2012 RTP.

FIGURE 4-1
Job Impacts of Clean Air Benefits and Measures

Note that job impacts in the REMI model are generated for each year which represents the difference between the baseline projections and a policy event (control measures, clean air benefits, etc.) An increase or decrease in the number of jobs represents the net flow of jobs from one year to the next as the economy continues to operate. These jobs are not necessarily

permanent because of the dynamic structure of an economy. There is no implication that the jobs created or forgone in a particular year will be sustained (e.g., same employer and employee) in subsequent years.

The job impact of air quality benefits is assessed separately for each benefit category: visibility improvements, health benefits, reduced congestion, and reduced expenditures on materials. Many of the benefits of improved air quality can be seen as both direct and indirect benefits to individuals living in the area. Reductions in morbidity would lead to reduced health care expenditures by the general public and employers (the cost of illness portion only).³ It was assumed that 60 percent of the reduced expenditures would benefit the employers as a reduction in the cost of doing business and the remaining 40 percent would flow back to the economy in the form of additional spending on all consumption categories. Furthermore, reductions in out-of-pocket health expenditures are used as a proxy for the quality-of-life value of morbidity benefits (i.e., reduced illness). The positive amenities from cleaner air (reductions in premature deaths and morbidity, the ability to see farther, reduced expenditures in refurbishing and cleaning to residences, and reductions in VMT and VHT) would induce more in-migration. Additional health care expenditures from economic migrants would more than compensate for the reduction in these expenditures due to avoided morbidity. During the 2014-2035 period, a net gain of approximately 3,910 more jobs annually, on average, from health benefits is projected. Moreover, decreased congestion could create an additional 32,986 jobs during the same period. Together, the quantified benefits could result in an average of 42,174 jobs created annually.

According to the REMI baseline forecast (adjusted to reflect SCAG projections), the four-county area's jobs would grow at an annual rate of 0.92 percent between 2009 and 2035 to 11.5 million jobs in 2035. The PM_{2.5} and ozone control measures will result in an average of 3,257 jobs forgone annually, on average, over the period from 2013 to 2035. Approximately, 50 percent of the jobs forgone (or 1,611 jobs forgone) annually are projected to result from the 143 transportation projects alone. These projects were assumed to be funded through local revenue sources and out-of-area funding sources (state and federal governments). However, it should be noted that operation and maintenance of these infrastructure projects will continue to be required long after these projects are completed. The District portion of the PM_{2.5} strategy would result in very few jobs forgone. The ozone strategy is projected to result in 1,639 jobs forgone.

The combined impact of clean air benefits and control measures would translate to an annual gain of 37,043 jobs, on average, from 2013 to 2035.

Job Impacts by Industry

Table 4-2 show the job impacts for the benchmark years 2014 and 2023, and the average annual job impact by industry between 2014 and 2035 for clean air benefits. In total, cleaner air would result in a creation of 42,174 jobs annually, on average, from 2014 to 2035 which is approximately 0.4 percent of the baseline jobs (employment projections without the implementation of the 2012 AQMP) during the same period. Approximately 91 percent of the

³It should be noted that reductions in health care expenditures accrued to the government sector were not accounted for in the analysis herein. These reductions could result in more positive impacts since the government sector may use the savings to increase spending in other critical areas or to reduce taxes and fees.

projected 42,174 jobs are due to the increased amenities resulting from reduction in morbidity and mortality, improved visibility, reduced materials expenditure and reduced traffic congestion.⁴ The sectors that are projected to have the relatively large share of jobs created over the period of 2014 to 2035 are accommodation and food services, government, retail trade, and real estate/rental/leasing. As the area becomes more attractive due to cleaner air, more people will move in and thus demand more services from these sectors. The jobs forgone in the truck transportation sector are due to the reduced demand for this sector resulting from reductions in VHT due to the implementation of SCAG TCMs.

TABLE 4-2
Draft [Final](#) 2012 AQMP Employment Impacts by Industry for Clean Air Benefits*

Industry	NAICS	Jobs		Average Annual (2014-2035)	
		2014	2023	Jobs	% Baseline

Total		2,262	30,145	42,174	0.399%

*Based on all the TCMs in the 2012 RTP.

Implementation of PM_{2.5} and ozone measures would, on the other hand, result in jobs forgone. Table 4-3 show the job impacts for the benchmark years 2014 and 2023, and the average annual job impact by industry between 2013 and 2035 for PM_{2.5} and ozone control measures. In 2014,

⁴Economic migrants are willing to move to an area with more amenities in exchange for lower earnings. This would lower the cost of doing business and increase the competitiveness of local industries. As a result, output will rise and more workers will be hired.

job impacts are the result of implementation of SCAG TCMs under the PM_{2.5} strategy and early implementation of incentive programs proposed in the on- and off-road measures. These are the sources for the majority of job impacts in 2023. Of the total 2,457 jobs forgone in 2023 from the ozone strategy, 70 percent are due to the on- and off-road measures.

Sectors of construction, and professional and technical services are projected to gain jobs. The heavy infrastructure investment resulting from the 143 transportation projects would certainly benefit those two sectors. On the other hand, ~~this the same construction~~ sector is assumed to participate in the voluntary/incentive programs proposed in the on- and off-road mobile source measures. The government sector is projected to experience jobs forgone due to the reduced spending elsewhere in order to compensate for the increase in these investments. The retail trade sector is projected to have a relatively large share of jobs forgone mainly due to the reduction in personal income resulting from the overall jobs forgone in the economy when clean air benefits are not considered. All the sectoral jobs forgone are less than one percent of the baseline projected jobs.

Table 4-4 shows the job impact by industry for clean air benefits and control measures as a whole. More industries would experience jobs forgone in 2014 than in other years because the negative effect of control measures dominates the positive effect of clean air. Over time the reverse is true, thus resulting in net job gains for most of the industries.

TABLE 4-4
Job Impacts by Industry for Clean Air Benefits and Measures Combined*

*Based on all the TCMs in the 2012 RTP.

Small Business Effects

The District defines a "small business" in Rule 102 as one which employs 10 or fewer persons and which earns less than \$500,000 in gross annual receipts. In addition to the District's definition of a small business, the federal Small Business Administration (SBA), the federal Clean Air Act Amendments of 1990 (CAAA), and the California Department of Health Services (DHS) also provide their own definitions of a small business. Two common characteristics of the SBA, CAAA, and DHS small business definitions are the following: (1) standards are unique to each industry type, and (2) the businesses have to be independently owned and operated, and cannot be dominant in their field.

The SBA's definition of a small business uses the criterion of either gross annual receipts (ranging from \$0.5 million to \$17 million, depending on industry type) or number of employees (ranging from 100 to 1,500). The CAAA classifies a facility as a "small business stationary source" if it (1) employs 100 or fewer employees, (2) does not emit more than 10 tons per year of either ROG or NO_x, and (3) is a small business as defined by SBA. The DHS definition of a small business uses an annual gross receipt criterion (ranging from \$1 million to \$9.5 million, depending on industry type) for non-manufacturing industries and an employment criterion of fewer than 250 employees for manufacturing industries.

Under the SBA's and CAAA's definitions of small business, the AQMP could potentially impact a wide range of small businesses. The number of affected small businesses will be fewer under the District's definition. Small businesses are more highly concentrated in non-manufacturing than manufacturing sectors. A few control measures such as CTS-01 on architectural coatings and CMB-03 on commercial space heating may affect small businesses. Since the affected businesses are not exactly known at this stage, additional analyses of the number and types of small businesses affected by control measure and the ensuing job impacts will be performed during individual rule development processes.

SUMMARY

[The employment impact assessments herein were based on the congestion relief benefit for all the TCMs in the 2012 RTP. Employment impacts based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

Clean air benefits are projected to result in a gain of 42,714 jobs annually, on average, from 2014 to 2035. Implementation of control measures is projected to have 3,257 jobs forgone annually, on average, from 2013 to 2035. The Draft [Final](#) 2012 AQMP as a whole would result in an annual net gain of 37,043 jobs, on average, from 2013 to 2035. The jobs created from clean air benefits would amount to 0.86 percent of the total four-county jobs in 2035. The jobs forgone from control measures would be 0.03 percent of the total jobs in 2035.

Without the 2012 AQMP, jobs in the four-county area are projected to grow at an annual rate of approximately 0.922 percent between 2009 and 2035. The Draft [Final](#) 2012 AQMP as a whole (clean air benefits and control measures) would result in an increase in the annual job growth rate by 0.033 percent. Looking at the benefits and costs separately, cleaner air from the 2012 AQMP would increase the job growth rate by 0.034 percent and bring it to an annual rate of 0.96 percent. On the other hand, control measures would slow down the rate of job growth by 0.001 percent, to 0.921 percent.

Nearly all of the industries would experience additional jobs created due to cleaner air. The sectors of accommodation and food services, government, retail trade, and real estate/rental/leasing would experience larger shares of jobs created due to additional demand for their products as more people migrate to the region and demand more services from these sectors.

The potential small business impacts of individual control measures will be further examined in the rule development process. In addition, as measures are developed into rules, their potential employment impacts will be specifically assessed.

CHAPTER 5

IMPACTS ON ECONOMIC GROUPS AND COMMUNITIES

Introduction

Costs by Sub-region

Clean Air Benefits by Sub-region

Job Impacts by Sub-region

Job Impacts on High- Versus Low-Paying Jobs

Impacts on Disposable Income

Impacts on Price Index by Income

Summary

INTRODUCTION

Socioeconomic issues have become increasingly important in recent years during the development of air quality regulations and policies. Evaluation of the distribution of job and cost impacts among ethnic and economic groups, as well as geographic communities, is a key topic to be considered.

While a socioeconomic assessment provides valuable information regarding the potential direct and secondary effects, the analysis does have some limitations. Establishing appropriate methods to estimate distribution effects is difficult given that few analytical models exist that can be easily adapted to air quality policy analysis. The lengthy data collection process makes it formidable to timely follow the rapidly-changing socioeconomic characteristics, especially in Southern California. Moreover, there is an inherent bias because costs tend to be more easily measured than benefits. Finally, there are additional uncertainties associated with examining subpopulations within the four-county area. Overall, socioeconomic assessments require substantially more data than what currently exists because existing data are often limited or based on small samples, thereby making estimates less reliable.

The REMI model, used to analyze potential impacts of the Draft [Final](#) 2012 AQMP, projects possible impacts on jobs, the distribution of jobs, income, and product prices based upon cost data for control measures and benefit data for each quantified effect of clean air. The reliability of such projections is dependent upon the validity of the input. [The assessments below were based on the congestion relief benefit for all the TCMs in the 2012 RTP. The assessments based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

COSTS BY SUB-REGION

The Draft [Final](#) 2012 AQMP requires emission reductions from stationary, area, on-road, and off-road sources. Emission reductions from stationary sources consist of those from point and area sources. Projected emission reductions in 2023 from area sources were assigned to a 4 kilometer by 4 kilometer grid and those from point sources were assigned to a facility in the 2008 emission inventory. The emission reductions for each quantified measure in each grid or facility were then aggregated to a total of 21 sub-regions. The annual cost for each quantified measure (annualized capital and annual operating and maintenance expenditures) during the implementation period was then allocated to each sub-region according to its proportion of emission reductions.

The cost of SCAG TCMs will be mostly financed by public funding through sales and gasoline taxes and bond issuance. The private funding through development agreements plays a small role and was allocated to the construction sector according to the location of projects. The public funding was assigned to each county according to project descriptions and then to each sub-region according to its population share in the county. For area, on-road, and off-road sources, the annual cost of each control measure was allocated to each sub-region according to its share of emission reductions, which was aggregated from emission reductions at air quality grids. Surrogate variables such as population were used to

distribute emission reductions to grids. For voluntary and incentive measures where emission reductions are not available, sub-region population was used for allocation.

As described in Chapter 3, the average annual cost of all quantified measures from 2013 to 2035 is projected to be \$448 million. Table 5-1 shows the projected cost share in each sub-region for all the quantified control measures by implementation jurisdiction. Nearly all the costs of PM_{2.5} measures are from TCM projects, the distribution of which among sub-regions reflects where the TCM projects are. The Los Angeles County central, San Fernando, west, and southwest sub-regions would experience most of the costs. The southwest beach community in Los Angeles County is projected to have the highest share (10 percent) of the cost for ozone measures that would be implemented by the District. This is mainly due to the control on refinery boilers from Control Measures CMB-01 (RECLAIM Phase II). The cost distribution of the Draft [Final](#) 2012 AQMP follows that of PM_{2.5} and ozone measures. The sub-regions with the highest costs are the central, southwest, and San Fernando areas of Los Angeles County.

TABLE 5-1
Cost Share by Sub-region for Control Measures

Sub-Region	PM _{2.5} Measures		Ozone Measures		All Measures	
	Millions \$	%	Millions \$	%	Millions \$	%

Total	\$327	100%	\$122	100%	\$448	100%

CLEAN AIR BENEFITS BY SUB-REGION

The Draft [Final](#) Plan is designed to bring northwest Riverside (the Mira Loma area), the only area in exceedance of the federal PM_{2.5} standard, into attainment. However, PM_{2.5} air quality benefits occur throughout the Basin. As shown in Table 5-2, the San Fernando Valley, southern Los Angeles County, and the northwest Riverside County would experience the highest proportions of the total \$10.7 billion air quality benefit. The western portions of Los Angeles and Orange Counties and the eastern and northern portions of San Bernardino County are projected to have the highest shares of health benefits due to high population density and/or lower PM_{2.5}. The health benefits from reductions in PM_{2.5} are expected to reach nearly \$4.1 billion in 2014 and \$2.2 billion annually, on average, from 2014 to 2035.

*Based on all the TCMs in the 2012 RTP.

An important element of the socioeconomic analysis is to identify how the proposed control strategy will impact the sensitive portions of the population, in particular, the segment of the community identified by the District's existing environment justice (EJ) guidance, which is an area that exceeds 10 percent of poverty rate with a cancer risk greater than 850 in a million or a PM_{2.5} concentration greater than 19.02 µg/m³. Figure 5-1 provides an overview of the impact of the 24-hr PM_{2.5} control strategy on exposure to PM_{2.5} to both the EJ and non-EJ portions of the

community. More detailed impacts on sub-populations will be conducted in the future. The figure shows the difference between the projected 2014 24-hour $PM_{2.5}$ concentrations with the control strategy applied compared with the baseline 2014 24-hr $PM_{2.5}$ concentrations. Overall across the Basin the majority of areas show 24-hour $PM_{2.5}$ air quality improvements. Only a small segment of the San Gabriel Mountains depicts a nominal negative impact of implementing the control program. Overlaid on each of the 4-km squared $PM_{2.5}$ grid cells are the 1-km squared grid depicting the EJ sub-areas of the region. As illustrated by the overlay, many of the sub-grid cells identified as EJ are located in the areas experiencing the greatest levels of air quality improvements. Those areas include the densely populated portions of metropolitan Los Angeles and southwestern San Bernardino counties. While continuing to show air quality improvements but to a lesser extent than the previously identified areas, Orange and the southern portion of Riverside counties depict a lesser EJ benefit. This is mostly due to the smaller EJ segment of the population.

FIGURE 5-1
Impact of 2014 Change in 24-Hour $PM_{2.5}$ Concentrations on EJ Areas

The majority of the congestion relief benefit would be attributed to Burbank, San Fernando, the southern portion of Los Angeles County, and northwest Riverside County. The west portion of Los Angeles County is projected to have the highest share of the visibility aesthetic benefit, which is calculated based on the number of households, visibility improvements (compared to the “no control” baseline scenario), net household income (net of housing cost), and percent of college degree holders in each sub-region. Table 5-3 shows

the values of these variables by sub-region from the 2006-2010 American Community Survey (ACS) estimates. In 2014 and 2023, southwest Riverside County and southwest San Bernardino County along with areas around San Bernardino City are projected to have the highest visibility improvement relative to its baseline air quality among all the sub-regions.

Information on net household income and percent of college degree holders for the benchmark years 2014, 2023, and 2030 are not available. The annual growth rates of net household income and percent of college degree holders, respectively, between the 2005-2009 and 2006-2010 ACS estimates in each sub-region were used to project the values of these variables for those benchmark years. County growth averages were used for sub-regions with negative growth rates between these two estimates or those with long-term unreasonably high growth rates. Additionally, SCAG household projections were used. The total willingness to pay for visibility improvement is higher in the sub-regions with more relative improvements in visibility and denser population due to their higher net household income and percentage of college degree holders.

TABLE 5-3
Determining Factors for Aesthetic Visibility Benefit by Sub-region

Sub-region	Households	Net Household Income (1995 \$)	% College Degree	% Visibility Improvement

Source: 2006-2010 American Community Survey

The visibility benefit analysis was performed at the 21 sub-region level by aggregating the predicted PM_{2.5} concentration data for each grid and the total light extinction coefficient at the nearest airport for each grid to 21 sub-regions. The congestion relief benefit was

assessed by aggregating the reductions in VMT and VHT at the air quality grid level to 21 sub-regions. The assessment of material benefit was performed at the county level and allocated to sub-regions according to their population and housing units within a county. All the assessments were first made for the benchmark years (2014, 2023, and 2030) in the air quality models and interpolated for interim years.

Table 5-4 shows that the \$554 per capita clean air benefit far more outweighs the \$23 per capita cost. Except for the central Los Angeles County, all sub-regions are projected to have much greater per capita benefit than per capita cost. The dis-benefit in central Los Angeles County is due to the congestion relief dis-benefit [resulting from all the TCMs in the 2012 RTP](#).

TABLE 5-4
[Average Annual](#) Per Capita Clean Air Benefit and Cost by Sub-region (in 2005 dollars)

JOB IMPACTS BY SUB-REGION

The baseline employment for Los Angeles County is projected to be 5.72 million jobs in 2014 and 6.11 million in 2023. Orange County is projected to have 1.93 million jobs in 2014 and 2.03 million in 2023. Riverside and San Bernardino Counties are projected to have 1.08 and 0.95 million jobs in 2014 and 1.26 and 1.08 million jobs in 2023, respectively.

The job impact analysis was performed at the 18 sub-region level where the San Gabriel East and West sub-regions were combined into the Los Angeles County East sub-region; the southwest Riverside sub-region was combined into the other Riverside sub-region; and the

San Bernardino City and southwest San Bernardino sub-regions were combined into the Chino-Redlands sub-region. The distribution of job impacts (Table 5-5) by sub-region very much mirrors that of clean air benefits and costs.¹ The eastern, southern, and San Fernando sub-regions in Los Angeles County and Riverside County are projected to have more jobs created than other sub-regions resulting from clean air benefits. In terms of the job impact of control measures, the majority of the jobs forgone are in Orange County. This is because the majority of SCAG TCMs in Orange County would be financed by development fees, which would have a heavy burden on one single sector of the economy—the construction sector. A sensitivity test shows that the same project financed by development fees would have 47 times as many jobs forgone as if it were financed by sales tax. For the entire Draft [Final Plan](#), all sub-regions would show positive job impacts as the four-county area becomes more competitive and attractive with the progress in clean air, which outweighs the negative job impacts of the cost of control measures alone.

TABLE 5-5
Average Annual Job Impacts by Sub-region for
Benefits, Control Measures and Draft [Final Plan](#)

Sub-region	Benefits (2014-2035)*	Control Measures (2013-2035)	Draft Final Plan * (2013-2035)	
			Jobs	% Baseline
LA CO Beach & Catalina	1,569	-35	1,466	0.34%
LA CO Burbank	2,153	17	2,076	0.50%
LA CO Central	1,158	66	1,172	0.16%

Total	42,174	-3,256	37,043	0.35%

*Based on all the TCMs in the 2012 RTP.

JOB IMPACTS ON HIGH- VERSUS LOW-PAYING JOBS

Occupations were grouped into five categories, lowest to highest, according to median weekly earnings. Table 5-6 shows the distribution of job impacts in 2014 and 2023 resulting from clean air benefits, control measures, and their combined impacts, respectively, among various occupational wage groups. All the groups are projected to gain from cleaner air.

¹ Job impacts herein are by place of work.

Group 1 would gain the most in 2014 and 2023. For control measures, Groups 1, 2, and 5 would have jobs forgone ranging from 0.008 percent to 0.055 percent relative to the baseline 2014 and 2023 employment, with Group 1 to be affected the most. Nearly all the groups would gain employment from the combined impacts of clean air benefits and implementation of control measures. Group 1 occupations include workers in retail sales and maintenance, assemblers, and food preparation and agricultural workers. Group 5 occupations are scientists, teachers, engineers, and managers/executives. The occupations in each group are listed in Table B-1 of Appendix B.

TABLE 5-6
Employment Impacts by Occupational Wage Group for
Clean Air Benefits and Control Measures

Group	Median Weekly Earnings	No. of Occupations	% Impact from Baseline					
			Clean Air Benefits*		Control Measures		Benefits & Measures*	
			2014	2023	2014	2023	2014	2023
1	\$352-\$517	19	0.031	0.355	-0.055	-0.041	-0.024	0.313
2	\$520-\$659	19	0.021	0.256	-0.008	-0.022	0.013	0.234
3	\$661-\$820	18	0.013	0.241	0.138	0.027	0.151	0.268
4	\$821-\$996	19	0.028	0.305	0.009	-0.016	0.036	0.289
5	\$1,027-\$1,729	19	0.025	0.266	-0.008	-0.026	0.017	0.239

*Based on all the TCMs in the 2012 RTP.

IMPACTS ON DISPOSABLE INCOME

Without the Draft [Final](#) 2012 AQMP, real disposable income is projected to grow at an annual rate of 2.245 percent between 2009 and 2035.² Clean air benefits of the Draft [Final](#) AQMP could bring the annual growth rate to 2.281 percent. Cleaner air increases amenity in the four-area area, thus bringing in more economic migrants. Population is projected to grow slightly more than real total disposable income, thus resulting in a decrease in per capita disposable income. Per capita real disposable income (total real disposable income divided by population) would decrease by \$891 in 2035 relative to the baseline projection.

IMPACTS ON PRICE INDEX BY INCOME

The REMI model develops price indexes of consumption goods for households in five income groups by comparing prices of those goods between the four-county region and the rest of the U.S. Table 5-7 shows the projected percentage change in the price of consumption goods in a market basket (those goods identified in the annual Consumer Expenditure Survey by the Bureau of Labor Statistics) by income group for clean air benefits, control measures, and their combined impacts, respectively, in the years 2014 and 2023. The first quintile represents households earning the lowest 20 percent of income.

² The real disposable income for the four county area is projected to be \$561 billion (2005 dollars) in 2009 and \$999 billion in 2035. Disposable income is the sum of the incomes of all the individuals in the economy after all taxes have been deducted (Baumol and Blinder, 1982).

TABLE 5-7
Impacts on the Price of Consumption Goods for
Clean Air Benefits and Control Measures
(percent of baseline*)

Household Income	Clean Air Benefits**		Control Measures		Benefits & Measures**	
	2014	2023	2014	2023	2014	2023
1st Quintile	-0.007	-0.013	0.060	0.040	0.052	0.025
2nd Quintile	-0.007	-0.027	0.059	0.039	0.052	0.013
3rd Quintile	-0.007	-0.024	0.058	0.039	0.052	0.015
4th Quintile	-0.007	-0.028	0.058	0.038	0.052	0.011
5th Quintile	-0.007	-0.020	0.060	0.038	0.052	0.018

*Relative to the rest of the U.S.

**Based on all the TCMs in the 2012 RTP.

The change here is relative to the baseline index of consumption goods. The price of consumption goods is projected to decrease by 0.007 percent in 2014 across all household income groups and by 0.013 to 0.028 percent in 2023 due to the attainment of the PM_{2.5} standard. Implementation of control measures is projected to increase the price of consumption goods from 0.039 to 0.06 percent for these same years across all household income groups. All household groups would experience increases in prices of consumption goods resulting from combined impacts of control measures and clean air benefits. The projected increase in the price is due to the pass-through of additional control costs by industries that are affected by a number of control measures.

SUMMARY

[The assessments herein were based on the congestion relief benefit for all the TCMs in the 2012 RTP. Impacts based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

Implementation of the Draft [Final](#) 2012 AQMP is projected to result in air quality improvements sufficient to attain the federal air quality standards in 2014 for PM_{2.5} and progress toward attaining the ozone standard in 2023. The San Fernando Valley, southern Los Angeles County, and the northwest Riverside County would experience the highest shares of air quality benefits. The western portions of Los Angeles and Orange Counties and the eastern and northern portions of San Bernardino County are projected to have the highest shares of health benefits.

The attainment of the ozone and PM_{2.5} air quality standards depends on full implementation of control measures that are proposed in the Draft [Final](#) 2012 AQMP. The costs of these measures will ripple throughout various communities. The sub-regions with the highest costs are the central, southwest, and San Fernando areas of Los Angeles County. These three areas are projected to have the highest cost shares from SCAG TCMs and relative higher cost shares from ozone measures.

All sub-regions are projected to have additional jobs created from cleaner air. Implementation of quantified control measures would result in jobs forgone between 2013 and 2035. Job gains from cleaner air would benefit all five wage groups that are comprised

of 94 occupations. Most groups would experience jobs forgone from implementation of control measures. However, there is no significant difference in impacts expected for high-versus low-paying jobs. The same is observed for impacts on the price of consumption goods from one household group to another.

Additional surveys on affected groups and communities need to be developed to better understand the detailed job impacts. Furthermore, additional tools need to be developed relative to presenting socioeconomic and air quality data geographically. Chapter 8 has a more detailed description of these proposed future enhancements to the socioeconomic analysis.

CHAPTER 6

IMPACTS ON COMPETITIVENESS

Introduction

Region's Share of U.S. Jobs

Cost of Production and Prices

Imports and Exports

Summary

INTRODUCTION

Regional economic competitiveness depends on various factors including business costs, workforce quality, public infrastructure, quality of life, and the regulatory environment. Air quality regulations directly affect business costs, quality of life, and the regulatory environment. Specifically, the Draft [Final](#) 2012 AQMP will affect regional economic competitiveness in two ways: (1) by imposing costs on business as a result of pollution control strategies; and (2) by improving the region's quality of life by reducing air pollution. Good air quality tends to attract highly qualified professionals, who, in general, are higher wage earners.

The REMI model, used to analyze potential impacts of the Draft [Final](#) 2012 AQMP, projects possible impacts on the cost of production, commodity prices, exports, and imports based upon expenditure made to implement each control measure and clean air benefits. [These impacts were analyzed based on the congestion relief benefit for all the TCMs in the 2012 RTP. Similar impacts based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

REGION'S SHARE OF U.S. JOBS

Table 6-1 shows the impacts of clean air benefits and control measures, as well as their combined impacts on the region's share of national jobs. As the air gets cleaner, the four-county region is predicted to gain a larger share of total national jobs through 2025. The increase ranges from 0.001 percent in 2014 to 0.014 percent in 2023, compared to the baseline projection without the AQMP. A similar trend and magnitude are also observed for the region's share of manufacturing jobs in the nation.

TABLE 6-1
Impacts on Region's Share of U.S. Jobs for
Clean Air Benefits and Control Measures (percent)

	Percent Share of U.S. Jobs for Benefits		Percent Share of U.S. Jobs for All Measures		Percent Share of U.S. Jobs for Combined Benefits & Measures	
	2014	2023	2014	2023	2014	2023
<u>Total Jobs</u>						
With Benefits & Measures*					5.127	4.962
With Benefits*	5.126	4.963				
With All Measures			5.126	4.948		
Without Draft Final 2012 AQMP	5.125	4.949	5.125	4.949	5.125	4.949
Difference	0.001	0.014	0.001	-0.001	0.002	0.013
<u>Manufacturing Jobs</u>						
With Benefits & Measures*					5.654	7.305
With Benefits*	5.656	7.306				
With All Measures			5.654	7.29		
Without Draft Final 2012 AQMP	5.655	7.292	5.655	7.292	5.655	7.292
Difference	0.001	0.014	-0.001	-0.002	-0.001	0.013

Some numbers are rounded.

*Based on all the TCMs in the 2012 RTP.

As investments in infrastructure and pollution control equipment or devices occur in the beginning of a control measure's implementation period (e.g., the year 2014), the region will continue its trend of having a larger share of the total national jobs. However, as the costs of implementing these measures are continually amortized over the project period, fewer jobs would be created, thus resulting in a decrease in the region's share of total jobs and manufacturing jobs in the U.S. (in 2023). The combined impacts of benefits and control measures show that the region's share of the total national jobs would increase by 0.002 percent in 2014 and 0.013 percent in 2023. The region's share of the U.S. manufacturing jobs would drop in 2014 and rise in 2023.

Due to the extremely small values presented here, neither the quantified benefits nor the quantified measures are expected to result in discernible differences in the four-county region's share of national jobs over the analysis period.

COST OF PRODUCTION AND PRICES

The four-county area has the most diversified metropolitan economy in the U.S. Cleaner air will attract more economic migrants into the area. As the mix of labor skills expands, the access to quality labor would have a positive impact on labor productivity, thereby reducing the cost of doing business for local industries. On the other hand, implementation of control measures increases the cost of doing business for affected industries.

Table 6-2 shows the percentage change in relative cost of production as a result of clean air benefits, control measures, and both combined in 2018 and 2023. These two years were chosen because they have relatively higher impacts than other years in the analysis period of 2013-2035. An index of 0 indicates that there is no change in the cost of production relative to the rest of the United States. An index of above or below 0 means that the cost of production in the four-county areas resulting from the Draft 2012 AQMP is higher or lower, respectively, than that in the rest of the U.S.

Most of the industries would experience a reduction in the cost of production due to clean air benefits. The transportation and warehousing industry is projected to experience the highest cost reduction (1.23 percent in 2014 and increase to 2.25 percent in 2023) because of reductions in vehicle hours traveled associated with business trips (Table 3-9). The same sector would also experience the highest increase in the cost of production (0.096 percent) from the implementation of control measures in 2023 because this sector would experience a relatively higher share of the total cost of the Draft [Final](#) Plan (Table 3-1). All the remaining sectors will experience a smaller magnitude of increase in production cost due to the 2012 AQMP control measures. The combined impact of clean air benefits and control measures shows a downward trend in the cost of doing business for the majority of industries.

TABLE 6-2
Impacts on Cost of Production Relative to Those in the Rest of the U.S.
for Clean Air Benefits and Control Measures

Industry	Clean Air Benefits*		Control Measures		Combined Benefits & Measures [±]

*Based on all the TCMs in the 2012 RTP.

Changes in production costs will affect prices of goods produced locally. The relative delivered price of a good is based on its production cost and the transportation cost of delivering the good to where it is consumed or used. The average price of a good at the place of use reflects prices of the good produced locally and imported elsewhere.

Based on the measurement of relative delivered prices in the REMI model, cleaner air is projected to result in lower delivered prices, as shown in Table 6-3. The effect of cleaner air on reducing the production cost in the transportation and warehousing industry is directly transmitted to a lower delivered price in this industry as well (0.96 percent reduction in 2023). Nearly all other industries share the same positive impact, which mirrors the effect of reduction in production cost. As expected, the relative delivered prices will rise as a result of implementing control measures throughout all the industries in the four-county economy. The impact of combined benefits and control measures on the delivered price very much mimics that on the cost of production. The lower cost of production translates to lower delivered prices.

TABLE 6-3
Impacts on Delivered Prices Relative to Those in the Rest of the U.S.
for Clean Air Benefits and Control Measures

*Based on all the TCMs in the 2012 RTP.

IMPORTS AND EXPORTS

Table 6-4 summarizes the overall impact of control measures, benefits, and their combined impacts, respectively, on the region's exports and imports relative to the baseline projections. Cleaner air will increase quality of life for residents, and make the area more attractive to live and more competitive for businesses. As more people migrate to the area, the additional supply of labor would dampen real wage rates, thereby lowering production costs and product prices. As a result, production is projected to rise relative to its baseline condition. Increased production would translate to increases in exports and make the area more self-sufficient, thus able to satisfy the additional demand from local residents and other industries. Part of the demand increase is projected to be fulfilled by increases in imports. The delivered price of products is projected to drop or stay the same.

Implementation of control measures is projected to decrease output (production) in the region as the cost of doing business rises. Demand for additional investments and other goods and services would be satisfied mostly by increases in imports. Demand for goods and services would decline because of the current and carry-over effects of higher product prices resulting from pass-through of additional control costs by affected industries. The

dampened demand would also result in a reduction in imports. Finally, lower production also exerts a negative impact on exports.

The combined benefits and measures are projected to increase demand for products and services as more people are moving into the area. In earlier years, imports would play a bigger role to satisfy the increased demand and there would also be a reduction in exports. As the region adjusts to a larger supply of labor due to migration, output and exports would rise. Overall, the cost of production and the delivered prices would drop or have no change.

It should be noted that the magnitude of all of these directional changes is relatively small when compared with the overall size of the four-county economy. For example, exports are projected to decrease by 0.012 percent of the baseline exports in 2023 resulting from implementing control measures.

TABLE 6-4
Impacts on Imports and Exports for Clean Air Benefits and Control Measures

	Clean Air Benefits**			Control Measures			Benefits & Measures**		
	2014	2023	2030	2014	2023	2030	2014	2023	2030

Cost of Production	NC ₋	-	-	NC ₋	+	+	NC ₋	-	-

A plus or minus sign means that there is an increase or decrease in the value of that economic variable resulting from benefits, measures, or both of the Draft [Final 2012 AQMP](#) relative to the baseline economic activities.

*Includes changes in demand due to changes in control requirements.

**Based on all the TCMs in the 2012 RTP.

NC = No Change

SUMMARY

The Draft [Final Socioeconomic Report](#) examines competitiveness of local industries in four areas: the Basin's share of national jobs, cost of production, relative delivered prices, and exports and imports. [These impacts were analyzed based on the congestion relief benefit for all the TCMs in the 2012 RTP. Similar impacts based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#)

The PM_{2.5} and ozone measures and clean air benefits of the Draft [Final 2012 AQMP](#) are not expected to result in discernible differences in the four-county region's share of national jobs. The impacts on product prices of nearly all the sectors are projected to be less than one percent of their respective baseline indices. The impacts on imports and exports are relatively small as well.

The competitive analysis focuses on the impact on various sectors of the local economy. Individual control measures could result in impacts on individual companies. Competitiveness at the company level will be further considered during individual rulemaking procedures, to the extent feasible.

| The actual effects of the Draft [Final](#) 2012 AQMP (including control measures and benefits) on regional competitiveness could deviate from the projected effects. The analysis assumes that air quality in other regions would remain unchanged. This ignores the fact that competing regions tend to follow the District's lead and adopt control measures with objectives similar to those proposed in the District or at a minimum have some level of control with its consequent costs. For example, a number of eastern states have adopted the California vehicle exhaust standards. To the extent that other regions implement similar air quality controls, the competitiveness edge that the region is projected to command due to increases in amenity from cleaner air would become smaller since other regions would also incur improvements in air quality.

CHAPTER 7

ASSESSMENT OF CEQA ALTERNATIVES

Introduction

Alternative 1—No Project (2007 AQMP)

Alternative 2—Localized PM Control

Alternative 3—Greater Reliance on NO_x Reductions

Alternative 4—PM_{2.5} Strategy Only

Comparison of Socioeconomic Impacts

Summary

INTRODUCTION

The California Environmental Quality Act (CEQA) requires that the District propose alternatives to the Draft [Final](#) 2012 AQMP. These alternatives should include realistic measures to attain the basic objectives of the proposed project and provide the means for evaluating the comparative merits of each alternative. The range of alternatives must be sufficient to permit a reasonable choice but need not include every conceivable project alternative. The CEQA Alternatives to the Draft 2012 AQMP are Alternative 1 (No Project, which is the 2007 AQMP), Alternative 2 (Localized PM Control), Alternative 3 (Greater Reliance on NO_x Reductions), and Alternative 4 (PM_{2.5} Strategy Only). The Draft [Final](#) Socioeconomic Report herein evaluates those alternatives that meet attainment of the air quality standards.

ALTERNATIVE 1—NO PROJECT (2007 AQMP)

Alternative 1 is continuation of the 2007 AQMP. It is assumed that all the short-term emission reduction targets outlined in the 2007 AQMP have been achieved so far. The only remaining measures to be implemented are the black box measures in the Clean Air Act Section 182(e)(5) and three off-road measures for marine vessel engines, locomotives, and recreational boats, as well as one on-road measure on smog check enhancements. According to the CEQA analysis, Alternative 1 will fall short of attaining the PM_{2.5} standard by 2014.

ALTERNATIVE 2—LOCALIZED PM CONTROL

Mira Loma monitoring station in western Riverside County is the only station that violates the federal 24-hour PM_{2.5} standard in the Basin. This alternative targets sources near the station in hopes of bringing the Basin into compliance. Three PM_{2.5} measures are proposed for this purpose and they would be implemented sequentially and only around the Mira Loma area. Control Measure ONRD-04 (Accelerated Retirement of Older On-road Heavy-duty Vehicles) under the Draft [Final](#) Plan will be implemented first, followed by Control Measure BCM-01 (Residential Wood Burning Devices), and Control Measure BCM-04 (Ammonia from Livestock Waste). Compared to the Draft [Final](#) 2012 AQMP, Alternative 2 also excludes Control Measure BCM-02 (Further Reductions from Opening Burning).

In terms of the socioeconomic analysis herein, the cost of Control Measure BCM-01 under Alternative 2 is assumed to be one-half of that under the Draft [Final](#) Plan as fewer and smaller rounds of media campaigns would be launched to alert residents about the high PM_{2.5} days under Alternative 2. The total cost of ONRD-04 would be the same between the Draft [Final](#) Plan and Alternative 2, but the distribution of the cost among sub-regions would vary. Control Measure ONRD-04 is part of the ozone strategy under the Draft [Final](#) Plan and would be implemented across the District. On the other hand, Control Measure ONRD-04 becomes a PM_{2.5} control measure under Alternative 2 with a more focused implementation surrounding the Mira Loma Station area. There are two phases of implementation for Control Measure BCM-04. Technology assessment is proposed for the first phase under the Draft [Final](#) Plan. The cost of reducing ammonia from livestock is proposed for Phase II under Alternative 2. Implementation of Phase I was assumed to have

no costs. The cost of implementing Phase II is projected to be \$2.2 million annually, on average, from 2016 to 2035 and is included in the cost of Alternative 2.

ALTERNATIVE 3—GREATER RELIANCE ON NO_x REDUCTIONS

This alternative relies more heavily on reducing NO_x emissions to achieve the PM_{2.5} standard. Since NO_x is a precursor to both PM_{2.5} and ozone, greater reductions in NO_x emissions would also lead to faster progress toward achieving the ozone standard. Compared to the Draft [Final](#) 2012 AQMP, CEQA Alternative 3 excludes Control Measure BCM-01 (Further Emissions Reductions from Wood Burning Devices), and accelerates the implementation of the CARB's statewide truck and bus regulation from 2014-2022 to 2014-2018 and that of the CARB's in-use off-road diesel vehicle regulation from 2014-2023 to 2014-2018.

ALTERNATIVE 4—PM_{2.5} STRATEGY ONLY

Alternative 4 is the same as the PM_{2.5} strategy portion of the Draft [Final](#) 2012 AQMP, which does not include any ozone measures. Under this alternative, the ozone SIP portion of the 2007 AQMP would not be affected nor would ozone measures be included in the Draft [Final](#) 2012 AQMP.

COMPARISON OF SOCIOECONOMIC IMPACTS

Table 7-1 compares the direct costs, direct air quality benefits related to PM_{2.5} compliance, and job impacts of the Localized PM Control, Greater Reliance on NO_x Reductions, and PM_{2.5} Strategy Only Alternatives to the Draft [Final](#) 2012 AQMP. [The comparisons were based on the congestion relief benefit for all the TCMs in the 2012 RTP. Comparisons based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#) Appendix D has a detailed breakdown of annual costs, clean air benefits, and job impacts for the Draft [Final](#) Plan and alternatives. The No Project Alternative will not attain the PM_{2.5} standard until 2019. As such, the No Project Alternative may not be SIP approvable as it does not attain the standard as expeditiously as practicable. The cost of this alternative includes the cost of the black box and that of some additional ozone measures for compliance with the ozone standard. On the other hand, the Draft [Final](#) 2012 AQMP will meet the PM_{2.5} standard in 2014 and the ozone measures under the Draft [Final](#) 2012 AQMP represent only a partial implementation of the black box. For this reason, the No Project Alternative cannot be meaningfully compared with the Draft [Final](#) 2012 AQMP, as it includes all of the “black box.”

TABLE 7-1
Average Annual (2013-2035) Impacts of AQMP and CEQA Alternatives

CEQA Alternatives*	Costs		PM _{2.5} Benefits**		Jobs for Combined Costs & Benefits**
	Millions of 2005 Dollars	Jobs	Millions of 2005 Dollars	Jobs	
Draft Final 2012 AQMP	\$448	-3,257	\$10,670	42,174	37,043
Alt 2—Localized PM Control	450	-3,334	9,526	37,088	32,104
Alt 3—Greater Reliance on NO _x Reductions	495	-4,715	11,141	44,408	37,709
Alt 4—PM _{2.5} Strategy Only	\$327	-1,620	<\$10,670	<42,174	<37,043

*TCM cost = \$326 million.

**Based on all the TCMs in the 2012 RTP.

Except for the PM_{2.5} Strategy Only Alternative, the costs of the Draft [Final](#) 2012 AQMP, and the Localized PM Control and Greater Reliance on NO_x Reductions Alternatives reflect both the PM_{2.5} compliance strategy and additional ozone measures for a partial implementation of the black box. The clean air benefit in Table 7-1, on the other hand, results from compliance with the PM_{2.5} standard, which includes measures under the PM_{2.5} strategy and ozone measures listed in Table 7-2.

TABLE 7-2
Ozone Measures Included in the PM_{2.5} Benefit Assessment

Measure No.	Title	Draft Final Plan	Alternative 2	Alternative 3
CMB-01	RECLAIM-Phase II	X		
CMB-03	Commercial Space Heating [NO _x]	X	X	X
CTS-01	Architectural Coatings [VOC]	X	X	X
CTS-02	Misc. Coatings, Adhesives, Solvents & Lubricants [VOC]	X	X	X
CTS-03	Mold Release Products	X	X	X
FUG-02	LPG Transfer & Dispensing--Phase II [VOC]	X	X	X
FUG-03	Fugitive VOC Emissions	X	X	X
OFFRD-01	SOON for Construction & Industrial Equipment [NO _x]	X	X	X
OFFRD-02	Freight Locomotives [NO _x , PM _{2.5}]	X	X	X
OFFRD-03	Passenger Locomotives [NO _x , PM _{2.5}]	X	X	X
A1-ON1	Accelerated CARB Truck & Bus Regulation			X
A1-OFF1	Accelerated CARB Off-road Regulation			X

Both the Localized PM Control and Greater Reliance on NO_x Reductions Alternatives have higher costs than the Draft [Final](#) 2012 AQMP and the PM Strategy Only Alternative. The Localized PM Control Alternative has lower benefit than the Draft [Final](#) 2012 AQMP. The PM_{2.5} Strategy Only Alternative has the lowest cost, but would result in fewer benefits than the Draft [Final](#) 2012 AQMP due to the absence of ozone measures.

The Localized PM Control Alternative is projected to have lower air quality benefits than the Draft [Final](#) 2012 AQMP and the Greater Reliance on NOx Reductions Alternative. Both the Localized PM Control and Greater Reliance on NOx Reductions Alternatives will not meet the federal PM_{2.5} standard until 2017. Although benefits may start to occur prior to 2017, it was assumed that in the analysis herein, benefits would not start until 2017. The Greater Reliance on NOx Reductions Alternative would benefit broader areas than the Draft [Final](#) Plan as NOx is more prevalent than PM_{2.5}. Therefore, the Greater Reliance on NOx Reductions Alternative has the highest benefit among all the alternatives. The congestion relief benefit is associated with SCAG’s transportation control measures. These measures do not vary by alternative; therefore, the congestion relief benefit is the same among all the alternatives. Table 7-3 shows the distribution of PM_{2.5} compliance benefits for all the alternatives among different benefit categories.

TABLE 7-3
Average Annual Quantified Benefits by Category by Alternative
(millions of 2005 dollars)

CEQA Alternatives	Total*	Health	Visibility	Congestion Relief*	Material
Draft Final 2012 Plan	\$10,670	\$2,247	\$696	\$7712	\$14
Alt 2—Localized PM Control	9,526	1,370	438	7,712	7
Alt 3—Greater Reliance on NOx Reductions	11,141	2,430	988	7,712	11
Alt 4—PM _{2.5} Strategy Only	<\$10,670	<\$2,247	<\$696	\$7,712	<\$14

**Based on all the TCMs in the 2012 RTP. The sum of individuals may not equal to the total due to rounding.*

SUMMARY

The Draft [Final](#) socioeconomic analysis can affect the selection of alternatives to the proposed Plan as identified in the Environmental Assessment for the Draft [Final](#) 2012 AQMP. In considering whether to adopt the Draft [Final](#) Plan or one of the alternatives, the District Governing Board will seek the best balance of greatest socioeconomic and environmental benefits and least adverse environmental and socioeconomic impacts, while meeting all legal requirements and attaining the NAAQS as expeditiously as practicable.

The No Project Alternative, which is the 2007 AQMP, cannot be meaningfully compared with the Draft [Final](#) Plan since the No Project Alternative would not comply with the PM_{2.5} standard until 2019 and is designed for the compliance of the ozone standard as well while the Draft [Final](#) Plan would comply with the PM_{2.5} standard in 2014 and implement part of the black box.

[The comparisons among all the alternatives were based on the congestion relief benefit for all the TCMs in the 2012 RTP. Comparisons based on the corresponding congestion benefit for the SIP-committed TCMs \(\\$519 million annually\) are in Appendix H—TCM Benefit at 2014 Level.](#) The Localized PM Control and Greater Reliance on NOx Reductions Alternatives would not comply with the PM_{2.5} standard until 2017. Although the Draft [Final](#)

Plan has a higher cost than the PM_{2.5} strategy Only Alternative, the Draft [Final](#) Plan would | have higher benefits due to the co-benefit from the ozone measures.

CHAPTER 8

RECENT REFINEMENTS, UNCERTAINTY, AND FUTURE ACTIONS

Introduction

Recent Refinements

Uncertainty and Caveats

Future Enhancements

INTRODUCTION

The District's socioeconomic analysis has evolved over the years. The Draft [Final](#) Socioeconomic Report for the Draft [Final](#) 2012 AQMP identified key areas for recent refinements. Despite the use of a variety of tools and the inclusion of these refinements in assessing the socioeconomic impacts of the Draft [Final](#) 2012 AQMP, the socioeconomic analysis herein could not address all issues. The assessment of some of these issues requires linking information from multiple fields and using data that is currently unavailable. Overcoming these constraints will require interdisciplinary research, data collection, and a combination of approaches. The District plans to continue to work with the Scientific, Technical and Modeling Peer Review Advisory Group (STMPRAG) and other interested parties to improve its socioeconomic analysis.

Issues that are not addressed in the Draft [Final](#) 2012 AQMP socioeconomic report will be pursued for future AQMP revisions. Described below are recent refinements, uncertainty of the current analysis, and recommended actions for the future.

RECENT REFINEMENTS

Recent refinements to the socioeconomic analysis cover the following areas: benefits and costs of clean air, distributional impacts on sub-regions and industries, and impacts on local competitiveness.

Benefits of Clean Air

The Draft [Final](#) Socioeconomic Report for the Draft [Final](#) 2012 AQMP further refines health benefit assessments for PM_{2.5} through the use of BenMAP. Concentration-response relationships between health effects and PM_{2.5} from recent literature were selected. The adult mortality estimate was based on a study for the Los Angeles Metro Area (Krewski et al., 2009). Compared to the 2007 AQMP, the chronic bronchitis effect of PM_{2.5} was dropped from the analysis while asthma attacks were added. Sensitivity tests were performed to examine adult mortality resulting from PM_{2.5} exposure relative to the federal standard (threshold) as opposed to no concentration (no threshold). More recent research (Kochi et al., 2006) was used for the value of a statistical life. Multiple health functions were employed for a single health effect to arrive at a range of avoided cases and associated monetary values. The health effect of non-fatal heart attacks was expanded from a single study (Peters et al., 2001) in the 2007 AQMP to also include four newer studies.

Distributional Impacts

A finer sub-region geography is used for the cost and benefit analysis herein. The four-county area is now divided into 21 sub-regions. The eastern part of Los Angeles County is split into the east and west San Gabriel Valley. Riverside and San Bernardino Counties now have three sub-regions each to reflect increased economic activities in new developments. Catalina Island is merged with the southwestern beach community in Los Angeles County. The refined geography allows for more detailed analysis of impacts at the community level.

The American Community Survey (ACS) 5-year estimates at the census tract level provide an important pillar for many segments in the analysis herein. Data on race and ethnicity of population presents an important backdrop of the current economy on which the analysis is based upon. Information on households, educational attainment, income, and housing costs was essential for the assessment of visibility and material benefits.

UNCERTAINTY AND CAVEATS

As with any complex analysis, some uncertainty is inherent in the methodology employed. Consequently, caveats need to be applied in interpreting the results. The key areas of uncertainty and caveats in this socioeconomic assessment are in estimating emission reductions, costs, air quality changes, and health benefits, among others.

Data

The cost analysis includes PM_{2.5} and ozone control measures. The former are for the demonstration of meeting the PM_{2.5} federal standard in 2014 and the latter show an interim progress toward meeting the ozone standard.

The projected costs of control measures could differ from the actual costs due to advancement of innovative technologies and unexpected modifications to existing plant structure to accommodate control devices. In the past, the District has worked with the CARB to examine actual costs during rule implementation. On the other hand, achieving the final increment towards attainment might result in higher costs as suggested by the STMPRAG.

The benefit analysis focused on reductions in exposure to PM_{2.5}. The co-benefits from reductions in ozone and nitrogen dioxides are not included. As such, the benefit assessment may be underestimated. The health benefit analysis in this report is limited by the availability of health studies that quantify health effects associated with exposure to various pollutants and their economic valuation. Not all the known adverse health effects caused by air pollution have been quantified. Similarly, not all other clean air benefits such as congestion relief related to personal trips are quantifiable at this time.

Exposure estimates are based on extrapolations to census boundaries. There is uncertainty in how well this captures actual population exposures.

There are several health effects estimates of dose-response functions in the literature for a given health effects. There are uncertainties and variability in these estimates. For example, the premature mortality estimate used in this analysis was taken from a study conducted in Southern California. Using the mortality function from this study gives estimates of premature mortality that are somewhat higher than those based on national multi-city studies.

The rapidly-changing structure of population and workforce in the four-county area makes uncertain the projection of distribution of job impacts in the long run.

Air Quality Models

Air quality modeling used the most current estimates of emissions, prognostic meteorological models, multilayered dispersion platforms (i.e., CMAQ), and sophisticated chemistry modules. Chapter 1 of Appendix V of the Draft [Final](#) 2012 AQMP provides a summary of the impacts of uncertainty for the various inputs and models used in an air quality simulation. The key areas of uncertainty impacting the estimation of future year health benefits arise from emission estimates, model layer structure, boundary specifications, and dispersion assumptions.

REMI Model

The REMI model, which was used to analyze the impacts of the Draft [Final](#) 2012 AQMP, projects possible impacts on jobs, distribution of jobs, income, cost of production, relative delivered prices, exports, and imports based upon cost data for control measures and the benefit data for each effect of clean air. The projections are based on national and local statistics for a cluster of economic actors such as industries and population by age and cohort. These statistics reflect the net changes of all the events on these actors and cannot be segregated into gross changes of individual events.

Due to data limitations the REMI analysis herein does not include permit costs associated with control devices and other costs that may be more applicable to individual facilities. During rule development more detailed industry- or facility-specific socioeconomic analysis will be performed to the extent feasible before the District or CARB adopts a regulation.

Because of cleaner air, economic migrants are willing to move into the Basin in exchange for lower earnings (wage and salary) than otherwise. Currently, there is no systematic approach to evaluating migration of retired persons as they do not belong to the labor force. Therefore, their willingness-to-pay (and non-wage generated income stream) for avoided morbidity and mortality is not accounted for in the migration functions that were used only for economic migrants in the labor force.

The actual effects of the Draft [Final](#) 2012 AQMP on regional competitiveness could deviate from the projected effects of quantified measures and benefits since the analysis assumes that all control costs are "extra" costs when compared to air pollution control costs in other regions, and underestimates the clean air benefits that would increase regional attractiveness. This ignores the fact that competing regions often adopt control measures similar to the District's or at least impose some level of control with additional costs.

FUTURE ENHANCEMENTS

Previous AQMPs have identified actions that would further enhance the ability to quantify and evaluate the benefits and costs of the proposed Plan. This Socioeconomic Report has accomplished several of these actions and identified others for future assessments. Enhancements to this Socioeconomic Report include finer geography for more detailed assessments of distributional impacts, incorporation of new concentration and response health functions for a range of health effects, and greater use of the ACS 5-year estimates from the U.S. Census Bureau.

The following enhancements are recommended for future AQMPs:

- Conduct a review of the District's socioeconomic analysis [to update methods and approaches, as appropriate](#);
- Quantification of uncertainty through sensitivity analysis and/or probabilistic confidence intervals;
- Include the value of a statistical life (VSL) related to health risks in future years of an individual's life and illness-specific VSLs;
- Incorporate health benefits resulting from reductions in air toxic pollutants such as diesel particulates;
- Expand sub-regional analyses to include environmental justice (EJ) areas. These areas may be classified by income or race;
- Evaluate potential social ramifications of migration and job losses;
- Analyze the impact of highly polluted areas on property values and rents and the ensuing impacts on the concentration of lower-income households; ~~and~~
- [Perform a periodic assessment of projections relative to reality to track the performance of various models that are used for socioeconomic analyses; and-](#)
- [Explore scenarios where other regions may adopt controls similar to AQMD's for the competitive analysis.](#)

Furthermore, future enhancements to health benefit assessments would include the impact of exposure to pollutants on life expectancy, differential impacts on various segments of the population, and identification of significant pollutant thresholds.

The socioeconomic analysis will continue to evolve to reflect changes in regulatory structure such as greater reliance on incentive programs and public financing strategy. Building a time series database would enhance the assessment on specific segments of an industry, facilitate the alignment with published governmental statistics, and strengthen the analysis on competitiveness impacts. To this end, future efforts may include the use of different databases to track existing facilities and new facilities, review of inspectors' reports for annotated information on firm turnover and closure, and identification of start-up companies in high tech disciplines.

APPENDIX A

ASSESSMENT METHODOLOGY

Introduction

Costs

Benefits

Other Socioeconomic Impacts

INTRODUCTION

The socioeconomic assessment of the Draft [Final](#) 2012 AQMP is divided into three segments: costs, benefits, and employment and other impacts. The following describes how each segment is assessed.

COSTS

Table A-1 lists the 33 stationary and mobile measures in the Draft [Final](#) 2012 AQMP for PM_{2.5} and ozone strategies, respectively, as well as the average annual costs of each control measure. There are nine PM_{2.5} measures and another 24 ozone measures. Six PM_{2.5} measures were quantified with costs. The remaining PM_{2.5} measures are ongoing programs with no additional projected costs. Two ongoing PM_{2.5} measures are also ozone measures. There is another incentive measure for stationary sources under the ozone strategy. All the mobile measures are voluntary and incentive programs, most of which are quantified.

TABLE A-1
Draft [Final](#) 2012 AQMP Control Measures

Measure No.	Control Measure Title	Average Annual [#]	No Cost Data ^{**}
PM_{2.5} MEASURES

[#]BARCT costs are applied to Phase I and II for three tons per day reductions.

[&]All measures are voluntary/incentive programs.

[#]Millions of 2005 dollars (2013-2035).

^{**}Please refer to Table 6-4 in the 2012 AQMP and respective measures in appendices IV (A) and IV (B) to the 2012 AQMP for additional information on measures without cost data.

Cost data have been developed for each of the 20 control measures listed in Table A-1. Direct costs from complying with the requirements of control measures include capital expenditures on control equipment, annual operating and maintenance costs for the equipment, costs of low-polluting (e.g., reformulated) materials, and potential savings related to new requirements. Investments in transportation projects, their annual operating and maintenance costs, and public funding from various sources such as gasoline and sales taxes are also included. Capital costs are annualized based on a 4 percent real interest rate and the economic life of the equipment or project. Costs from each measure are allocated to the 21 sub-region geography depicted in

Figure A-1 based on emission reductions at a point source or gridded emission reductions (with each grid measured by 16 square kilometers) aggregated to the sub-region level.

FIGURE A-1
21 Sub-region Geography

Cost estimates for SCAG transportation control measures were provided by SCAG. Assumptions from CARB current regulations were used for cost quantification of mobile source measures. Control cost estimates for all other measures were based on information from equipment vendors, raw material manufacturers, and affected industries.

BENEFITS

Better air quality will reduce adverse impacts to human health and building materials, and improve visibility. Some of these effects can be measured and are quantified in monetary terms relative to the baseline “no additional control” scenario for key benchmark years.

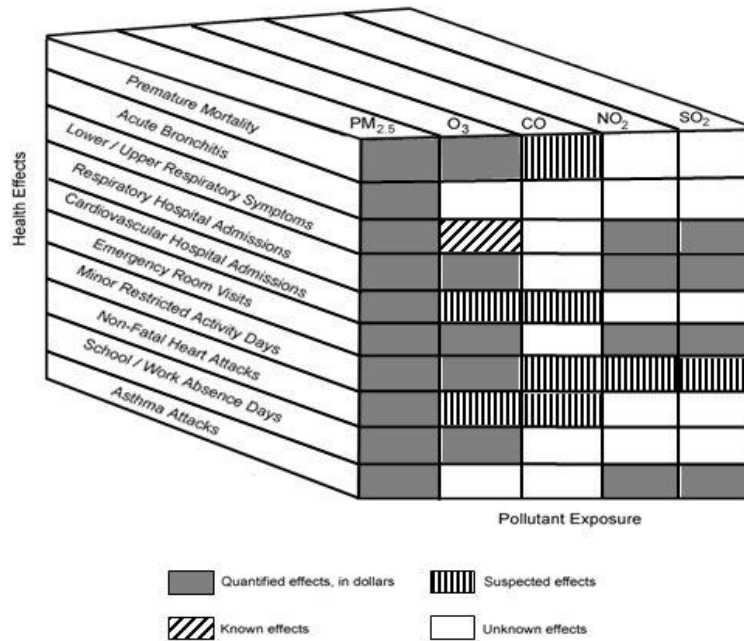

Quantifiable Benefits

The benefits of better air quality in terms of improved human health, reduced damage to building materials, and improved visibility were estimated based on previously published studies. Transportation control measures would improve traffic flow, resulting in reductions in vehicle miles and hours travelled.

Health

Based on numerous published epidemiology studies, observed health effects have been linked with the exposure to ambient PM_{2.5}, ozone, and NO₂. Epidemiology studies use data on the reported incidence of disease and attempt to discern an association with the concentration of ambient air pollutants measured at the time. Figure A-2 shows the correspondence between pollutants and adverse health effects. The greater breadth of the recent epidemiology literature allows for a refined characterization health effects than was possible in the past. A new concentration-response relationship between asthma attacks and and PM_{2.5} has been established. There have also been additional PM_{2.5} mortality studies specific to the Los Angeles area since the 2007 AQMP.

FIGURE A-2
Health Effects of Criteria Pollutants

The health benefit analysis was performed via the U.S. EPA approved BenMAP model (Version 4.0.52), which is an integration of air quality data, epidemiological studies, population and demographic data, and valuation of health effects. The modeling results from the CMAQ Model (Community Multiscale Air Quality Model) were used to show the ambient concentration changes of PM_{2.5} from implementation of PM_{2.5} and ozone measures (see Appendix V of the Draft Final 2012 AQMP). The CMAQ model projects air quality improvements at each grid cell from implementing the Draft [Final](#) 2012 AQMP as compared to the baseline conditions absent such additional control. To estimate health benefits, the results from the CMAQ model were fed into the BenMAP model. The BenMAP model then calculates the increased or decreased exposure of the four-county area's population to PM_{2.5} from the Draft [Final](#) 2012 AQMP, compared to baseline

projections of these pollutants. These comparisons were made for the years 2014 and 2023 for PM_{2.5}, using projected population by age cohort and gender from REMI (adjusted to the SCAG forecast) for 18 sub-regions and demographic distributions between 16 square kilometer grids and census tracts based on the 2010 Census. The projected change in exposure to PM_{2.5} brought about by implementing the Draft [Final](#) 2012 AQMP was then used in the concentration-response functions for changes in specific health effects, including mortality. Finally, dollar values in terms of willingness to pay to avoid a health effect or cost of treating an illness were used to estimate monetary value for health effects. It was assumed that future years beyond 2023 would have the same health benefits as 2023.

It should be noted that reductions in PM_{2.5} and NO_x from control measures would reduce exposure to ozone and NO₂ related health effects.

Visibility

The benefits associated with improved visibility were estimated by using a percentage of the public's willingness to pay for improved visibility as determined through housing prices (Beron et al., 2001). The Beron et al. study was conducted at the census tract level and based on matching housing sales data with air quality data and neighborhood statistics in the 2000 Census in the four-county area. The average willingness to pay per household for visibility improvements reflects the household income net of housing cost, education, and visibility improvements in each tract.

For the Draft [Final](#) 2012 AQMP, the willingness to pay for visibility improvement was calculated at the sub-county region level for the benchmark years 2014, 2023, 2030, and 2035. The empirical visibility models developed for four locations (Rubidoux, Long Beach, Ontario, and Burbank) in the Basin for the 1991 AQMP were used to estimate future year visibility for the 21 sub-regions. Empirical equations that relate visibility to concentrations of visibility reducing particulate chemical species were used. To estimate future year visibility for each sub-region, average sub-regional chemical species concentrations were calculated for sulfate, nitrate, organic and elemental carbon, respectively. The chemical species concentrations for future year base and control scenarios were taken from the results of the CMAQ modeling analysis. The visibility data at the sub-region level for 2014, 2023, and 2030 was developed by summing the multiplication of the predicted PM_{2.5} concentration at each grid by the total light extinction coefficient (in 10⁻⁴m⁻¹) at the nearest airport for that grid across all the grids within a sub-region. The 2035 visibility data was assumed to be the same as the 2030 visibility data. The trend in household income and education between the American Community Survey (ACS) 2005-2009 estimates at the sub-region level was used to develop the values for these two variables for 2014, 2023, 2030, and 2035.¹ The projected number of households at the county level from the SCAG forecast was distributed to sub-regions according to the 2006-2010 ACS household counts for each sub-region to calculate the total willingness to pay for each sub-region.

¹ If the growth rates are negative in a given sub-region between the two periods of ACS estimates, respective county weighted averages were used for trend projections.

The public's willingness to pay as determined through housing prices reflects the value of many benefits including improved health and reduced damage to materials and property as well as improved visibility. In an effort to avoid the double counting of those other benefits and account for the visibility aesthetics only, this analysis attributes only 45 percent of the total willingness to pay factor to visibility. The determination to use a 45 percent factor was based upon a 1994 study prepared by Loehman et al.

Materials

The material benefit assessment was made at the county level and allocated to sub-regions based on the proportions of household counts in various sub-regions in the ACS 2006-2010 estimate. PM_{2.5} concentration data for 2014, 2023, and 2030 at seven locations was used to estimate the decreased costs of repainting wood and stucco (Murray et al., 1985) and cleaning indoor surfaces (Cummings et al., 1985). It was assumed that the 2035 PM_{2.5} concentrations at these stations would be the same as those in 2030. The 4.81 ratio of the total suspended particulate matter (TSP) to PM_{2.5} was used to convert PM_{2.5} to TSP, which was used in the original material benefit assessment by Murray et al. (1985). Reductions in cleaning and repainting costs were assessed for the benchmark years 2014, 2023, 2030, and 2035 based on the projected households that were converted to housing units via the ratio of the two in the ACS 2006-2010 estimate at the county level. Results for interim years were interpolated.

Traffic Congestion Relief

Congestion reduces operating speeds of vehicles, thus resulting in travel delays and increased shipping and storage costs for businesses. Congestion also prevents vehicles from operating under their optimum conditions and thereby increases the operating and maintenance costs of vehicles. Using various studies on congestion costs (SCAG 2004 and Association of Bay Area Governments 2002) and potential reductions in VMT and VHT, congestion benefits in the form of reduced vehicle operating and maintenance expenditures and value of lost time due to the Draft Final 2007 AQMP were assessed at the sub-region level. Data on reductions in VMT and VHT were provided by SCAG.

Unquantifiable Benefits

Full quantification of health effects is hindered by the lack of known quantitative relationships between pollutant concentrations and the incidence of health effects. In some cases, these quantitative relationships may be known, but the air quality data needed to perform the calculations may be uncertain.

Further establishment of relationships between poor air quality and its damages, as well as the measurement of ~~these~~ damages, is key to quantifying the benefits from improved air quality in the areas of plant life, livestock, building materials, and human health effects. Inadequate data does not allow full assessments to be made at this time. Benefit assessments which incorporate only quantified benefits

significantly underestimate the total benefits as a result of implementing the Draft [Final](#) 2012 AQMP.

OTHER SOCIOECONOMIC IMPACTS

The four-county economy will be affected as control measures in the Draft [Final](#) 2012 AQMP are implemented, industries spend resources to comply with new requirements, and transportation infrastructure is built. Implementation of the Draft [Final](#) 2012 AQMP could lead to differential impacts on industries at different times.

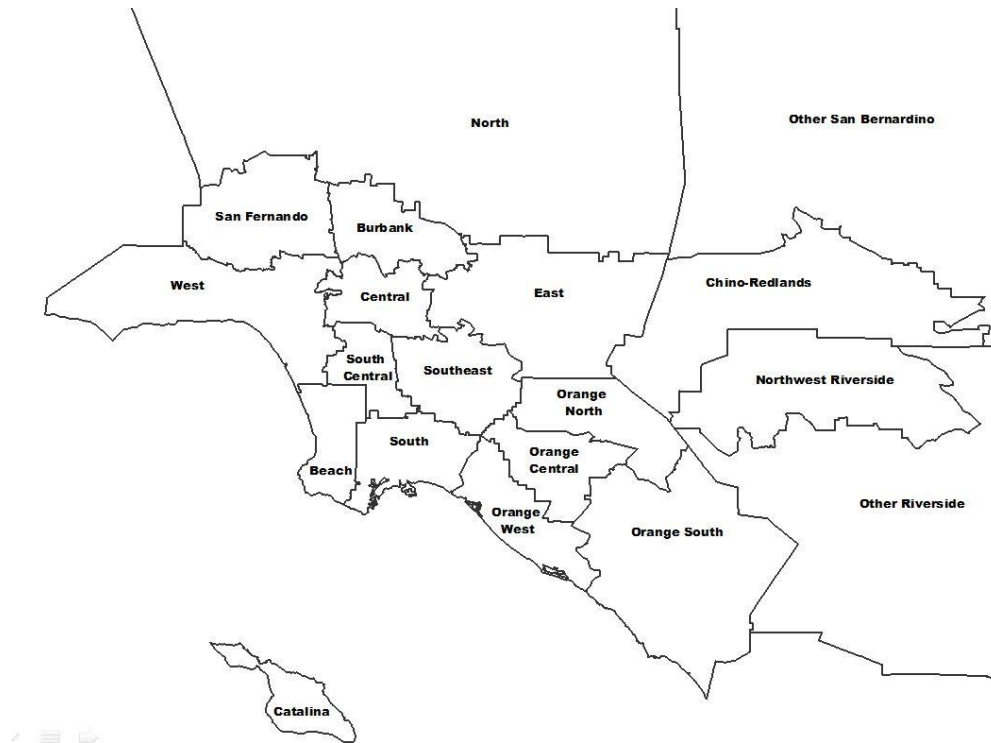

REMI Model

District staff relies on the REMI (Regional Economic Models, Inc.) model to estimate potential employment impacts and other socioeconomic impacts (e.g., product prices, cost of production, and income) of quantified measures and benefits. The REMI model is widely used by the U.S. EPA, CARB, SCAG, other state and local agencies, academicians, and consultants. The REMI model incorporates state-of-the-art modeling techniques and the most recent economic data. The REMI model has been independently evaluated and found to be "technically sound" by the Massachusetts Institute of Technology (Polenske et al., 1992).

The REMI model is built on published data from 1969 to the present with econometrically estimated parameters and can be used to simulate the impact of public policies on the economy of Los Angeles, Orange, Riverside, and San Bernardino Counties. The REMI model allows an assessment of the economic impacts that a policy (such as an AQMP revision or a proposed rule) may cause to each sub-region economy (Figure A-3) for 70 private and public sectors which correspond to three-digit NAICS codes in most cases. The REMI model for the Draft [Final](#) 2012 AQMP combines the San Gabriel Valley East and West into one sub-region, and the San Bernardino City and San Bernardino Southwest areas into another sub-region. The Riverside Southwest and other Riverside areas are combined into one sub-region. Economic impacts include those on jobs, costs of inputs in the production process, personal income, gross regional product, and product prices. A detailed description of the REMI model is provided in Appendix B—The REMI Model.

Impact analyses in the REMI model follow a two-step process. First, the national economic projection provided by the Bureau of Labor Statistics (BLS) is used to determine the local baseline economic forecast without any policy change. Second, the direct costs and benefits of a policy are input to the REMI model to generate an alternative forecast for the local economy with the policy. The difference between the baseline and alternative forecasts gives the total effects of the policy. The baseline forecast is recalibrated to ensure consistency with SCAG's population and employment forecasts. Appendix C—Adjustment of the REMI Control Forecast—provides a detailed description of the recalibration process.

FIGURE A-3
Analysis Domain

The assessment of job and other socioeconomic impacts was performed for all control measures under the PM_{2.5} and ozone strategies, clean air benefits, and PM_{2.5} control measures and associated clean air benefits, respectively.

Input to REMI

To estimate employment impacts from quantified measures, direct costs associated with each of the control measures were utilized as inputs into the model. Implementation costs of measures were distributed in two ways. First, they were distributed to the regulated industries based on the proportion of emission reductions of these industries by geographic location, as proposed in the Draft [Final 2012 AQMP](#). These costs are the additional cost of doing business. Second, these costs are additional sales to industries which supply necessary equipment and services. These sales were assumed to occur where the regulated industries are or where emission reductions would take place. The analysis is performed from the implementation year of a control measure to the year 2035.

In addition to the categories already described, a number of benefits from clean air were quantified and input into the REMI model. These benefits are estimated for those benchmark years when air quality data was available. To provide continuous forecast estimates, estimates for years between benchmark years were interpolated

linearly. Quantifiable benefits include improved visibility, reduced damages to materials and health, and relief from traffic congestion. Visibility improvements and reductions in mortality and morbidity in terms of the willingness to pay and the present value of the future income stream were translated into additional amenities to the four-county area via the migration equation for economic migrants age 65 and below. Reductions in morbidity would lead to reduced health care expenditures by the general public and employers (the cost of illness portion only). It was assumed that 60 percent of the reduced expenditures would benefit the employers as a reduction in the cost of doing business and the remaining 40 percent would flow back to the economy in the form of additional spending on all consumption categories. Congestion relief benefits were input as a decrease in the cost of doing business for the trucking and warehousing industry and a decrease in sales for auto repair services. Better traffic flow would result in reduced demand for transportation services. Consumers were assumed to re-spend the savings from vehicle operation and maintenance on all consumer goods. The congestion relief benefit to the owners of light-duty/passenger vehicles and commuters and the material benefit accrued to residents were translated into additional amenity benefits.

Output from REMI

To assess the impacts on socioeconomic groups, the impacts on product prices identified by the REMI model were overlaid on consumption patterns of various income groups to examine the changes in consumer price indexes of these income groups. The data on consumption patterns are from the Bureau of Labor Statistics' Consumer Expenditure Survey.

To assess the impacts of a policy on the competitiveness of the four-county region, the following factors were evaluated: the region's share of national jobs in those industries whose products are also sold in the national market, the impacts on product prices and cost of production by industry, and the changes in imports and exports. These factors were selected based on a review of effects of past public policies on a region's competitiveness.

APPENDIX B

THE REMI MODEL

Introduction

Framework of the REMI Model

Economic Geography Linkage

Assumptions of the REMI Model

Verification of the Model

Enhancements to the Model

INTRODUCTION

In an effort to expand socioeconomic impact assessments for proposed rules and AQMP revisions, the District has been using a computerized economic model from Regional Economic Models, Inc. (REMI) to assess the socioeconomic impacts on the four-county economy since 1990. The REMI covers the geographic area within the counties of Los Angeles, Orange, Riverside, and San Bernardino. The structure and assumptions of the model are briefly described below.

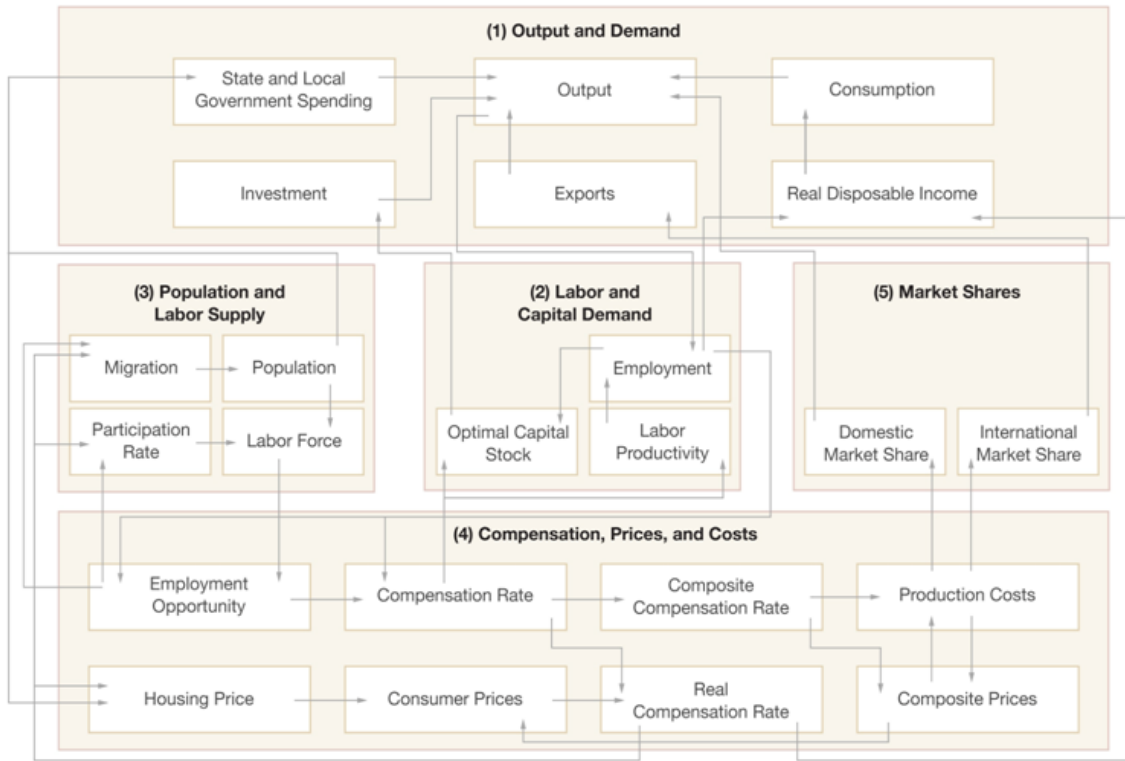

FRAMEWORK OF THE REMI MODEL

The District's REMI model links the economic activities in the counties of Los Angeles, Orange, Riverside, and San Bernardino. The model used for the 2012 AQMP assessment is unique in that each county is further divided to account for the politically, socially, economically, and geographically diversified structure of the Southern California economy. There are 10 sub-county regions in Los Angeles County, four in Orange County, two in Riverside County, and two in San Bernardino County. The divisions of the sub-regions were originally developed in 1996 and have been updated to reflect the 2000 Census.

The REMI model for each sub-region is comprised of a five block structure that includes (1) output and demand, (2) labor and capital, (3) population and labor force, (4) compensation, prices and costs, and (5) market shares. These five blocks are interrelated and the linkages are shown in Figure B-1. Each block is built upon a two-step process. First, producers and consumers throughout all regions of the country are assumed to have similar behavioral characteristics. Because of these similarities, statistical techniques are used to estimate economic responses based on studies performed throughout the U. S. The second step of the modeling process is region specific, and involves calibration of the model based on region-specific historical data.

The standard structure has 66 private non-farm industries (3-digit NAICS), three government sectors and a farm sector, 94 occupations, and 88 final demand sectors. The demographic/migration component captures population changes due to births, deaths, migration, and changes to special population (e.g., prisoners and college students); and has 808 ages/gender/race/ethnicity cohorts. The input-output module contains detailed inter-industry relationships for 403 sectors and is used to assess the detailed inter-industry effect of a policy change. Results from the input-output module are fed through population, price and economic geography equations to produce a complete economic and demographic assessment.

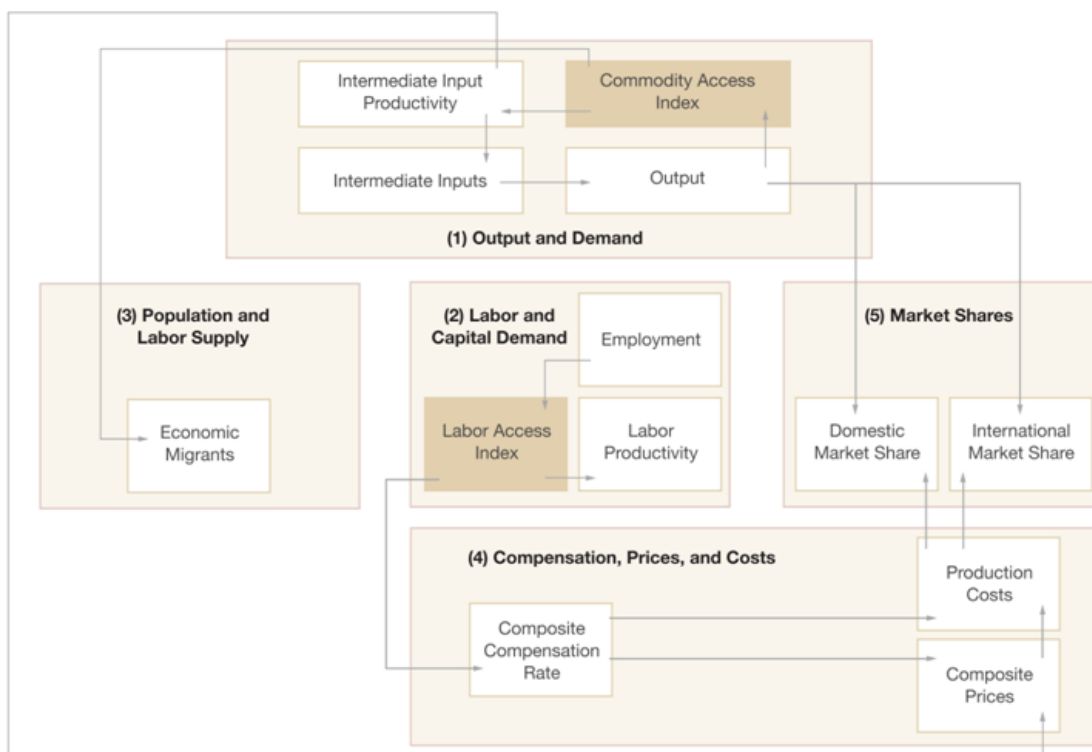

FIGURE B-1
Components of REMI Model

ECONOMIC GEOGRAPHY LINKAGE

The economic geography module (Figure B-2) explains dispersion and agglomeration effects among competing factors in urban and regional economics through two indexes in the model. The commodity index assesses the impact of increased access to intermediate inputs on increased productivity and thus a reduction in production cost. Consumers would benefit as well due to the increased access to goods and services. The labor index captures the positive impact on labor productivity and cost as access to labor with a mix of skills expands. As land price rises and congestion sets in, economic activities tend to disperse.

FIGURE B-2
Economic Geography Linkage

ASSUMPTIONS OF THE REMI MODEL

The REMI model has been built based on well-established economic theory and is updated regularly to incorporate new findings in economic theory and new historical data. Major assumptions behind the REMI model fall into the following three categories: overall, production, and population and labor. The major assumptions behind the REMI model are as follows.

Overall

1. Production costs, such as capital equipment, labor and fuel, are allowed to be substituted based on the changes in relative costs of these inputs to those in the United States. Total production costs are the sum of input costs weighted by their usage.
2. Location of a firm is driven by profitability.
3. All industries sell to both local and national markets. The model calculates the proportions of local demand that an industry can satisfy and its export share. Exports are divided into shipments from one sub-county region to the remaining regions (18 regions altogether) and sales outside of the four counties (Los Angeles, Orange, Riverside, and San Bernardino).

4. The economic geography module accounts for productivity and corresponding price effects due to access to labor and other production inputs. The labor access index (Block 2 in Figure B-2) as well as the nominal wage rate determines the composite wage rate, which, in turn, affects the cost of production along with prices of other inputs. The delivered price of a good or service is based on the cost of the commodity at the production site and the cost of delivering the commodity to the destination place. This price weights the delivered prices from all locations that ship to the home region and is calculated relative to the delivered prices in all other regions.
5. The REMI model consists of exogenous and endogenous economic variables. Values of exogenous variables are determined outside of the model. Exogenous variables are a driving force of change in the regional economy. The resulting changes are reflected in the values of endogenous variables calculated by the model. Therefore, policy changes can be simulated by changing exogenous variables whose values are developed by AQMD staff as input to the REMI model. For example, increases in demand for control equipment due to a rule can be simulated by increasing the sales of the supplier of control equipment. The impact of such a policy change includes changes in employment, among others.
6. There will be two avenues for market expansion. First, as the cost of production decreases, firms become more competitive in the export market and more competitive with imports. Second, markets are assumed to expand as a region's economy grows.

Production

1. Production costs affect regional competitiveness which impacts the shares of local and export markets. As the relative production costs increase, there will be a reduction in the proportion of local demand which can be satisfied locally as imported goods are substituted for local goods.
2. Production levels drive labor demand which interacts with labor supply to determine wage rates. Combined with other production costs, e.g., capital and fuel costs, wages determine relative production costs in the four-county region compared to the rest of the United States.
3. Production levels are determined by the total demand which consists of consumption, investment, government spending, and net exports. Employment is determined by the level of production and labor intensity, i.e., number of employees per unit of production.
4. An increase in demand will increase production by a factor greater than one because of indirect impacts.

Population and Labor

1. There are four types of migrants: international migrants, retired migrants, former military personnel, and economic migrants. These economic migrants are individuals

moving to the region for employment opportunities. They respond to both economic and amenity factors.

2. The demographic section of the model predicts the number of births and deaths that occur in the population. Labor supply is derived from the indigenous labor force and potential job migrants.
3. Labor is segmented by occupation as well as by industry. Employment within an industry is translated to occupation level employment through the use of occupational skill requirements by industry.

VERIFICATION OF THE MODEL

The REMI model for the Southern California geography was independently evaluated by the University of Pittsburgh in 1989 to determine its forecasting and simulation capabilities. The model's performance was judged to meet accepted standards of practice (Cassing and Giarratani, 1992).

ENHANCEMENTS TO THE MODEL

The District's socioeconomic assessment process is an evolving one. The assessment has expanded from impacts on directly affected industries to include employment impacts on all industries with the use of the REMI model. In 1992, enhancements were made to the REMI model to allow the assessment of impacts on different income groups and on low- versus high-wage groups.

Using the nationwide median weekly earnings of full-time workers from the 2010 Bureau of Labor Statistics (BLS) Current Population Survey (CPS), 94 occupations in the REMI model were ranked in ascending order of earnings and divided into five equal (quintile) groups. Table B-1 shows how the 94 civilian occupations were ranked.

TABLE B-1
Ranking of Occupational Earnings

Occupation	Median Weekly Earnings	Quintile Group
Other food preparation and serving related workers	\$352	1
Entertainment attendants and related workers	\$369	1
Cooks and food preparation workers	\$391	1
Other transportation workers	\$393	1
Agricultural workers	\$400	1
Textile, apparel, and furnishings occupations	\$401	1
Food and beverage serving workers	\$405	1
Fishing and hunting workers	\$416	1
Forest, conservation, and logging workers	\$416	1
Other personal care and service workers	\$419	1
Grounds maintenance workers	\$433	1
Building cleaning and pest control workers	\$444	1
Funeral service workers	\$455	1
Personal appearance workers	\$455	1
Nursing, psychiatric, and home health aides	\$457	1
Retail sales workers	\$470	1
Food processing occupations	\$476	1
Material moving occupations	\$495	1
Assemblers and fabricators	\$517	1
Other healthcare support occupations	\$520	2
Helpers, construction trades	\$521	2
Supervisors, food preparation and serving workers	\$522	2
Other protective service workers	\$528	2
Other education, training, and library occupations	\$545	2
Animal care and service workers	\$572	2
Information and record clerks	\$584	2
Woodworkers	\$599	2
Water transportation occupations	\$599	2
Financial clerks	\$601	2
Other production occupations	\$601	2
Communications equipment operators	\$619	2
Other office and administrative support workers	\$621	2
Occupational and physical therapist assistants and aides	\$622	2
Supervisors, personal care and service workers	\$622	2
Printing occupations	\$625	2
Material recording, scheduling, dispatching, and distributing occupations	\$635	2
Transportation, tourism, and lodging attendants	\$640	2

TABLE B-1 (Continued)

Occupation	Median Weekly Earnings	Quintile Group
Secretaries and administrative assistants	\$659	2
Motor vehicle operators	\$661	3
Supervisors, building and grounds cleaning and maintenance workers	\$664	3
Construction trades and related workers	\$675	3
Metal workers and plastic workers	\$694	3
Supervisors, farming, fishing, and forestry workers	\$719	3
Miscellaneous community and social service specialists	\$740	3
Supervisors, transportation and material moving workers	\$743	3
Vehicle and mobile equipment mechanics, installers, and repairers	\$744	3
Supervisors, sales workers	\$749	3
Health technologists and technicians	\$757	3
Supervisors, office and administrative support workers	\$761	3
Other teachers and instructors	\$789	3
Other sales and related workers	\$791	3
Supervisors, production workers	\$800	3
Counselors, Social workers	\$803	3
Legal support workers	\$806	3
Life, physical, and social science technicians	\$820	3
Other installation, maintenance, and repair occupations	\$820	3
Other construction and related workers	\$821	4
Media and communication equipment occupations	\$848	4
Electrical and electronic equipment mechanics, installers, and repairers	\$855	4
Librarians, curators, and archivists	\$863	4
Religious workers	\$878	4
Plant and system operators	\$881	4
Law enforcement workers	\$891	4
Drafters, engineering, and mapping technicians	\$895	4
Sales representatives, services	\$899	4
Art and design occupations	\$912	4
Primary, secondary, and special education teachers	\$918	4
Entertainers and performers, sports and related occupations	\$950	4
Supervisors, construction and extraction workers	\$955	4
First-line supervisors/managers, protective service workers	\$956	4
Media and communication occupations	\$957	4
Sales representatives, wholesale and manufacturing	\$958	4
Supervisors of installation, maintenance, and repair workers	\$964	4
Life scientists	\$968	4
Extraction workers	\$996	4

TABLE B-1 (Continued)

Occupation	Median Weekly Earnings	Quintile Group
Business operations specialists	\$1,027	5
Fire fighting and prevention workers	\$1,044	5
Other healthcare practitioners and technical occupations	\$1,078	5
Financial specialists	\$1,083	5
Health diagnosing and treating practitioners	\$1,092	5
Other management occupations	\$1,125	5
Social scientists and related occupations	\$1,144	5
Postsecondary teachers	\$1,166	5
Architects, surveyors, and cartographers	\$1,209	5
Physical scientists	\$1,225	5
Rail transportation occupations	\$1,234	5
Operations specialties managers	\$1,289	5
Computer specialists	\$1,289	5
Advertising, marketing, promotions, public relations, and sales managers	\$1,300	5
Mathematical science occupations	\$1,339	5
Air transportation occupations	\$1,365	5
Engineers	\$1,381	5
Top executives	\$1,621	5
Lawyers, judges, and related workers	\$1,729	5

The percentage changes of a policy on each quintile of earnings can thus be reported for occupational wage rate, employment, and wage bill.

The Quarterly Census of Employment and Wages (QCEW), formerly ES-202 data (excluding self-employment), from the BLS for the four-county area provides the average annual wage per worker (full-time and part-time) for the 66 private non-farm industries in the REMI model. By ranking the 66 industries in ascending order of average annual wages per worker, we can divide them into five equal groups, as shown in Table B-2:

TABLE B-2
Ranking of Compensation Rates by Sector

Sector	Average Annual Wages	Quintile Group
Private households	\$7,387	1
Real estate	\$11,125	1
Forestry and logging; Fishing, hunting, and trapping	\$14,882	1
Food services and drinking places	\$18,204	1
Personal and laundry services	\$19,147	1
Performing arts and spectator sports	\$19,239	1
Social assistance	\$20,153	1
Agriculture and forestry support activities; Other	\$21,058	1
Amusement, gambling, and recreation	\$21,730	1
Transit and ground passenger transportation	\$23,453	1
Repair and maintenance	\$25,242	1
Retail trade	\$27,135	1
Administrative and support services	\$27,785	1
Accommodation	\$30,897	2
Nursing and residential care facilities	\$31,614	2
Oil and gas extraction	\$32,075	2
Museums, historical sites, zoos, and parks	\$34,177	2
Educational services	\$34,490	2
Rental and leasing services; Lessors of nonfinancial intangible assets	\$35,172	2
Membership associations and organizations	\$37,384	2
Leather and allied product manufacturing	\$37,914	2
Truck transportation; Couriers and messengers	\$37,931	2
Construction	\$39,803	2
Apparel manufacturing	\$40,176	2
Warehousing and storage	\$41,030	2
Textile product mills	\$42,795	2
Furniture and related product manufacturing	\$42,883	3
Wood product manufacturing	\$43,528	3
Food manufacturing	\$47,928	3
Textile mills	\$48,014	3
Printing and related support activities	\$48,941	3
Scenic and sightseeing transportation; support activities	\$50,252	3
Securities, commodity contracts, investments	\$51,548	3
Ambulatory health care services	\$53,143	3
Waste management and remediation services	\$54,920	3
Professional and technical services	\$56,553	3
Plastics and rubber products manufacturing	\$56,879	3

TABLE B-2 (Continued)

Sector	Average Annual Wages	Quintile Group
Fabricated metal product manufacturing	\$57,869	3
Motion picture and sound recording industries	\$59,544	3
Nonmetallic mineral product manufacturing	\$60,007	4
Monetary authorities	\$61,682	4
Hospitals	\$63,453	4
Miscellaneous manufacturing	\$64,847	4
Wholesale trade	\$66,672	4
Insurance carriers and related activities	\$66,838	4
Mining (except oil and gas)	\$68,291	4
Machinery manufacturing	\$70,295	4
Support activities for mining	\$71,093	4
Beverage and tobacco product manufacturing	\$72,929	4
Paper manufacturing	\$73,520	4
Primary metal manufacturing	\$73,525	4
Broadcasting, except Internet; Telecommunications	\$75,030	4
Electrical equipment and appliance manufacturing	\$75,388	5
Air transportation	\$76,238	5
Publishing industries, except Internet	\$76,806	5
Motor vehicle manufacturing	\$77,869	5
Internet services and data processing; Other information services	\$79,517	5
Water transportation	\$80,369	5
Transportation equipment mfg. excl. motor vehicles	\$94,053	5
Rail transportation	\$100,255	5
Chemical manufacturing	\$103,237	5
Computer and electronic product manufacturing	\$104,116	5
Management of companies and enterprises	\$108,279	5
Utilities	\$111,659	5
Pipeline transportation	\$115,724	5
Petroleum and coal products manufacturing	\$151,997	5

The percentage change in employment, wage bill, and wage rate resulting from a policy can thus be reported for each quintile of wages, by sector.

The 2010 Consumer Expenditure Survey (CEX), published by the BLS, provides a continuous flow of information on the buying habits of American households. The CEX reports average annual expenditures and characteristics of households by income group. There are five income groups: from the households earning the top 20 percent of income to those earning the bottom 20 percent of income.

By linking consumption expenditures in the REMI model with spending patterns of the eight income groups in the CEX, we can then develop a composite price change for consumer goods for each income group.

In 1996, the REMI model for the South Coast economy had expanded from a county-based model with four counties to a sub-county model with 19 sub-county regions as Los Angeles and Orange Counties have grown denser and Riverside and San Bernardino Counties have sprawled to accommodate economic migrants. Catalina Island had since been merged with the Los Angeles Beach sub-region. The resulting 18 sub-region geography provided opportunities for the integration of economic and air quality data, resulting in a more balanced outlook of socioeconomic impacts of public policy.

APPENDIX C

**ADJUSTMENT OF THE REMI CONTROL
FORECAST**

The [Draft Final](#) 2012 AQMP uses SCAG's forecasts on population, employment, and other economic variables for future emission projections (Health and Safety Code Section 40460). The REMI model is used in the AQMP to generate a baseline forecast from which the effects of a policy are evaluated. The REMI and SCAG forecasts use different data inputs and assumptions.

The REMI model uses employment data published by the Bureau of Economic Analysis (BEA) while SCAG uses data published by the Bureau of Labor Statistics (BLS). Employment statistics released by the BLS and BEA differ because they contain different data sources and estimation procedures. BLS employment statistics are the product of the Quarterly Census of Employment and Wages (QCEW) Program, which is based on workers covered by the state unemployment insurance (UI) and unemployment compensation for federal employees (UCFE). The BEA data includes more complete coverage of employees who are not covered by the UI and UCFE and uses additional data sources to estimate employment in the farm sector, private households, private elementary and secondary schools, non-profit organizations, and so on. The BEA data is also adjusted to account for misreporting under the UI and UCFE. The BEA data include federal military jobs and a much higher estimate of the self-employed than the BLS data. The self-employed are embedded in the estimates of sectoral employment in the BEA but are listed separately from the sectoral employment in the BLS.

An audit of the District's socioeconomic analysis methods by Massachusetts Institute of Technology recommended further evaluation of the inconsistency between the REMI and SCAG forecasts (Polenske et al., 1992). The District and SCAG commissioned the Center for the Continuing Study of the California Economy (CCSCE, 1994) to determine the sources of inconsistency between these forecasts. The CCSCE recommended a three-step process to ensure consistency between REMI and SCAG forecasts:

- REMI and SCAG should use the same U.S. projections for population and employment;
- REMI and SCAG should use the same birth rates by age cohort; and
- REMI and SCAG models should use similar rates of growth for employment projections.

The 2012 release of the 70-sector REMI model was adjusted in 2012 in preparation for work on the 2012 AQMP. This version of the REMI model has the same U.S. population projections as the SCAG model (Census, 2008). REMI's U.S. employment growth is based on the BLS 2018 employment projection, which is the same data source as SCAG's employment projection. Therefore, no further adjustment to the REMI U.S. forecast is needed.

SCAG's birth rates for four race/ethnicity groups (White, Black, Hispanic, Asian & Other) and eight age cohorts for each of the four counties in a five-year interval were incorporated into the REMI model from 2008 to 2035. The five-year interval fertility rate targets were interpolated for in-between years to ensure smooth birth rate patterns. Birth rates for a particular county were used for its subregions.¹ Specifically, the percentage differences between SCAG and

¹ There are 10 subregions for Los Angeles County, four for Orange County, and two each for Riverside and San Bernardino Counties, respectively, in the REMI model.

REMI's birth rates were calculated and applied to the model using the birth rate variable within the model. The resultant birth rates are within 0.5percent of the target birth rates.

After the above adjustments the REMI and SCAG models continued to display different growth rates of employment. SCAG has employment projections at a higher aggregate industry level than REMI's. Therefore, for each five-year interval (beginning in 2008), employment by REMI industry by sub-region was calculated as a percentage of the total employment of the SCAG industry within that county where the subregions belong. Based on SCAG employment growth rates for each five-year interval, the corresponding REMI target growth rates were derived using the 2008 REMI employment data as a starting point. A trend function was developed to interpolate values for intervening years (2008-2020 and 2020-2035). The annual growth rates by industry by sub-region were entered into REMI using the Employment Update function via a multiplicative adjustment to ensure that the adjusted forecasts reflect SCAG growth rates and are incorporated into the baseline.

Additionally, REMI adjusted the population growth trends using the International Migration variable, which affects the most likely source of discrepancies in demographic estimates within California. Population of each sub-region was calculated as a share of the corresponding county. Based on the 2008 population data and projected 2020 and 2035 REMI population, and population growth rates from SCAG, a county population growth pattern was created. As with the employment adjustment, the 5-year interval population growth targets were linearly interpolated for interim years. The data was entered in a control forecast as changes to the population between 2008 and 2035.

Adjustments to the employment growth rates and population were carried out iteratively to ensure that the percentage change in employment and population for the periods of 2008-2020 and 2020-2035 was consistent between the two models at the county level.

Table C-1 shows the region-wide difference in population between 2008-2020 and 2020-2035 for the unadjusted and adjusted REMI and SCAG forecasts. Table C-2 compares the employment growth rates between the unadjusted and adjusted REMI and SCAG forecasts for the periods of 2008-2020 and 2020-2035. The difference of the employment growth rates of the two forecasts is less than one percentage point for the four-county region.

Table C-1
Unadjusted and Adjusted REMI versus SCAG Population Comparison
(in percent growth rate)

	2008-2020			2020-2035		
	Unadjusted REMI	Adjusted REMI	SCAG	Unadjusted REMI	Adjusted REMI	SCAG

AQMD Responses to Comments from Economists

INTRODUCTION

Several economists have peer-reviewed the District's Draft Socioeconomic Report. Specifically, Professor J.R. DeShazo assisted in reviewing the value of a statistical life used for the PM2.5 mortality assessment. Professor Gloria González-Rivera, Professor Lisa M. Grobar, Professor Emeritus Jane Hall, Mr. Stephen Levy, Professor Paul Ong, Dr. Frederick R. Treyz, and Professor Karen R. Polenske have reviewed the entire Draft report. All of their comments received as of the publication date of the Draft Report are included in their entirety in this appendix.

BIOGRAPHIES

Professor **J.R. DeShazo** is Professor Public Policy, Vice Chair of the Department of Public Policy, and Director of the Luskin Center for Innovation at UCLA. His expertise includes public finance, organizational governance, and the willingness-to-pay for health risk reductions. He has several recent peer-reviewed publications on the willingness-to-pay subject. His other research covers environmental issues such as greenhouse gases and solar power. Professor DeShazo holds a Ph.D. in Urban Planning from Harvard University. He was a Rhodes Scholar while completing his M.Sc. at Oxford University.

Professor **Gloria González-Rivera** is Professor of Economics at the University of California Riverside. Professor González-Rivera is a Fulbright Scholar. Her research focuses on the development of econometric and forecasting methodology with applications in financial markets, volatility forecasting, risk management, and agricultural markets. She is Associate Editor for the International Journal of Forecasting, and has been elected to the Board of Directors of the International Institute of Forecasters. Professor González-Rivera received her Ph.D. in economics from the University of California, San Diego where she wrote her dissertation under the tutelage of 2003 Nobel Laureate Professor Robert F. Engle.

Professor **Lisa M. Grobar** is Professor of Economics at California State University, Long Beach and serves as Director of the CSULB Economic Forecast Project. She is a regional economist with specialization in southern California economy. Dr. Grobar has co-run the annual forecasting conference for the Long Beach economy and southern California counties since 1990. Her recent research focuses on the various sectors in the Long Beach economy, including Long Beach airport, nonprofits, overnight tourism, and downtown Long Beach. Professor Grobar received her Ph.D. in economics from the University of Michigan.

Professor Emeritus **Jane Hall** of California State University, Fullerton has performed extensive research on the economics of regulation and the environment. Her research covers a broad range of topics, including national economic policy, the Asian economic crisis, and the economic costs of pollution. She has conducted studies on the valuation of health effects of ozone and particulates for various regions in California, including southern California, the San Joaquin Valley, and the Bay Area. Professor Hall earned her Ph.D. in energy and resources from the University of California, Berkeley.

Mr. **Stephen Levy** is Director and Senior Economist of the Center for Continuing Study of the California Economy (CCSCE) in Palo Alto. CCSCE provides an independent assessment of economic and demographic trends in California. Mr. Levy works with public institutions and

private companies on various issues (such as long-term planning challenges) related to the California growth trends, including county and sectoral projections. Mr. Levy is the principal author of CCSCE's annual report series on the California economy. Mr. Levy has a master's degree in economics from the Massachusetts Institute of Technology (MIT).

Professor **Paul Ong** is Professor of Urban Planning and Social Welfare at the University of California, Los Angeles. Professor Ong has conducted studies based on sub-county demographic statistics from the census data. The study subjects include differential impacts on race and ethnicity of various events such as job and industry turnover, urban traffic, and other social issues. He served as an advisor to the U.S. Bureau of the Census, the California Department of Social Services, and the California Department of Employment Development. Professor Ong earned his Ph.D. in economics from the University of California, Berkeley.

Dr. **Frederick R. Treyz** is CEO of Regional Economic Models, Inc. (REMI). As CEO of REMI, Dr. Treyz is responsible for research, development, consultation, and management of regional forecasting and policy analyses with clients across U.S. and Europe. During his time as CEO, Dr. Treyz has overseen the annual data update and delivery of over 100 economic models that are used for energy, environmental, economic development, and other policies that affect various economies. Dr. Treyz holds a Ph.D. in Regional Science from the University of Pennsylvania.

Professor **Karen R. Polenske** is Professor of Regional Political Economy and Planning at MIT. She has performed numerous researches on using input-output models for economic impact analyses. Her current research includes comparative analyses of energy use, pollution generation, and industrial-technology options in the People's Republic of China (China), Brazil, and India; and regional implications of fuel use on food security in the United States. She is a past President of the International Input-Output Association. She won the 1996 North American Regional Science Distinguished Scholar Award. Professor Polenske holds a Ph.D. in economics from Harvard University and worked under the tutelage of 1973 Nobel Laureate Professor Wassily W. Leontief.

AQMD RESPONSES TO COMMENTS FROM ECONOMISTS

Table F-1 has a summary of major comments from the peer-review economists and AQMD responses.

TABLE F-1
AQMD Responses to Comments from Peer-Review Economists

Peer Review Economists	Comments	Responses
Professor J. R. DeShazo, UCLA	<ol style="list-style-type: none"> 1. Support Dr. Deck’s recommendation of the value of a statistical life (VSL) estimate based on Kochi et al. (2006). 2. Consider VSLs associated with health risks in future years of a person’s life. 3. Include illness-specific VSLs. 	<ol style="list-style-type: none"> 1. The comment is noted. 2. The recommendation will be one of the future enhancements as indicated on pp. 8-3 to 8-4 in Chapter 8. 3. Please see the response to Comment 2 above.
Professor Gloria Gonzalez-Rivera, UC Riverside	<ol style="list-style-type: none"> 1. Recommend sensitivity analyses for different scenarios and/or the use of probabilistic confidence intervals. 2. Recommend uniformity in table presentation; clarify the concept of job impacts; and include more disaggregated numbers in the presentation of CEQA alternatives. 3. Recommend monitoring of projections from models such as REMI, BenMAP, and CMAQ 4. Report trends for industries other than manufacturing and include more discussions on why other regions are more successful in achieving standards. 	<ol style="list-style-type: none"> 1. Sensitivity analyses performed in the Draft Socioeconomic Report included premature deaths relative to the federal PM_{2.5} standard, avoided cases of non-fatal heart attacks, VHT reduction benefit associated with personal trips, and CEQA alternatives in Chapter 7. Many of the model applications for the clear air benefit assessment were based on peer-reviewed publications where confidence intervals were available for probabilistic models. These publications are cited in the reference section of the Report. The District applications, in many cases, reflect the middle estimates. This recommendation is also listed as one of the future enhancements in Chapter 8. 2. Appendix D has been added to provide annual costs and benefits from 2013 to 2035 for major components of clean air benefits and costs, as well as jobs impacts. An average annual line has been added to the time-series charts in Chapters 3 and 4. A paragraph below Figure 4-1 has been added to clarify the concept of jobs. 3. This recommendation is also listed as one of the future enhancements in Chapter 8. 4. The 1st paragraph on p. 2-5 and the last sentence in the 1st paragraph on p. 2-10 have been added as a result.

**TABLE F-1
(Continued)**

Peer Review Economists	Comments	Responses
Professor Gloria González-Rivera, (cont'd)	5. Add the attractiveness of clean air to high wage earners and provide explanations on why certain sectors in Tables 6-2 and 6-3 in Chapter 6 are more or less impacted.	5. Please see the last sentence in the 1 st paragraph on p. 6-1 and the revised last paragraph on p. 6-2.
Professor Lisa Grobar, Cal State Long Beach	<ol style="list-style-type: none"> 1. Examine possible feedback effects of clean air on population, jobs, and congestion. 2. Check the GDP number of \$768 billion for South Coast in 2010 & include details on regional differences between LA-OR & RS-SB. 3. An average annual job gain of 37,043 from 2013 to 2035 is not an insignificant number in light of the increase in baseline jobs of 90,240. 4. Include leisure trips in the VHT benefit calculation and add it to the total VHT benefit; and provide justifications on why one-half of wage rate was used to monetarily quantify reductions in VHT from commute trips. 5. Include a table showing health benefit by age cohort. Health benefits may benefit low income households more. 	<ol style="list-style-type: none"> 1. The baseline economic forecast provided by SCAG already assumed that the region would continue to make necessary investments in air quality. For this reason, the baseline forecast includes the 2012 AQMP. Please see the discussion on p. 1-6. 2. The \$768 billion number is in 2005 constant dollars. The 2nd paragraph on p. 2-5 noted that there would be differences in regional economies. 3. A paragraph below Figure 4-1 has been added to clarify the concept of job impacts, which is a reference to the difference between two different projections as opposed to baseline jobs in one projection. Also, please refer to the summary section on p. 4-7 for a more refined presentation. 4. On p. 3-14, the District made an attempt to quantify the VHT reduction benefit associated with personal trips. However, the District has elected to present a more conservative estimate for this segment by not including it in the total congestion relief benefit. 5. The 2nd to the last paragraph on p. 3-8 noted that the elderly are more susceptible to premature deaths. Table 2-2 has a distribution of the elderly by sub-region. By and large, health effect functions do not vary by age group except for a few categories. The last two sentences in the 2nd paragraph on p. 3-9 addressed the potential for more benefits to low income households resulting from reductions in morbidity.

TABLE F-1
(Continued)

Peer Review Economists	Comments	Responses
Professor Lisa Grobar, (cont'd)	<p>6. The government sectors would also be beneficiaries of reduced health expenditures. Include more details on simulation methodologies of health benefits in REMI in Chapter 4. Provide citations on the migration functions used to capture the amenity effect.</p> <p>7. Revise the disposable income section to make it more readable. Provide more discussions on Tables 5-5 and 5-6 regarding the lowest earning group and the lowest quintile of households. Also, clarify the significant level of these impacts.</p> <p>8. Include the effect of air pollution on property values & concentration of low-income households in the environmental justice (EJ) analysis.</p>	<p>6. The government sector's beneficiary role in reduced health expenditures is discussed in the footnote on p. 4-3. The 1st paragraph on p. 4-3 has more details on the simulation methodologies of health benefits. Please see the reference section and p. 4-1 for the citation on migration functions.</p> <p>7. The Report has noted the slight differences across different income groups from year to year. Also, in the summary section of Chapter 6, the Report noted the small magnitude of these metrics given the size of South Coast economy and additional analyses may be required during rulemaking when control measures are moved to the rule development phase.</p> <p>8. The recommendation on EJ analysis is included as one of the future enhancements in Chapter 8.</p>
Professor Emeritus Jane Hall, Cal State Fullerton	<p>1. Include benefits to agriculture and horticulture.</p> <p>2. Include ozone-related morbidity and mortality effects.</p> <p>3. Clarify the basis for PM2.5 mortality value (VSL) and specific refinements to the selection of health effects.</p> <p>4. Discuss distributional effects on ethnic group.</p> <p>5. Report distributional impact by sub-region on a per-capita basis.</p>	<p>1. Reductions in damages to plants due to cleaner air are mostly related to ozone. These reductions will be assessed in 2015 when the ozone attainment plan is due.</p> <p>2. See discussions in Paragraph 3 on p. 1-1 and the response to Comment 1 above.</p> <p>3. Please see additional discussions in the 2nd to the last paragraph on p. 3-8 and 2nd to the last paragraph on p. 8-1.</p> <p>4. Due to resource constraints, health effects on ethnic population will be conducted for the next AQMP, as stated in Chapter 8.</p> <p>5. Please see per capita clean air benefit and cost in Table 5-4.</p>

**TABLE F-1
(Continued)**

Peer Review Economists	Comments	Responses
<p>Mr. Steven Levy, CCSCE</p>	<ol style="list-style-type: none"> Request that the District make a comparison between 2007 and 2012 AQMP Socioeconomic Reports because of the differences in major components of costs and benefits. Question the large size of the congestion relief benefit and the small size of the health benefit. Recommend that the District reduce references to REMI model descriptions of the economy; question the District’s description of data sources of SCAG’s population projections; and dispute the District’s characterization of the BEA/BLS employment concepts. 	<ol style="list-style-type: none"> District staff strengthened the discussion of the Draft 2012 AQMP on the 2nd to the last paragraph on p. ES-1, added Footnote 4 on p. 3-2 regarding the relationship between Regional Transportation Plan (RTP) and TCMs, and provided a list of TCMs along with its costs, project life, and funding sources in Appendix E. <u>The magnitude of costs and benefits depends on the emission reductions required to achieve the federal clean air standards. PM_{2.5} levels have improved dramatically over the past two decades. In 2011, both the annual PM_{2.5} standard and the 24-hour PM_{2.5} standard were exceeded at only one air monitoring station, Mira Loma, in northwestern Riverside County. As such, compared with the 2007 AQMP, the 2012 AQMP requires much smaller emission reductions beyond today’s control level in order to achieve the PM_{2.5} standard in 2014, thus leading to smaller costs and benefits than the 2007 AQMP when only non-TCMs are considered.</u> The VMT and VHT data came from the SCAG transportation model as stated in Chapter 3. Assumptions used to calculate the monetary benefit of this segment was described on pp. 3-11 to 3-13. District and SCAG worked closely to verify the validity of VMT and VHT data. The relationship between the VMT and VHT monetary benefits in the Draft socioeconomic report was also supported in the SCAG analysis of its 2012 RTP. <u>The congestion relief benefit in the September 2012 release of the Draft Socioeconomic Report was for all the TCMs in the 2012 RTP. The SIP-committed TCMs in the 2012 AQMP has an estimated benefit of \$519 million annually, which is incorporated in Appendix H.</u> The size of health benefit is reflected by the amount of controls required to attain the federal PM_{2.5} standard, which was discussed in Table 3-1. SCAG uses the BLS employment concept for economic projections. In presenting the economic analysis of the 2012 RTP, SCAG used IMPLAN (https://implan.com/v4/index.php?option=com_multicategories&view=article&id=634:634&Itemid=71) and REMI, both of which are based on the BEA employment concept. Mixing BLS/BEA concepts in one presentation will create inconsistency.

**TABLE F-1
(Continued)**

Peer Review Economists	Comments	Responses
		<p>SCAG uses multiple data sources and procedures to fine-tune its populations and employment projections. The intent of the Report was not to follow all the steps that SCAG had taken, but rather to focus on SCAG’s starting and ending points, which was verified by SCAG staff.</p> <p>For differences between BEA and BLS employment, please refer to http://www.bea.gov/faq/index.cfm?faq_id=104. The major source of the BLS employment statistics is the Quarterly Census of Employment and Wages (QCEW) Program. According to http://www.bls.gov/cew/cewfaq.htm#Q14, “Because the QCEW data is based on an establishment census which counts only filled jobs, it is likely that a multi-job holder will be counted two or more times in QCEW data.” Also refer to http://www.bea.gov/regional/pdf/spi2006/11%20Employment.pdf for the relationship between the BLS and BEA employment statistics.</p>
Mr. Steven Levy (cont’d)	<p>4. Include impacts of the 2012 AQMP on population and unemployment rate.</p> <p>5. Add a caveat on the cost distribution to reflect that costs may be borne by company headquarters located elsewhere.</p> <p>6. Which parts of the AQMP create competitiveness changes?</p>	<p>4. The baseline economic-demographic forecast provided by SCAG assumed that the region would continue to make necessary investments in air quality continuation of federal highway funding that would be necessary for the four-county area to make the infrastructure investments for implementation of the 2012 RTP in order to keep the region competitive nationally and globally. For this reason, the baseline forecast includes-reflects the full implementation of the 2012 AQMPRTP. Please see the discussion on p. 1-6. Population changes are already reflected in the baseline forecast. Job impacts in REMI are job counts, not head counts. The unemployment rate has to be calculated based on head counts.</p> <p>5. Please see Footnote 2 on p. 3-1. In cases where company headquarters (located elsewhere) pay for control costs, the costs in the Report would be more conservative.</p> <p>6. Please refer to pp. A-8 to A-9 in Appendix A, Footnote 2 on p. 4-1, and Footnote 4 on p. 4-3 for the competitiveness impact.</p>

**TABLE F-1
(Continued)**

Peer Review Economists	Comments	Responses
Professor Paul Ong	<ol style="list-style-type: none"> 1. Provide ex post evaluation of REMI projections. 2. Define race and ethnicity used in Chapter 2 and include a discussion on a lag in job recovery after the Great Recession. 3. Transportation mode shifts may reduce congestion relief benefits. 4. Clarify work versus residence site in Table 5-4 5. Discuss why the biggest reduction in relative prices would occur in the transportation and warehousing sector. 6. Expand EJ analysis. 	<ol style="list-style-type: none"> 1. This recommendation is one of the future enhancements, as stated in Chapter 8. 2. The 2nd sentence in the last paragraph on p. 2-1 defines race and ethnicity concepts used to compile estimates in Table 2-1 and Figure 2-1. The lag in job recovery is noted in the 1st paragraph on p. 2-11. 3. <u>TCM and TCM-like projects have led to overall reductions in trips, including very small amount of reductions in transit and non-motorized trips. Thus, potential risk from increases in journey time of other modes is minimal. Additionally, extra wait time or inconvenience due to carpool is considered in mode choice utility equations. Relative to the overall journey time, carpool wait time tends to be relatively small. Finally, the estimated PHT (person hours travelled) reductions from modeling results are higher than the VHT (vehicle hours travelled) reductions. The District will work with SCAG to ascertain whether mode shift impacts were incorporated in its transportation model.</u> 4. Please refer to the last paragraph on work site on p. 5-6. 5. Please refer to the last paragraph on p. 6-2. 6. An EJ analysis of the PM2.5 concentration changes in 2014 is included on pp. 5-3 to 5-4. AQMD staff will continue to explore ways to further enhance the analysis.
Dr. Fred Treyz	<ol style="list-style-type: none"> 1. Include reductions in damage to plants and animals as well as the value of reduced vehicle hours. 	<ol style="list-style-type: none"> 1. Reductions in damages to plants due to cleaner air are mostly related to ozone. These reductions will be assessed in 2015 when the ozone attainment plan is due. The value of reduced vehicle hours is discussed on pp. 3-11 to 3-13.

Memorandum

To: Sue Lieu, PhD, Program Supervisor, Socioeconomic Section
South Coast Air Quality Management District

From: Dr. J.R. DeShazo, Professor and Research Center Director, UCLA

Date: 9/22/2012

Subject: Review of Dr. Leland Deck's Recommendation for the Value of a Statistical Life in the 2012 Air Quality Management Plan Analysis

The South Coast Air Quality Management District (AQMD) wishes to quantify the value of health improvements that individuals receive as a result improved air quality. Individuals may value improved air quality for a variety of reasons. However, the vast majority of the quantifiable benefits come from risk reductions that individuals will experience premature death from air-pollution related illnesses. The approach most frequently used by regulatory agencies, such EPA and DOT to value mortality risk reduction, is to estimate the value of a statistical life (VSL). The AQMD asked Dr. Leland Deck of Stratus Consulting Inc. to review and update the VSL estimate to be used in the 2012 Air Quality Management Plan (AQMP).

The purpose of this memorandum is to review Dr. Deck's recommendation of using the VSL approach and his more specific recommendation of employing an average estimated VSL of \$6,730,000 based on Kochi et al. (2006).

1. Understanding how the Value of Statistical Life (VSL) is constructed

The VSL is constructed by measuring the collective willingness to pay for small risk reductions for large numbers of people. A purely hypothetical example may help to illustrate this. If an air pollution policy reduces the probability of death for a group of a million people from 5 in 1,000,000 \rightarrow 4 in 1,000,000, then we would say that risk reduction of one in a million ($\Delta\Pi = 0.000005 - 0.000004 = 0.000001$). And it saves one "statistical life" with certainty among this group of one million people.

Next, we want to value of the collective risk reduction attributed to this policy. If these 1,000,000 people are each willing to pay \$6 for this policy that reduces the group's statistical risk by one in a million, then we can calculate a VSL of \$6,000,000 (i.e., $\$6 \times 1,000,000$). Critical to this VSL calculation is knowing that, in this hypothetical example, people were willing to pay an average of \$6 in return for a one in million risk reduction. Policy applications of the VSL typically involve one of two cases. In most policy evaluation contexts the VSL is multiplied by an expected overall number of "deaths avoided" to produce an estimate of overall expected benefits.

20 or even 30 years from the present. This period of time before the future health risk would be realized is call the latency period.

One important innovation in VSL studies since the publication of Kochi et al. (2006) has been their ability to accommodate latency and to measure the value of risk reductions in future years of the individuals' lives. The most systematic treatment of latency in VSL is by: Cameron, Trudy Ann and J.R. DeShazo. 2012. "Demand for Health Risk Reductions." Forthcoming. *Journal of Environmental Economics and Management*.

Table 1 below presents the latency results for Cameron and DeShazo (2012a). They explore the effect of illness latency (the time in the current health state before the illness or injury occurs) on *WTP* to avoid health risks for an individual with an assumed 0.05 discount rate, household income of \$42,000 and for whom the lifetime risk is to be reduced from 0.004 to 0.001. In this table, the authors array their five basic examples of different illness profiles across the top of the table. This study estimates the conventional VSL to be about \$6.7 million so it is in line the current literature.

What is interesting is how the latency of the risk incidence effects willingness to pay for risk reductions. In the body of the table, they display sets of mean *WTP* estimates (and 90 percent ranges) for one individual aged 35 now, and for another individual aged 65 now. The age at onset of each illness is varied to include immediate onset, as well as onset at decade intervals starting five years from now.

Focusing first on the current period or "sudden death now" scenario in the first column of Table 1, their point estimates suggest that the 65-year-old has a considerably higher *WTP* (\$5.91)¹ to reduce the risk of sudden death now than the 35-year-old (\$0.72), although the 90 percent intervals overlap. Their results suggest that the sign and size of the difference depends greatly upon the specific age groups that one compares. In looking forward to future illnesses, however, as in the subsequent rows of Table 1, both 35-year-olds and 65-year-olds seem to have a lower *WTP* to avoid the same illness profile when symptoms commence at a later age.

Their selection of disease latency results can be compared to just a small number of extant empirical studies. [Hammitt and Liu \(2004\)](#) find that *WTP* declines at a 1.5 percent annual rate for a twenty-year latency period, while [Hammitt and Haninger \(2010\)](#) (p. 71) find that *WTP* does not vary significantly with latency. From our Table 4, delaying by twenty years the time at which sudden death might occur (from five years to 25 years hence) actually *increases WTP* by 96 percent for 35-year-olds. For 65-year-olds, however, a similar twenty-year delay (postponing the risk of sudden death from five years to 25 years hence) does reduce *WTP*, in this case from \$4.37 to essentially zero (not shown in the table). Comparing these results to the existing empirical literature on latency, [Alberini et al. \(2006\)](#) find that for respondents aged 40 to 60 years, delaying the "time at which the risk reduction occurs" from 10 years to 30 years reduces *WTP* by more than 60 percent in samples from both Canada and the U.S. This may reflect the fact that their youngest respondents are forty years old, whereas ours range down to 25 years of age.

¹ Their micro-risk results can be converted to VSLs by multiplying by 1,000,000.

An entire sub-field within environmental economics is devoted to trying to provide valid and accurate estimates of people's willingness to pay for mortality reductions for use in VSL estimates. Dr. Deck's memo provides a useful review of the history of studies upon which regulators have relied in the past. The EPA's 1997 VSL estimate was based on an average individual willingness to pay of \$7.88 for a one in a million risk reduction for VSL of 7.87 million (2005\$ and 2010Y) (U.S. EPA, 2010). This estimate of willingness to pay came from Viscusi's (1992) survey of 26 studies, including 21 wage hedonic studies, and 5 stated preference (contingent valuation method) studies published between 1974 and 1991.

2. Dr. Deck's recommended VSL

Dr. Deck recommends rejecting the EPA's proposed approach in favor of a meta-analysis performed by Kochi et al. (2006). Dr. Deck argues that the advantages of relying on Kochi et al.'s VSL estimate of \$6,730,000 involve the "simplicity" of choosing only one study, and that it lies in the middle of the other meta VSL estimates. While I do not find these convincing advantages, I do agree with him that it is a well done meta-study and has several advantages over the EPA's approach. First, the Kochi et al. study contains many more published studies. Second, it includes more recent studies that have been able to utilize much better valuation methods and techniques than studies completed before 1991. Third, Kochi et al. includes studies that valued risk reductions from a wider array of health hazards, beyond only workplace injuries which comprised the majority of studies used by EPA.

Thus, if AQMD wants an average VSL estimate based broadly on a set of studies that is both reasonably contemporary, diverse methodologically and diverse across types of mortality risk, the Kochi et al. estimate is a very reasonable choice. This diversity does have a small drawback in that the variance of estimated mean VSL in Kochi et al. is slightly larger and produces slightly wider confidence intervals, which generally is less desirable. However, the study's other noted strengths outweigh this one small less desirable aspect of their VSL estimate.

3. AQMD Plan for coming refinements in health risk valuation

The U.S. EPA is actively grappling with how to better refine its own use of the VSL. In order to help AQMD anticipate some of these changes for the future, I briefly discuss the role of latency in VSL analysis and illness-specific VSLs.

A. Incorporating health risks latencies into VSLs

All of the studies upon which Kochi et al. is based estimate the individuals' willingness to pay for risk reduction in the current period only. For example, wage-risk studies estimate the individuals' willingness to pay to reduce their risk of death during that current year of employment. When AQMD achieves a reduction in air pollution exposures, it benefits some individuals (especially children and elderly) in the current period as well individuals in future years. Indeed, most individuals (children, adults and seniors) benefit by reducing their risk of illness onset in future years of their life. For example, many will benefit from lower risk by avoiding or deferring the onset of respiratory illnesses, heart disease or lung cancer 5, 10,

TABLE 1
 VSL (IN \$MILLIONS) FOR DIFFERENT DISEASE LATENCIES
 (BASE ON TABLE 4. CAMERON AND DESHAZO, 2012)

<i>Illness profile:</i>	1.	2.	3.	4.	5.
<i>Age no; onset</i>	Sudden death	1 years sick, nonfatal	5 years sick, nonfatal	1 year sick, then die	5 years sick, then die
<i>Now 35 years old – symptoms start:</i>					
now	\$ 0.72 (-4.30, 5.92) ^a	\$ 1.92 (-0.29, 4.27)	\$ 2.68 (0.50, 4.89)	\$ 4.47 (-0.13, 9.06)	\$ 9.66 (5.12, 14.86)
at age 40	1.17 (-2.79, 5.14)	1.74 (-0.30, 3.87)	2.42 (0.44, 4.41)	4.07 (0.55, 7.65)	8.49 (4.88, 12.61)
at age 50	1.91 (-0.61, 4.44)	1.38 (-0.26, 3.11)	1.92 (0.35, 3.49)	3.55 (1.52, 5.79)	6.48 (4.46, 8.88)
at age 60	2.30 (0.32, 4.37)	1.06 (-0.17, 2.35)	1.45 (0.34, 2.59)	3.13 (1.46, 5.01)	4.77 (3.22, 6.60)
at age 70	2.19 (0.43, 4.00)	0.77 (-0.05, 1.62)	1.01 (0.33, 1.72)	2.54 (0.87, 4.28)	3.10 (1.67, 4.67)
at age 80	1.40 (0.21, 2.63)	0.47 (0.11, 0.86)	0.60 (0.31, 0.90)	1.42 (0.34, 2.53)	1.04 (0.47, 1.63)
<i>Now 65 years old – symptoms start:</i>					
Now	\$ 5.91 (1.61, 10.24)	\$ 3.83 (1.70, 6.24)	\$ 3.85 (1.77, 6.07)	\$ 3.67 (-0.45, 8.06)	\$ 0.15 (-4.45, 4.52)
at age 70	4.37 (1.40, 7.29)	3.33 (1.42, 5.44)	3.28 (1.51, 5.16)	2.73 (-0.04, 5.45)	-0.05 ^a (-2.98, 2.90)
at age 80	1.73 (-0.07, 3.49)	2.14 (0.86, 3.52)	1.81 (0.77, 2.90)	.98 (-0.51, 2.54)	-0.28 (-1.78, 1.16)

Notes: See notes to Table 2. Assumes discount rate = 0.05, income = \$42,000. Signs of parameter estimates are unconstrained.
^a Negative simulated values of the *WTP* for a micro-risk reduction can be interpreted as zero. Negative values can result when there is a random draw from the fitted distribution of the marginal utility of income that is negative, or for the marginal (dis)utility of an adverse health state that is positive. The quadratic-in-age forms for marginal (dis)utilities of adverse health states also do not preclude negative draws for extreme values of age. To keep the estimation algorithm simple, we do not attempt to impose sign restrictions on the utility parameters (many of which are systematically varying).

B. Illness-specific VSLs

Dr. Deck's proposed approach is to use the average of many studies, most of which focus estimating individual willingness to pay to avoid a current period risk in dying at work. However, reducing individuals' air pollution exposures reduces their risk of dying of respiratory diseases, lung cancers and heart disease. There is no reason to expect that people's willingness to pay to avoid a death on job to be same as their willingness to pay to reduce of risk of dying from one of these three broad types of illnesses.

It should not be surprising that individuals value different illness risk reductions differently. These estimates of *WTP* are simply measures of individuals' inverse demands for different "goods." Each illness represents a different prospective illness profile that involves a sequence of future health states including pre-illness years, sick-years, potential recovered years, and potential lost life-years. Massive strokes or heart attacks and major accidents may involve no morbidity and sudden mortality. In contrast, the vast majority of cancers, heart diseases, respiratory illnesses and other threats, as targeted by health and environmental policies, involve systematically differing health states: the individual's status quo health state before illness onset, some number of partial or whole sick-years, potential recovered/remission years and lost life-years if the illness or injury leads to premature mortality.²

Several authors have estimated specific illness VSLs³, however, the following paper provided the most comprehensive and consistent comparison across illnesses.

Willingness to Pay for Health Risk Reductions: Differences by Type of Illness." (2012 b) T.A. Cameron and J.R. DeShazo. *Journal of Health Economics*.

Cameron and DeShazo (2012) provide estimates of VSLs associated with the prospect of dying from each of eleven major illnesses, plus traffic accidents, using a representative sample of the U.S. population and a common methodological framework. The results are presented below in Table 2.

For illness (respiratory disease, lung cancer and heart disease) that AQMD reduces the risks for, we see is very different magnitude of willingness to pay to reduce those illness specific risks among the U.S. population. These estimates range from a high of \$7.2-\$8.3 million of heart disease and heart attack, to \$3.4 and \$9.6 for lung cancer for non-smokers and smokers respectively and to a low of \$2 million for respiratory disease.

² Inverse demand for a given disease risk will also differ with the individual's ability to mitigate that particular risk as well as perceptions of the timing and size of competing health risks that might strike first.

³ Other researchers have provided single-illness estimates and a few have even valued two or more illnesses within a single study (Ian Savage (1993); James K. Hammitt and Jin-Tan Liu (2004); Sujitra Vassanadumrongdee and Shunji Matsuoka (2005); George Van Houtven et al. (2008)).

Table 2
VSL by Illness Type (Cameron and DeShazo, 2012b)

Disease	WTP by 45-year olds	Weighted average *
Heart Disease/ Heart Attack	\$7.02/\$8.28	
Breast Cancer	8.91	
Prostate Cancer	8.01	
Stroke	7.30	
Colon Cancer	5.03	
Lung Cancer	3.46	} \$5.02
- Smokers	9.07	
Traffic Accidents	1.53	
Skin Cancer	1.12	
Respiratory Disease	2.00	} 3.13
- Smokers	6.06

COMMENTS TO THE DRAFT 2012 AQMP

GENERAL ASSESSMENT

The Draft 2012 AQMP aims to achieve the federal PM_{2.5} standard by 2014 and partially implement state measures towards the 8-hour ozone standard by 2024. The Draft offers a detailed description and evaluation of the costs and benefits associated with the controls and measures to improve air quality in the South Coast Basin, which includes the four counties of Los Angeles, Orange, Riverside, and San Bernardino. In addition, it provides an assessment of the socioeconomic impacts as they relate to the creation/destruction of jobs, competitiveness of the local industries, production costs and production prices, and local imports and exports. Costs and benefits are projected over 22 years from 2013 to 2035.

The District should be praised for a superior execution of such a complex and important mandate. The evaluation of costs and benefits is a difficult exercise because of the inherent uncertainty that is involved in such a long term forecast which, in this particular case, is compounded by the absence of market prices for intangible goods such as human health, visibility, and relief of traffic congestion. Nevertheless, the analysis is sound as it relies on a set of cautious assumptions, state-of-the-art systems such as REMI, BenMAP, and CMAQ, official databases such as Census data, the ACS survey, BEA and BLS data, and access to experts in the local community and academic institutions. The Draft is subject to the limitations imposed by the current research frontier in engineering systems, medical science, and socioeconomic models, and by the current resources to construct extensive data sets. Given the geographical and economic heterogeneity of the Basin, it is noteworthy the effort to assess the economic impacts within a finer geography (21 sub-regions) than that of the county line.

I provide three general recommendations that aim to improve the understanding of projected costs and benefits and the uncertainty of these projections. I will follow with some specific comments for each chapter of the Draft.

R1. Quantification of uncertainty in the projections

The Draft provides estimates of costs and benefits. Since these estimates rely on a set of assumptions, it would be advisable to provide a measure of uncertainty. I would recommend two options: sensitivity analysis or/and probabilistic confidence intervals. With sensitivity analysis, it would be possible to create a set of scenarios. Three scenarios, e.g. conservative, average, liberal, could provide a range of costs and benefits, which is much more informative than a single figure.

1

Gloria González-Rivera
Professor of Economics
University of California, Riverside

September 2012

The benefits of such an approach are the provision of risk in the estimates, the attenuation of biases towards under or overestimated figures, and a better guide for monitoring the estimates over time. When possible, the range of estimates may be reported with a probability statement. This approach may not be feasible for all the components of the evaluation process given the nonlinear nature of the REMI model. However, some intermediate inputs, mainly those that rely in econometric analysis, e.g. MWTP, could be presented in a format such as 90% or 95% confidence intervals.

It seems that the REMI model could be exploited further to provide a range of socioeconomic impacts because the inputs to REMI would be also provided in a range format.

If it is not possible to implement the scenario approach in this Draft because of limited resources and time constraints, I will recommend implementing it in future AQMPs and listing it in the "Future Enhancements" section of the Draft 2012 AQMP.

R2. Time series information and averages

I would recommend providing time series plots from 2013 to 2035 for all the projections in the Draft. Figure 3-2 (Control Cost by Year) and Figure 4-1 (Job Impacts of Clean Air Benefits and Measures) are good examples. Similar figures for quantifiable benefits and other quantifiable impacts will be desirable as they will offer a more complete picture of the projections and an immediate visualization of trends, if any.

I would recommend uniformity in the tables of the Draft. Some tables contain figures for 2014 and 2023, some others add 2030 or 2035. All tables should contain information for the three benchmark years of 2014, 2023, and 2030 (or 2035).

Most tables contain a last column with average annual figures either for costs or benefits or other impacts. The Draft focuses the analysis on these annual averages. However, this average should be interpreted with care for those time series with an obvious trend (downward or upward). In the following figures, Figure 3-2 (downward trend) and Figure 4-1 (upward trend), I have plotted the annual averages provided in the Draft.

Gloria González-Rivera
 Professor of Economics
 University of California, Riverside

September 2012

FIGURE 3-2
 Control Cost by Year*

FIGURE 4-1
 Job Impacts of Clean Air Benefits and Measures

The reported average annual cost is \$448 million and the average annual number of jobs is 37,043. These numbers are not “average” in the statistical sense as they do not represent a measure of central tendency; over the forecasting period, they occur mostly once in time, i.e. the average cost happens in 2019-2020 (omitting the outlier year of 2026), and the average number of jobs happens around 2024. Given the trends in these time series, the costs will be much higher than the provided average before 2019 and much lower after 2020 (with the exception of those in 2026); and the job impact will be much lower than the provided average before 2024 and much larger after 2024. I would recommend explaining the meaning of these averages in the Draft, stating that the presence of trends implies that the reduction in costs or the benefits in job creation will accrue over time according to an estimated average annual growth rate.

September 2012

R.3 Monitoring of the projections

Since the forecasts span a long period of 22 years, it would be advisable to establish a dynamic monitoring mechanism to track the projections every few years. How often will be determined by the resources available but intervals of 2 years seem reasonable. Monitoring will bring more flexibility to the long-term forecast by making it adaptive to the ever-changing macroeconomic conditions, updated data sets, updating of models and econometric estimates, revision of assumptions, and advances in the engineering, medical, and economic sciences.

I would recommend a periodic assessment of the projections provided by the systems, i.e. REMI, BenMAP, and CMAQ models. It would be of interest to track the performance of these systems over time because they are fundamental tools in the analysis of the Draft AQMP. I also recommend including a small section in the Draft commenting on the projections and their corresponding realizations as well as achievements and disappointments of the previous 2007 AQMP.

SPECIFIC COMMENTS PER CHAPTER

Chapter 1. Introduction

Page 1-3. In Figure 1-1, the column for 2008-2012, item 21 should read 2000 and 2010 Census SF Data.

Page 1-4. There is political uncertainty about the future of the ACS survey; the House Budget Bill passed in May 2012 included the elimination of ACS. As a precautionary measure, the District should start thinking about a good substitute for the information provided by ACS.

Chapter 2. Economy and Air Quality

Page 2-1. Report the percentage of the four-county South Coast Basin GDP in relation to California GDP.

Page 2-5. Similar to Figure 2-2, it would be informative to report the trends in the largest industries in the Basin in addition to manufacturing: Real Estate, Government, Retail, and Information.

Page 2-7. The section "Other Economies" is very informative but it begs the question why these areas (Bay Area, San Diego, and Houston) have less severe air quality problems. This section needs more discussion on the differences/similarities among their economies and why they are more successful on achieving the standards of air quality. Roughly, it seems that there are two important factors: population and larger coastal areas (geography and topography). Regression

4

Gloria González-Rivera
Professor of Economics
University of California, Riverside

September 2012

models could help to understand the cross-sectional differences in air quality across different economies.

Page 2-10. In Figure 2-3, it seems that ozone changes stabilized after 1999. Some explanation is needed to understand whether this is somehow a technical barrier, or lack of measures, or unsuccessful initiatives aiming to lower ozone levels.

Page 2-11. In the last paragraph, first line, it should say “..... projected sectoral share of employment for 2020, and 2035.....” (remove 2008).

Chapter 3. Costs and Benefits

I would advise adding commentary on how plausible the assumptions are and whether they are more or less conservative. It will be helpful to explain the assumptions within some context such as standard practice or scientific literature.

Page 3-6. The information in Table 3-3 is too aggregated. I would recommend providing more detail on the large items “Reduction in Mortality” and “Congestion Relief”. These are huge benefits and it is difficult to judge how realistic these figures are. The average benefit over 2014-2035 may not be informative enough if all gains are projected to happen by the end of the forecasting period. Please provide a time series of these benefits to judge the accrual rate over time.

Page 3-10. In Table 3-10, the benefits figure for 2014 (\$948 millions) is not in agreement with the discussion in the chapter. In Chapter 4, page 4-1, the benefits are stated as \$5.95 billion in 2014.

Chapter 4. Employment Effects

Page 4-3. State the projection of total number of jobs from 2013 to 2035 due to clean air benefits. It seems that this figure is around 800,000. The REMI prediction is over 2.4 million net jobs created between 2009 and 2035. Given the actual state of the local and national economy, a figure of 800,000 (30% of REMI prediction) may be a bit optimistic. This is an instance where a range figure will make more sense.

Chapter 5. Impact on Economic Groups and Communities

The information provided in this chapter is too aggregated as it focuses only on average numbers. Please see my recommendation R2. There may be data limitations that preclude a more detailed assessment, if so please state it.

Gloria González-Rivera
Professor of Economics
University of California, Riverside

September 2012

Chapter 6. Impacts on Competitiveness

Clean air has also indirect effects on the quality of the work force. Good air quality will be attractive to highly qualified professionals, which in general are also high wage earners.

Pages 6-3 and 6-4. In Tables 6-2 and 6-3, explain in more detail why the Real Estate, Rental, and Leasing industry will be the most negatively impacted and the Transportation and Warehousing industry the most positively impacted.

Chapter 7. Assessment of CEQA Alternative

The analysis is too aggregated. Time series of impacts, costs, and benefits for each alternative will provide a better comparison among alternatives because we could evaluate intertemporal substitution effects.

Comments on the Draft Socioeconomic Report for the Draft 2012 AQMP
Lisa M. Grobar, Ph. D.
Professor of Economics
California State University, Long Beach

I. General Comments

Page ES-2 of the report outlines the key results, including the annual benefits attributable to the Draft 2012 AQMP. Of the total \$10.7 billion in benefits, \$7.7 billion is attributable to congestion relief, \$2.2 billion is attributable to health impacts, \$0.7 billion is attributable to visibility improvements and \$0.014 billion to reduced damage to materials.

Given the overwhelming importance of the congestion relief estimate, I feel that the report should place more emphasis on the relatively important congestion and health benefits, and less on the relatively unimportant visibility and materials impacts.

For example, the report mentions a number of transportation projects, or transportation control measures (TCMs), embedded in the Draft 2012 AQMP that are designed to reduce congestion, including arterials, grade crossing improvements, high occupancy vehicle lanes, etc. These measures will serve to reduce congestion in the region.

However, one of the anticipated and estimated benefits of the cleaner air that will result from the AQMP will also be faster growth in regional population and jobs, as migration flows respond to the region's improved environment. In Chapter 4, these benefits are quantified as an incremental annual average net gain of 37,043 jobs from 2013-2035, a figure that is not insignificant given that the baseline projection is an annual gain of 90,240 jobs.

It does not appear that the report incorporates the incremental effect that this faster population growth and job growth would have on traffic congestion. Faster population and job growth would feed back into the congestion calculations, reducing the net congestion benefit. It would be interesting to know how much of the benefit might be offset by faster population and job growth in the region. Figure 1-3 on page 1-8 suggests there is not an attempt to capture this feedback effect.

On the other hand, congestion benefits may be significantly understated in the report for several reasons. First, benefits from congestion relief for leisure (or non-business) trips are not included. This seems no more difficult (and the methodologies no more controversial) than the efforts made in the report to estimate the value of improved visibility. I would urge the researchers to try to estimate the value of these benefits and add them to the net total.

Second, the value of reductions in daily vehicle hours traveled for commuting purposes is estimated at an hourly wage of half the average wage rate (EDD). There is no discussion of how this particular value was arrived at – for example, why only half of the average wage, versus the entire average wage? The value of reductions in daily vehicle hours traveled for business trips is estimated at an hourly wage rate of \$21.84 for truck drivers, but certainly there are drivers in many occupations that are driving for business purposes. Why choose that particular wage?

Given the importance of the congestion benefits in this report relative to the total estimated benefits, I think that their measurement deserves more sophisticated analysis and a better justification for the underlying assumptions.

By contrast, the health benefits attributable to the Draft 2012 AQMP are analyzed using sophisticated modeling techniques (the BenMAP model).

One suggestion I have in this area would be to include a table showing the health impacts by age cohort. On page A-5, the report mentions that these calculations were made in the process of generating the report. It might be helpful for policy-makers to see these results as they might, for example, place a higher weight on health benefits to children than for other age groups. An examination of impacts on children might also help to differentiate between some of the alternative measures discussed in Chapter 7.

The report mentions that efforts will be taken in the future to refine the Socioeconomic Report. One enhancement is to expand sub-regional analysis to include environmental justice (EJ) areas classified by income or race. I would suggest a slightly different but related approach. The report could attempt to break out areas of the region that suffer particularly high levels of baseline pollution, and then analyze the benefits of the proposed projects to these areas. These areas will be highly correlated with income, because the high baseline pollution will make these areas less attractive, driving down home values and rents.

An example of this can be found in my research (Grobar (2008))¹, that analyzed the characteristics of the populations residing within 7.5 miles of the 10 largest US container ports. I found that in these “port districts,” poverty and unemployment rates were significantly higher than in the surrounding metropolitan areas. This suggests that the negative externalities generated by the ports, such as pollution and congestion, have driven down property values and rents in these areas so that they attract more low-income households.

This is also likely to be true of the corridors running along the busiest freeways, and other pockets of real estate that are unusually impacted by pollution from other local transportation or manufacturing activities. Once a large set of these areas are identified within the region, the differential impact of projects in the AQMP on these areas could be analyzed.

With regard to Chapter 4:

In this section, the report identifies the two main ways in which cleaner air will generate expanded economic activity in the region. The first is a switch in consumer expenditures from health care (100% local production) to general consumer purchases (which includes expenditures on goods imported into the region). The second is the improved quality of life, which will lead to increased migration into the region, increasing the labor supply and local demand.

Regarding the first channel, I think the discussion in Chapter 4 is incomplete. On page 4-2, it states that “reductions in out-of-pocket health expenditures are used as a proxy for the quality-of-life value of morbidity benefits (reduced illness).” This suggests that the measured impact of health improvements is limited to the reduced out-of-pocket costs that consumers will pay for health care in an environment with better air quality.

However, in the methodology explained in Appendix A on page A-9, the report states that “it was assumed that reductions in morbidity would lead to reduced health care expenditures by the general public and employers. It was assumed that 60 percent of the reduced expenditures would benefit the employers as a reduction

¹ Grobar, L. “The Economic Status of Areas Surrounding Major US Container Ports: Evidence and Policy Issues,” *Growth and Change*, Vol. 29, No. 3, 2008, pp. 497-516.

in the cost of doing business and the remaining 40 percent would flow back to the economy in the form of additional spending on all consumption categories.” If, in fact, this does describe how these impacts are calculated, then the impact to businesses from reduced morbidity should be discussed and explained in Chapter 4.

Another problem is that the report ignores the potential benefits to the government sector resulting from decreased healthcare costs. The National Health Expenditure Accounts break out US health care expenditures by payer. For 2010, total health expenditures were \$2.6 trillion, and these expenditures were made by the following payers²:

Payer	Percent of Total Health Consumption Expenditures
Households	28%
Private Businesses	21%
Federal Government	29%
State & Local Government	16%
Other	6%

Thus, private businesses and the government sectors would be the main beneficiaries of the reduced health care expenditures resulting from reduced morbidity and mortality attributable to cleaner air, whereas the impact on consumers would be relatively small.

Taking this into account, it is likely that the draft report is overestimating the “expenditure switching” impacts of the 2012 AQMP. As federal, state and local governments experience a reduction in health care costs, they could allocate those resources in other ways (for example, increase spending on local education, or on local infrastructure). Thus, employment might be reallocated from one local use (health care) to another (schools).

It is possible that the government might rebate the savings back to taxpayers in the form of a tax cut, which would then cycle back into consumer expenditures.

² Source: <http://www.cms.gov/Research-Statistics-Data-and-Systems/Statistics-Trends-and-Reports/NationalHealthExpendData/Downloads/tables.pdf>

However, if even part of the government savings on health care is reallocated to other local government activities, the result will be a greater net positive impact on jobs than is described in the Draft Socioeconomic Report.

Another interesting issue to explore is the potential impact that this reduction in health care costs could have on different income groups. A study by Holahan and Zedlewski (1992)³ explores this topic. They find that persons in the lowest income deciles devote nearly 20% of cash income to health expenditures, compared to about 8% for persons in the highest income decile. Higher income households consume more health care, but much of their care is paid for by private insurance that is paid for by their employers.

Since this article was published some time ago, these figures may not represent the current reality. But the article does suggest that the burden of household health care expenditures falls disproportionately on the poor. Thus, improvements in air quality that reduce health care spending might be expected to have a progressive impact, by easing the health expenditure burden on poor households.

In terms of the second channel of job benefits stemming from greater migration into the region, the report is short on specifics, even in the methodology appendix. It references “migration functions” used in the generation of the estimates. But these functions are never explained. It would be useful to provide some detail on the way that these functions are constructed, at least in Appendix A.

II. Specific Comments

Page 2-4 For some reason, the report cites a four-county GDP of \$768 billion in 2010, where the BEA is reporting \$845 billion. Perhaps the report is citing an older number for private industries that got slightly revised, because the BEA currently reports private industry GDP at \$762 billion. But given that the text and Table 2-3 report the contribution to the economy of the government sector, it seems that the \$845 billion should be reported as the total GDP.

Also, I get slightly different GDP shares than Table 2-3, possibly for this reason. Based on the latest numbers, the government share should be 10% of GDP, the real estate, rental and leasing share should be 18%, the wholesale share should be 7%,

³ Holahan, J. and S. Zedlewski, “Who Pays for Health Care in the United States? Implications for Health System Reform,” *Inquiry*, Vol. 29, No. 2, (1992), pp. 231-48.

and the accommodation and food services share should be 3%. I'm also wondering why the construction and transportation/warehousing sectors are left off of the table, since employment and output numbers are available for both of these sectors.

In addition, I think it would be useful to break out Table 2-3 into LA-Orange and Riverside-San Bernardino, because the results are quite different. Compared to LA/Orange, the GDP of Riverside-San Bernardino is much more concentrated in areas such as retail, transportation & warehousing, and government, and less concentrated in areas such as real estate renting and leasing, professional/scientific & technical services, and finance.

I find the section of Chapter 2 entitled "Other Economies" to be a bit perplexing. There are a lot numbers presented here, but not much analysis, and I'm not sure what point is trying to be made here. I guess we could conclude that it is reassuring that these other areas also have a high proportion of their workforce in the government sector, although San Diego is a special case with its high proportion of federal government workers.

Otherwise, the distribution of employment is quite different from area to area, and it's not clear how to assess the impact that air quality rules have had on these differences.

Page 5-6 - The discussion about disposable income is difficult to understand, and I would recommend that this segment be re-written for clarity. For example, I think the sentence:

"The decrease in per capita disposable income from cleaner air is because of the higher growth rate of population than that of total real disposable income. "

means to say that real disposable income is growing more slowly than the population. This would imply that the migrants attracted to the region have lower average incomes than the residents in the baseline plan. Why is this the case? Do we know anything about these migrants that would explain this result (perhaps they are younger than the residents in the baseline plan)? I think this section of the report needs to be better explained.

Page 5-8: Here it claims there are no significant differences in impacts expected for high versus low-paying jobs, and that the same is observed for impacts on the price of consumption goods from one household group to another.

Yet in Table 5-5, the lowest earning group suffers a net decline in employment in 2014 while all other groups experience a net gain. This seems to me to be an important difference.

Also, in Table 5-6 the lowest quintile of households (in terms of income) experiences the biggest increase in the price index of consumption goods as a result of the pass-through of additional control costs by industries affected by control measures, more than twice the impact on households in the 4th (next-to the top) quintile.

Perhaps what the authors want to convey is that none of the impacts in Tables 5-5 and 5-6 are significantly large to worry about. If so, they need to make a stronger case for this (at what point would the impacts be large enough to be considered “significant”?)

Page 6-1: This section on regional competitiveness looks at how these benefits and control measures will affect the region’s share of national jobs. It seems like the underlying assumption here is that air quality in the rest of the nation is held constant as regional air quality improves, thus causing an improvement in relative air quality for the region. This relative improvement drives the increase in economic migration into Southern California.

However, the end of the chapter acknowledges the possibility that other regions are moving forward with air pollution controls as well. If this is the case, the benefits to regional competitiveness may be even smaller than those estimated, as air quality will be improving in the rest of the nation as well as in the region. On the plus side, as noted, the extra costs may also have less impact on regional competitiveness because other regions will also be incurring these costs.

To the extent that other regions are implementing similar air quality controls, the impacts on relative competitiveness will be even smaller than those estimated in this chapter.

Page 8-4: I think the idea of trying to identify significant pollution thresholds could potentially be very useful in future modeling. It is likely that some of the impacts being estimated (such as the relationship of economic migration to regional pollution) are not linear. Understanding these thresholds could help policy-makers to better understand the trade-offs between costs and benefits of control measures.

Review of the *Draft Socioeconomic Report* for the Draft 2012 AQMP for the South Coast Air Quality Management District, 17 September 2012, Jane V. Hall, California State University, Fullerton.

In general the draft report is clearly written and presented. Most of the specific questions and comments that follow relate to chapters 3 and 5, which focus, respectively, on expected benefits and distributional impacts.

Specific questions and comments:

1. Page A-3: Since most of the quantifiable benefits of standard attainment are related to human health, it would make more sense to reorder this sentence and list that benefit first. Benefits to agriculture and horticulture should also be listed. (Also page 3-5.)
2. Table 3.3 appears to present results that do not always match those mentioned in the text. This might be the result of some estimates being reported for different years, some for specific years and others for annual averages across the time frame of the analysis.
3. Page 3-9: What does the first sentence mean? I think that it means the benefit was analyzed down to the level of the NAAQS rather than to the level of the stricter state standard. That is, the NAAQS is effectively the threshold. This should be clarified, and if the NAAQS is the threshold, why is that the case?
4. Ozone-related morbidity effects are omitted from the health benefits assessment, which is baffling given that such effects are well documented, can be quantified and impose significant detrimental impacts on exposed populations. No clear explanation for this is given in the Executive Summary, or in chapter 3. Nor is this point discussed in chapter 8 where it might be discussed as a future enhancement. Granted, PM 2.5-related effects are much more significant in economic terms, primarily because of the much larger mortality effect, but the ozone-related effects are not trivial in either economic or human terms. The USEPA 2011 draft RIA for the NAAQS ozone revision can be found at http://www.epa.gov/glo/pdfs/201107_OMBdraft-OzoneRIA.pdf

5. Ozone-related mortality is also omitted. It is possible to justify this based on how small the effect might be, but USEPA now includes this in its RIAs and the NRC report on ozone-related mortality recommended that it be included in benefit analyses. Some mention should be made that this is a potentially important effect, and why it is not included should be explained since it no longer fits into the cannot-be-quantified category. (National Research Council 2008. *Estimating Mortality Risk Reduction and Economic Benefits from Controlling Ozone Air Pollution*. National Academies Press. Washington, DC.)
6. What is the basis for the PM2.5 mortality value? What base value was used and how was it adjusted for income and inflation? I can assume this comes from Deck and Chestnut (2006), since that is the only likely source cited in the references. USEPA has done significant work since then that could be referred to (see point 8 below).
7. Similarly, I am unsure what RR factor was used for mortality, given that Laden et al. (2006) and Jerrett et al. (2005) are cited, but there is no discussion.
8. In line with point 7, was consideration given to using Krewski et al. (2009) which extended the time frame and updated the previous ACS studies? USEPA relied significantly on this in the 2012 RIA of the proposed PM2.5 NAAQS: *Regulatory Impact Analysis for the Proposed Revisions to the National Ambient Air Quality Standards for Particulate Matter* June 2012
http://www.epa.gov/ttn/ecas/regdata/RIAs/PMRIACombinedFile_Bookmarked.pdf
9. As far as I know, the most recent work on ozone and PM2.5-related health benefits in the SoCAB was published in 2011: "Valuing Health Effects: the Case of Ozone and Fine Particles in Southern California," Victor Brajer, Jane Hall, and Frederick Lurmann, 2011, *Contemporary Economic Policy*, 29(4), 524-535, based on a 2008 study *The Benefits of Meeting Federal Clean Air Standards in the South Coast and San Joaquin Air Basins*, 2008, with Victor Brajer and Frederick Lurmann, Institute for Economic and Environmental Studies at California State University Fullerton, research funded by the William and Flora Hewlett Foundation.

There are of course differences between the draft socio-economic assessment of the 2012 AQMP and that study since there are differences in assumptions, base years, etc. Nonetheless it might be useful to be familiar the study since comparisons could be made.

http://business.fullerton.edu/centers/iees/reports/Benefits_of_Meeting_Clean_Air_Standards_11-13-08.pdf

10. Chapter 8 indicates that since the last socioeconomic analysis several new approaches to health benefit assessment have been included, but again it is impossible to figure out what these are precisely, or how they were carried out. Generally, there is more precision in explaining how visibility and travel time benefits were assessed than is the case for health benefits.
11. The discussion and analysis of the potential distributional impacts of the AQMP does not address impacts by ethnic group. This is an important aspect of assessing potential effects on environmental justice and should be addressed. Chapter 8 notes that this is an enhancement to be considered in future assessments, but it would be helpful to include such an assessment sooner.
12. Distributional impacts by sub-region and income levels should also be reported as per-capita values.

SUBJECT: Review of Socioeconomic Report—Part One

The Draft Socioeconomic Report for the draft 2012 Air Quality Management Plan has two principal components:

- An analysis of the draft plan's costs and benefits
- An analysis of the economic impacts of the draft plan

This memo reviews the analysis of costs and benefits. A second memo will address the analysis of economic impacts.

Overview

The estimation of costs and benefits for the draft plan show a large difference between benefits and costs with the benefits much higher than the costs.

The cost-benefit analysis is comprehensive given the tools available to the District and should be the primary tool for assessing the overall impact of the plan on residents and the economy within the South Coast Air Quality Management District.

The economic impacts discussed in the second memo are small relative to the size of the economy (usually much less than 1%) and can guide the District in understanding how the plan affects jobs and income within different parts of the region and for different groups.

I have two principal recommendations for revising the discussion of costs and benefits of the draft 2012 AQMP:

- Include a discussion of the differences between the final 2007 socioeconomic report and the draft 2012 findings since the differences are

quite large for some components of costs and benefits. Explain the reasons for these differences.

- Provide a more complete discussion of how the SCAG Regional Transportation Plan (RTP) was used in the socioeconomic analysis including which components of the plan are included as TCMs in the socioeconomic analysis and how the cost estimates were developed. Collaborate with SCAG to ensure that the socioeconomic analysis of transportation measures is consistent with SCAG plans and findings.

Estimation of Total Costs and Benefits

Although both the 2007 Socioeconomic Report and the draft 2012 Socioeconomic Report show a large margin of total benefits to total costs, the composition of costs and benefits are quite different between analyses of the 2007 and 2012 AQMPs. The overall results are compared below after which I pose a number of questions seeking clarification of the methodologies and results.

Plan Costs

From the 2012 draft report:

The average annual control cost of all PM_{2.5} and ozone control measures is projected to be approximately \$448 million from 2013 to 2035, of which TCMs have an annualized cost of \$326 million.

From the 2007 report

The cost for implementing the Plan was estimated for both quantified and unquantified measures. The projected cost for 33 quantified short-term measures is approximately \$1.8 billion per year. Transportation control measures alone account for 24 percent of the total quantified cost. The cost of unquantified measures is projected to be approximately \$523 million per year.

This seems like a large difference in annual costs. Moreover, in the 2012 analysis the transportation control measures (TCMs) account for 73% of the annual costs while in the 2007 plan they account for 24% of quantified costs.

Are these cost differences the result of 2007 plan measures that have been adopted already, a difference in discounting the costs or the base year for converting to constant dollars or differences in cost estimation methodology.

TCM Costs

The SCAG Regional Transportation Plan identifies costs of \$524.7 billion or approximately \$21 billion per year while the draft report identifies \$326 million per year. The draft says that the TCMs include “large infrastructure projects”. If that is true, how can the annual costs be so much lower than the SCAG estimate even if one accounts for discounting into constant 2005 dollars?

Is it possible that the AQMD analysis did not include all of the TCM costs on the theory that they will not be paid directly by region residents and businesses? If so, that should be disclosed so readers can assess the reasonableness of such an assumption. This is an important area to relate to assumptions made by SCAG in developing cost estimates for their RTP.

It would be helpful to see a list of the SCAG RTP projects that were considered as relevant TCMs in the cost analysis. The gap between \$326 million and \$21 billion per year requires some explanation. Which parts of the SCAG RTP are included in the AQMP control measures and which are excluded and what are the relative costs.

Distribution of Costs

I would note more clearly in reference to Table 3-1 on annual costs by industry that in nearly all cases, the AQMP costs are less than one tenth of one percent of total industry costs. In addition I would add a caveat to the estimation of costs by county or sub-region. The methodology appears to allocate costs according to where facilities reducing emissions are located. Yet, many facilities are owned by companies headquartered elsewhere and the costs may not come directly from anyone in the county where the facility is located. As a result, I am not sure the geographical allocation of costs makes much sense to pursue as a socioeconomic indicator.

Plan Benefits

From the 2012 report:

TABLE 3-3
 Quantifiable Benefits of Draft 2012 AQMP
 (millions of 2005 dollars)

Benefit	Average Annual (2014 to 2035)
Reduction in Morbidity	\$23
Reduction in Mortality	2,225
Visibility Improvement	696
Reduced Materials Expenditures	14
Congestion Relief	7,712
Total	\$10,670

From the 2007 socioeconomic report:

The 2007 Plan is projected to comply with the federal PM_{2.5} and ozone standards with a quantified average annual benefit of \$14.6 billion between 2007 and 2025. The \$14.6 billion includes approximately \$9.8 billion for averted illness and higher survival rates, \$3.6 billion for visibility improvements, \$966 million for congestion relief, \$204 million for reduced damage to materials, and \$18 million for increased crop yields.

The overall magnitude of annual benefits (\$10.7 billion versus \$14.6 billion is somewhat similar **but the composition of total benefits between the 2007 and 2012 plan analyses is markedly different.**

The 2007 annual health benefits were estimated at \$9.8 billion compared to \$2.2 billion in the 2012 analysis while the congestion relief benefits were estimated at \$966 million per year in 2007 compared to \$7.7 billion per year in the 2012 analysis.

The report provides an excellent explanation of how the 2012 health benefits were derived. What were the changes in methodology or other factors that account for the much smaller annual benefit estimates in the current AQMP analysis?

Congestion Relief Benefits

The report provides a good explanation of how congestion relief benefits were calculated. They are the result of reduced driving (fewer vehicle miles traveled) and time savings from reduced congestion delays.

In the year 2014 an estimated \$161 million of savings on vehicle operation and maintenance is expected, as shown in Table 3-8. By the year 2035, the estimated savings would rise to \$739 million.

The operating and maintenance costs for passenger and light duty vehicles were assumed to be 19.6¢ per mile (AAA, 2012). Operating and maintenance costs for medium-duty and heavy-duty trucks were assumed to be 61¢ per mile (ATRI, 2011).

TABLE 3-8
Reduced Vehicle Operating and Maintenance Costs by Type of Vehicle
(millions of 2005 dollars)

Type of Vehicle	2014	2020	2035	Average Annual (2014-2035)
Autos	\$130	523	901	598
Trucks	31	123	212	141
Total	161	646	1,113	739

Daily VHT reductions associated with commute trips were multiplied by an annual conversion rate of 250 and an hourly wage rate of \$10.78, which is half of the average wage rate (EDD, 2012), to arrive at the annual benefit of spending less time on commuting. Daily VHT reductions from business trips were also multiplied by an annual conversion rate of 250 and an hourly wage rate of \$21.84 for truck drivers (ATRI, 2011) to arrive at the annual benefit from VHT reductions for business trips. Savings from reduced travel time for business and commute trips is estimated at \$358 million for 2014 and at \$13.8 billion for 2035, respectively, as shown in Table 3-9.

TABLE 3-9
Savings from Reduced Travel Time by Trip Type
(millions of 2005 dollars)

Type of Trip	2014	2020	2035	Average Annual (2014-2035)
Business	\$59	\$657	\$2,291	\$1,156
Commute	299	3,305	11,529	5,817
Total	\$358	\$3,962	\$13,820	\$6,973

I have several questions with regard to these estimates.

- Can the District and SCAG be more specific about what measures create the reductions in VMT and VHT? Is it infrastructure investment, people switching from driving to transit, more people living closer to work as a result of land use policies or other factors?
- The savings from VHT reduction are much larger than the savings from VMT reduction. What is the cause of these differences in terms of TCMs and/or behavior change?
- The congestion relief benefits (\$7.7 billion per year on average) are quite large compared to the estimated annual costs (\$326 million per year). Can you provide more explanation as to why this is so and why the ratios are so much different than in the 2007 analysis?

Four Final Thoughts

I would place the summary at the beginning of each chapter. The summaries are well written and help readers focus on the important results. Often large amounts of each section address impacts that are very small in relation to the size of the region. But the summaries focus attention on the big picture results.

In all relevant chapters I would strengthen the use of SCAG forecasts and findings. In many ways the AQMP rests on the SCAG economic and demographic forecasts and, in the case of costs and benefits, on the SCAG Regional Transportation Plan and Sustainable Communities Strategy.

Approximately 40% of the RTP funding is not in place currently. Although the SCAG RTP identifies potential sources for these funds as in Table 2 of the RTP executive summary, there is some uncertainty regarding these funds and I suggest including this uncertainty in the list of AQMP caveat and uncertainties, particularly since the congestion relief benefits are such a large portion of overall draft plan benefits.

I would consider addressing benefits before costs and perhaps placing Table 3-1 in an appendix or at the end of the chapter.

FROM: Stephen Levy
SUBJECT: Review of Draft Socioeconomic Report—Part Two

This memo focuses on the analysis of economic impacts discussed in Chapters 4, 5 and 6 and the issues in describing the economy between REMI and SCAG discussed in Chapter 2 and Appendix C.

Overview

I suggest major revisions to the framing of the economic impact findings and revisions to individual chapters.

My areas of concern at the big picture level are:

- Most reported impacts are tiny in comparison to the size of the economy, especially when you consider we are talking about impacts in 10 to 25 years from now. While in some cases impacts are compared to the size of the economy, this is not true consistently throughout the report. If you look carefully in the text (but not found in the executive summary) you can find that total changes in job levels from the AQMP are approximately .4% of the regional job total.

The negligible impact on the overall economy is the principal finding of the AQMP socioeconomic analysis as it was for AB 32 and the economic impact analysis by CCS of SCAG's emission reduction policies.

In addition the draft is clear in places that the REMI theory of added jobs is that they will induce population growth, which will also be tiny if you show the numbers. It is implicit but never stated that these jobs will not reduce unemployment or raise real income. In this context the 37,000 added jobs are even tinier. Read the discussion later in the memo about the report's disposable income findings.

1

Finally, there is a possible inconsistency between the job impact analysis of the 2012 RTP (174,500 jobs on average) and the socioeconomic report estimate. Is it true that the socioeconomic analysis included only approximately 25% of the RTP costs? I recommend that the District and SCAG discuss a consistent narrative about job impacts.

- The narrative goes back and forth between how SCAG describes the economy and how the REMI model describes the economy. Since the SCAG growth rates are used by AQMD and the SCAG actual job estimates and forecasts are used in the RTP analysis, which is the critical component of benefits and costs, using any REMI numbers to describe the economy is confusing and potentially misleading. I would sharply reduce any references to REMI model descriptions of the economy or forecast growth, especially since the REMI definition of jobs is not only different and confusing in the report context but basically out of sync with how other organizations describe the number of jobs.

See the discussion below of Chapter 2 and Appendix C.

- The discussion of the baseline is confusing. I believe the REMI baseline is the REMI forecast adjusted to reflect the SCAG growth forecast. Is that correct? And then the impacts of the AQMP would be the difference between if the control measures are adopted and if not—is this correct? On the other hand, I believe the position of the draft is that the SCAG growth forecast anticipated and incorporated the RTP and AQMP. Is this correct?

So, what exactly does it mean that the plan “creates” 37,000 jobs? Is this more than SCAG forecast or would it be less than the SCAG forecast if the plan were not adopted?

But the real challenge is that everything is **tiny at the aggregate regional level** and the report does not help readers to that conclusion. Moreover, the net benefits are also tiny compared to regional GDP which will be over \$1.5 trillion by 2035.

- There are a number of small mistakes and inconsistencies that, while they do not change any of the major findings, could damage the credibility of the report.

Now I go chapter by chapter.

Chapter 4 on Employment Impacts

It took me four times to read this paragraph below at the beginning of the chapter to see that the last date here was 2023, not 2035, and that is why both the benefit and cost estimates were different from the average annual estimates reported in Chapter 3. It is a confusing and perhaps unnecessary paragraph.

Implementation of the Draft 2012 AQMP will reduce morbidity and mortality; improve visibility; decrease expenditures on household cleaning and refurbishing building surfaces; and provide relief to congestion, as discussed in Chapter 3. The total quantifiable benefit of the Draft 2012 AQMP amounts to approximately \$5.95 billion in 2014 and \$9.1 billion in 2023. The PM_{2.5} and ozone measures would result in an annual cost of approximately \$510 million in 2014 and \$357 million in 2023. Both benefits and costs will affect the employment base in the four-county economy.

I would find a way to add a column for the percentage change in job levels in each time period. Is there some reason why you are not showing 2035 on Table 4-1 below?

Job Impacts of Quantified Clean Air Benefits and Measures			
Category	2014	2023	Average Annual
Clean Air Benefits & Measures (2013-2035)	2,988	28,187	37,043
Clean Air Benefits (2014-2035)	2,262	30,146	42,174
Congestion Relief	348	20,371	32,986
Visibility Improvements	1,008	5,313	4,947
Reduced Materials Expenditures	133	191	179
Health Benefits	774	4,146	3,910
Control Measures (2013-2035)	731	-1,929	-3,257
TCMs	715	537	-1,611
District PM _{2.5}	7	-10	-4
Ozone Strategy	26	-2,457	-1,639

Results from modeling all the categories are slightly different from the sum of results from modeling each category one at a time because of nonlinearity of the REMI model.

This paragraph from 4-3 will be confusing to readers trying to reconcile the AQMD reports to published SCAG growth forecasts.

According to the REMI baseline forecast (adjusted to reflect SCAG projections) there would be 11.5 million jobs in 2035 in the four-county area. There would be over 2.4 million net jobs created between 2009 and 2035 with an annual rate of growth at 0.92 percent.

When this summary section gets cleaned up, I would place it at the beginning of the chapter as I would with all summary sections.

It is important to note that the 90,240 jobs per year are NOT equivalent to the 37,043 jobs annually. The 90,240 jobs per year are cumulative while the 37,043

are not. A careful reader could figure this out from the comparison of growth rates but otherwise it is confusing since 37,043 looks like a big jump from 90,240.

Is there a way to turn the paragraph into a table? Again I don't like the reference to REMI's 11.5 million jobs. I would use the SCAG growth forecast numbers. While you have to use the REMI framework for analysis using their model, you do not have to use their numbers in the narrative.

Finally, at some point you should have a table that shows the population change associated with the job change. The draft mentions increased migration several times but never that I saw quantifies the population change. That would also be a good place to include the unemployment rate.

Without the 2012 AQMP, jobs in the four-county area are projected to grow at an annual rate of about 0.922 percent between 2009 and 2035, which would be approximately 90,240 jobs per year. Clean air benefits and control measures would result in a net gain of 37,043 jobs annually, which translates to an increase in the annual job growth rate by 0.033 percent relative to the baseline projected growth rate between 2009 and 2035. Cleaner air from the 2012 AQMP would result in an additional 42,714 jobs created per year. This would increase the job growth rate by 0.034 percent and bring it to an annual rate of 0.96 percent from 2009 to 2035. On the other hand, the quantified measures would result in 3,257 jobs forgone, thereby slowing down the job growth rate by 0.001 percent, to 0.921 percent. The four-county region is projected to have 11.5 million jobs in 2035. The jobs created from clean air benefits would amount to 0.4 percent of the baseline jobs, on average. The jobs forgone from control measures would be 0.03 percent of the baseline jobs, on average.

Chapter 5 on the Allocation of Economic Impacts to Communities and Groups.

In my opinion this chapter is misleading by not reminding readers that the impacts discussed are small compared to relevant regional totals. The draft takes pages and pages to disaggregate small numbers into even smaller numbers. See below for suggestions on how to clarify the relative magnitude of numbers.

TABLE 5-1
Cost Share by Sub-region for Control Measures

Sub-Region	PM _{2.5} Measures		Ozone Measures		All Measures	
	Millions \$	%	Millions \$	%	Millions \$	%
LA CO Beach & Catalina	\$16	5%	\$12	10%	\$28	6%
LA CO Burbank	16	5%	3	3%	19	4%
LA CO Central	32	10%	7	6%	39	9%
LA CO North	18	5%	4	3%	22	5%
LA CO San Fernando	32	10%	7	6%	39	9%
LA CO SG Valley East	17	5%	4	3%	21	5%

4

LA CO SG Valley West	26	8%	5	4%	31	7%
LA CO South	23	7%	7	6%	30	7%
LA CO South Central	26	8%	5	4%	32	7%
LA CO Southeast	32	10%	7	6%	39	9%
LA CO West	23	7%	5	4%	29	6%
Orange Central	16	5%	7	6%	23	5%
Orange North	8	2%	4	3%	11	3%
Orange South	15	5%	6	5%	21	5%
Orange West	12	4%	5	4%	17	4%
Northwest Riverside	3	1%	8	6%	11	2%
Other Riverside	3	1%	4	3%	7	2%
Southwest Riverside	2	1%	4	4%	7	2%
San Bernardino City	3	1%	8	7%	11	2%
Other San Bernardino	2	1%	3	3%	5	1%
Southwest San Bernardino	2	1%	6	5%	8	2%
Total	\$327	100%	\$122	100%	\$448	100%

On the cost allocation to industry tables in Chapter 3, the draft helpfully adds a column that shows the impacts as a percent of total output. A similar column would be personal income of each sub-region.

I don't think the allocation of costs using the methodology in the text is either helpful or accurate. On the other hand the allocation of benefits by sub-region makes some sense.

If you are committed to publishing these numbers I would add a % of baseline jobs column to table 5-4.

I find the discussion of disposable income counterintuitive and confusing. At the very minimum if it is true, it wipes out any rationale for mentioning job gains as if they were a positive factor.

IMPACTS ON Disposable Income

Without the Draft 2012 AQMP, real disposable income is projected to grow at an annual rate of 2.245 percent between 2009 and 2035.¹ Clean air benefits of the Draft AQMP could bring the annual growth rate to 2.281 percent. Per capita real disposable income (total real disposable income divided by population) would decrease by \$891 in 2035 relative to the baseline projection. On the other hand, the PM2.5 and ozone measures would lower the projected growth rate of the real disposable income slightly to 2.244 percent annually relative to the baseline projection in 2035. This would result in a minor increase in per capita real disposable income by \$8 in 2035.

The decrease in per capita disposable income from cleaner air is because of the higher growth rate of population than that of total real disposable income. The annual population growth rate from 2009 to 2035 is projected to be 0.9 percent with clean air benefits alone as opposed to the baseline annual growth rate of 0.792 percent. Implementation of quantified control measures is projected to decrease the annual population growth rate to 0.79 percent.

Let's start with the population. I recommend a table that supports the final paragraph. I confirm that going from 16.9 million residents in 2008 to 20.9 million in 2035 is a 0.790% average annual growth rate (the 0.792% figure must use unrounded numbers??). So what is the population growth related to clean air benefits alone that gets you to .9%? I get 21.3 million people in 2035 to reach this percentage. Are you arguing that the approximately 120,000 added jobs in 2035 raise the population by 433,000 residents? That seems large.

I see the implication on population of the clean air measures and from the control measures but do not see the population impact of both combined. I really think a table would help that includes the 2035 population and 2008-2035 growth rates.

Then I would want to see and have explained why this relatively small increase in average population (probably less than 100,000 given the ratio of 2 people per job) would outweigh the gain in real disposable income.

For now the report is saying 1) there are net benefits, 2) there are small job increases and then 3) real income goes down. Is that really true?

The price index section illustrates the challenge of giving some context to the results. The first problem is that without a table it is hard to see how the two components—clean air benefit impacts and control measure impacts—add up. The paragraph starts by saying reduced prices then goes to increased prices. A table would help and the overall conclusion should be stated first and then the two components broken out.

But the real problem is that these are just difficult numbers to read without an example. For example, if an iPad cost \$500, then a .06 percent increase would increase the cost to \$500.30.

The change here is relative to the baseline index of consumption goods. The price of consumption goods is projected to decrease by 0.007 percent in 2014 across all household income groups and by 0.013 to 0.028 percent in 2023 due to the attainment of the PM_{2.5} standard. Implementation of control measures is projected to increase the price of consumption goods from 0.039 to 0.06 percent for these same years across all household income groups. All household groups would experience increases in prices of consumption goods resulting from combined impacts of control measures and clean air benefits. The projected increase in the price is due to the pass-through of additional control costs by industries that are affected by a number of control measures.

Before I do the competitiveness chapter, I want to review Chapter 2 and Appendix C as the report does not accurately characterize the differences between the SCAG and REMI forecasts and methodology.

Appendix C

The statement below is not accurate and will affect some other parts of the report such as the first table in Chapter 6.

This version of the REMI model has the same U.S. population projections as the SCAG model (Census, 2008). REMI’s U.S. employment growth is based on the BLS 2018 employment projection, which is the same data source as SCAG’s employment projection. Therefore, no further adjustment to the REMI U.S. forecast is needed.

SCAG did not use Census 2008 population while REMI did and, as a result, the initial forecast U.S. job levels in 2035 are not the same. SCAG used lower U.S. immigration and population projections, a result confirmed by Dowell Myers in newly released U.S. population projections based on the 2010 Census and lower immigration trends than were included in the 2008 Census baseline.

The statement below is technically not accurate but the important message is that most of the difference between the SCAG/BLS/EDD estimates and REMI job estimates are in the estimate of self employed.

The BEA data include federal military jobs and a much higher estimate of the self-employed than the BLS data.

This is technically inaccurate because the number of self employed people is not much, if any, higher in the REMI forecast but, rather, the number of Schedule C, form 1040 jobs per person is higher. If the number of self employed were higher in the REMI forecast, than the unemployment rate would be lower and the labor force participation rates would be higher—all of which is not true.

Here is another point.

Below are the adjustment tables from Appendix C. I believe the adjustment was done in accordance with CCSCE earlier suggestions but do note the large differences in pre-adjustment growth rates for population and employment. These would be worth discussing so if anyone asks, the District could have a better answer than “that’s what the models show”.

Table C-1
Unadjusted and Adjusted REMI versus SCAG Population Comparison
(in percent growth rate)

	2008-2020	2020-2035

	Unadjusted REMI	Adjusted REMI	SCAG	Unadjusted REMI	Adjusted REMI	SCAG
Los Angeles	8.60%	6.80%	6.40%	10.30%	9.10%	9.10%
Orange	13.50%	9.50%	9.30%	13.60%	5.00%	4.60%
Riverside	28.70%	23.50%	23.00%	22.90%	29.10%	29.20%
San Bernardino	11.50%	12.90%	13.20%	13.40%	20.60%	20.50%
4-County Total	12.30%	10.10%	9.80%	13.10%	12.50%	12.60%

TABLE C-2
Unadjusted and Adjusted REMI versus SCAG Employment Comparison
(in percent growth rate)

	2008-2020			2020-2035		
	Unadjusted REMI	Adjusted REMI	SCAG	Unadjusted REMI	Adjusted REMI	SCAG
Los Angeles	17.70%	5.30%	5.00%	13.90%	6.20%	5.90%
Orange	18.70%	0.10%	0.10%	14.90%	8.80%	9.40%
Riverside	24.20%	39.10%	40.20%	20.60%	33.20%	32.80%
San Bernardino	16.30%	17.20%	16.90%	14.60%	28.60%	29.30%
4-County Total	18.40%	8.40%	8.20%	14.80%	12.10%	12.20%

Now part of the answer is that REMI began with higher U.S. growth rates, which brings us to the first table in Chapter 6.

Chapter 6 on Competitiveness

There are two important positive contributions of the chapter. The first is the sentence below, which in my opinion, should be replicated throughout the report as in the executive summary and employment chapters.

Due to the extremely small values presented here, neither the quantified benefits nor the quantified measures are expected to result in discernible differences in the four-county region's share of national jobs over the analysis period.

The second contribution is

The actual effects of the Draft 2012 AQMP (including control measures and benefits) on regional competitiveness could deviate from the projected effects. First, the analysis assumes that all control costs are "extra" costs when compared to air pollution control costs in other regions. This ignores the fact that competing regions tend to follow the District's lead and adopt control measures with objectives similar to those proposed in the District or at a minimum have some level of control with its consequent costs. For example, a number of eastern states have adopted the California vehicle exhaust

standards. The Draft Socioeconomic Report underestimates the benefits from clean air that would increase regional attractiveness.

As in other chapters, the summary would be more helpful at the front.

Let's look now to Table 6-1. REMI has the region losing a share of national jobs.

SCAG has the region gaining a share of national jobs from 5.16% in 2010 to approximately 5.30% in 2035. This is just another example of why the REMI numbers should not be used in the report. In addition in the SCAG forecast manufacturing jobs rise from 5.6% of the national total to 5.7%. However the increase in the REMI forecast seems strange particularly since they have the regional share of total jobs declining. I don't think whether Imperial or Ventura counties are in or out will affect the results.

TABLE 6-1
Impacts on Region's Share of U.S. Jobs for
Clean Air Benefits and Control Measures (percent)

	Percent Share of U.S. Jobs for Benefits		Percent Share of U.S. Jobs for All Measures		Percent Share of U.S. Jobs for Combined Benefits & Measures	
	2014	2023	2014	2023	2014	2023
<u>Total Jobs</u>						
With Benefits & Measures					5.127	4.962
With Benefits	5.126	4.963				
With All Measures			5.126	4.948		
Without Draft 2012 AQMP	5.125	4.949	5.125	4.949	5.125	4.949
Difference	0.001	0.014	0.001	-0.001	0.002	0.013
<u>Manufacturing Jobs</u>						
With Benefits & Measures					5.654	7.305
With Benefits	5.656	7.306				
With All Measures			5.654	7.29		
Without Draft 2012 AQMP	5.655	7.292	5.655	7.292	5.655	7.292
Difference	0.001	0.014	-0.001	-0.002	-0.001	0.013

Some numbers are rounded.

I don't understand why the year 2035 never appears on tables and 2023 is usually the end date.

I don't understand the discussion of delivered prices. Are you arguing that the AQMP will reduce imports and therefore reduce the cost of goods sold in the region?

I would think the statement below might be controversial statement and might need some more explanation.

The combined impact of clean air benefits and control measures shows a downward trend in the cost of doing businesses for the majority of industries.

How does table 6-3 relate to the earlier table (5-6) on price impacts?

Finally, I could use more explanation of exactly what parts of the AQMP create competitiveness changes. For example, what is the relative weight of visibility impacts, congestion relief and control measure costs?

Chapter 2

You start out fine citing EDD, not REMI estimates of wage and salary jobs.

Los Angeles, Orange, Riverside, and San Bernardino Counties collectively constitute one of the largest regional economies in the United States. The jurisdiction of the SCAQMD includes all or the majority of the populated portions of these four counties. In 2010, the four-county area's gross domestic product (GDP) was \$768 billion (2005 dollars), which was 5.9 percent of the nation's gross domestic product (U. S. BEA, 2012). These counties had 17.1 million people in 2010, which was 45.8 percent of California's total population or 5.5 percent of the U.S. population. In addition, there were 6.3 million wage and salary workers in the four-county area in 2011, a 44 percent share of the state's total wage and salary workforce (EDD, 2012b).

There are numerous examples of potential confusion with the use of REMI job estimates and forecasts as opposed to the EDD/BLS data used by SCAG and every other major forecasting firm.

I understand the need to use REMI data to do the impact analysis but I recommend using plain vanilla SCAG/EDD/BLS data to describe the job base in the region.

More than 8.9 million jobs supported the \$768 billion GDP in 2010. The sectors that had the highest shares of jobs were government (12 percent), retail trade (10 percent), health care and social assistance (10 percent), professional, scientific, and technical services (8 percent), manufacturing (7 percent), accommodation and food services (7 percent), and administrative and waste management services (7 percent).

The paragraph below is good and would be helpful in clarifying and interpreting the baseline and resulting changes in job levels.

SCAG projections (which form the baseline projections for the Draft 2012 AQMP) assumed that the four-county area would continue making the necessary infrastructure investments in air quality and transportation improvements to keep it competitive nationally and globally. For this reason, SCAG projections reflect the full implementation of the 2012 RTP and the necessary air quality programs that would be in compliance with the federal Clean Air Act (CAA). In other words, the baseline forecast does not represent a scenario of no further air quality control regulations or programs beyond what is already adopted, or the potential consequences of not meeting the federal air quality standard (e.g., 2 to 1 offset ratio for new and modified major sources and withheld highway funding under the CAA).

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

Evaluation of
“DRAFT SOCIOECONOMIC REPORT
FOR THE DRAFT 2012 AQMP”

Consulting Report For
South Coast Air Quality Management District

Paul Ong with assistance from Jonathan Ong¹

Ong and Associates Consulting

September 17, 2012

¹ Jonathan Ong extracted, assembled, verified and analyzed the data for Part III (Example of EJ Analysis), and contributed to the final writing of the report.

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

Introduction

This report presents an assessment of “Draft Socioeconomic Report for the Draft 2012 AQMP,” dated September 2012 and prepared by the South Coast Air Quality Management District (a.k.a. AQMD or District). For the purpose of this report, the District’s draft will be referred as the DRAFT. The evaluation is conducted by Paul Ong, who has been contracted as a private consultant. Dr. Ong is a professor at UCLA’s School of Public Affairs, trained as an economist and urban planner, and an expert on the study of socioeconomic inequality. He previously contributed to the District’s socioeconomic analysis and served on several AQMD advisory committees. The author is solely responsible for all analyses, interpretations and opinions, and retains intellectual ownership of the ideas. As a product funded by a public agency, the content of this report is considered to be in the public domain. Due to limited resources and time, the assessment is not comprehensive. Instead, it focuses on key points identified by the by the author, with a focus on issues related to environmental justice.

AQMD is commended for conducting an extensive socioeconomic analysis of its 2012 Air Quality Management Plan (AQMP or Plan). The Plan will have significant impacts, and it is critically important to estimate the costs and benefits to the region’s people and economy. It is equally important to estimate how those outcomes are distributed among groups of stakeholders, economic sectors and communities. The Plan is judged to achieve a greater degree of economic efficiency when the benefits outweigh costs, and this is achieved mainly by promoting collective action that reduces environmental externalities. The Plan projects a sizeable monetized net gain. Some estimates of individual components are problematic and perhaps overly optimistic, particularly regarding the benefit from congestion relief, which will be discussed later. Despite these potential flaws, the author’s opinion is that the Plan would produce an overall improvement.

The distributional outcomes, however, are less obvious because AQMD’s socioeconomic analysis has severe limitations in addressing equity. This is particularly true in the analysis of environmental justice (EJ), which revolves around environmental inequality along racial and economic lines, and policies and programs to redress differential burden. AQMD has made marginal improvements since 1989, but failed to incorporate analytical advances in the field, leading to an incomplete and imprecise EJ evaluation of the potential future impacts of AQMP.

The remainder of this report is divided into three parts. Part I contains general feedback in the form of comments, questions and recommendations on points identified by the author as being problematic, ambiguous or in need of further work. Again, this is not a comprehensive review of the entire report, only select items that stood out within the limited time available to conduct a review. Part II critiques the report in terms of its limited EJ analysis. It includes a discussion on EJ concepts and practices, which provide a framework to assess the Plan. Part III provides an example of how an EJ analysis could be conducted using data from the AQMP. For this report, more emphasis is placed on evaluating EJ related issues since others are able to cover the non-EJ elements. The report

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

concludes with some recommendations, with the most important one being a rapid implementation of a full and detailed EJ analysis of the Plan.

Part I: General Feedback

This section contains comments, questions and recommendations on points that are deemed to be problematic, ambiguous or incomplete. Where appropriate, the location is identified.

Page ES-2 contains imbalanced handling of “unquantifiable” elements of costs and benefits due to omission. The DRAFT explicitly points out that there are “benefits which are still unaccounted.” This is true, but the DRAFT does not acknowledge there are likely unaccounted costs. This is a problem that also appears later in the DRAFT.

Page ES-3 uses the term “southwest” but this geographic area does not match any of the sub-regions used in the DRAFT.

Page 1-7 states that REMI was assessed as being “technically sound”, but that is based on a 1992 assessment. There should be an ex-post evaluation of previous projections to establish performance. Clearly, it is important to decompose any divergence between the projections and subsequent observed outcomes (job levels and growth) into at least three components: those due to unexpected exogenous changes (e.g., national economic driver taken from projections from other sources), assumptions about key inputs, and model parameters. This exercise would help understand REMI's overall performance, and gauge the District's overall confidence in relying on this tool for policy purposes.

Page 2-1 introduces the use of race and ethnicity as important categories but does not give a definition. The Census collects separate information on race and Hispanic origins, categories that can overlap. For example, there are African Americans who are of Hispanic origins, but it is unclear how they are classified in the DRAFT. It is also unclear how multi-racial individuals are classified, although I assume that they fall into the “other” category. The classification scheme should be made explicit.

Page 2-10 discusses the “great recession.” While it correctly states NBER's declaration of the recession ending in 2009HQ, it would be useful to acknowledge that there is a lag in the recovery of the job market. This is “normal” for most business cycles, but the lag in jobs creation and reduction in the unemployment rate is more pronounced and protracted this time. Moreover, it is important to point out that California and Southern California in particular lag the nation in both business and labor-market recovery, due in part to the drag from the severe housing foreclosure crisis.

Page 3-3 shows a sharp peak in costs. Please provide an explanation. Also, the overwhelming concentration of the project costs in a single year raises the questions about adjustments costs during and after the peak. Are there possible short-run price distortions in affected markets?

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

Page 3-5 should include a section on unquantified costs, parallel to that on unaccounted benefits discussed in later sections of the DRAFT.

Page 3-5 contains Table 3-2, which should include a breakdown of costs by major program interventions (PM v. Ozone, or TCM v. other). Are all PM reductions related only to TCM?

Page 3-6 includes benefits from congestion relief from SCAG's TCM. TCM should also produce other benefits; therefore, it would be useful to have separate columns listing the benefits from TCM and the other proposed interventions.

Page 3-13 contains calculated benefits from congestion relief that appears problematic. There are two issues because of the proposed travel related interventions, which includes mode shift. One, the calculation does not account for non-travel times (wait time in particular, but also adjustment to schedule to coordinate joint travel), which increases if travel shifts from solo automobile travel to other modes. The second is that the appropriate travel time should be measured in hours of passenger travel and not VHT (vehicle hours traveled). The mode-shift interventions (to the degree that they effective) would increase average persons per vehicle, and the benefit calculations do not account for this, at least as far as I can figure. Both of the two mentioned factors would reduce the benefits.

Page 4-2 shows that a major source of projected job gains (89%) will come from congestion relief, and Page 4-3 claims that the improved environment "would induce in-migration." Pages 6-2 and 6-3 state that the biggest reduction in relative prices would occur in transportation and warehousing, but that sector only accounts for a small percent of the job gains. It is very difficult to judge the reasonableness of these projections (particularly induced in-migration) because there is not sufficient detail on how the estimates were generated. The appendices provide only a skeletal discussion on how inter-regional competition is modeled. There is also no information about the "baseline" for the rest of the nation, which should also have plans to improve air quality. There is too much of a black box. Moreover, there is also the potential problem of over estimating benefits from congestion relief mentioned above.

Finally, it is unclear if Table 5-4 is referring to jobs by work site or by residence of workers. This can make huge difference.

PART II: Evaluation of EJ Analysis

This section reviews the DRAFT's EJ analysis, or more correctly stated, this section comments on the DRAFT's neglect of this critical element. Environmental justice revolves around environmental inequality along racial and economic lines, and policies and programs to redress differential burden. Much of the early EJ battles were directed at the role of government in locating activities that place a greater burden on disadvantaged communities. In more recent years, public agencies have attempted to address this problem. At the federal level, President Clinton's 1994 Executive Order 12898 directed

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

federal agencies to incorporate EJ in their programmatic activities, and there has been a proliferation of EJ related policies and programs at the state, regional and local levels, with California and its regional air districts being among the most active. EJ concerns at AQMD predated the Executive Order, and some progress has been made. This includes, for example, the establishment of an Ethnic Community Advisory Committee, which has been reconfigured as the Environmental Justice Committee.

Given this context, it is rather disappointing that the AQMP socioeconomic analysis is so limited, failing to incorporate analytical practices developed in recent years. The socioeconomic analysis fails to establish a baseline by not identifying EJ geographic areas, not determining the current and projected cumulative environmental (including health) burdens by EJ categories, and not fully estimating the EJ-related distribution of costs and benefits. The DRAFT implicitly acknowledges shortcomings in this area because it makes a vague recommendation to "Expand sub-regional analyses to include environmental justice (EJ) areas" that "may be classified by income or race." In other words, it is postponing a serious EJ analysis until some unspecified future time.

To better understand the reasoning for the above opinion, it is useful to offer a conceptual and analytical framework. For purposes of assessing the potential implication of the AQMP, the appropriate unit of analysis should be defined as geographic areas that have the following characteristics:

- (1) Socially and politically disadvantaged, specifically those who have relatively less influence in decision making, leading to being vulnerable to disproportionate adverse environmental impacts. In practice, the relevant populations are the racial and ethnic groups protected by civil rights laws.
- (2) Low economic status, which makes an area more susceptible to market forces, such as lower land values, less financial ability to "purchase" environmental amenities, and less able to overcome costly-information barriers.
- (3) Suffer from previous adverse environment related decisions, leading to higher cumulative negative health and other outcomes.

The geographic area is a spatial unit that is a "community of common interest," including traditional elements, such as common demographic and SES characteristics, shared localized institutions and networks, recognized as an identifiable place by internal stakeholders and external groups. This concept is used in political redistricting based on judicial rulings. For EJ purposes, CIC should also include common environmental liability. Observed spatial environmental inequality is the product of selective settlement patterns, that is, income constraints force disadvantaged households to purchase lower priced housing in environmentally degraded areas (compensating variation). Spatial environmental inequality also includes post-establishment actions, for example, when governments and firms target disadvantaged areas as dumping grounds.

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

EJ policies and practices are designed to address the gap in environmental quality. This includes having a more inclusive decision-making process that provides meaningful participation for EJ communities. This can be accomplished through open public forums, active solicitation of input, establishment of EJ advisory committees, and representation on key committees. A second practice involves changing organizational practices that integrate explicit EJ concerns into policies and programs with quantifiable objectives. Technical capacity should be enhanced with EJ expertise through both internal staffing and consultation with external experts. Finally, the organization should actively monitor and evaluate its activities and efforts to refine policy and programmatic interventions, and to improve effectiveness in achieving EJ goals and objectives.

The fundamental EJ goal should be closing the absolute and relative gap in cumulative environmental burdens. Improving air quality for all is a desirable outcome, but is not sufficient to ensure progress toward environmental equity. For example, it is possible that an intervention could generate improvements for both EJ and non-EJ communities, but disproportionately benefit the latter. The consequence is that the environmental gap actually increases. This is analogous to the popular economic concept of a rising tide lifts all boats. If the more affluent vessels gain much more, then economic inequality will grow. A necessary criterion for promoting EJ is that net benefits should disproportionately favor the most disadvantaged. A possible operational definition for the most disadvantaged communities would be a category that includes neighborhoods that are among the top quintile in terms of overall environmental risk (due to the multiple factors described earlier). Moreover, EJ neighborhoods should be among the bottom third or quartile along individual dimensions denoting relative advantage.

The above framework can be used to evaluate the DRAFT AQMP and the associated process. In terms of EJ participation, AQMD has consulted its Ethnic Community Advisory Committee, which has been replaced by the Environmental Justice Committee. It is questionable whether the Committee has enough technical expertise to fully understand the nuances and complexities involved in conducting the socioeconomic analysis. This was the case for the Environmental Justice Committee based on the author's participation and observation of that group. Its members were mostly community representatives, advocates and laypersons; therefore, they were dependent on AQMD staff to inform them about the details. Without independent sources of expertise, it is difficult for the Committee to effectively question or challenge the staff. This can reduce participation to being merely token and symbolic. The author does not have any knowledge to whether the District consulted with external EJ experts during the analysis, but if that was done, it was not evident in the DRAFT.

The DRAFT does not contain EJ explicit goals and objectives. Their absence would make it difficult to assess whether AQMP would promote environmental justice. One could argue that EJ concerns are implicit since AQMD has expressed its support for the general principles through past statements by the Board and staff. However, broad principles need to be implemented concretely and integrated throughout the District's operation, including the Plan.

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

The DRAFT fails to adequately operationalize the EJ concept into analytical units. The sub-areas do not have the spatial resolution to differentiate EJ neighborhoods from non-EJ neighborhoods within each sub-area and to identify localized hot-spots. Another problem is the set of criteria defining an EJ area. There is nothing stated in the DRAFT, but the District does have a definition used for other programs. One criterion that can be evaluated is the one related to economic status. According to AQMD, an EJ area should have a poverty rate (the percent of the population living under the federal poverty line) of at least 10%. This rate appears to be arbitrary and unrealistically low. When applied to the sub-areas listed in the DRAFT, 16 of 21 would qualify, accounting for 81% of the region's population. This may be an over estimate since the poverty rates reported in the DRAFT were rounded to whole percentage points. Even with a threshold of greater than 10%, 14 sub-areas would qualify, housing 73% of the population. This extraordinary high proportion of the total population certainly would not identify the truly disadvantaged.

Without a detailed technical analysis, it would be difficult to implement the EJ component of Figure 1-2, "Assessment Tool Kit," displayed on page 1-6. The available tools do not produce the information needed to reasonably estimate the "Ethnic and Community Impacts" in terms of environmental justice; consequently, any "policy consideration" would most likely be incomplete and imprecise, and possibly inappropriate.

PART III: Example of EJ Analysis

This report goes beyond a critique, which finds serious shortcomings in terms of addressing EJ concerns, by offering an example of how an EJ analysis could be implemented. It uses data from the DRAFT. It is important to note that the exercise is very partial due to limited information, inadequate spatial units, and simplifying assumptions. Moreover, the methods used are not definitive, and there can be other appropriate analytical approaches. There are two parts to the exercise. The first is to compare the proportionate share of the costs and benefits for geographic units defined by EJ-related. The second is a rough estimate of the proportionate share of the costs and benefits for "disadvantaged" and "advantaged" populations.

Since EJ is spatial (both the population and environmental risks are defined by location and place), a critical analytical technique is to examine the geographic distribution of environmental burdens and improvement relative to the distribution of the population. This is done by creating a modified benefit to cost ratio. More specifically, the index is defined as a sub-area's share of the estimated total benefits divided by its share of the estimated total costs. Using this index rather than a simple benefit-to-cost ratio has the advantage of not directly relying on the estimated dollar amounts (which may have some biases on the benefit side, as discussed earlier) and is easier to interpret. This modified ratio, a benefit-to-cost parity index, is consistent with the concept that disadvantaged areas should receive a disproportionately greater share of the outcomes of a policy and/or programmatic intervention. Values greater than one for EJ areas would indicate that the desired EJ objective is being achieved. Values of less than one indicate that the proposed

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

action or actions could increase the gap, even if it improves environment quality in those areas. (Additional calculations are needed to determine how the outcome affects the absolute and relative cumulative environmental and health gap.)

The following two graphs plot the benefit-to-cost parity index against two criteria frequently used to identify possible EJ areas, the minority proportion of the population (minority defined as the combined total of African Americans and Latinos) and the poverty rate. The other major criterion is some measure of cumulative environmental risk, but the Plan does provide such data. It should be noted that the term "minority" refers to disadvantaged racial and ethnic groups rather than their numerical share of the population. Southern California has become a "majority minority" region, so the combined disadvantaged groups comprises a numerical majority.

Figures 1 and 2 summarize the results of the first part of the analytical exercise. To achieve positive EJ outcomes, the parity index should be relatively higher for disadvantaged areas. The points do not indicate a simple linear pattern, with the values in the middle being higher than at the two ends. Both graphs are fitted with a second-order curve, which indicates that the more disadvantaged sub-areas gain proportionately less from the Plan. Interestingly, the inflexion points are roughly at values equal to the minority share of the region's total population (52%) and average poverty rate (14%). The most disadvantaged sub-areas have indices of less than one. The results indicate that EJ objectives are not being met through the Plan.

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

The second part of the exercise is to construct a benefit-to-cost parity index for minorities and people below poverty, which can be defined as the ratio of a group's share population relative to the group's share of an outcome. The basic calculations are the same as those discussed for sub-areas, but we replace spatial units with socio-economic groups. The first step is to estimate a group's share of estimated benefits. This is done by multiplying the group's share of the population in a given sub-area times the estimated benefits for that sub-area. The second step is to sum across the 21 sub-areas to derive an estimated total benefit for the group. The group specific sum is then divided by the estimated total benefits for the District, resulting in the group's share. These steps are repeated on for estimated costs, and the two resulting group shares are used to calculate the benefit-to-cost parity index. This process is applied to all relevant groups (minority and non-minority, poor and non-poor). The interpretation of the index is the same as above, values greater than one for EJ areas would indicate that the desired EJ objective is being achieved.

Figure 3 reports the results of the second part of the analytical exercise. Overall, the outcomes are consistent with those from the first part of the analytical exercise, that is, EJ objectives are not being met. The index is lower than one for both minorities and poor people, indicating that disadvantaged populations gain less than advantaged populations, thus failing to close the environmental gap.

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

Despite its crudeness, the analytical exercise in this section points to what is possible. The hope is that this example would serve as a rough roadmap for improving the socioeconomic analysis with respect to environmental justice.

CONCLUSION

The District is to be commended for undertaking an extensive assessment of the potential socioeconomic impacts of the Plan. In many areas, AQMD uses well established procedures and techniques within the profession. There is room for improvement, and many of my recommendations are listed in Part I. Of particular concern are the estimated benefits from congestion relief, both in terms of the calculations related time savings and job generations.

In my opinion, the major and most serious flaw is the lack of a systematic and detailed environmental-justice analysis. Given that various stakeholders have advocated for this for decades, it is disappointing (and frustrating) to see so little progress. In fact, there is only a vague commitment to possibly conducting such an analysis in some unspecified future. It is my strong recommendation that AQMD fast-track the integration of a sophisticated EJ analysis into the socioeconomic assessment of the AQMP.

Although there will be many challenges to implementing the recommendation, it is feasible. Given the critical importance of EJ in developing a fair plan that improves the region's air and redresses past inequalities, an EJ analysis should be a high priority in terms of allocating resources. Moreover, there appears to be good reason to conduct the analysis because the findings from Part III are troubling. Of course, they should not be considered definitive, and a more refined EJ analysis with appropriate geographic scale

Evaluation of AQMD's Draft Socioeconomic Report by Paul Ong

and data could produce different findings. But if the results hold, then the District should find ways to modify the Plan so it can achieve EJ goals and objectives, or develop other actions to offset any negative EJ outcomes. Sound decision making on this issue will require further analysis and better information.

Frederick R. Treyz, CEO of Regional Economic Models, Inc.

Useful extensions of the analysis would include consideration of reduction of illness, reduction of building deterioration, reduction of damage to plants and animals and the value of reduced vehicle hours. By not including these factors, the AQMP understates the benefits of the plan. Thus the economic study should be seen as a conservative estimate.

The most important extension would be inclusion of the value of reduced vehicle hours. Transportation improvements often have economic effects in terms of transportation-related issues such as businesses' access to employees with specialized skills and talents, and business transportation costs and competitiveness; and at the same time have environmental effects, in particular changes in vehicle hours travelled which changes the level of emissions and other factors.

Beyond this, no further comments are necessary.

APPENDIX G

NO TCM ~~BENEFIT~~ SCENARIO

No TCM Benefit Scenario

No TCM and Related Benefit Scenario

INTRODUCTION

The average annual congestion relief benefit of \$7.7 billion from 2014 to 2035 in the Draft Socioeconomic Report for the Draft 2012 AQMP is for all TCM-type projects in the 2012 Regional Transportation Plan (RTP). However, committed TCMs in the 2012 AQMP are comprised of only the first two years of TCM-type projects in the 2012 RTP. In response to stakeholders' comments, a No TCM Benefit Scenario was conducted. It excluded the potential commensurate congestion relief benefit associated with the committed TCMs in the 2012 AQMP.

Another scenario—No TCM and Related Benefit—removed costs of TCMs and related congestion benefits from the Draft Final 2012 AQMP. This scenario focused on the costs of District's measures and their related benefits.

NO TCM BENEFIT SCENARIO

~~The following~~All the tables related to control measures for this scenario show contribution of TCM projects to PM_{2.5} strategy in terms of costs and job impacts. Also, the \$7.7 billion congestion relief benefit is removed from the clean air benefit estimation in the Draft Final Socioeconomic Report. All other related tables that are affected by exclusion of the congestion relief benefit in the Draft Final Socioeconomic Report are updated ~~as attached~~below. All the table numbers are preceded with a "G" and end with an "A."

TABLE G-6-4A
 Impacts on Imports and Exports for Clean Air Benefits and Control Measures

	Clean Air Benefits			Control Measures			Benefits & Measures		
	2014	2023	2035	2014	2023	2035	2014	2023	2035
Demand*	+	+	+	-	-	-	+	+	+
Imports	+	+	+	+	+	+	+	+	+
Self Supply*	+	+	+	-	-	-	-	+	+
Exports	+	-	-	-	-	-	-	-	-
Output (Production)	+	+	+	-	-	-	-	+	+
Delivered Price	-	+	+	-	+	+	-	+	+
Cost of Production	-	+	+	-	+	+	-	+	+

A plus or minus sign means that there is an increase or decrease in the value of that economic variable resulting from benefits, measures, or both of the Draft [Final](#) 2012 AQMP relative to the baseline economic activities.

*Includes changes in demand due to changes in control requirements.

TABLE G-7-1A
Average Annual Impacts of AQMP and CEQA Alternatives

CEQA Alternatives*	Costs		PM2.5 Benefits		Jobs for Combined Costs & Benefits
	Millions of 2005 Dollars	Jobs	Millions of 2005 Dollars	Jobs	
Draft Final 2012 AQMP	\$448	-3,257	\$2,958	9,037	5,378
Alt 2—Localized PM Control	450	-3,334	1,814	4,007	459
Alt 3—Greater Reliance on NOx Reductions	495	-4,715	3,429	11,209	5,994
Alt 4—PM _{2.5} Strategy Only	\$327	-1,620	<\$2,958	<9,037	<5,378

TABLE G-7-3A
Average Annual Quantified Benefits by Category by Alternative
(millions of 2005 dollars)

CEQA Alternatives	Total	Health	Visibility	Material
Draft Final 2012 Plan	\$2,958	\$2,247	\$696	\$14
Alt2—Localized PM Control	1,814	1,370	438	7
Alt 3—Greater Reliance on NOx Reductions	3,429	2,430	988	11
Alt 4—PM _{2.5} Strategy Only	<\$2,958	<\$2,247	<\$696	<\$14

NO TCM AND RELATED BENEFIT SCENARIO

Under this scenario, the cost of the Draft Final 2012 AQMP represents only those measures proposed by the AQMD. The cost of TCMs is excluded from the analysis. Consequently, the congestion relief benefit associated with the TCMs is also removed from the benefit of clean air. Under this scenario, the annual cost of the Draft Final Plan is projected to be \$122.7 million with a projected annual benefit of approximately \$3 billion. Relative to the No TCM Benefit Scenario, all the affected tables are updated and presented below. These table numbers are preceded with a “G” and end with a “B.”

APPENDIX H

TCM BENEFIT AT 2014 LEVEL

INTRODUCTION

The average annual congestion relief benefit of \$7.7 billion from 2014 to 2035 in the Draft Socioeconomic Report for the Draft 2012 AQMP is for all TCM-type projects in the 2012 Regional Transportation Plan (RTP). However, committed TCMs in the 2012 AQMP are comprised of only the first two years of TCM-type projects in the 2012 RTP. In order to analyze the benefit from the SIP-committed TCMs between 2014 and 2035 and due to the data constraint, it was assumed that the congestion relief benefit would stay constant at the 2014 level. This estimate is conservative because

- Only those projects that will be operational in the first two years are included in the 2014 benefit, and
- Some of the committed TCM projects will not be fully completed and operational in the first two years.

The 2014 congestion relief benefit from the SIP-committed TCMs is estimated to be \$519 million in 2014 and would continue from 2015 to 2035. The following tables corresponding to those in the Draft [Final](#) Socioeconomic Report have been updated to reflect the annual \$519 million congestion relief benefit. [All the table numbers are preceded with an “H.”](#)

TABLE H-3-3
 Quantifiable Benefits of Draft [Final](#) 2012 AQMP
 (millions of 2005 dollars)

Benefit	Average Annual (2014 to 2035)
Reduction in Morbidity	\$23
Reduction in Mortality	2,225
Visibility Improvement	696
Reduced Materials Expenditures	14
Congestion Relief	519
Total	\$3,477

TABLE H-3-10

Delivered Price	-	-	+	-	+	+	-	+	+
Cost of Production	-	-	+	-	+	+	-	+	+

A plus or minus sign means that there is an increase or decrease in the value of that economic variable resulting from benefits, measures, or both of the Draft [Final 2012 AQMP](#) relative to the baseline economic activities.

*Includes changes in demand due to changes in control requirements.

TABLE H-7-1
Average Annual Impacts of AQMP and CEQA Alternatives

CEQA Alternatives*	Costs		PM2.5 Benefits		Jobs for Combined Costs & Benefits
	Millions of 2005 Dollars	Jobs	Millions of 2005 Dollars	Jobs	
Draft Final 2012 AQMP	\$448	-3,257	\$3,477	12,299	8,498

Chemical Engineering, Various Issues

Footnotes:

1. The Marshall and Swift (M & S) Indices were used to convert current dollars to 2005 dollars for all the control measures except TCMs.
2. Nominal dollars in TCMs were converted to 2005 dollars based on an annual compounded inflation rate of 3.2 percent.
3. CPIs were used for conversions to 2005 dollar in the assessment of all clean air benefits.

| **APPENDIX [GJ](#)**

GLOSSARY

American Community Survey (ACS): The ACS is an ongoing statistical survey that samples a small percentage of the population every year to provide up-to-date information about the social and economic needs of communities.

Acute Health Effect: An adverse health effect that occurs over a relatively short period of time (e.g., minutes or hours).

Acute Respiratory Symptoms: Any respiratory disease-related symptoms including chest discomfort, coughing, wheezing, sore throat, head cold, chest cold, sinus trouble, hay fever, headache and doctor-diagnosed flu.

Air Quality Simulation Model: A computer program that simulates the transport, dispersion, and transformation of compounds emitted into the air and can project the relationship between emissions and air quality.

Ambient Air: The air occurring at a particular time and place outside of structures. Often used interchangeably with “outdoor” air.

APCD (Air Pollution Control District): A county agency with authority to regulate stationary, indirect, and area sources of air pollution (e.g., power plants, highway construction, and housing developments) within a given county, and governed by a district air pollution control board composed largely of the elected county supervisors. (See AQMD).

AQMD (Air Quality Management District): A group of counties or portions of counties, or an individual county specified in law with authority to regulate stationary, indirect, and area sources of air pollution within the region and governed by a regional air pollution control board comprised mostly of elected officials from within the region. (See APCD).

AQMP (Air Quality Management Plan): A Plan prepared by an APCD/AQMD, for a county or region designated as a non-attainment area, for the purpose of bringing the area into compliance with the requirements of the national and/or California Ambient Air Quality Standards. AQMPs are incorporated into the State Implementation Plan (SIP).

Asthma Symptom Days: Days in which asthma symptoms are present in asthmatic individuals.

BenMAP Model (Environmental Benefits Mapping and Analysis Program): A computer model designed to estimate general population exposures to air pollutants. The model uses air quality data from the CAMx Model as inputs for exposure calculations. The model is structured in a manner that allows for consideration of spatial and temporal variations in concentrations, variations in human time activity, and mobility of the population.

CAA (Federal Clean Air Act): A federal law passed in 1970 and amended in 1977 and 1990 which forms the basis for the national air pollution control effort. Basic elements of the act include national ambient air quality standards for major air pollutants, air toxics standards, acid rain control measures, and enforcement provisions.

CARB (California Air Resources Board): The State's lead air quality agency consisting of a 11-member Governor-appointed board. It is responsible for attainment and maintenance of

the State and federal air quality standards, and is primarily responsible for motor vehicle pollution control. It oversees county and regional air pollution management programs.

CMAQ (Community Multiscale Air Quality Model): A three dimensional photochemical grid model used to simulate ozone and PM_{2.5} formation.

Cardiac Hospital Admissions: Hospital admissions due to heart-related ailments or disease.

CCAA (California Clean Air Act): A California law passed in 1988 which provides the basis for air quality planning and regulation independent of federal regulations. A major element of the Act is the requirement that local APCDs/AQMDs in violation of the CAAQS must prepare attainment plans which identify air quality problems, causes, trends, and the actions to be taken to attain and maintain California's air quality standards by the earliest practicable date.

CEQA (California Environmental Quality Act): A California law which sets forth a process for public agencies to make informed decisions on discretionary project approvals. The process aids decision makers to determine whether any environmental impacts are associated with a proposed project. It requires environmental impacts associated with a proposed project to be identified, disclosed, and mitigated to the maximum extent feasible.

Clean Air Benefits: These include reduced morbidity, avoided mortality, visibility improvements, increased crop yield, traffic congestion relief, reduced spending on refurbishing sensitive building materials, and less damage to plant life and livestock resulting from attaining federal and state air quality standards.

CO (Carbon Monoxide): A colorless, odorless gas resulting from the incomplete combustion of fossil fuels. Over 80% of the CO emitted in urban areas is contributed by motor vehicles. CO interferes with the blood's ability to carry oxygen to the body's tissues and results in numerous adverse health effects. CO is a criteria air pollutant.

Concentration-Response Function: A mathematical relationship derived to calculate the number of cases of a specific health effect expected in a population exposed to a given ambient concentration of an air pollutant.

Chronic Bronchitis: Chronic lung disease characterized by frequent coughing, increased sputum production, and interference with oxygen exchange between air and blood in the lungs of severely affected individuals.

Chronic Health Effect: An adverse health effect which occurs over a relatively long period of time (e.g., months or years).

Consumer Expenditure Survey (CES): The CES collects information on the buying habits of American consumers. The survey consists of two components: (1) a Diary survey completed by participating consumers for two consecutive 1-week periods; and (2) an Interview survey in which the expenditures of consumers are obtained in five interviews conducted every 3 months. Each component of the survey queries an independent sample of consumers which is representative of the U.S. population. Over 52 weeks of

the year, 5,000 consumers are sampled for the Diary survey. The Interview sample is selected on a rotating panel basis, targeted at 5,000 consumers each quarter.

Current Population Survey (CPS): The CPS provides monthly statistics that serve as measures of both current labor force utilization and overall performance of the U.S. economy. The information collected from a sample of 60,000 households relates to the employment status of the entire population. For the employed, there are data on hours worked, full-time and part-time status of workers, and usual weekly earnings. For the unemployed, data routinely are collected on duration of unemployment, the respondent's job status at the time that his or her jobless spell began, and job-seeking methods used. Among those not in the labor force, data are obtained for so-called discouraged workers, who have ceased active job hunting.

Discounted Cash Flow Method: A method to evaluate the present worth of a stream of expenditures in future years. Future expenditures are discounted based on the interest rate and the length of the period in which the expenditures are made.

Disposable Income: It is the sum of the incomes of all the individuals in the economy after all taxes have been deducted.

Dose-Response Function: A mathematical relationship which expresses the likelihood of a connection between exposure to a specific amount of an air pollutant (inhaled dose) and one or more responses elicited by exposure to the specific pollutant. For human health evaluations, responses are health effects, e.g., eye irritations and restricted activity days. For agriculture, the responses are changes in crop yields.

Emergency Room Visits: Visits to emergency rooms by individuals in need of urgent or immediate treatment.

Grid Cell: An area bound by evenly spaced horizontal and vertical bars or lines.

Episodic Model: A photochemical grid model that typically simulates air quality for a 3-5 day period, e.g., the CAMx Model used for the ozone attainment demonstration .

Hedonic Prices: Hedonic prices are a method to compute the price of a good that is not traded in the market based on the price of a traded good that has the attribute of the non-traded good. Based on the amount of the attribute, the imputed price of the non-traded good is a fraction of the price of the traded good. For example, air quality is an attribute of real estate.

Mobile Sources: Sources of air pollution such as automobiles, motorcycles, trucks, off-road vehicles, boats and airplanes. (Contrast with stationary sources.)

NAICS Code: The North American Industry Classification System (NAICS) has replaced the U.S. Standard Industrial Classification (SIC) system. NAICS was developed jointly by the U.S., Canada, and Mexico to provide new comparability in statistics about business activity across North America. Economic units that use like processes to produce goods or services are grouped together. NAICS reflects the structure of today's economy in the U.S., Canada, and Mexico, including the emergence and growth of the service sector and

new and advanced technologies. NAICS also provides for increased comparability with the International Standard Industrial Classification System (ISIC, Revision 3), developed and maintained by the United Nations.

Nitrogen Oxides (Oxides of Nitrogen, NO_x): A general term pertaining to compounds of nitric acid (NO), nitrogen dioxide (NO₂), and other oxides of nitrogen. Nitrogen oxides are typically created during combustion processes, and are major contributors to smog formation and acid deposition. NO₂ is a criteria air pollutant, and may result in numerous adverse health effects.

Off-Road Mobile Sources: Mobile sources of air pollution (vehicles) which are not authorized to operate on streets and highways. Examples include trains, boats, aircraft, farm equipment, and earthmoving equipment.

On-Road Mobile Sources: Mobile sources of air pollution (vehicles) which are authorized to operate on streets and highways. Examples include passenger cars, trucks, and buses.

Ozone: A strong-smelling, pale blue, reactive toxic chemical gas consisting of three oxygen atoms. It is a product of the photochemical process involving the sun's energy. Ozone exists in the upper atmosphere ozone layer as well as at the earth's surface. Ozone at the earth's surface can cause numerous adverse health effects and is a criteria air pollutant. It is a major component of smog.

Ozone Precursors: Chemicals such as hydrocarbons and oxides of nitrogen, occurring either naturally or as a result of human activities, which contribute to the formation of ozone, a major component of smog.

PM_{2.5} (Particulate Matter): Major class of air pollutants consisting of tiny solid or liquid particles of soot, dust, smoke, fumes, and mists. The size of the particles (2.5 microns or smaller, about 0.0004 inches or less) allows them to enter the air sacs (gas exchange region) deep in the lungs where they may get deposited and result in adverse health effects. PM_{2.5} also causes reduced visibility and is a criteria air pollutant.

PM_{2.5} Model: Modeling approaches to assess contributions to primary and secondary PM_{2.5}. Primary PM_{2.5} source apportionment is accomplished by receptor models and secondary particles such as sulfate and nitrate are apportioned to their precursors utilizing the Particle-In-Cell (PIC) dispersion model.

Premature Mortality: Death before the term of life expectancy.

Quantifiable Clean Air Benefits: Clean air is not a commodity exchanged in a market. The contingency valuation method or the hedonic pricing is often used to assess the monetary benefit associated with clean air. There are instances where association between an effect and clean air (cause) cannot be quantitatively established or is unknown, thus precluding the application of the contingency valuation method or hedonic pricing. Quantifiable clean air benefits are those benefit categories where monetary values can be placed based on past literature.

Reactive Organic Gas (ROG): A reactive chemical gas, composed of hydrocarbons, which may contribute to the formation of smog. Also sometimes referred to as Non-Methane Organic Compounds (NMOCs) or volatile organic compounds (VOCs).

Regional Economic Models, Inc. (REMI) Model: The REMI model is an economic and demographic forecasting and simulation model designed to examine the economic and demographic effects resulting from policy initiatives or external events in a local economy. For the socioeconomic analysis of the 2007 AQMP, the REMI 8.0.9 70-sector model for the 19 sub-regions within the counties of Los Angeles, Orange, Riverside, and San Bernardino is used.

Respiratory Hospital Admissions: Hospital admissions due to respiratory illness.

Restricted Activity Days: Days when activities are either fully or partially restricted due to illness, which include days spent in bed and days missed from work.

Relative Response Factor (RRF): A measure of simulated concentrations in a future year compared to those in a historical year from an air quality model.

Smog: A combination of smoke, ozone, hydrocarbons, nitrogen oxides, and other chemically reactive compounds which, under certain conditions of weather and sunlight, may result in a murky brown haze that causes adverse health effects. The primary source of smog in California is motor vehicles.

Standard Industrial Classification (SIC) Code: The SIC code is used to classify all establishment-based federal economic statistics by industry. The SIC code facilitates the comparability of establishment data in the U.S. economy. The classification covers the entire range of economic activities and defines industries in accordance with the composition and structure of the economy.

State Implementation Plan (SIP): A document prepared by each state describing existing air quality conditions and measures which will be taken to attain and maintain national ambient air quality standards (see AQMP).

Stationary Sources: Non-mobile sources such as power plants, refineries, and manufacturing facilities which emit air pollutants. (Contrast with mobile sources.)

Sulfur Dioxide (SO₂): A strong smelling, colorless gas that is formed by the combustion of fossil fuels. Power plants which may use coal or oil high in sulfur content can be major sources of SO₂. SO₂ and other sulfur oxides contribute to the problem of acid deposition. SO₂ is a criteria pollutant.

Total Suspended Particulate Matter (TSP): Airborne particles that are less than 100 micrometers.

U.S. EPA (Environmental Protection Agency): The federal government agency charged with setting policy and guidelines, and carrying out legal mandates, for the protection of national interests in environmental resources.

VHT: Vehicle Hours Traveled.

VMT: Vehicle Miles Traveled.

Visibility: The distance that atmospheric conditions allow a person to see at a given time and location. Visibility reductions from air pollution are often due to the presence of sulfur and nitrogen oxides, as well as particulate matter.

Volatile Organic Compounds (VOCs): Hydrocarbon compounds which exist in the ambient air. VOCs contribute to the formation of smog and/or may themselves be toxic. VOCs often have an odor. Some examples of VOCs are gasoline, alcohol, and the solvents used in paints.

Willingness to Pay (WTP): WTP is an approach to measuring monetary values of benefits received from non-market goods such as environmental quality. The methods used to arrive at a WTP value include surveys and hedonic price functions.

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

IND-01: *The Ports of Los Angeles and Long Beach have provided comments on control measure IND-01: Backstop Measure for Indirect Sources of Emissions from Ports and Port Related Sources (Port Backstop Measure). Through the Clean Air Action Plan (CAAP), the Ports have voluntarily implemented programs to reduce emissions from a variety of port-related sources. The Ports have commented that the AQMD “reconsider its approach and allow the continuation of the successful collaborative work by the ports, regulatory agencies and other stakeholders under the voluntary Clean Air Action Plan and the San Pedro Bay Standards.” As a result, the Ports have requested that the Port Backstop Measure be removed from the 2012 AQMP. The Ports have commented that they “can’t accept any regulatory action by the AQMD that will result in AQMD oversight and approvals of port actions, or enforcement actions by the AQMD on the ports for failure of the port industry to meet the ports’ emission reduction goals.”*

The AQMD staff agrees that the Ports have made significant progress in reducing emissions. It still remains however, that the Ports of Los Angeles and Long Beach are collectively the single largest fixed source of air pollution in Southern California. Port sources such as marine vessels, locomotives, trucks, harbor craft and cargo handling equipment, continue to be the largest sources of NO_x, PM_{2.5} and PM_{2.5} precursors in the region. These sources play a major role in the Basin’s ability to achieve the national PM_{2.5} ambient air quality standards. The AQMD staff believes that it is appropriate and necessary to include a backstop measure to ensure that the Basin’s largest source of NO_x and PM_{2.5} emissions maintains its course of emission reductions.

In response to comments from the Ports, the AQMD staff has made revisions to the Port Backstop Measure that further clarifies the intent and rule development process. AQMD staff has clarified that a backstop rule will become effective only if emissions from port-related sources exceed targets for NO_x, SO_x, and PM_{2.5} in 2014. In addition, the measure has been revised to further clarify that if additional emission reductions are needed, the Ports would be required to submit a plan on only the emission reduction shortfall. The backstop rule would not require any strategy to be implemented that lacked legal authority, was not cost-effective, or was found to be infeasible. In addition, staff clarified that the backstop rule would include time extension to achieve the targets, if necessary. Lastly, language has been added to the measure regarding enforcement of the port backstop rule. The AQMD staff is committed to continue to work collaboratively with the Ports, agencies, environmental community groups, industry representatives, and other interested parties through the rule development process.

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

IND-01: BACKSTOP MEASURE FOR INDIRECT SOURCES OF EMISSIONS FROM PORTS AND PORT-RELATED FACILITIES [NO_x, SO_x, PM_{2.5}]

CONTROL MEASURE SUMMARY

SOURCE CATEGORY:

IF THE BACKSTOP MEASURE BECOMES EFFECTIVE (I.E. IF EMISSIONS FROM PORT-RELATED SOURCES EXCEED TARGETS FOR NO_x, SO_x, AND PM_{2.5}), AFFECTED SOURCES WOULD BE PROPOSED BY THE PORTS AND COULD INCLUDE SOME OR ALL PORTS AND PORT-RELATED SOURCES (-(E.G., MARINE VESSELS, LOCOMOTIVES, TRUCKS, CARGO HANDLING EQUIPMENT, HARBOR CRAFT, MARINE VESSELS, LOCOMOTIVES, AND STATIONARY EQUIPMENT), TO THE EXTENT COST EFFECTIVE STRATEGIES ARE AVAILABLE)

CONTROL METHODS:

IF THE BACKSTOP MEASURE BECOMES EFFECTIVE, EMISSION REDUCTION METHODS WOULD BE PROPOSED BY THE PORTS AND POTENTIALLY COULD INCLUDE CLEAN TECHNOLOGY PORT AND PORT FACILITY EMISSION CONTROL PLANS, FUNDING PROGRAMS, CONTRACTUAL LEASE REQUIREMENTS PROVISIONS, PORT RULES, TARIFFS, AND/OR INCENTIVES/DISINCENTIVES TO IMPLEMENT MEASURES, TO THE EXTENT COST EFFECTIVE AND FEASIBLE STRATEGIES ARE AVAILABLE

EMISSIONS (TONS/DAY): *NO
CHANGE TO THIS SECTION*

DESCRIPTION OF SOURCE CATEGORY

This control measure is carried over from the 2007 AQMP/SIP. If the backstop measure goes into effect, affected sources would be proposed by the ports and could include some or all port-related sources (trucks, cargo handling equipment, harbor craft, marine vessels, locomotives, and stationary equipment), to the extent cost effective and feasible strategies are available.

Other sources—i.e. sources that are unrelated to the ports—would not in any way be subject to emission reductions under this measure (including through funding of emission reduction measures, or purchase of emission credits, by the ports or port tenants).

Background

Emissions and Progress. The ports of Los Angeles and Long Beach are the largest in the nation in terms of container throughput, and collectively are the single largest fixed sources of air

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

pollution in Southern California. Emissions from port-related sources have been reduced significantly since 2006 through efforts by the ports and a wide range of stakeholders. In large part, these emission reductions have resulted from programs developed and implemented by the ports in collaboration with port tenants, marine carriers, trucking interests and railroads. Regulatory agencies, including EPA, CARB and SCAQMD, have participated in these collaborative efforts from the outset, and some measures adopted by the ports have led the way for adoption of analogous regulatory requirements that are now applicable statewide. These port measures include the Clean Truck Program and actions to deploy shore-power and low emission cargo handling equipment. The Ports of Los Angeles and Long Beach have also established incentive programs which have not subsequently been adopted as regulations. These include incentives for routing of vessels meeting IMO Tier 2 and 3 NOx standards, and vessel speed reduction. In addition, the ports are, in collaboration with the regulatory agencies, implementing an ambitious Technology Advancement Program to develop and deploy clean technologies of the future.

Port sources such as marine vessels, locomotives, trucks, harbor craft and cargo handling equipment, continue to be among the largest sources of PM_{2.5} and PM_{2.5} precursors in the region. Given the large magnitude of emissions from port-related sources, the substantial efforts described above play a critical part in the ability of the South Coast Air Basin to attain the national PM_{2.5} ambient air standard by federal deadlines. This measure provides assurance that emissions from the Basin's largest fixed emission source will continue to support attainment of the federal 24-hour PM_{2.5} standard. ~~such as marine vessels, locomotives, trucks, harbor craft and cargo handling equipment, adversely affect air quality in the local port area as well as regionally. Without substantial control of emissions from port-related sources, it will not be possible for this region to attain federal ambient air quality standards for ozone or PM_{2.5}. Reductions in PM_{2.5} emissions will also reduce cancer risks from diesel particulate matter. Port sources also contribute to cancer risks.~~

Clean Air Action Plan. The emission control efforts described above largely began in~~in~~ 2006 when the Ports of Los Angeles and Long Beach, with the participation and cooperation of the staff of the SCAQMD, CARB, and U.S. EPA, adopted the San Pedro Bay Ports Clean Air Action Plan (CAAP). The CAAP was further amended in 2010, updating many of the goals and implementation strategies to reduce air emissions and health risks associated with port operations while allowing port development to continue. In addition to addressing health risks from port-related sources, the CAAP sought the reduction of criteria pollutant emissions to the levels that assure port-related sources decrease their “fair share” of regional emissions to enable the Basin to attain state and federal ambient air quality standards.

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

The CAAP focuses primarily on reducing diesel particulate matter (DPM), along with NO_x and SO_x. The CAAP includes proposed strategies on port-related sources that are implemented through new leases or Port-wide tariffs, Memoranda of Understanding (MOU), voluntary action, grants or incentive programs.

The goals set forth in the CAAP include:

- Health Risk Reduction Standard: 85% reduction in population-weighted cancer risk by 2020
- Emission Reduction Standards:
 - By 2014, reduce emissions by 72% for DPM, 22% for NO_x, and 93% for SO_x
 - By 2023, reduce emissions by 77% for DPM, 59% for NO_x, and 93% for SO_x

In addition to the CAAP, the Ports have completed annual inventories of port-related sources since 2005. These inventories have been completed in conjunction with a technical working group composed of the SCAQMD, CARB, and U.S. EPA. Based on the latest inventories, it is estimated that the emissions from port-related sources will meet the 2012 AQMP emission targets necessary for meeting the 24-hr PM_{2.5} ambient air quality standard. The projected emissions from port related sources are included in the “baseline” emissions assumed in this plan to attain the PM_{2.5} standards.

While many of the emission reduction targets in the CAAP result from implementation of federal and state regulations (either adopted prior to or after the CAAP), some are contingent upon the Ports taking and maintaining further actions which are ~~voluntary in nature~~ not required by air quality regulations. These ~~voluntary~~ actions include the Expanded Vessel Speed Reduction Incentive Program, lower emission switching locomotives, Green-Flag Program, and incentives for lower emission marine vessels. ~~Clean Truck Program, Oceangoing Vessel Low Sulfur Fuel Program, and the Shore-side power and Auxiliary Marine Power Program.~~ This AQMP control measure is designed to provide ~~an “insurance policy” that provides~~ a “backstop” to the Ports’ actions to provide assurance that, if emissions do not continue to meet projections, the ports will develop and implement plans to get back on track, to the extent that cost effective and feasible strategies are available. ~~and ensures that the emission targets from port-related sources are met in a timely manner.~~

Regulatory History – *no change to this section*

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

PROPOSED METHOD OF CONTROL

The goal of this measure is to ensure that NO_x, SO_x and PM_{2.5} emissions reductions from port-related sources are sufficient to attain the 24-hr federal PM_{2.5} ambient air quality standard. This measure would establish targets for NO_x, SO_x, and PM_{2.5} for 2014 that are based on emission reductions resulting from adopted rules and other measures such as railroad MOUs and vessel speed reduction that have been adopted and are being implemented. These emissions from port related sources are included in the “baseline” emissions assumed in this plan to attain the 24-hour PM_{2.5} standard. Based on current and future emission inventory projections, ~~anticipated emission reductions from port related sources~~ these rules and measures will be sufficient to achieve attainment of the 24-hr federal PM_{2.5} ambient air quality standard. ~~This measure is divided into two phases. The Phase I R~~requirements adopted pursuant to this measure ~~are~~ will become effective only triggered if emission levels exceed the above targets projected to result from the current regulatory requirements and voluntary reduction strategies that are assumed and relied upon in the 2012 AQMP are not realized. Once triggered, the ports will be required to develop and implement a plan to reduce emissions from ~~their port-related~~ sources to meet the emission targets over a time period. The time period to achieve and maintain emission targets will be established pursuant to procedures and criteria developed during rulemaking and specified in the rule. ~~This control measure is designed to ensure that the necessary emission reductions from port related sources projected in the 2012 AQMP milestone years are achieved.~~ The Phase II is designed to reduce emissions if it is later determined through a SIP amendment that additional region wide reductions are needed due to the change in Basin-wide carrying capacity for PM_{2.5} attainment. In this case, the ports will be required to develop and implement a plan to further reduce their emissions on a “fair share” basis.

This control measure will be implemented through a District rule. Through the rule development process the AQMD staff will establish a working group, hold a series of working group meetings, and hold public workshops. The purpose of the rule development process is to allow the AQMD staff to work with a variety of stakeholders such as the Ports, potentially affected industries, other agencies, and environmental and community groups. The rule development process will discuss the terms of the proposed backstop rule and, through an iterative public process, develop proposed rule language. In addition, the emissions inventory and targets will be reviewed and may be refined if necessary. This control measure applies to the Port of Los Angeles and the Port of Long Beach, acting through their respective Boards of Harbor Commissioners. The ports may have the option to comply separately or jointly with provisions of the “backstop” rule.

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

Elements of Backstop Rule

Summary: This control measure will establish enforceable nonattainment pollutant emission reduction ~~goals-targets~~ for the ports in order to ensure ~~attainment-implementation~~ of the 24-hr PM2.5 attainment strategy in the 2012 AQMP. The “backstop” rule will ~~be implemented~~ go into effect if aggregate emissions from port-related sources exceed specified emissions targets. If emissions do not exceed such targets, the ports will have no control obligations under this control measure.

Emissions Targets: The emissions inventories projected for the port-related sources in the 2012 AQMP are an integral part of the 24-hr PM2.5 attainment demonstration ~~by-for~~ 2014 and its maintenance of attainment in ~~2019~~ subsequent years. These emissions serve as emission targets for meeting the 24-hr PM2.5 standard. ~~Future targets will be developed for the ozone standards in future SIP revisions.~~

Scope of Emissions Included: Emissions from all sources associated with each port, including equipment on port property, marine vessels traveling to and from the port while in California Coastal Waters, locomotives and trucks traveling to and from port-owned property while within the South Coast Air Basin. This ~~analysis-measure~~ will make use of the Port’s annual emission inventory, either jointly or individually, as the basis for the emission targets. The inventory methodology to estimate these emissions is consistent with the CAAP methodology. Other sources—i.e. sources that are unrelated to the ports—would not in any way be subject to emission reductions under this measure (including through funding of emission reduction measures, or purchase of emission credits, by the ports or port tenants).

Circumstances Causing Backstop Rule Regulatory Requirements to Come Into Effect: ~~The Phase I of the “backstop” requirements will be triggered if the reported aggregate emissions for 2014 for all port-related sources exceed the 2014 emissions targets-milestone. The rule may also provide that it will come into effect if the target is met in 2014 but exceeded in a subsequent year. The Phase II requirements will be triggered after a two-step evaluation. First, the Basin fails to meet the 24 hr PM2.5 standard as demonstrated in the 2012 AQMP and there is a change in Basin wide carrying capacity, in which case a new reduction target for each pollutant will be established through a full public process of amending the AQMP. The second step will evaluate the feasibility of further emission reductions from port related sources using a “fair share” methodology. District staff will work with the ports, other stakeholders, CARB and U.S. EPA to perform such a feasibility analysis and present it to the the Governing Board at a regularly scheduled public meeting. If the target is not exceeded, the ports would have no obligations under this measure.~~

ATTACHMENT F

Changes To Control Measures IND-01, CMB-01, CTS-01, and CTS-04

Requirements if Backstop ~~Triggered~~ Rule Goes Into Effect: If the “backstop” rule ~~is-goes into triggered effect~~, the Ports would submit an Emission Control Plan to the District. The plan ~~should-would~~ include measures sufficient to bring the Ports back into compliance with the 2014 emission targets. ~~(Phase I) and to further reduce their emissions to the new target based on their contribution to the total inventories, necessary in meeting the 24-hr PM_{2.5} standard through a SIP amendment (Phase II).~~ The Ports may choose which sources would be subject to additional emission controls, and may choose any number of implementation tools that can achieve the necessary reduction. These may include ~~environmental lease conditions, port rules, tariffs or incentives~~ clean technology funding programs, lease provisions, port tariffs, or incentives/disincentives to implement measures. As described below, the ports would have no obligation under this measure to implement measures which are not cost-effective and feasible, or where the ports lack the authority to adopt an implementation mechanism. The District would approve the plan if it met the requirements of the rule. ~~Failure to implement the plan would be a violation of this control measure.~~

RULE COMPLIANCE AND TEST METHODS

Compliance with this control measure will depend on the type of control strategy implemented. Compliance will be verified through compliance plans, and enforced through submittal and review of records, reports, and emission inventories. Enforcement provisions will be discussed as part of the rule development process.

COST EFFECTIVENESS AND FEASIBILITY

The cost effectiveness of this measure will be ~~determined~~ based on the control option selected. A maximum cost-effectiveness threshold will be established for each pollutant during rule development. The rule will not require any additional control strategy to be implemented which exceeds the threshold, or which is not feasible. In addition, the rule would not require any strategy to be implemented if the ports lack authority to implement such strategy. If sufficient cost-effective and feasible measures with implementation authority are not available to achieve the emissions targets by the applicable date, the District will issue an extension of time to achieve the target. It is the District’s intent that during such extension, the ports and regulatory agencies would work collaboratively to develop technologies and implementation mechanisms to achieve the target at the earliest date feasible.

CMB-01: *Clarification under Emissions Reduction discussion.*

CMB-01: FURTHER NO_x REDUCTIONS FROM RECLAIM – PHASE I

[NO_x]

EMISSIONS REDUCTION

Phase I reductions target a range of 2-3 TPD NO_x. During the rule development phase, staff may refine the emission reductions to include growth and other unforeseen issues. Phase I is expected to be adopted in 2013 and the shave will be implemented/triggered for compliance year 2015, if the attainment of 24-hr PM_{2.5} standard is not met by 2014. If not triggered in 2015, these reductions will be a part of the 3 – 5 TPD of NO_x reductions for Phase II of CMB-01. Note that the California Health and Safety Code requires the District to monitor the advancement in Best Available Control Retrofit Technology (BARCT), and if BARCT advances, the District is required to periodically re-assess the overall facility caps, and reduce the RTC holdings to applicable equivalent command-and-control BARCT levels.

CMB-01: FURTHER NO_x REDUCTIONS FROM RECLAIM – PHASE II

[NO_x]

EMISSIONS REDUCTION

Staff's initial analysis shows that approximately 1-2 tpd additional NO_x RTC reductions are feasible for the second phase from the RECLAIM universe (from the overall 3-5 tpd NO_x RTC reductions discussed in the first phase). During the rule development phase, staff may refine the emission reductions to include growth and other unforeseen issues at this stage. Phase II is expected to be adopted by 2015 for implementation beginning in 2020. It should be noted that since there are substantial NO_x reductions needed by 2023, if additional reductions are feasible and cost effective, they will be evaluated during rulemaking. Note that the California Health and Safety Code requires the District to monitor the advancement in Best Available Control

PROPOSED METHOD OF CONTROL

[REPLACE PARAGRAPH 3 WITH THE FOLLOWING]:

In a subsequent phase, the control approach would revise the LVP-VOC exemption if speciated LVP-VOC survey data and research results show ~~an opportunity to further reduce VOC emissions~~ reductions from consumer products are needed. CARB and AQMD staff will work with stakeholders to identify cost-effective, technically-feasible controls from consumer product categories or others. Any proposed amendments to ~~the Consumer Products Regulations to revise the LVP-VOC exemption~~ reduce VOC emissions would be vetted through a full public process.

ERRATA SHEET FOR AGENDA #30

Adopt Draft Final 2012 Air Quality Management Plan Board Meeting December 7, 2012

1. Kindly insert the following additional resolution language on page 8 of Attachment A:

BE IT FURTHER RESOLVED, that the South Coast Air Quality Management District Governing Board does hereby direct staff to work in conjunction with CARB to provide annual reports to U.S. EPA describing progress towards meeting Section 182(e)(5) emission reduction commitments.

2. Please make the following changes in Appendix IV-A (including modifications found in Attachment F) to the emissions reduction discussion for the following control measures:

CMB-01: FURTHER NOX REDUCTIONS FROM RECLAIM – PHASE I

EMISSIONS REDUCTION

Phase I reductions target a range of 2-3 TPD NO_x. During the rule development phase, staff may refine the emission reductions to include growth and other unforeseen issues. Phase I is expected to be adopted in 2013 and the shave will be implemented/triggered for compliance year 2015, if the attainment of 24-hr PM_{2.5} standard is not met by 2014. If not triggered in 2015, these reductions will be a part of the 3-5 TPD of NO_x reductions for Phase II of CMB-01 and will be incorporated into the 2015 AQMP. Note that the California Health and Safety Code requires the District to monitor the advancement in Best Available Control Retrofit Technology (BARCT), and if BARCT advances, the District is required to periodically re-assess the overall facility caps, and reduce the RTC holdings to applicable equivalent command-and-control BARCT levels.

CMB-01: FURTHER NOX REDUCTIONS FROM RECLAIM – PHASE II

EMISSIONS REDUCTION

Staff's initial analysis shows that approximately 1-2 tpd additional NO_x RTC reductions are feasible for the second phase from the RECLAIM universe (from the overall 3-5 tpd NO_x RTC reductions discussed in the first phase). During the rule development phase, staff may refine the emission reductions to include growth and other unforeseen issues at this stage. Phase II ~~is expected to be adopted by 2015~~ will be incorporated into the 2015 AQMP for implementation ~~beginning in~~ by 2020 using

[the BARCT analysis that is developed in 2013 and 2014.](#) It should be noted that since there are substantial NOx reductions needed by 2023, if additional reductions are feasible and cost effective, they will be evaluated during rulemaking. Note that the California Health and Safety Code requires the District to monitor the advancement in Best Available Control Retrofit Technology (BARCT), and if BARCT advances, the District is required to periodically re-assess the overall facility caps, and reduce the RTC holdings to applicable equivalent command-and-control BARCT levels.

3. Kindly replace the following language from page 1 of Attachment A - Resolution:

WHEREAS, the 1997 9-hour ozone standard became effective on June 15, 2004, with an attainment date for the South Coast of ~~December 31~~ [June 15](#), 2024; and
